12-22-2018 **End of Prius.** A newbie started a new thread on the big Prius forum drawing this conclusion: *"...I made this prediction a while back. Toyota has said for quite some time that they want hybrid models for all vehicles in their line up. I've said that once the Corolla gets a hybrid model - the Prius is dead."* He then provided some links to support the narrative of Toyota's advancement. I could see how such an impression could be made. But that requires looking backward with the assumption of no market change. It shouldn't take much to see how "cars" are no longer the dominant force. In fact, the automotive market has shifted in such a profound way to the support of guzzlers, it should be obvious. Apparently, some don't see that though. Perhaps this helped: Prius will continue to evolve. It's a hatchback morphing into the higher end of mainstream. We've seen the large screen and more comfortable seating in back introduced, in addition to leading the plug-in hybrid choices. Corolla will be a complimentary offering, staying in the very affordable category for those still seeking a sedan. I have witnessed all of the generational offerings over the years... 1997, 2000, 2003, 2009, 2012, 2015, 2017... and have owned 5 of those Prius models over the past 18 years. Each upgrade delivered continued improvement to the hybrid system, while staying true to the mission of decreased emissions & consumption, keeping the design affordable, and adapting to the changing market. Seeing Toyota diversify Prius into more models and spreading the technology to all of their common vehicles is what everyone (customers, dealers, stockholders, employees, and executives) all want. That's what keeps the profit coming without major disruption to the business flow... which now, is more critical than ever with such political & economic risk growing. Getting people to abandon traditional vehicles is key. We see how common it is for owners to have an expectation of continuous improvement once they've taken that initial step. Problem is, there must be variety and it must be affordable. This is basic economics many early-adopters fail to recognize, especially with respect to tax-credit dependency and infrastructure shortcomings. In other words, Prius will remain viable for years to come, leading the way for the rest of the fleet.

12-22-2018 **Clueless Comments.** Stuff like this getting posted on a regular basis makes me sigh: *"They increased it since gen 1 volt owners were desirous of a car that would go 50 miles without using gas. It was one of the rare times GM allowed User Feedback to aid in design."* I really don't know how such naive can purists on a venue dedicated to educating. We get information on a regular basis pointing out the necessity of understanding the larger market. Seeing beyond just early-adopters is absolutely essential and stressed to make that point. Some just plain don't get it though. I responded to that nonsense with: That is exactly what not to do when you are trying to adapt a niche to appeal to mainstream buyers. There were many warnings about not taking advice from early-adopters too. Knowing that's how many have fallen into the innovator's dilemma trap, GM followed through anyway. GM should have retained the "40 mile" capacity, allowing the battery-pack to shrink to provide size, weight, and cost improvement. At the same time, focus on making the interior more common of a fit and less of an emphasis on performance. The results of not doing that have been disastrous. Sales didn't increase and now Volt is being discontinued without a successor established. The technology should have been spread to other choices by not. That was key to hybrid success. GM's failure to focus on the correct audience was a terrible choice.

- 12-22-2018** **Losing Credibility.** The website looked upon as *"that"* resource to get any & all information related to EV news is really facing a struggle now. Years ago, they just ignored both the plug-in hybrid market and focused solely on EV sales. That set the stage for giving preference, since so much focus was placed on such a narrow audience. Lack of balance is always a warning sign to seriously concern. What are you risking by allowing a barrier to be formed? In this case, it is the encouragement of smug. Whoa! We are really starting to see it now. There's so much short-sightedness, it's troubling. The blatant disregard for how much dependency had been placed on the tax-credits is really bad. It's just shrugged off though as rhetoric. They see high demand now and refuse to recognize its just a stage, that sales will fall afterward. How much they'll fall is a big mystery. But with gas here just \$2.18 per gallon now, there's not much hope for continued growth... especially as the choices expand... which is how credibility becomes a problem. Outright dismissal of those choices and they pursue isn't how you build credibility as an information resource. Then, there's this: *"Can't wait for the laggards, shills, shorters, and haters to gnash their teeth and once again try and spin this negatively as they contort their feeble minds trying to counter Tesla's success and customer satisfaction numbers!"* Notice the pattern? We saw the same defensiveness get worse and worse with Volt. No matter what you ended up posting, they would fight back. They end up calling you a *"troll"* and try their best to drown out anything you post. How is that constructive? How is that a way to allow a venue to evolve? Turning into a website that refuses to accept critical thought is a very, very back sign.
- 12-23-2018** **Big Oil.** We're seeing the outcome of *"Drill Baby Drill"* reveal itself as a financial mistake on a monumental scale. There's way too much supply now. Flooding the system with far more inventory than what's needed should have recognized as a horrible decision. All of us striving for green choices saw the imbalance. So, even if there was sound reason for more drilling, there wasn't much of any renewable investment taking place. Heavy emphasis on a resource with a finite quantity available is foolish. That's without even taking the pollution aspect into account. Knowing those fossil fuels are responsible for serious damage to our health and environment is no reason to turn a blind-eye. Just ignoring the problem won't make it go away; unfortunately, those in the *"Big Oil"* industry are taking it a step further. They are encouraging consumption because there isn't any reason to worry about getting oil from unfriendly sources. Encouraging such waste with such an uncaring attitude is sickening... but no surprise. We knew there would be a backlash at some point. Waiting until Tesla ramps up production, then abruptly hits tax-credit expiration without any hope of political support for renewal, is timing that was very easy to predict. The fact that GM's fall is happening within the same timespan is a happenstance they won't let slip by. Those loses will be used to fuel rage and stir fear of change. A lengthy article published 2 weeks ago by the New York Times spelled out this administration's plan to allow cars to emit more pollution. Adding to that was last week's presentations in favor of coal at the Climate-Change summit, a sickening display of denial from this administration. Even though we have the technology for renewable electricity and the use of it in electrified transportation, there are some who just plain don't care.

12-24-2018 **Newbie Vague.** Things can turn ugly quickly when a newbie (new forum member) makes such a vague claim: "*a BEV is significantly more efficient than an ICE*". My guess was the person was quite clueless about how many different ways that comment could be interpreted. I made sure that was brought to the attention of everyone quickly. Awareness is very helpful in touchy situations. Hopefully, this helped:

Being new here, it's best to pay close attention to advice intended to help prevent misunderstandings. In this case, posting an absolute like that could be interpreted as an attempt to greenwash. The reason is you posted an extreme as if to present that as the only choice available. Misleading by omission or being vague is a common problem we have to deal with.

There are a wide variety of choices available, far more than just "BEV" or "ICE" as presented. In fact, that is how Prius came about... and the misconceptions we had to deal with for years following rollout. People didn't understand just how profound of an efficiency improvement a system designed to exploit the efficiencies of both technologies could be. A poorly informed audience can easily be manipulated, intentional or not.

A prime example of this (pun intended) is when you read through this article published just a week ago titled "*Toyota struggles to save breakthrough Prius hybrid*". It seems innocent enough, until you take a closer look. The source is from Detroit. That in itself gives reason for pause with so much anti-hybrid history. A few writers from there still have a deep hatred for hybrids, so the point of verifying claims is important. Of course, it's best to not take unfamiliar sources at face value anyway.

Notice what barely got a mention? Prime got only this: "*including a plug-in hybrid version*". We've seen other sources intentionally mislead by downplay. The information presented portrays Prius as a dead-end technology with no opportunity for advancement or that consumers have shown no interest when the option was readily available. We all know Prius Prime is only at the early stages still, not even rolled out yet to a large portion of the country. The complete absence of any data is a dead giveaway. Watch for vague references like that.

The fact in the opening related to "*demand*" is misleading too. That claim of "*Demand exploded when it reached the U.S. three years later.*" tells us what? How do you measure demand when supply is limited to dealer-order only? No supply being available on dealers lots until 4.5 years later reveals the writer's claim was inaccurate, at best. Prius rolled out in Dec 1997. Dealer inventory in the U.S. wasn't made available until May 2002, and even then it was very limited. True demand explosion was in Oct 2003, as clearly indicated by a simple Wiki lookup of Prius history.

If you are trying to make a safe assumption about an article, giving the writer benefit of doubt, assume they are totally clueless about the plug-in market. Most people have no idea that world has any potential beyond being a niche any time soon. Reality is though, that is how Toyota will save Prius. The twist is, that won't be a struggle. It won't take long either. Toyota simply had the patience and foresight to rollout based on affordability and market understanding.

Upon studying Prius history, you'll see that Toyota intentionally held back certain design features. They downplay with the intent to target & research. That's how their upgrades have been so well received. Most people never notice those subtle clues though. It's far too easy to just accept what others have conveyed. So, use care with the words you choose. We welcome new input. Those perspectives are priceless, if well informed.

12-24-2018 **Asking Questions.** The newbie took it well, by asking a question: *"I still question why we continue developing hybrid technology when there should be a bigger push for longer range lower cost EVs and wider spread charging infrastructure..."* I answered with: What you mean by *"hybrid technology"* is another example of vague references. We have no idea. Clarification is necessary. After 20 years of variation, it should understandable how assumptions come into play. There's a wide variety of designs all sharing the same label. I suggest taking a close look at Prius Prime. The advanced heat-pump and the extremely efficient traction motor & controller should be a clue as to how PHEV tech contributes to BEV progress... and that's without even considering the related investment in the battery-pack. As to charging infrastructure, you've totally overlooked how much influence plug-in hybrids have toward home upgrades. For many, it is extremely complex & expensive. That reduces favor significantly for BEV purchase consideration. It doesn't for PHEV though. In fact, many buyers will take the plunge with PHEV and not upgrade until ownership after a year or two. That's key. Being able to charge a PHEV entirely using nothing but a shared 120-volt connection at just 8 AMPs is a very important factor for market potential. Many households cannot support more than just a single plug-in vehicle at the same time. There's much fear & uncertainty related to plugging in too. So, this phased approach is a means of quickly reaching a very wide audience. Think about the likelihood of the purchase of a second plug-in vehicle. Without tax-credit help and the early-adopter market saturated, an approach like Toyota's with heavy emphasis on PHEV penetration is a large opportunity to exploit... a means of carrying over developed technology at lower cost and attracting loyal customer interest. In other words, what is there to question knowing that additional information?

- 12-25-2018** **Market Shift.** More questions are getting asked. That's a good sign. This was caught my attention *"With the lack of any real enthusiasm shown by Toyota in marketing the Prime ever since 2017 till date (even with solid sales), do you think the Prime was nothing more than a compliance car for Toyota?"* I'm always drawn in to questions of a polarizing nature, when they present facts as an either/or situation. I'm always happy to point out what they overlooked, that other choice they weren't even aware of. In this case, that was: It's not lack of enthusiasm or compliance. It's studying the market while waiting to get past the early-adopter stage, and refining design & production along the way. Prius Prime/PHV directly targets mainstream buyers, those who may otherwise consider the purchase of a traditional vehicle. That's quite different from Tesla, GM, or Nissan appealing to enthusiasts. Attracting showroom shoppers is much more difficult. The benefit of patience should be obvious now with challenges related to tax-credit dependency becoming evident. Look at the mess GM is having to deal with for Volt. So much more expensive of an MSRP was good reason to avoid getting pulled into that fallout mess. Keep in mind that Prius Prime/PHV is a worldwide product too. United States inventory will benefit later from a production ramp-up, especially with the potential for mid-cycle updates. Like all things Prius related, there is always waiting required.
- 12-25-2018** **\$2.06 per Gallon.** It is rather surreal to see the price of gas so low. This outcome was inevitable. You cannot just *"Drill Baby Drill"* without consequences. In this case we pumped oil to flood the market (I know, bad puns) with supply there was no demand for. This is basic economics. Too much will force providers to accept a reduced price. How the industry figured this would someone just work to provide profit for everyone is a big mystery. Supposedly, growth of the market (both in vehicle quantity and gas consumption) would keep the balance. That, of course, assumed the failure of plug-in vehicles. If guzzling was promoted enough, no one would care... right? Turns out though, the proof of climate-change is becoming so obvious, attempts to deny or make excuses are starting to become absurd. Even the blatant avoidance is now called out. You can't get away from the evidence. Cheap gas only makes the situation worse. It's a losing battle no matter what they do. Resisting change has consequences.
- 12-26-2018** **Summary.** This brings about an undeniable confirmation of the *"too little, too slowly"* concern being genuine: *"Billed as an emblem of GM's engineering prowess and pivot toward alternative propulsion vehicles, this vehicle essentially invented the concept of the plug-in hybrid. It was critically acclaimed and generated a loyal base of enthusiasts. But sales never reached initial expectations, and GM is turning its attention to battery-powered cars that don't have a backup gas generator like the Volt."* All those years of enthusiasts fighting me, only to later find out the information I was sharing was indeed constructive. There was a suspicion that I was somehow trying to undermine GM in favor of Toyota. The idea of cooperation across automakers to build a bridge to the future was too far fetched; so unbelievable, they easily dismissed it as trolling. Their naive & smug attitudes contributed to this painful ending. Rather than usher in a successor to Volt prior to subsidy phaseout being triggered, they wasted the opportunity by endorsing a dead-end. It was such a closed-minded approach built on meritless hope and vague intention, there was no possible way to succeed... simply due to there no even being an agreement of what the goals were. Ugh.

12-26-2018 **Emotion.** To the surprise of no one, we're seeing reports like this now: "*The workers are also angry that GM, helped by the \$1tn corporate tax enacted last year, has spent nearly \$14bn on stock buybacks since 2015, money that could have been invested in developing next-generation vehicles.*" They say their loyalty being outright dismissed as a "*kick in the stomach*". Sadly, they didn't participate in the online battles I did, where facts of why fighting was necessary were outright dismissed. The supporters turned enthusiasts turned antagonist made up an endless not to accept evidence being presented. I'd point out how GM's choices to favor power & range of Volt reflected a corporate direction of seeking praise & profit, rather than investing in the future. All those warnings about "*too little, too slowly*" were provided to expose that lack of forward direction. GM got off on a tangent of enjoying the moment. That kept those employees gainfully employed for years. Falling from a position of sustainability was inevitable though. GM wasn't working on a means of stirring interest from their dealers. Ironically, that is exactly what the antagonists mocked Toyota about with Prius. Only problem, I kept pointing out the progress with Camry hybrid and the upcoming rollout of RAV4 hybrid. Now, we are just a week or two away from the next-gen RAV4 hybrid being delivered. An affordable SUV providing a 39 MPG combined rating. There's no way GM can compete with that... or the reality of how easy plug augmentation could be. It's just a matter of following the Prime formula, adding more battery and a one-way clutch. It's sad about so many jobs being lost, especially when it could have been prevented. But it wasn't... and supporters are still unwilling to address the reasons why. That's especially sad.

12-27-2018 **4 Steps.** Do this process sound familiar? 1) Deny. 2) Attack. 3) Play the Victim. 4) Change the Subject. That is the strategy our president has been following for years. I would elaborate on the first, adding comment about the denial being a list of excuses too, not just spinning goals that were stated actually meant something different. We see each of the stages every time a major topic comes up. It's the tactic for never having to deal with the problem. This is why enthusiasts always got so angry when I'd bring up accountability. Having a specific quantitative measure forced them off track, disrupting the regular cycle of greenwash. Volt discussions provided countless examples of that over the years. It was an effort to do everything possible to avoid addressing problems. This is why I pushed back on supposed solutions. I could see the pattern. That indicated lack of substance. They were just stepping around the mess, never making any effort to deal with it. Having witnessed this all firsthand and now seeing the consequences about to play out is fascinating.

12-27-2018 New Tech. Things are getting really messy. I had no idea the situation would be approached with such ignorance. It makes me feel naive, despite being so well informed about audience. This one certainly doesn't have a clue: *"It's not just about hybrid tech. It's about new tech. that is where Prius is losing ground. Tesla is the new Prius. Prius is following, not leading."* That's just rhetoric being spread without any thought behind it. Where's the merit to support claims? Something... anything... to show how progress is measured. What ground? Leading who? Ugh. I started fresh with this particular new thread veering so far off track so quickly...

The definition of leadership doesn't say or even infer anything about "new" being criteria:

- 1) the position or function of a leader, a person who guides or directs a group.
- 2) ability to lead.
- 3) an act or instance of leading; guidance; direction.

Knowing your audience is vital. Who are you trying to lead?

This is all about getting ordinary people to actually change. Tesla has done a wonderful job of fulfilling the desire of early-adopters, but their reach to mainstream buyers without the \$7,500 tax-credit is far from certain. Toyota's ability to draw interest from the common consumer is well proven with Prius, but their history is loaded with disappointment from enthusiasts. Understand that difference?

We are embarking on a time when the market overwhelmingly prefers vehicles larger than Prius and have very little interest in new tech. That means delivering a well-rounded choice. An affordable offering with a wide-array of conveniences complimented by a modest EV drive has the potential to appeal to a large audience of everyday shoppers.

That's the type of leadership we need. Notice how that's the opposite of what GM did. Their attempt to deliver a choice with the *"it's worth it"* approach failed on a tragic level. Sales never reached beyond enthusiasts. It was an expensive niche without an mainstream successor... the very thing Toyota is striving to avoid with Prius evolving into Prime... an extremely difficult challenge of leadership.

In short, the belief that range or power equates to being a leader of mainstream change doesn't have merit. It is leadership, but not with the audience which changes the status quo.

12-28-2018 **Dashcam Purchase.** Talking to anyone who drives on a regular basis, you'll get comments about wanting one when mention of dashcam is made. The topic is clearly one that's been on everyone's mind. We all see the accident footage. So, we know you can be witness to incredible acts of stupidity. I finally got one, but that wasn't the purpose, nor would it be a replacement to the high-quality equipment I used for the Prius videos. This was just for everyday use, to have a camera effortlessly recording when I drive. You never know what you'll encounter that you would like to retain. On our trips, we see a beautiful sunset or scenery rather predictably... yet, never have something to capture it readily available. Regular cameras don't work for that purpose either. Dependent upon batteries, you cannot run them non-stop for hours. Then get hot. A dashcam using a tiny super-capacitor doesn't. They are finally starting to deliver 4K resolution now too. I got one yesterday that's really just 2K, but up-converts to 4K. That means it has enough resources to deliver 2K well. I'll be able to capture video and occasionally snap a photo at the same time. I might be able to stream what I see too. Reviews of the Wi-Fi are very encouraging. You don't know until you try. So, that's what I'm doing. The plan is to share some video too. Stay tuned.

12-29-2018 **Setting Expectations.** A big dose of reality was warranted. It's like watching an accident about to happen, which viewing in slow-motion. You know it isn't going to be pretty. You also know it could have been prevented. No matter how much you try to share information, certain people will refuse to accept it. The advice is wasted on someone hell bent on supporting a hopeless risk. Oh well, it makes them feel better for now. Later, they'll just pretend what they said never happened anyway:

Know your audience. Those comments are very much from the perspective of an early-adopter. The way mainstream buyers of new vehicles shop is quite different. First, they won't have the influence of a \$7,500 tax-credit. Second, they will primarily stick to their favorite brand and rarely consider another automaker. Third, they will immediately dismiss a BEV if they haven't ever been exposed to one yet, and even then it will be a challenging sales. In other words, make sure a realistic timing expectation is stated.

Far too many here don't recognize being in the low-hanging-fruit stage still. We haven't even seen sales begin directly against the true competition yet, traditional vehicles. Enthusiasts have no concept of how intimidating the idea of wiring up their garage for 240-volt charging can be. Besides the possibility of their service-panel being poorly located or underpowered, there's the uncertainty of equipment & installation cost. That's just for support of a single vehicle. Think about how many households have at least 2. And none of that takes into account those who won't have a plug available at their apartment or the extreme expense of super-high-speed charger locations.

It will be a rude awakening for many who enjoy the well-proven technology everyday but see their own peers not showing any interest. This is why PHEV choices will play such a large role in the transition away from traditional vehicles. The plug-in hybrid provides opportunity charging, to allow the technology to be exploited beyond just covering daily commutes, without ever bringing up depletion concerns.

Again, I can't stress this enough... Know your audience. Given another generational-cycle, things will be much improved. Until then, we are still very much in the spread-the-knowledge stage. Introduction to the technology from the well-informed is what must take place over the next few years for the stage of purchase consideration to be realistic for the masses.

Ordinary consumers have much to learn prior to those next-gen offerings they could potentially purchase. Remember, what we have now is very much restrained by cost & production limitations anyway. Prepare that future audience.

12-29-2018 **Renewed Battles.** Former antagonists try to stir new trouble on new websites. It doesn't work well though. The older venues served as a steady source for fake news by publishing ambiguous information using an interface which contributed to misleading. Most don't do that anymore. They desire integrity over popularity. I find it intriguing to participate in renewed battles knowing the tables have turned, in both respect to the posting and market change. Today, I fought back with: Yes, know your audience. 8 years later, Volt is still just a 4-seater with limited leg & head room. Prius Prime offers more leg & head room, but didn't bother offering a narrow middle seat since the market (audience) has shifted to RAV4 for that. You want the comfortable 5th position, you buy a larger vehicle. Currently, the hybrid model of RAV4 offers 39 MPG at a competitive price with traditional vehicles. In a few years, a plug could be added to make it an affordable PHEV. Right now, we see that Honda is testing that potential with Clarity. Why GM never implemented Voltec in Equinox or Trax is obvious, the technology was too expensive. So, abandoning Volt is no surprise to anyone. As for what I stated about Volt on every story, it was not as you claim. I mentioned TOO LITTLE, TOO SLOWLY on a regular basis. That's because GM did not spread their technology. It should have been done prior to tax-credit expiration. Lack of diversification is what harmed their business investment, becoming a costly liability... hence ending production. This is why many would like to see a CRV or Pilot from Honda and a RAV4 from Toyota as plug-in hybrids within the next few years. We know the audience has changed. They now prefer small SUV choices. That's why allowing Prius to morph into less of a family hauler is just fine. Parents with older children need choices too.

12-30-2018 **2019 Expectations.** Speculation is growing, without substance... of course. Most is based upon anecdotal observations, claiming a pattern in history, but failing to actually see the bigger picture. It's an easy trap to fall into. When change is coming remains a total mystery. Something could be announced within the next 2 weeks for the Detroit auto show. But even if that does happen, it doesn't mean availability soon. There could be an abbreviated 2019 model year, just a brief carry over, then a 2020 model rolled out early. We saw that with the gen-3. I got mine in May of 2009, even though it was a 2010 model. So, when is anyone's guess. What is a little easier to guess about with some degree of confidence though: Larger capacity shouldn't have been an expectation. Toyota wasn't about to make the same mistake as GM by increasing capacity based on enthusiast feedback. They set the 40 km (25 mile) target for good reason. Focus has been to make the plug-in hybrid offerings as well-balanced of a choice as possible. That meant placing attention elsewhere, like packaging. We were very specifically told by Toyota that the choice of the physical size & shape of the rollout battery-pack was to keep it affordable and to retain its robust longevity design. That set an implicit expectation of a possible mid-cycle update... like 2 years later, the 2019 model. It is realistic that cell & stack arrangement has been altered to provide more cargo room. We know it will happen someday. Patience. Another something we can surmise is a bump in charging rate. The maximum pull currently from a 240-volt connection is 3.6 kW. When you use an aftermarket device to measure Charge-Mode rate, there's an interesting reveal... as documented in the video I compiled to share for a future discussion, just like this. The gas-engine provides a rate of 7.2 kW to the battery-pack. We could potentially see that in a mid-cycle update for connecting with a plug. It builds upon opportunity charging, something quite advantageous for vehicles with smaller capacities. Lastly, keep in mind that hardware & software refinements could contribute to increased range, even without changing the kW capacity of the battery-pack itself.

12-30-2018 **Best Selling.** There has been a struggle on the big plug-in website. It's experiencing an identity crisis. Just like with Volt, purpose is uncertain. They want to promote anything with a plug, but their history was to disregard plug-in hybrids. It was all about providing information & support for EV choices. The rise of PHEV offering combined with GM's struggle has drawn in a new and unexpected audience. So, they are trying their best to find a balance to please everyone. So far, that isn't working. I pounced on this: "*The best selling plug-in hybrids since 2010 are...*" It was basically greenwash material from the perspective of attempting to avoid presenting a narrative. Volt = 152,486. Prius PHV/Prime = 88,117. You can't just omit vital information components and present numbers like that without detail. Ugh! I called them out on that:

That's so vague of a statement, it doesn't serve a constructive purpose.

First, the numbers presented should emphasize they are United States only. If you considers numbers from the rest of the world through the end of 2017 for Prius PHV/Prime, there another 63,197 sales unaccounted for. Add to that another roughly 25,000 to account for 2018 sales outside the United States. All those most definitely should be counted, since they are very much part of the economy-of-scale benefit. That overall volume is how production-cost is reduced. Knowing that, we see Prius PHV/Prime far outsold Volt, even when you add in the Opel (European) model.

Second, Prius PHV (gen-1) was only a mid-cycle update rolled out to 15 states. Never being offered in 35 states means you get a very distorted representation of actual demand. Further, Prius Prime (gen-2) still isn't available outside of most of the coastal states. The middle of the United States only has special-order availability and only for select dealers. That too contributes to a misrepresentation of demand. Without supply, how can that be accurately measured?

Third, production of Prius PHV was halted in June 2015. That left a major inventory void from then until January 2017. That's 1.5 years of sales implied by the "*since 2010*" that should be counted. Again, there's no supply to indicate demand. Additionally, rollout of Prius PHV didn't start until January 2012. So, there's the entire 2011 year not accounted for either.

Fourth, the measure of true demand cannot be measured properly until subsidies are no longer skewing price. When a plug-in vehicle is faced with the true competition... traditional vehicles ...and must directly compete on the showroom floor without early-adopter tax-credit influence, then we will know what mainstream consumers really think of the offerings.

In short, that indication of "*best selling*" doesn't really tell us anything meaningful with respect to change of the status quo.

12-31-2018 **\$1.99 per Gallon.** What an unexpected surprise! I didn't think I would ever see the price of gas so low, especially during a holiday. How do you sell anything green when it's so affordable to guzzle? It's the worst nightmare for promoting EV interest based on saving money from gas purchases. Refilling the tank is so cheap (relatively speaking), there's no incentive to change. Why bother taking on any risk when a SUV is waiting for you to own? This is how cars started to fall out of favor. Now, the situation is exacerbated with so much of an over-supply of oil. People simply aren't going to care. This is why it was vital for Toyota to make the RAV4 hybrid such an affordable option. When such a small premium is required, it becomes trivial math. That uncaring person will recognize the gas saving and call it good enough. Whether or not the numbers actually work out doesn't matter. They will accept a small contribution toward the cause, as long as it truly is small and there's no inconvenience. The fact that Toyota was smart enough to make the best package for RAV4 one of the hybrid configurations could be called a brilliant move. Why not? It's the second step in traditional vehicle phaseout. After making a hybrid option available, you begin to replace the popular traditional choices with more hybrids... especially when gas is so cheap.

1-01-2019 **Tesla Killed Prius.** The article spelling out the end of the hybrid era. Naturally, there's was barely a mention of Prime. I find that the dead giveaway. Avoidance is a major clue most of the time. Why wasn't it more than just a vague reference? Inventory is almost never addressed. I did some online searches. There are only a few dozen available on the West Coast. Within 500 miles of Minnesota, I found just 17. Concentration was on the East Coast, favoring the north. Along that stretch, there were about 700. That's it. All are 2018 models too. The burndown of supply and painful silence of Toyota leads me to believe there will be news coming soon. My expectation is it will come with the press showcase in less than 2 weeks at Detroit. A nice compliment to the next-gen RAV4 hybrid and Prius AWD e rollouts would be something new for Prime. It would explain the availability holdout. This isn't anything new. Toyota did that with debuts of both Prime and with Prius itself. Anywho, I sounded off with: The focus of this article takes too narrow of a view. Had it been "*How EV killed the Hybrid*" instead, that would have been a constructive look of the entire market. The reach of 2018 was only to early-adopters with the benefit of a \$7,500 tax-credit. 2019 is the true measure of progress and it won't be focused on just Prius. The next-gen RAV4 hybrid will take the "*conventional*" buyers by storm. It's quite obvious when you read an article from a GM source and they omit mention of Toyota's newest offering entirely. 39 MPG from a 219 horsepower system for only \$28,000 will definitely draw in SUV shoppers. Tesla has a great deal of potential, but the mainstream market is far more fickle than early-adopters.

1-01-2019

Dead. I wondered when the topic would be stirred on the big Prius forum. It was the afternoon of the first day of the next tax year by a Volt-1 owner. He never upgraded to a Volt-2 and has shown interest elsewhere. So, coming from him was sensible: *"The name Volt will be dead, but it doesn't mean the concept will. I'm sure GM will continue on with it in some form or another."* It was obvious damage control... which is an opportunity for me to jump into the discussion, and I did without hesitation: That *"concept"* was never clear. In fact, that contributed to the demise of Volt. Enthusiasts tried prompting the *"EREV"* identifier, but kept changing the definition each time another plug-in hybrid rolled out. Basically, GM had no idea what direction to take. It was obvious 12 years ago, when Volt was first revealed. Almost immediately, we got mixed messages of purpose. Goals were unrealistic and the target market uncertain. The true death part though is the simple fact that there is no successor. Tax-Credits were intended to help push a product into the mainstream; instead, GM decided to abandon the technology just as phaseout approached. In other words, GM wasted a massive amount of opportunity. Someday when a realistic offering debuts, GM will have to start all over. Sadly, we knew back when Volt-1 was rolled out that the market was gravitating toward SUV choices and that GM had little interest in promoting a compact hatchback. Yet, we saw a Volt-2 without anyone beyond those taking advantage of the \$7,500 discount wanting to purchase it. Those owners did what they could to promote, but SUV shoppers couldn't care less. It was an ideal example of what not to do. GM took praise for a subsidized niche and let their minions spin Toyota as an automaker *"kicking & screaming"* in resistance to mainstream offerings. The hope was that GM's silence would go unnoticed, that their reluctance to actually address change of the status quo would be overlooked due to Volt. Two-Mode failed to reach ordinary consumers. So did Volt-1 and Volt-2. Now, they only have an awkward Bolt that doesn't appeal to even their own dealers to stock as inventory. Needless to say, GM isn't taking the situation seriously. Making fun of Toyota for their seemingly timid approach will be their downfall. The potential for Toyota's fleet of everyday hybrids... Corolla, RAV4, Camry, C-HR ...to later offer a plug is enormous. So what if none are standout vehicles? The point is for the technology to become common. In short, ugh. What a waste.

1-01-2019 **Let It Go!** Ugh. This just never ends: "*there'll be no major changes to prime. maybe a fifth seat. maybe.*" He throws out comments about the middle seating daily. It makes me crazy that he refuses to see the car market has changed. People wanting family movers are switching to SUV choices. Denying that is futile. Yet, he still wants Prius to remain like it was imagined 3 generations ago. Seeing it adapt to become more like a luxury offering and less like an economy vehicle is unacceptable. He doesn't want Prius to change, period. I'm not going to allow him to pollute the discussions anymore, continuously interjecting comments like that without any constructive acknowledgement of the rest of Toyota's fleet. That dismissal of information is as bad as the antagonists. In fact, that is basically what he is becoming by refusing to recognize the bigger picture. Oh well, he had this coming: You're obsession is such a wasted effort. Prime is morphing into a more than just an "*economy*" offering, so the idea of forcing back to something it was +15 years ago is pointless. Toyota has moved on. Camry delivers 52 MPG and the potential for a plug. RAV4 with its 39 MPG will be exploring that as well. Both are larger vehicles targeting the family audience. Put another way, I find it absurd for you to expend so much effort hoping for a squished middle spot. It's not comfortable sitting there in a regular Prius. Anyone who's taken the time to consider options for a people mover would simply purchase a larger vehicle. So even if the convenience of trading the comfortable & handy center armrest with storage for a seat, that won't be a draw anyway. Know your audience. The market has shifted.

1-01-2019 **Who's Schedule?** I see comments like this on a regular basis: "*There should be a fully electric successor to the Prius by now. Toyota failed us all.*" It comes from those focused only on the EV market. That niche distorts their reality. They don't understand how difficult it is to reach ordinary people. The everyday person couldn't care less about plugging in, since they have no background. Think about how misconceptions there are to overcome too. All I can do is point out their lack of insight: Fully electric by now? No. Cost is clearly not there yet for mass-market acceptance. The entire industry is still showing dependence upon tax-credit subsidies, investment capital, and the support of early-adopters. We thank all those who contribute to the cause, but the death of plug-in hybrids is grossly exaggerated. Automakers are a for-profit business. Dumping new product on dealers with poorly informed customers, no infrastructure, and an appetite for guzzling cheap gas makes no sense whatsoever. How well did Nissan or BMW's exploration into that approach work? Tesla's advantage is not having that legacy to address, but that makes reaching loyal legacy buyers a challenge. To say "*Toyota failed us all*" means turning a blind-eye to ordinary consumers. We see that Prime delivers all-electric commutes for many owners. Keep in mind, the small battery-capacity makes it an affordable choice, delivering a MSRP so low it can compete directly with traditional vehicles. How many fully electric vehicles can do that? Think about how my vehicles per year are required. Not understanding cost & volume makes constructive discussion basically impossible. 200,000 tax-credits is less than a single top-selling vehicle in this market. To be both popular & profitable, it takes far more than just a large battery-pack.

1-01-2019 **Top Story.** It's amazing to see how many positive votes the post with this got: "*Prius was always an unassuming very conservative styled car.*" It came from an article published claiming how Tesla killed Prius, and was labeled as the "*Top EV Story Of 2018*". That website caters heavily to early-adopters and very much thrives on attention from the low-hanging fruit. To think that anyone would spin Prius as "*unassuming*" is remarkable. This is why fake news was able to get such a grip on our society. Cheering the crowd rather than noticing what everyone not at the event is saying allows such misleading. They don't critical think. It's become mindless. Evidence all around goes unnoticed. I fired back though, stirring the post to get noticed: Attempting to push that narrative is what I would call the "*Top EV Story Of 2018*". You can't be serious. Prius was mocked from way back even before the word "*smug*" was coined and the South Park episode aired. 15 years ago Prius was labeled as "*fugly*" and mocked relentlessly for being a standout vehicle, that the only reason people purchased one was to make a statement about being green. This is why so many mainstream consumers turn their back on EV advancements. Prius was the only midsize hatchback available back then and it delivered 50 MPG for a competitive price. Years later when the next-generation was rolled out, it had established a strong reputation for reliability & resale... and the look was anything but conservative styled. RAV4 hybrid is what really turned the table. For only \$800 more than the traditional model, you could get Prius technology in a SUV. The market lost interest in all types of cars, as sales of the entire segment confirm.

1-01-2019 **Disappointment.** For 2 years, we've had a Prius enthusiast who owns a Prius PHV express disappointment about Prime. He had unrealistic expectations. And after 2 more years of the same, with complaints on a regular basis, it's getting quite annoying. He just plain does not want to accept results different from what he anticipated: "*lets face it, prime has been a disappointment, as have gen4 sales. this isn't about camry or rav4, it is about prius losing sales to tesla, and that is a fact. if toyota knew their audience, they wouldn't have to give up to \$8,000 off to sell them.*" More than anything, it's the diversification coming from Toyota that makes him crazy. Prius no longer being the premiere family mover is too difficult to accept. I let him have it: You clearly don't understand Toyota's strategy... probably by having focused so much on seating. That red-herring has wasted so much of your time. Now, please read closely. I'll take the time to explain. First is to recognize audience: TOYOTA IS NOT COMPETING WITH TELSA. Got it? They are working to establish plug-in hybrid technology by transforming their own fleet. That push away from legacy offerings is a major undertaking, well worth putting some money on the hood in select markets. The real-world data they get in return is priceless. So what if early-adopters seeking a new experience and taking advantage of the \$7,500 discount experience Tesla? That in no way guarantees future purchases anyway. Just look at how many conquest sales GM gained with Volt only to lose later to Tesla. It's all about changing the status quo, not scoring praise by pursuing low-hanging fruit. Keep in mind that 200,000 tax-credits is a drop in the bucket. Through November of last year, Toyota sold 298,991 Camry; 257,093 Corolla; 224,128 Tacoma; 221,386 Highlander; and 159,189 RAV4 in the United States alone. That perspective is very important to knowing why focus on Tesla isn't important. Toyota must appeal to their dealers. That means the new technology offerings must deliver a nice profit and be easy to sell. Aggressive rollout of TNGA and the spread of hybrid choices is so important for that reason. In the meantime, PHV/Prime likely came close to 60,000 purchases globally in 2018. Knowing all that above, now explain how it is disappointing.

- 1-01-2019 Tradeoffs.** Discussion of how we got to this situation has been interesting. With Volt dead and Tesla tax-credits now in phaseout status, the problem of cheap gas and fossil undermining has been pushed aside. More and more attention is being put on Toyota. I find that quite peculiar. Why? The source makes you wonder too, especially with comments like this: *"I'm a big fan of PHEVs, especially as only cars... but one needs to be realistic about the tradeoffs."* That's the want verses need issue so convoluted, nobody can reply... which may be the point. After all, that is exactly what our president does to push his agenda. I don't put up with that though, as I pushed back with: Ironically, not seeing that a 5th is rarely ever needed and not acknowledging the large cargo area from folding down seats are great examples of being unrealistic. Both are excellent tradeoffs. It's weak arguments of claimed necessity that discredit sources like this as anything beyond group think. That is what killed Volt. Few saw the pattern then (a clear repeat of Two-Mode history), so it is no surprise the same mistakes playing out again. Balance for an affordable price is what mainstreams shoppers seek. That is why Prius was so successful. Rather than delivering more capacity & power, Toyota carefully weighed tradeoffs to find a pleasing middle... a concept clearly not embraced by many of the posters here.
- 1-01-2019 Not Happy.** Today's post was supposed to be an attack on Prius. I kept that from happening by forcing the bigger picture. Some were not happy, especially this person: *"Finish the sentence: I have changed the subject from Prius to RAV Hybrid, because..."* Of course, I took that as an invitation to stress the point: ...because the market has shifted interest to SUV choices and the AWD model of Prius won't be available for a few weeks still. I find it intriguing to see topic spin as an attempt to polarize. Rather than seeing Toyota's effort to diversify, it's a one-size-fits-all perspective being pushed. That's the very thing that killed Volt. GM failed to spread the technology. In other words, I didn't actually change the subject. I drew attention to the fact that the single-mindedness was creating a false narrative of what's really happening. The goal is to end the production of traditional vehicles with electrified choices. That's exactly what Toyota is aggressively pursuing. What other automaker is addressing their entire fleet of Cars & SUVs like that?
- 1-01-2019 Same Dance.** How times have we heard a different song for the same dance? This time, it was: *"The hybrid rose on the rise in price in gasoline, and now falls with the fall in gas prices. And yet fully electric vehicles continue to rise. How could that be?"* I wasn't pleased: That narrative has a fundamental flaw. From Jan. 2000 to Dec. 2005, there was no tax-credit available for hybrids. All you'd get for purchasing a green vehicle was a \$2K deduction, which worked out to between \$300 and \$400 for most people. Despite that, sales of Prius grew to exceed the 100,000 annual milestone. EV purchases have yet to prove their ability to reach mainstream volume without tax-credit help, which is quite generous at \$7,500. As for the narrow-minded view that a plug-in hybrid cannot have a huge impact to being green, you're fighting people on the same team. Those are really messed up priorities that the oil industry will appreciate. Even with a small battery-pack in Prius Prime, owners commute can dramatically reduce oil consumption... to the point where some are entirely electric. Also, keep in mind that hybrid choices were very limited then and some automakers were fighting fiercely against electrification, most notably GM and VW. There was no sense of electrification being the future like it is now.

- 1-02-2019** **Median.** I get quite annoyed by those who don't understand what averages actually tell us. The assume middle, which is often quite incorrect when looking at the actual data. That's why detail is always requested. Statistics can be used to mislead. Intentional or not, that is the outcome. I made sure that was clear: Average is a misleading indicator. Since it is not weighted in any way, the value is distorted by an extreme. In this case, that extreme is Model 3. To accurately build a true representation of the market, a straight average must be avoided. Otherwise, the number will end up feeding a narrative. Median is the more informative value, as this real-world example points out: *"The average U.S. worker today earns roughly \$46,641 a year, according to data from the Social Security Administration. The median salary in the country; however, is only \$30,533, which tells us that a greater number of people earn less than the average than more."* On a regular basis, that same problem comes up with vehicle pricing. The value is distorted without any context to tell us what it really represents.
- 1-03-2019** **Lesson Learned.** The verdict of this is what made antagonists suddenly vanish: *"I guess they've learned a lot from the two generations of Volt and from the Bolt, but they sure have failed to use the tax credits to move into the mass market. Very disappointing."* Looking back at discussion threads just a few months ago, you would have never expected such an abrupt change. They were dishonest, offensive, and sometimes even hostile. Why they held on to the bitter end, while watching so many of their peers abandon ship, seems to be a matter of pride. Too proud to admit defeat is unfortunate. That's how the history repeats again later. Not learning from mistakes is a painful outcome easily avoided. But then again... Two-Mode, Volt-1, Volt-2, Bolt... how many times could they be fooled into believing an *"it's worth it"* approach would result in a large number of people willing to pay a premium? Each of those failed attempts had the *"leap frog"* hope. Their technology advance would outsell Prius. None did. The struggle to draw customers from within (not conquest from outside) never bore any fruit. I knew it was futile, simply because you cannot out Prius a Prius without understanding its formula for success. It comes down to appealing to mainstream consumers. If you do, enthusiasts will feel let down. A vehicle without emphasis on size & power isn't worth consideration, as far as they are concerned... which is now why I haven't heard from certain individuals now. They seem to have recognized their mistake.

1-04-2019 **Balance.** A few old foes are still posting, but the nature of what gets put in their message is changing: *"If sales was the criterion for pulling the plug on the Volt as the author asserts, then the Corvette would have to go before the Volt. For all of 2018 GM sold 9680 Corvettes, but 18,306 Volts..."* That is obviously a damage control effort, but at least it is somewhat constructive. In the past, I couldn't even get those enthusiasts to discuss GM's own fleet. They always made it into a pissing match about Toyota. That childish rhetoric turn greenwash became a very big problem. They put up such a massive offense, there wasn't any defense to speak of. That puts Toyota in a position to score a lot of points when they aren't paying close enough attention. We're seen that play out now too. For now though, I'm happy to actually get a little somewhat constructive discussion about our biggest legacy automaker here continuing to make mistake after mistake about serving the future. It's really hard to tell if the executives don't understand or just don't care. My reply was: Sales are a criterion. Balance is the overall measure. Corvette has a carefully planned supply/demand balance and is priced accordingly. Just the right amount of people are willing to pay a high-premium for a low-volume vehicle. Dealers are willing to stock as inventory accordingly. That's what specialty offerings are all about. Volt was promoted from reveal back in 2007 as a mainstream vehicle. That meant a much lower price with a much lower profit. But since it would be sold in high-volume (60,000 minimum annual), that would be acceptable for dealers. Volt failed to meet its supply/demand balance.

1-04-2019 **Patience.** Not having any is what most problems emerge from. Wanting quick gratification and only simple steps to achieve goals is what we have grown to expect... here, anyway. Our mindset in the United States is quite different from that in Japan, where they have a culture promoting patience. That translates to resting on laurels here and gets you the *"laggard"* label. There's little merit to support the claim, but the online community of early-adopters don't care. They don't see the *"EV market"* as a first step, one that is mostly low-hanging-fruit. The whole idea that \$7,500 of tax-credit money having a major influence in demand would get shunned. For years, I had to endure the claim that GM would lower MSRP in sync with subsidy phaseout. Somehow, GM was already making so much profit, it wouldn't matter. Really? Even with the \$7,500 discount in the tax-filing return format, sales were still well below what is necessary for a vehicle intended for the masses to be sustainable. These blog entries document their terrible expectations based on greed & pride. It's really sad. But at least not all the legacy automakers share that need for a quick & easy return, as I stated: No sense of patience, eh? Toyota has been focusing on global distribution, refining production along the way. Rushing to sell more in the United States would have been pointless. It's very difficult to argue that it wasn't sensible waiting until dust had settled from the inevitable GM fallout. In the meantime, real-world data from owners is being shared. In my case, I'm averaging 125 MPG despite several 80 mph trips from Minnesota through South Dakota to Wyoming and back. My entire commute is EV, so the spin about range being bad is a load of greenwash.

1-05-2019 **Did Wrong.** An article drawing attention to the situation GM put itself in stirred this: *"No one in this thread stated that."* It came from a frequent poster on the big Prius forum who refuses to look at the bigger picture, a problem common with discussions online. I was annoyed, but it did provide a nice chance to provide summarization:

Don't turn a blind-eye to the hundreds of times someone else has said that somewhere else. You know all too well the *"Tesla lowered the prices of their cars to ease the pain of the phaseout, so who says GM won't do the same thing."* was an expectation scores of die-hard enthusiasts claimed on a regular basis.

We had to deal with never-ending attacks on Prius PHV & Prime from allegations that Volt was already making a large enough profit to absorb the loss of the tax-credit without interruption. Those *"in this thread"* knew it was a red herring, since the goal was to grow sales significantly, not just to maintain the niche level. So, even with the discount, it wouldn't be enough. Regardless, that was stated.

Now that we are in a hindsight situation, it is clear the GM disaster called Volt wasted opportunity... a point I made hundreds of times as a counter-measure. Conquest sales did nothing to achieve change within GM's own customer base. As a result, there is no successor establish... or even announced... for their dealers to embrace. Showroom shoppers are flocking to the Trax, Blazer, and Equinox offerings instead... all without a plug or even a hybrid option.

As for GM's choice to squander what they learned from Volt-1 to make an even less appealing-to-mainstream Volt-2, it explains the abrupt shift to Bolt instead. Competing with Toyota was a big mistake. Profit was totally unrealistic. Seeing initial sales disappointment of Bolt should have made the need to promote their solution change for *"range anxiety"* by a plug-in hybrid to now instead an electric-only obvious. They didn't bother competing with either Nissan or Tesla though. That opportunity was wasted too.

This is why the *"Who is the market for Volt?"* question got asked so often. GM started with a frustration to beat Toyota, but could not deliver something affordable. Switching targets didn't make any difference. Affordability would be key regardless of who. A compelling reason to draw interest from guzzlers to plugs must be an appealing stick-price... as the tax-credit loss clearly confirmed.

Whether or not you want to accept that big-picture analysis doesn't change the outcome. Exactly as this thread topic states, GM *"did wrong"* with their approach. The question now is how Toyota will handle the spotlight. They carefully preserved tax-credits, a move often criticized prior to Volt's demise. It already sheds new light on the market opportunity Toyota patiently waited for.

1-05-2019 Global Distribution. The smug coming from certain EV owners feeling "*vastly superior*" is annoying to have to deal with. They mock plug-in hybrids and have no interest in seeing the big picture. Their focus on the EV market is detrimental. Whether they recognize that or simply don't care remains a mystery. I just keep providing information regardless: Toyota focused on their global distribution, sending a small number of supply to each of their markets. The first year there were 51,000 available in total. That's quite good for a production including new tech, specifically the carbon-fiber hatch and the aero-glass rear. Last year was likely around 60,000 available. This is how you establish a foothold, working out details of how to approach mass distribution by testing out each of the customer bases ahead of time. Again, it made no sense whatsoever rushing to our particular market knowing the GM fallout could be rather intense. We all saw how GM wasted tax-credits on Volt for conquest sales. They should have been focused on changing their own status quo instead, so they would be able have momentum built to take advantage of the phaseout period, much like Tesla did. Toyota is clearly using their tax-credit allocation carefully, with the hope of doing the same thing. This is why Prime inventory was low in many places and non-existent in others. Being able to grow sales to a sustainable & profitable level takes careful planning. Toyota now has a market to tap that won't constantly face competition with Volt. In fact, the wait with Prime has provided a wide-open field to play in.

1-05-2019 December Sales. The year-end rush to take advantage of tax-credits in the current filing-year was favorable to Honda. Clarity took the top spot for December, though only by 11 more sales than Prime. That provided discussion opportunity online. I asked: What is the availability of Clarity? Supply of Prime is at just 800 models for the entire country and limited to specific markets. Toyota has been burning down inventory and holding out rollout to many of the central states. Waiting for the inevitable Volt fallout GM had to deal with and the unique Tesla situation (loss of tax-credits combined with virtually no competition) was good reason to lay low in the meantime. It also raises speculation of possible mid-cycle updates to increase appeal of the current approach. That could be recognition of Honda's market potential. Clarity is a compelling balance of what the market may embrace... which is good news for Toyota. Seeing a RAV4 plug-in hybrid would help endorse large scale abandonment of traditional vehicles. We only need to prove a few very recognizable choices sell well without tax-credits... which means there's still a few years wait. Honda's current success is very encouraging for the entire market. There is strong potential to build upon.

1-05-2019 **2019 Perspective.** Asking this question came about from an article titled that: "*Does Toyota See the Future?*" It was published as a 2018 summary. Knowing most people don't have much foresight, I wanted to make sure to capitalize on the opportunity. What could I convey that would break them of their hold of last year's perspective. This year will be very, very different. Seeing that right away may be a challenge though. We'll find out, hopefully with some feedback from this:

This biggest problem with that question is most people see it from the perspective of 2018. Recognition of how different the market will be in 2019 is key.

Tesla scrambled to get ahead of tax-credit phaseout, building production capacity to dramatically reduce impact. With investor capital and an unusually large early-adopter audience, their effort seems to have established opportunity for sustainability. That's great, but doesn't really apply to anything the legacy automakers must do.

GM is finding out the hard way what that actually means. Even though it should have been obvious that dealers were GM's true customer (know your audience), that fact was clearly not understood. GM's message of conquest conveyed a feeling of disinterest to change the status quo. Dealers could continue to focus on the push of high-profit guzzlers.

What did that mean for Toyota? It meant a mess to deal with. Legacy automaker push to abandon cars in favor of SUVs and Trucks meant an especially hard push from Toyota to get their dealers to embrace change... which sent a message of "*no interest*" toward plugging in. Toyota's push to deliver an extremely efficient Camry hybrid and RAV4 hybrid meant delay for Prius Prime promotion.

That left Prius hybrid in a very awkward position. The decision to give it a standout look didn't help in a market with rapidly declining gas prices. Fortunately, timing of mid-cycle updates provided an opportunity to change that look and introduce AWD. Transforming Prius to deal with market change is confirmation of Toyota seeing and responding. Holding off on full rollout of Prime further confirms recognition of the need to adapt.

Long story short, the answer is "yes".

1-05-2019 **Demise.** What more can be added to this: "*The demise of the Volt shows the lack of leadership at GM.*" Turns out, there's quite a bit: Who knew the "*over promise, under deliver*" would become even worse. GM has turned into an "*all bark, no bite*" automaker. They just sat on the Volt-1 approach, delivering a Volt-2 which appealed even more to enthusiasts. GM leadership simply wasn't interested in leading mainstream change. Enjoying praise from conquest sales become the downfall, a dangerous trap to fall into when profitability is at stake. As we can now plainly see, Toyota was well aware of this problem... and even nailed the timing. Producing just 60,000 Prius PHV/Prime to prepare for higher volume rollout later while refining hybrid design in the meantime (most notably, the next-gen RAV4 hybrid) is looking to be a well played business move. MSRP of their plug-in hybrid system is low enough to compete directly with traditional vehicles. Ironically, the 2-year anniversary of Prime ownership for me will be on the very day GM's tax-credit phaseout becomes a cold-hard reality... April 1. The heavy dependence on that \$7,500 subsidy will be halved, making those challenging sales so difficult Volt won't come up as a recommendation anymore. Toyota delivered a well-balance offering, one that seems to have too short of a range until you actually drive it for awhile. You can enjoy commutes & errands in EV and get remarkable MPG following depletion. It has been quite interesting to hear comments from early-adopters who really didn't understand the larger market or what it really takes to change the status quo. 2019 is definitely going to be a year to remember.

1-06-2019 **Old Enemies.** They have returned. Seeing Prime go from barely a mention most days to drawing attention routinely has stirred some emotion from long ago. They don't like Prius or Toyota. That sentiment is quite easy to see too. From pushing a narrative to outright lies, they are spreading the greenwash quite a bit now. The quote I chose to reply to, within the long string of obvious hate posts, was one comparing Tesla to Toyota. There's no way to constructively do that. They have completely different business models and time lines. It makes no sense putting them side-by-side for analysis. With so little in common, that should be obvious. But many of these names now stirring trouble were antagonists of the past. So, being constructive was not their goal. It was to undermine in any way they could. I kept my response to that brief: \$44,000 for the base price of Model 3 overwhelmingly confirmed it appealed to early-adopters taking advantage of the remaining \$7,500 tax-credit. Comparing that low-hanging-fruit to ordinary consumers is an apple/orange situation, telling us virtually nothing about the upcoming market when more choices are available and the subsidies are used up.

1-06-2019 **Investing.** The frequency of smug posting is on the rise: "*The best? That's a laugh. They stopped innovating a long time ago, and it's catching up with them.*" We're getting attack after attack on Prius Prime. That's a very good sign. No attention means they don't feel there's any kind of competitive threat. Getting sense attitude on a regular basis is confirmation of worry. I watch for downplay. Comments starting with stuff like this are key: "*No serious offering...*" It's simple to understand why too. Simply look for substance. If there isn't any detail to actually back up the claim, it's just rhetoric being stirred to undermine progress. In this case, they see Toyota advancing forward. Most people don't recognize how though. That's the problem with most consumers. They simply purchase a mature product. How it got to that stage is something they'll never bother to find out. It's not a priority. That naive is what antagonists hope to exploit. I mess up those plans by provided information. This particular nugget of detail was quite pleasing to share: Toyota is investing 1.5 trillion yen (\$13.9 billion) in its battery business. So what if the hare is ahead early in the race? We're still very much in the early-adopter stage.

1-07-2019

Apologists. We didn't often get discussion on the Volt blog about Volt. That feel apart years ago. The final Friday last October was different though. A discussion thread was started about GM taking a stand related to upcoming loss of tax-credits. It was what many of us had been waiting for. This was the beginning of the inevitable fallout. There was indeed a lot of apology posts as a result, enthusiasts making excuses to justify the fate of Volt. It's another way of stating they were in full "*damage control*" mode. Belief was that it would become a battle, building up as year-end approached. Refusal to accept the reality that GM hadn't diversified, that they had rested on their laurels, was too difficult to accept. Hypocritical callouts was something they wanted to avoid at all costs. So, the battle fizzled. Posts ended a few days later from all but one apologist working hard to preserve some pride. That continued for another 2 weeks without any progress. I let him exhaust himself trying to find ways to excuse GM's lack of progress. His own "*laggard*" insults applied more and more to his own position. It was quite intriguing to witness. We all knew it was over. To our surprise though, it wasn't a soft fade into history. A week after he finally gave up and all posts on that blog ended, there came the announcement of closures & layoffs. Suddenly, there was a declaration of defeat. Exactly 1 month after the big apology thread, a true end had come. It was over. Commitment they had all long hoped for never happened. I called them out on their short-sightedness summarizing with: "*MSRP of \$36,620 for a compact wagon selling at a rate of 1400 per month, despite a \$7,500 tax-credit, is not high-volume product for sustained profitable sales.*" It was followed by a long series of attacks denying I had ever called out anything constructive. This is why I documented that history as it was unfolding. I knew a day of reckoning would come and they feared it. Every post was quickly negative-voted to hide the contents. It was fascinating to watch. There was no more apologizing at that point. They were angry. I made sure they understand how their group-think allows the website to become a source of fake news. An attempt to misquote me by attaching someone else's words wasn't even too low for them to try. I saw it all and reminded them how their personal attacks failed miserably. Posts turned to a state of panic. That's when you know they have finally recognized the end had come. Phew! Rewriting history is what follows... the last resort for an apologist... admitting defeat but spinning it to be ok... like that was planned all along. Ugh. Rereading that long thread today certainly was interesting. It comes down to the reality that GM didn't target its own customers with Volt. There was never a sincere effort to change the status quo. Sales of SUVs and Pickups would continue as usual with Volt providing a "*halo effect*" for the automaker. It ended with the needs of business far outweighing technical praise. As I said from the very beginning, great engineering is not enough.

1-07-2019 **LOL Toyota.** Exactly as anticipated, without Volt getting in the way of progress anymore, there's a surge of interest toward Toyota. Much of it is negative, but that's still better than being ignored. It gives me a great opportunity to climb up on the soapbox... which I was especially happy to do upon reading "**LOL Toyota**" as the title of a new thread posted on the big Prius forum. It was from a well known antagonist. I followed the link to the article he had made that comment about, then posted:

The writer is just another one of those supposed experts who is really just an observer looking through the lens of the "*EV market*". It's quite obvious there's little understanding of how to make true change happen for the masses, especially when Tesla is used as a basis of comparison.

These articles all follow the same format. They make assumptions based upon early-adopter behavior and figure ordinary shoppers will just naturally follow suit. Complete disregard for tax-credit influence, family budgets, basic knowledge of charging people lack is common. They just focus on the technology and believe dealers will magically embrace change quickly. The writers also naively think there aren't forces working against status quo disruption.

Watch for the lack of a bigger picture. When there's no reference to the rest of the industry, it's likely just an attack piece targeting a specific vehicle or automaker. That's actually a clear sign of worry, in this case, that Prius Prime is stirring concern. The smug title of this topic reinforces that rhetoric of the past too. When enthusiasts doesn't like the direction genuine change is taking, we see articles like this.

What I specifically look for is the lack of understanding of how the hybrid system actually works. Antagonists will reveal they are clueless about how Prius Prime operates if you give them the chance to make a fool of themselves. They end up stepping in their own poo. Then you can just blow them off as another obsessive enthusiast not actually interested in change for the masses.

Remember, publications will publish articles to draw attention to themselves. So, seeing an article that stirs primal emotion based on misleading information is, sadly, a common practice. The hope is the misdirection will result in lots of comments being posted and repeat visits.

1-07-2019 **Observation.** I know he'll regret saying this: "*the way it looks at the present.*" He did, so I replied back with that context he chose: Basing progress on anecdotal observation of what's happening at the moment will give that impression. But if you do some digging behind the scenes, looking for stuff that won't be easy to see, you'll find Toyota is investing 1.5 trillion yen (\$13.9 billion) in its battery business. So what if fruit of their hidden effort doesn't show up for a few more years still? Toyota's focus has always been on ordinary shoppers, not those who have lots of disposal income to buy the latest & greatest. Toyota doesn't seek glory or praise from enthusiasts. They sell a lot of vehicles each year, over 10 million. Most are just affordable choices that are so common, not much attention is given. Selling to the masses is far more difficult than just appealing to a niche, especially when there's a tax-credit to exploit. We can still have high hopes for Tesla, but we need to be realistic about audience. Their buyers are profoundly different from those Toyota is targeting.

1-07-2019 **Niche.** Yup, he regretted the observation comment. We continued on though: "*As for selling to the masses, you can't sell to the masses until you first sell to the niche.*" Keeping it constructive, I added:

What does that actually mean? How do you view the technology implemented in Prime and Mirai? Aren't they helping to shake out details of how to produce for the masses?

Dealers won't suddenly embrace a long-range EV offering. We understand that reality all too well. That's why Toyota is flushing out traditional vehicles by introducing a wide array of hybrid choices. They are setting the stage without major disruption to the business. Why do so many believe the shift to EV must be dramatic?

Think about where Toyota will be 2 to 3 years from now. When cost has finally come down to being realistically affordable (priced competitively with traditional choices), Toyota will start dropping traditional production. Going all hybrid is a clear & painless next step in electrification that carries along the entire fleet. Heck, Prius could even go plug-in only at that point. It's an endorsement that sends a powerful message of commitment to change.

Look at how terrible that has gone so far for GM and Nissan; for that matter, consider Ford & BMW too. VW is still nothing but talk. And Honda is very small. None of those large legacy automakers share resemblance to Tesla, so comparisons make no sense. They will require a different approach. That's why articles like this are pointless, just hype to draw readers to a publication.

Think about the big picture. How will each automaker get beyond a single first offering? Mainstream consumers could easily look at just one choice as a niche. Keep in mind how GM was never able to successfully spread the technology from Volt into another vehicle in their product-line. Getting beyond niche is very difficult. This is why Toyota figured out how to make a variety of compelling hybrid choices prior to tackling the challenge of adding plugs.

1-08-2019 **Challenges.** You should wonder how closely people pay attention, especially upon reading this: "*Tesla set the bar higher this year, but what do they plan for next year, will they stick with 5,000 M3 a week or will they surpass that? By how much and how fast?*" I suspect the circumstances of what's actually taking place and the factors involved are being overlooked. Most people never mention the possible impact the loss of subsidies could have. It's as though they assume that financial boost really didn't make any difference, despite overwhelming evidence to the contrary. Oh well. All you can do is point out the challenges that still remain: Tesla had a \$7,500 tax-credit and pretty much zero competition. At some point, all the low hanging fruit will be gone. Getting MSRP down without profit loss is the most urgent concern. That's why Model Y is on the way. Market saturation is a problem, even the other factors aren't an influence. This is why Toyota is steering clear of such issues, choosing to deal with those challenges prior to exposure.

1-08-2019 **Progress.** Sometimes, I slip some exposition into a discussion: Not understanding how easily adapted Toyota's hybrid system is to include a plug is why so many posts here are filled with supposed conspiracy & doom. That's really unfortunate. Know your audience. To make Prius into Prius Prime, a one-way clutch was added. That allowed the gas-engine to disengage entirely and the secondary motor to switch from being a generator to providing extra propulsion power. It's an elegantly simple (and cost effective) approach that will be implemented for Corolla hybrid later this year for the market in China. Perhaps following that, we'll get the same upgrade here for RAV4 hybrid. This approach is an effective means of drawing dealer interest, an easy option to stock with small risk and decent margins. What other automaker has such a wide-reaching plan set for phasing out traditional vehicles very quickly with little disruption to both employees & customers? Meanwhile, do we really want to turn a blind-eye toward other automakers who offer just token quantities and limited choices? Think about 2018 sales for Toyota. How many of those 10.4 million worldwide were hybrids? Think about the 9% penetration in North America climbing to 15% in just 2 years. How many more is that? Preventing that many new traditional vehicles from being purchased is a major step forward. It makes including a plug on the next purchase much easier too. So basically, customers won't ever see the conspiracy & doom stirred here by enthusiasts. It will just be a natural progression away from guzzlers.

1-08-2019 **Staging.** Read through discussions. Many threads will reveal the same pattern: lack of foresight. That's a real problem. Not setting expectations is like building a house in the middle of nowhere. Will there be others nearby later? Will there be a park and stores? Will there be water, natural gas, electricity, and sewage? What about roads connecting it to the road of the area? Its purpose remains a complete mystery without some type of context like that. Heck, just breaking ground doesn't even inform you about what the house itself will be like. That's the way we see much of the industry now. GM is obviously a major problem still. But so is VW. How is a series of detail-less vehicle announcements telling us anything useful? They certainly aren't setting any real expectations that way. It just feeds hype. Thankfully, Toyota isn't doing the same, as I routinely point out: No one knows where the market will go. In fact, Toyota seems to be the only legacy automaker preparing for the only part that can be predicted... demand surge. When word gets out that EV have finally hit a price parity with traditional vehicles, a supply problem will emerge. Dealers without enough EV inventory will have to sell something else. Since Toyota will have a variety of hybrids and plug-in hybrids to choose from, it won't be too impactful for the dealer. For legacy automakers attempting to skip those offerings entirely, nothing but traditional vehicles will be available. What would you rather buy? Think about resell value. Think about the price of gas. Toyota will have already built up a strong reputation for the reliability of their electric drive. Range plays no role in the assessment of quality. Those hybrids offer a powerful means of staging the transition to plugs.

1-09-2019

Silence. That old daily blog for Volt has grown silent. The parent website keeps publishing new topics, but there are no comments being posted anymore. Quite literally everyone has abandoned it... even those nasty few antagonists who hung on to the bitter end. Volt is dead. They all knew it was in a death spiral 11 months ago when things horribly fell apart. There just wasn't a new daily topic anymore. The moderators had vanished and the homepage wasn't automatically updating correctly anymore. Yet, there was a futile effort to spread hope. Even though GM had abandoned everything that Volt was meant to represent as a "*range anxiety*" solution by choosing to deliver Bolt instead, they pushed on. It made no sense. With the end of tax-credits approaching anyway, what was the point? Volt was far too expensive to compete with anything, especially with the limited head & leg room. Having a fake middle seat doesn't matter when the other dimensions come up short. Who were they expecting to fool? They kept on with their attacks though. It was bizarre to witness. I was collecting a treasure trove of information about innovator's dilemma, watching mistake upon mistake compound the situation. It was a failure on an unbelievable scale. They just didn't want to give up under any circumstance. Pride kept making it worse and worse. Sound familiar? It was this incredible real-world drama playing out. How would it end? Would they see it coming? Or was it a situation of suddenly realizing your all alone. Every single person who had fought the good battles with you disappeared, one by one, until they were all gone. The last sentence in the last blog entry mentioning the doomed plug-in hybrid was this: "*Tax credit goes away and so does Volt.*" That sums up what happened, in addition to pointing out what had been predicted many, many years ago. Unless Volt was able to achieve a MSRP that was nicely under \$30,000 prior to the tax-credit hitting phaseout, there was no chance at all of it being able to survive. \$33,520 after 2 generations and 8 years of availability is far too expensive to compete directly with traditional vehicles. It should have been \$5,000 less by now to stand a chance. That's why Toyota set their price-point for Prime even lower. It was absolutely critical to deliver something affordable. Enthusiast opinions didn't matter. It was interest from mainstream consumers. They would play a vital role in effort to change the status quo. No token vehicle can achieve that. Only high-volume sales bring about true change. Those nasty trouble makers are well aware of that not too. Their silence says it all.

1-10-2019 **Unintended Consequences.** Sometimes, even the most sincere of efforts can result in unforeseen outcomes... which unfortunately, can be really bad. That is what we are witnessing now with that collapse of enthusiasm here. January 1st brought a naive sense of celebration. People were absolutely delighted with the success Tesla had ushered in... until they started to notice that was only the first major milestone of what is looking to be a very long & difficult race. Losing the tax-credits is a very problem to have to deal with. The lowest priced Model 3 is now \$44,000 and that's not all that well loaded. It's still really nice, but that's far too expensive to even remotely be considered competition with anything middle-market would be purchasing in high-volume. Looking at the legacy automaker who was supposedly the great leader of the new age of electrification, we find Volt... a plug-in that became such a subtle symbol of smug, it is only now that the consequences promoting the "*it's worth it*" approach are getting attention... very negative attention. That emphasis on range & power being absolutely necessary has soured our market. Automakers simply aren't seeing it as worth it, ironically, to try to sell here. Why bother when the bar has been set so high? The markets in China & Europe are far more receptive to balance choices than the audience here in the United States. We get giant guzzlers, while the rest of the world is getting targeted for realistic plug-ins. Fortunately, the model of Prius Prime here is basically the same as Prius PHV everywhere else. So, we'll still get shipments of limited inventory. But for now, there really isn't anyone knocking. It's sad. That obsession for more is pushing growth opportunity to other places. We are no longer the premiere market. They were horribly wrong about the "too little, too slowly" concern raised 10 years ago. Very close to an entire decade passed without them figuring out how to adapt. Their choice to stay true, absolute refusing to change under any circumstances, had dire consequences. The enthusiasts certainly didn't intend to kill the very thing they most wanted to succeed, but's exactly what they did. Ugh.

- 1-11-2019** **Goodbye.** There was an article just published as an epitaph for Volt. It was an interesting history... a narrative... since it excluded so many important details. I found the title ironically fitting: "*The perfect car for a future that never was.*" Due to the fact that so many vital bits of information were omitted, the "*never*" part was quite fitting. Their version of history started in 2006, back when Prius was king and its purpose was all about saving gas. Huh? No mention whatsoever was made about the primary goal of Prius: significant reduction of emissions. Excluding that entirely meant the rest of the article had no merit. Purpose was either not understood or the writer simply didn't care. I continued reading despite that. Sure enough, Volt was presented as a clean-slate solution. It was supposed built as a "*hack*" by adding a "*complex motor-generator*" and a "*big hole for the battery was cut from the middle of an existing compact car platform*". No mention whatsoever was made about how GM was already aggressively attempting to compete with Prius by rolling out their Two-Mode system. They pretended none of that took place and Voltec emerged at that moment from scratch, rather than the true history of it being the next step in Two-Mode evolution. So, of course, the plug-in prototype wasn't included. They just pretended that never existed. That gave the impression GM did more in a shorter amount of time and there were no other projects that failed along the way. Ugh. From there, comparisons focused on Tesla. That, of course, completely ignored both Model S and Model X. The writer portrayed the situation as if Volt's only competition was the Roadster. And you guessed it, there wasn't a peep about Leaf. The pressure put on GM by Nissan was never part of this narrative. For that matter, neither was the plug-in hybrid model of Prius. It was very much a greenwash article. To exclude so much information, there's no possible way to consider that journalism. It was basically just a fluff piece to make mourners feel better. Stuff like that how history repeats. Some people choose to rewrite history to make them feel better. That choice to ignore certain realities is why mistakes get repeated. Ugh.
- 1-11-2019** **In Other Words.** Changes for GM in terms of electrification go well beyond just Volt. That's quite apparent now. It really looks like they have completely given up on the idea of any plug-in hybrid here in this market. In China, that's an entirely different situation. That market isn't anywhere near as demanding. It's far easier to appeal to that audience, especially with their driving conditions. They don't have vast open roads to routinely travel as we typically do for many here. They will likely have less challenges to deal with in terms of infrastructure too. Setting up public chargers here is a nightmare. Using them afterward isn't any better. Expensive, confusing, and inconvenient isn't a good way to promote plugging in. That's why Toyota focusing heavily on building an audience for the not-so-distant future makes so much business sense. Convincing a RAV4 hybrid owner to get a plug-in hybrid for their next purchase is far easier, especially with Prius Prime establishing reputation for reliability now, than GM trying to draw interest from someone who purchased a 2019 Chevy Blazer. Heavy emphasis on highly-profitable SUV guzzlers is not the way to promote electrification. It is yet another example of how GM gets in the way, creating a major impediment for the market, without actually advancing it much... or any. I stated what I see now as the dust settles from the latest fallout this way: Basically, GM never found a way to out Prius any model of Prius... especially the plug-in. That design was far too expensive to actually work as a choice for the masses. And after 8 years of struggle to draw mainstream interest, GM is giving up. Blending engine & motor failed 3 times.... Two-Mode.... Volt-1.... Volt-2.

1-12-2019

The Fight. It was brutal. Prius was challenged by a platform clearly not designed to compete with Prius. Looking back at my own blog entries from 12 years ago, I see the reveal of Volt was nasty right from the start. There was immediate criticism about cost. How could GM possibly deliver something affordable? We knew little about how rollout of Two-Mode later that year would interest the market. There's was the BAS offering too. With so much hype and so little substance, adding to that with an announcement of plug-in intentions made it a time of uncertainty... for GM. On the Toyota side, Prius was standing strong... hence the never-ending attacks. Remember, Toyota did indeed reach their annual worldwide goal of 300,000 sales early. So, considering that whole mix along with GM's bizarre "*Live Green, Go Yellow*" ethanol push the previous year, it was an odd time for the automotive market. Needless to say, things feel apart quickly. Lack of clarity will do that. 11 years and 11 months ago (that's just 5 weeks after the reveal), Volt had been escalated to GM savior. With gas at \$2.09 per gallon and the extreme expense it would take to deliver a "40 mile" plug-in hybrid, all logic had been lost. It turned into a fight fueled by greenwash & hype. It was a nightmare with a new marketing term: *E-Flex*. Remember that original label for the Volt concept revealed at Detroit all those years ago? It's long forgotten history now... about to be squashed by a future with less fighting, we hope. Seeing efforts from Hyundai/Kia and Honda enjoy success with their plug-in hybrid offerings, there is an expectation of Toyota helping to lead those efforts into the minds of ordinary consumers. My hope is a mid-cycle update being revealed in a few days for Prius Prime. Seeing a new cell/stack arrangement to fit the battery-pack better into the cargo area would help bump interest. With engineering as my background, it would have been a fun project to reconfigure such a vital component. Timing is always the problem though. What if Detroit isn't the best venue for a reveal like that? What if something closer to Earth Day were used instead? After all, Toyota is already busy with RAV4 hybrid and Prius AWDe rollouts, along with the 2020 Supra reveal. Nonetheless, my hope is for it to happen soon, since the death of Volt has ended fighting. Blogs have been dead. There is literally no rhetoric anymore. It's bizarre. To have that the attention of such a relatively calm audience would be remarkable. An increase in range isn't necessary. An increase in power isn't necessary. Finding a way to appeal more to the "*Next-Gen Prius*" buyer is key. For the regular model, that's comes in the form of offering all-wheel-drive. For the plug-in model, it seems likely that an emphasis on cargo convenience would be beneficial. After all, we know a Corolla hybrid and Corolla PHEV are both on the way. Prius must complement the fleet, not compete with other offerings. That's why Volt had problems from the start. It didn't have a target. No audience from within GM's own customer base meant an endless struggle to appeal to an unknown shopper. Who was the market for Volt?

1-13-2019 Understanding, Risk. I saw this as an opportunity to start another blog series: "*That is still the norm for most manufacturers.*" It was a comment made in response to a friend pointing out that Toyota includes their advanced safety features on all models, standard. We ask why the rest of the industry isn't doing the same. What makes them hesitant to promote technology advancements related to safety? That's a risk. With all the emphasis on "*risk*" taking, that aspect was completely overlooked. The enthusiasts only regard "*risk*" as a measure of pushing EV range. That's quite narrow-minding and I intend to draw attention to their limited perspective. It's far too easy to fall into that trap. So, I suspect some of it is just a group-think issue. Some simply aren't aware that more than one type of risk exists. Unfortunately, being fed a specific perspective is how narratives come about... hence this effort to raise understanding. Hopefully, I'll get a few to see the bigger picture, starting with the ask of: Why? It makes no sense giving GM credit for taking risk when they don't even do that. It's bad enough calling them a leader when they don't take the risk spreading their technology to a vehicle their own loyal customers would actually buy. No SUV choice with Voltec after how many years of waiting? I remember a Two-Mode plug-in... the Saturn Vue SUV... being promoted for 2009.

1-13-2019 Understanding, Operation. It never ceases to amaze me how times a new thread about hybrid type is started and the participants don't have any idea how Volt actually works. Some have been members of the forum for years. Some even own a Volt. GM did such a terrible job of promoting their technology, it's no wonder there's confusion among ordinary consumers. But when an enthusiast goes out on a rant and attacks you with the label of "*troll*", you get rather annoyed finding out they didn't understand. Their own lack of knowledge stemming from the horribly vague posts we continually have to deal with makes constructive discussion very difficult. They argue without merit. That's why I push for detail. Even without an understanding of how the hybrid actually operates, you can judge the approach based on actual outcome. Far too often, on-paper calculations don't translate to realistic expectations. That usually comes about from the over-simplification of what the vehicle must deal with as you drive. Anywho, I encountered this again today with a discussion about Nissan's e-Power hybrid. It is the SERIES type, the same approach GM had originally promoted Volt to be, but without a plug. GM never delivered that. BMW did though. The absence of detail obscured logic. No one bothered to ask for specs or even bother to search for real-world data. It quickly became an argument of principle. Ugh.

1-13-2019 Understanding, Stages. The difference between American and Japanese business approach is so vast, it's surprising sales don't appear more polarized. My guess is people have grown numb to the signs, choosing to dismiss the obvious in favor of whatever makes them feel good. A new discussion raised on the big Prius forum about GM's choice to focus EV efforts on Cadillac brought out the usual crowd, many of which I have on ignore due to their close-mindedness. They don't want to understand. They like the online debate. That is their feed good. So, you get a lot of troll bait from them. The replies are clearly worded in a vague & provocative manner to stimulate emotional response. I usually ignore them. This was an opportunity to spread a little understanding though, for those lurkers reading the thread. This was the start of the provoke: "*Toyota's goal does not seem to be...*" I read the rest, but saw no point in repeated what has already been posted countless times to him in the past. Instead, he got:

It's a waste of time explaining to how important of a step Toyota is taking with their delivery of a 39 MPG hybrid. Not understanding the value of how that \$28,000 offering will appeal to the common consumer obsessed with the idea owning a SUV means not understanding change. These are carefully thought out constructive stages targeting the uninformed & uninterested. So what if there is no plug yet?

I'm certainly not going to be an enabler making excuses for EV offerings that are clearly not able to compete with traditional vehicles yet. I'm going to encourage the abandonment of traditional vehicles immediately. Purchase the hybrid that fits your needs. Its ownership will make the taking the next step with a plug simple, as well as get a much cleaner vehicle on the road immediately. Plug will follow later.

There's a long wait for affordable EV choices still. Dependency on subsidies overwhelmingly confirms that. Toyota's newest hybrid platform now provides a quick & easy means of getting the transition moving in high-volume. What other legacy automaker offers side a wide array of cleaner choices already? Turning a blind-eye to why people resist change is what that "*seems to be*" tells me about this audience here.

You know I dealt with the vastly superior rhetoric from Volt enthusiasts from the very beginning. So when I say I recognize the same attitude in these discussions, there's no denying recognition of that pattern. It's the same "*if you don't change the way I want you to, it doesn't count*" nonsense. Change is difficult. Change takes time. Change will not take the path you want it to.

Don't let actions necessary to encourage change get dismissed as unimportant.

1-13-2019 Understanding, Emissions. When an antagonist asks an "If" question, but alert. That's a tactic often used to stir discussion they enjoy being part of. In other words, they already know the answer and just want a repeat opportunity to state their position again. It's really annoying when you spot the pattern, knowing it's really a stall. This is the equivalent of a "*need more info*" request when an overwhelming amount of evidence has already been collected... for example, the "*global warming*" issue. In my youth, it was questioning whether or not smoking was harmful. Everyone knows; yet, the revert back to still asking keeps happening. Ugh. Today, it was: "*If the goal is to replace traditional vehicles with electrified choices, and that means full hybrid or better, and that does not require a plug, how do we measure that Toyota is a leader? Shouldn't fleet or segment mpg averages tell the story?*" That was clearly an attempt stir discussion, since we already all know the measure is vehicle counts. Fighting back directly rarely works though, especially if the question becomes a learning moment for newbies. So, I answered this way: You completely missed the point. That goal is one of many stages leading away from vehicles of the past, replacing them with *CLEAN* and efficient choices right away. The reduction of smog-related emissions has nothing to do with MPG either. Don't forget that much of our electricity is derived from dirty sources. That's why getting everyone to switch to a vehicle with at least a SULEV emission rating provides so much of an impact to the air-quality problems we face. The benefit of carbon emissions also being greatly reduced doesn't require an EV. Achieving that goal can be from a plug-in hybrid. My driving is 80% electricity. The rest is with SULEV rated emissions. That's a dramatic improvement from an affordable offering. It starts with that first goal, getting people to abandon traditional vehicles.

1-13-2019 Understanding, Attacks. When the answer to a question is disliked, they'll ask again but interject a personal twist: "*But apparently it will take the path you want it to?*" Those obvious attempts to distract & discredit are troll bait. The intent is to ultimately undermine discussion. Hope for any chance for objectively is remote. It's worth trying. I did this time: I now have 6-Sigma certification, adding to my many years of learning of how the automotive market works. So, it's not my want, it's what my research tells me about change. Like it or not, mainstream consumers are fickle, poorly informed, and often rank emotion higher than logic. So, no matter how you present engineering marvel, they just plain will not care. That's what the overall failure of Volt taught us. EVs surpassing the hybrid market this year doesn't tell us anything about true demand. Appealing to early-adopters with tax-credits is just low-hanging fruit. The far more difficult challenge is what comes following that stage. You can't actually measure hybrid demand anyway. There were not any competitive offerings until very recently. With the market shifting heavily in favor of SUV purchases, measure against the appeal of a hatchback or sedan doesn't make any sense. You will be continue to be disappointed with Toyota's approach. Get over it already! How many times must you be told their formula to success is very different from what you want? The business of change for them is to move the masses with a slow unrelenting push. The drama you hope for won't happen. That's not the way they operate.

- 1-14-2019 Understanding, Hypocrites.** The death of Volt is quite undeniable that this point... to the degree that all hope is lost for any type of successor. Many former enthusiasts are sighting reasons for disappointment which echo exactly what I stated years ago. Their former position is swept under the rug, hoping no one will notice their opposition in the past. The fact that some are saying what I said, word for word, is so hypocritical I'm not sure what to do. It wouldn't be that bad if it was just a matter of recognition their error. They don't even have to admit to having made a mistake. It's the attempts to rewrite history to conceal that activity which stirs emotion. This type of behavior to protect reputation is how history repeats itself. Erasing that record of the past gives others nothing to learn from. It sets the stage for failure. Ironically, we've been through this before. Each time I'd point out the repetition, sighting how well current activity matched choices of the past, they'd do everything in their power to deny a pattern... which in itself, was part of the pattern. Now, I'm reading my own comments coming from them... like how GM moved too slowly, that they should have diversified long before the tax-credits expired. Ugh. It's the denial that makes me angry. I can look up statements from those same individuals showing they were opposed to what they claim they supported all along. Grrr.
- 1-15-2019 Understanding, Irony.** There are so many "Ugh" moments now, it's hard to know how to respond. This was the standout statement today: *"Seems a poorly thought out strategy to burn through the tax-credit threshold without any plan to use it to help ramp up mass production."* My concern of GM doing exactly that was dismissed without any consideration. The enthusiasts labeled me as a troll and fought relentlessly in favor of GM's approach. No matter how many times I repeated *"too little, too slowly"* sighting that hard deadline as a serious upcoming problem, they dismissed those words of warning. It was blind how that somehow Volt would suddenly see a sales surge, even when GM announced Volt's antithesis would be produced. The very thing those enthusiasts campaigned against with the *"range anxiety"* solution of EREV was actually coming to fruition. All those years of fighting EV were suddenly turned upside-down. That's ironic. The very thing they feared the most... even more than Prius... was now the very thing GM had endorsed. So, of course, they needed a scapegoat. Rather than drawing attention to the undeniably ironic problem, they attempted to divert as much attention as possible elsewhere. That was fairly effective, until now. Bolt is the winner. Exactly as I predicted with the confusion involved with the naming has played out. So many still mix up Volt with Bolt, there's a save face response of *"that's what I meant"*. GM set the stage for easier discontinuation. It was so far beyond suspicious, I couldn't believe the effort expended to deny. It was dismissed a coincidence, nothing more, then attention was diverted elsewhere. Toyota is always the favorite distraction, as I had to deal with today. That will come back to bite them later too: It's ironic how Toyota was attacked relentlessly and was given the *"laggard"* label for avoiding that very situation. Whenever I pointed out that missed opportunity, GM enthusiasts did everything possible to divert attention to another topic. Funny how the table has turned. That was a valid concern not to be busy brushed aside, especially while belittling others in the process.

1-16-2019 Understanding, Messaging. A big chunk of my blogging over a decade ago involved documenting the mixed messages coming from GM. That automaker was an endless source of change. They set expectations, exploit the resulting meritless hope, then switch to something else. There was no clear direction. Purpose always remained a mystery. We saw that on a regular basis with Two-Mode. No one ever really knew what that technology was meant to accomplish or even whom it targeted. That situation of uncertainty was compounded by Volt. Right from the start, goals weren't clear. Was the engine to be a basic emergency backup, supplying emergency power in the event of unexpected battery depletion, or was it to be a full-power system complement. In other words, would it be an EV or a hybrid. No one ever really know what that HV mode was intended to deliver. Upon rollout, disagreement grew. That's why sales suffered. No one really understood the messaging. Press releases provided a mix of purposed, never really clarifying purpose. That's why the introduced of Bolt brought about so much chaos. It compound the problem of intend with the problem of audience. This is why the asking of "*Who?*" increased over time. GM was originally thought to be competing with Prius. Then it switched to Leaf. Then it switched to Model 3. No one had any idea what GM was trying to accomplish. That's why Toyota was the favorite distraction, spinning their "*traditional to hybrid*" goal as overly simplistic and not accomplishing much. Hype from GM spinners made a much bigger impression of achievement, even though very little was actually delivered. You know... "*over promise, under deliver*" ...that problem with GM starting long before even Two-Mode came about.

1-16-2019 Understanding, Trust. Fear at the beginning of Volt was that it would become a replay of EV1, that GM would rollout a product, then sight low demand as a reason to end production. Decry of such concern was intense. That would never happen, period. Now... 12 years later... we see that is exactly what happened. There's an overwhelming sentiment growing of GM having made a serious mistake of prematurely ending their efforts with plug-in hybrids. It was the lack of any effort to diversify that raised my concern. When Volt-1 sales struggle became blatant, there should have been talk of strategy change. GM abruptly dropping MSRP without any growth result, the problem should have been a major reconsider. Remember the stir to get a second model introduced, one with an affordable configuration (smaller battery & motor) to make it competitive and possibly profitable? Remember all those posts complaining about not spreading the technology to a common GM offering, like Cruze or Malibu? That rollout of ELR was a dead giveaway GM didn't care about making "*Voltec*" a common choice in their fleet. Heck, even the marketing term of "*EREV*" remained ambiguous. There was never any agreement what it actually meant. That's how trust is lost. Each failure to support a perceived purpose takes away from the hope of it ever being achieved. GM kept making steps in the wrong direction, each with proclamations of amazing progress from enthusiasts. Ordinary consumers don't accept nonsense like that. They only see the failed effort. In this case, GM tried, then gave up. Volt was showing potential, then it got cancelled. Think about how that looks when plug-in hybrid choices from Hyundai/Kai, Honda, and Toyota are all being promoted. Why did GM stop? Not knowing makes trusting their next effort very difficult.

1-17-2019 Plug-In Hybrids. Voices of reason begin to emerge over time, as we are starting to see now: *"As long as batteries remain in short supply, PHEVs are the main route to electrification."* Losing touch with how ordinary people perceive a situation is a very real problem. That's the difference between a "supporter" and an "enthusiast". The one recognized that problem. The other dismisses it as rhetoric. In this case, the situation is quite complex. There are several challenges which much be addressed. That confuses matters and makes online discussion very difficult. It's far too easy for a topic thread to lose focus. That's why those blogs with only a lifespan of a day or two are basically worthless... except how I use them, as an opportunity for learning more about argument perspectives and making discoveries. If you watch patterns and carefully read posts, you'll sometimes discover a clue about what's really taking place. There can be a subtle mention of technology or audience that most people overlook. That's online treasure for those trying to find true solutions. In this case, finding out how the potential for plug-in hybrids can be used to accelerate electrification proliferation. Put in more simple terms, I'm trying to identify what is truly preventing mainstream progress:

Combine that [short supply] with the reality that most households are barely able to support a single EV. Sharing a 120-volt connection is pushing it just for the one. But that's all some people have. Their service-box is too far away from the garage or doesn't have the capacity available. That makes the consideration of a second EV basically impossible.

Like it or not, there will be quite a market for PHEV choices until both production & infrastructure shortcomings are dealt with. We see how GM pulled out, implying no demand. It really did turn into a form of sequel to EV1, where they killed a product with lots of opportunity.

It's unfortunate EV purists created a divide, unwilling to acknowledge an affordable plug-in solution like Prime could help bridge a future to EV ubiquity. My commute in is usually 100% electric. Sometimes, I wander elsewhere after work instead of going home. So what if the engine runs then? Seeing my overall consumption at 80% electricity is a major step away from gas. It's a simple solution for the early stages of EV.

Seeing the shortcomings combined with obvious cost/subsidy hurdles to still overcome, it makes now sense not embracing what PHEV can do for speeding up market transition. Those choices target the masses, while the EV purists can lead the way for future purchases... the obvious upgrade later, an easy sell once you start plugging in routinely.

1-17-2019 **Loyalty.** I found this compelling: "*There is little brand loyalty in this transition to EVs. Toyota had better be careful.*" It was posted on a discussion thread on the EV blog about Toyota's recent comment regarding EV take over. He said the belief was overstated. The article provoked discussion by calling Toyota "*blissfully unaware and unprepared*". Being a social media site with the purpose of drawing online participation, coming across such an intentionally polarizing provoke was par for the course. It shouldn't surprise anyone. I joined in, of course. But my participation is to inform: There is no sense of loyal from early-adopters. They understand the technology and have the means of taking advantage of the generous tax-credit. So, the jump on the opportunity regardless of who is providing it. The true measure of demand doesn't emerge until the subsidy is gone and there is actual competition. This is the painful lesson learned from Volt. A large portion of sales/leases were the conquest type. When other choices came along, those owners jumped ship. Toyota was smart enough to avoid that loss GM is now having to deal with. Toyota couldn't care less about enthusiast's online comments, a teeny-tiny fraction compared to their over 10 million customers each year. In other words, what's the rush? There's very little substance, if any, to the "*knocking*" in this current market. In fact, they seem to be playing negatives, exploiting attention stirred by a hungry media by poking the "*now*" crowd with in-the-moment comments. Know your audience. In the meantime, Toyota just quietly pushes along refining their electric system in hybrid & fuel-cell vehicles, waiting for the time to offer a vehicle with a large battery-pack to the masses at a cost directly competitive to traditional vehicles.

1-17-2019 **Gamble.** It started with this: "*It is sad that Toyota is sitting on the sidelines.*" Then it ranted for a bit, and finally ended with: "*Doing nothing seems like an incredible gamble.*" I didn't even bother bringing up the aspect of risk. I just focused on the game, pointing out how Toyota was very much in the game: Toyota is rolling out their next-gen RAV4 hybrid, an ideal platform to offer a plug. That AWD system offers substantial electric-motor power yearning for a larger battery-pack. It's affordably priced (\$28K) and offers impressive hybrid efficiency (39 MPG) for such a large, comfortable vehicle. Think about what that plug-ready system has for potential, especially while building loyalty & reputation in the meantime. Claiming that is nothing takes quite a bit of denial. It's an undeniable effort to diversify offerings. Don't forget the RAV4 model of the past that was an EV. It had a cost far beyond anything realistic for mainstream sales, but it did an excellent job of confirming Toyota's preparation for the future with a plug. So what if they aren't moving as fast as enthusiasts would like? They aren't the ones who provided sustainable profit. They just test the waters... which everyone appreciates... but they don't represent ordinary consumers. In fact, most don't actually know much about the automotive business. Their technical expertise often distracts from the challenging reality of low-margin, high-volume sales. Toyota is very much in the game. They just aren't playing a position that gets much cheering.

- 1-17-2019** **Pre-Game.** A few are still attempting damage-control efforts for GM. These comments are really getting old now, not stirring much reply anymore: "*They are late to the Li-ion game, after all....*" Part of that loss of interest is having provided the insight of big picture perspective. Even the newbies (and I suspect the lurkers) online are noticing most of what has already played out has been nothing but "*pre-game*" type activity, that the true "*game*" has yet to begin. That's even better than my observation of "Tortoise and the Hare" similarities. The first race was nothing but practice before the real thing. After all, sales with subsidies don't represent how the technology will actually be received by the typical consumers. Ordinary showroom shoppers won't have a generous tax-credit helping them make their purchase decision. In fact, the very idea that an automaker who produces several million vehicles annually won't really see much of a benefit of 200,000 credit purchases spread over several years. It's too small to be meaningful with respect to sustainable profit. Strong business depends upon sales expectations being met on a continued & predictable basis. So, the nonsense still coming from a few enthusiasts is beyond annoying. It's intentionally disruptive and I don't like it. So, a callout to draw attention to their efforts to undermine is necessary from time to time... as it was today: Like I said, spreading FUD. As for claiming "*late*", that's just rhetoric. No one cares about the pregame except those actually watching it. Subsidized sales are warm-ups prior to the actual game starting. Having that generous tax-credit available obscures true demand. We saw that with the way GM exploited theirs, wasting them on conquest sales for Volt rather than establishing something capable of sustained profitable sales. The game starts when showroom shoppers get involved. That's after government incentives have ended and early-adopters moved on. It's not rocket science. It's business. When just an ordinary person considers a plug-in purchase the same way 10's of millions of others do each year, that's when you know.
- 1-18-2019** **Insults.** Gotta like this: "*Hybrids can only be a stepping stone from ICE to EV for the slow and faint hearted, never anything more.*" That new spin on smug is an insight into how the dismissal becomes so easy. Hearing statements like that routinely makes resisting change the norm. It empowers the status quo... which is the very opposite of the message that comment was intended to convey. Rather than helping electrification along by endorsing any form of it, they are downplaying. That essential step is how overcoming the intimidation will take place. The scale is absolutely enormous too. Knowing that it will still take at least a decade for the foothold to take place... that's the time needed to establish a market by experiencing a full generation of a mainstream offering... is a difficult message to convey. People don't want to accept that reality. But with cars, that's a very normal expectation. The masses watch & wait. It's what we had to deal with from hybrids. Gen-2 Prius was the first mainstream offering. Gen-3 was a big hit among ordinary consumers. (Gen-1 targeted early-adopters.) That's the way things are. People have other priorities. Insulting them is a terrible mistake. I conveyed that sentiment this way: Know your audience. Calling people "*slow and faint hearted*" is turning a blind-eye to finding out why there is resistance. Those hurdles must be addressed, not dismissed as invalid.

- 1-18-2019** **Risk.** I found this ironic: "*A Kodak moment is not when a company takes a risk to stay relevant. It's when a company fails to do so.*" It came from someone pushing a smear campaign against Toyota, doing everything he can to portray the automaker as close to death. It's somewhat absurd reading his posts. The propaganda is so obvious; yet, he thinks the message is undebatable. Statement of fact using vague references and limited scope is such a waste of constructive discussion opportunity. It undermines threads by stirring rhetoric. Others chime in to repeat the same meritless claims. They feed on each other, never actually providing content of substance. Just repeat the mantra. Ugh. I found it redeeming to respond to that nonsense with: Ironically, investing in the hybrid platform to offer an affordable plug-in option later is taking a risk.
- 1-18-2019** **Audience.** You get reason for pause when a troublemaker parrots back your own catch phrase: "*Know your audience.*" He clearly doesn't understand what that actually means. In fact, he's basically turning into a troll. More and more, I'm seeing nothing but worthless post messages. They will be one sentence comments without a quote, just a general sentiment of agree or disagree. Most of the time, you know clue what he is actually responding to. He doesn't care. That behavior is to draw attention to himself, bumping his post count up as some type of badge of authority, without doing anything worthy to earn it. Ugh. That's what I have to deal with though. I've heard others grumble upon noticing that behavior too. He's not breaking any forum rules, so there's no way to stifle the activity. It's an effective means of undermining. That's why many blogs lose participants. Thankfully, most forums offer an ignore feature. Sadly, that doesn't help many newbies who aren't aware that some people are not there to help. Oh well. I just keep posting what I can to keep topics relevant. In this case, it was with: Toyota does and they are well aware of how Tesla's current draw is completely isolated from ordinary consumers. As for the cannibalizing, that's true for all legacy automakers... most of whom are afraid to even mention the issue. At least Toyota is setting the stage by phasing out traditional vehicles.

1-18-2019 **Stalemate.** Hearing from others is interesting: *"It is obvious that Toyota is stalemated with this "disadvantage" that Tesla does NOT have."* That's a perspective based primarily in anecdotal observation, I assume. Seeing Toyota's necessity to address diverse customers and the corresponding responses isn't easy. Most people focus entirely on a single effort. In most cases of the past, it was all about Prius. They wouldn't see anything else. Not seeing anything else is what contributes to my assessment of someone being an antagonist. Recently, that single-mindedness has shifted to Mirai. You have to wonder why they don't recognize the big picture. I often see *"EV market"* referred to as the entire relevance of conversation. The world outside their niche doesn't exist from their perspective. It's bizarre... but not surprising. Many like to live in their own world. It's human nature to filter. That's a survival instinct... which means, all I can do is try to get some to notice there's more to the topic than what they have noticed so far. In this case, Toyota has lots of opportunity. Tesla is just a player on the team. The game hasn't really even begun yet. When Toyota does play, it will be on the same team... not a competitor. It's that audience problem. Understanding what will be sold is very important. Only customers interested will buy. Purchases cannot be pushed. Remember those *"one size fits all"* arguments of the past? That's what inspired my reply: Some of us pointed out years ago that GM would be even worse off having chosen to push Volt, wasting tax-credits on an approach that didn't compel their own customers to switch. Addressing how to change the status quo is something Toyota is aggressively working on. Giving Prius AWD and pushing RAV4 hybrid is clear evidence of trying to get their customers to accept letting go of the past. So, the assessment of *"stalemate"* isn't accurate.

1-18-2019 **Spin.** When you corner an antagonist, proving your point, they attempt to change what you said by stating something different. In this case, he took my phaseout to mean the vehicle itself, rather than the technology it used: *"What specific "traditional vehicles" are they phasing out? They just introduced the new Supra - 100% ICE. Stupid, at least make it a hybrid like the i8."* Those reading the thread not paying close enough attention will get drawn into that diverse attempt without even realizing the topic was intentionally shifted to undermine the discussion. This isn't as easy to notice as moving the goal posts. Rather than not meeting an objective, they try to change what that objective represented. It's the usual trolling we see to keep posts active. Never allowing a conclusion to be drawn is key. I find it very frustrating how some use forums for their entertainment, rather than a venue for exchanging information. Oh well. There will always be those who waste resources. My attempt to un-spin was: Phaseout of traditional vehicle production has been mentioned so many times over the years, it's difficult to not recognize that reference. Don't you remember any of the press releases about offering a hybrid model for every vehicle? As for the Supra, there will always be niche offerings. The point is to move the fleet forward, which is exactly what the HSD system does. It standardizes motor & battery-pack while improving emissions (SULEV rating, as well as carbon reduction) across all mainstream offerings.

- 1-18-2019 Profits.** Many who participate in the forums just want to discuss basic. So even when a complex topic is brought up, the response is usually something of simplicity. The knowledge & experience needed to have an exchange of critical thinking just plain isn't there. Having some background related to accounting, marketing, or economics is absent. Lacking those essentials for understanding business choices makes everything on the big-picture perspective a challenge. For example: *"VW spent a large amount on a BEV dedicated car platform with the first model coming out this year in Europe. The profits can't be that tiny."* How exactly was that conclusion drawn? So many factors influence profit, it's an equation experts struggle with for years. Seeing someone solve word problems in just a single post is amazing! Ugh. I try to interject wisdom when I can. Pointing out history to offer a parallel to compare can be helpful. Hopefully, this was: Just like that paradigm-shift experienced by the computer industry decades ago, the automotive industry must now adjust to low-margin sales. Those who remember that history, it was quite significant. We saw major players leave the game. Approach to sales and product offerings required major change. Who would emerge as a strong player was not obvious. People turning a blind-eye now to subsidies and pretending base-price is competitive with common choices are in for quite a reality shock.
- 1-19-2019 Growth.** It gets confusing even when attempts to be constructive take place: *"As Toyota expands the number of hybrid models, we can expect these numbers to increase, which is a good thing."* This is where detail comes into play. Vague statements kill the opportunity to continue exchanges of observation & experience... preventing any hope of providing informed predictions. A somewhat effective means of overcoming that is to provide counts setting expectations. Scale is often overlooked. Stages of reach are too. That makes the increase of sales difficult to grasp. And that's without even taking into account that the market itself is a moving target. With so many factors intermingling, you have to keep any numbers shared in focus. Distractions come from too much. Misunderstandings comes from not enough. There's a delicate balance. I try to walk that line: Toyota stated they expect hybrid penetration here (North America) for their fleet to increase by 6% in the next 2 years, from 9% to 15%. That's growth of about 150,000. So, where the supposed *"hurt"* from Tesla happens is uncertain. At a time when the EV market is still just going after low-hanging fruit, it's difficult to take the doom & gloom predictions seriously. RAV4 hybrid looks like it will be a major contributor to that progress away from traditional vehicles, targeting their core buyers with a cleaner more efficient choice. What other legacy automaker will be attempting something similar within the same next 2 years? We're certainly not going to see 75,000 annual more electrified anything here from the so-called leader GM in that timespan. In other words, reality is about to set in.

1-19-2019 The Next Stage. We are starting to engage in a new level of discussion... finally, a serious step away from rhetoric of the past. Though, complex risk.... like making safety standard, rather than a package option... still are not acknowledged. It's at least some progress. This helped that sentiment along: "*Now, do you think that will actually increase the market share of hybrids in the general market?*" I had much to say about it too:

Consideration of what the computer industry did to overcome the same low-margin problem is very important at this point. Knowing that history, you wouldn't ask the question.

Their solution was divergence. Each manufacturer took a different direction, attempting to capture what they thought would be a large enough market for them to sustain profitable business in their new paradigm. That's why I keep repeating KNOW YOUR AUDIENCE over and over again.

In fact, that was the very reason I kept asking "*Who is the market for Volt?*" on a regular basis. I could see GM was making that fundamental mistake and kept getting personally attacked for questioning those actions. Turns out, I was quite correct. They were pursuing sales in a market with very few potential buyers. They didn't understand the shift. It was old-school logic failing in a changing business.

In other words, whether or not market share increases is meaningless. GM's choice to disregard their own customers in favor of conquest proved to be a terrible decision. Toyota observed that targeting mistake and has taken great risk to avoid it. Which is rather ironic, since many claimed they were not taking any risk. Toyota will focus on their own customers. That's why it doesn't matter what others do.

This is easier to see if you switch economic perspectives from micro to macro. You'd notice that variance in battery suppliers & chemistries alone are enough to confirm each automaker will take a different path. Then, of course, there's the reality that some automakers are abandoning cars entirely and others are transforming them.

Haven't you noticed the risk Toyota has taken by steering Prime in the direction of being a step-up vehicle, no longer favoring the Prius "*family mover*" image anymore? That's why they risked elimination of the middle seat, to more closely mimic "*post children*" offerings. That is also why it wasn't deemed essential to maximum cargo space. Priorities have changed.

That spin & short-sightedness we have to deal with from people not recognizing necessary approach changes coming and how much more complex choices will become is unfortunate. This is why I appear to get rather terse sometimes. It needs to be stressed that reaching electrification goals won't be the same for each automaker.

To put it shortly, the formula for success in the past doesn't work anymore. So, the measure of progress and success won't be the same either.

- 1-20-2019** **Timing.** We're finally getting back to basics, a simple matter of timing: *"I was hoping for changes in 2019 and now I am hoping that 2020 will be the time for the Prime's refresh."* That equates to the effort to find solid information, for an actual sales. Those nasty days of hype & distraction are fading away. Thank goodness! Now, I can turn to posts like this: It is possible the 2020 model could have a mid-cycle update and it is possible that could be released to make the 2019 a short run. We've seen new model-year rollout take place as early as May. That would mean paying careful attention to what happens as Earth Day approaches... which is the same timeframe when GM triggers their first major tax-credit reduction... opening up the market for a Toyota blitz. The most recent hope for some plug-in update news was as anticipated the week prior... a silent unknown, the usual quiet from Toyota. In this case, that was especially fitting, because Detroit's final January auto show was all about old-school speed & power... which is why attention was focused entirely on Supra. The mindset of Earth Day is so much more fitting. It's part of the game with Prius. There is always waiting involved and green draws its own audience. We know Toyota has a major battery investment underway. We know they are pushing the spread of their technology. We know that being both affordable & profitable remains priority. We also know these things take time. So, it's a guessing game. Think about what the other automakers are struggling to deliver.
- 1-21-2019** **Reviewers.** Confirmation of how poorly informed enthusiasts are on the blogging site for all type of plug-in vehicles become obvious when a review is taken at face value. That's a sign that other connect & comments are probably not credible if there is nothing provided to support the claim. In this case, there wasn't anything more than a vague reference. There wasn't even a quote included. It was just a generalized claim of the engine starting. That turns into a belief that self-validates, simply from seeing its repetition. Having no source is common though. Spreading of rhetoric thrive on ignorance & complacency. Anywho, you can only imagine how many down-votes I got from posting the following information: Reviewers often don't notice the difference between "EV Auto" and the pure "EV" only mode. It's easy to overlook the fact that the first allows the engine to run briefly during times of high demand and the latter to prevent running unless the speed (84 mph) or temperature (14°F) thresholds exceeded.
- 1-21-2019** **Inconvenient Truth.** This is another one of those bits of information that wrecks a narrative. I have a feeling I'll be referring back to the detail I uncovered with respect to this 2 weeks ago on a regular basis: *"What an odd twist. We have been hearing all along that Toyota doesn't want to build electric vehicles now we find out the Toyota is the primary supplier of batteries for Tesla."* That message being heard is rhetoric antagonists have been spreading. Angered by the approach Toyota is taking, which varies dramatically from most others, they portray an image of disinterest & resistance. It is false to anyone who takes the time to study, but most don't. The sad reality is many just listen to those stirring trouble. I'm aware of the work Toyota has done with Panasonic. I have watched progress over the years and the effort to always deliver an affordable, robust product. When it comes to batteries, that means taking the time to do it right. Trying to discuss the situation with impatient & uninformed online posters is almost a futile endeavor. Fortunately, I stumble across a nugget of data so helpful, it speaks for itself. The following is exactly that... which I will spread again, and again, until they finally acknowledge: The recent Bloomberg information about Toyota investing 1.5 trillion yen (\$13.9 billion) in its battery business is at odds with the *"doesn't want to build"* narrative. So, many just choose to ignore that inconvenient truth.

1-21-2019 **Saving Face.** Ugh. How do you respond to this nonsense: "*This is the Japanese way to save face.*" It's ironic, so many won't recognize how well the situation applies to them. That's why hypocrisy is such a common problem. I find it vindicating. When you read between the lines to figure out what they actually want, you know a big automaker like Toyota striving to reach the ordinary consumer is the one to back. As much as the long-range electric-only vehicles convey a sense of a promising future, there is the problem of cost none of the enthusiasts want to address. Heck, even supporters trying to be constructive have become very close-minded to the reality of tax-credit expiration being a very ugly situation. Sales with that \$7,500 weren't exactly easy, despite those consumers being low hanging fruit... the easiest type. The appeal was exclusively from those known as early-adopters. They are the ones who are well informed and willing to pay a premium. The loss of that \$7,500 incentive makes even that audience shy away. That means appealing to mainstream consumers is basically impossible. With a price in the low 40's, there is simply no way to draw ordinary consumers. Sadly, most discussions don't even get that far. Most are much more generic, simply calling names and making excuses. That's what you get when there is little to no substance right from the start. It's what makes posting this response so easy: That's better than engineering by press-release and niche rollouts. Reality is, the propulsion tech is already developed and it is waiting for batteries to be exploited. Meanwhile, refinements continue. Don't pretend the PHEV and FCEV designs don't share EV components.

1-22-2019 Progress & Understanding. We have a long way to go still, but there is hope when you see this: *"Finally, we want SUVs. Why are there almost no plug in hybrid SUVs on the market? There's the Outlander PHEV..."* It is at least a hint of market recognition. Of course, not everyone notices the bigger picture at the same time or in the same way: *"Everyone else is doomed. Uh-huh."* Those two quotes from two different people on that general blog for all plug-in vehicles, has somewhat of a diverse audience... with respect to what they'll endorse. Sadly, most suffer from group-think and are very much in the enthusiast category. Representation of ordinary shoppers is quite rare. So, I have to deal with their perspective, using logic like this:

Osborne Effect alone could have such a huge impact, likely turning the already highly competitive market into a mess. Besides that stall of current sales and potential for long delivery waits later, excitement could stir ill-informed purchases. That risk of reputation from customers not really understanding what they buy can have serious negative consequences. That's where the doom comes into play. It's actually a reflection of their own support failing.

Think about how risk is perceived. A majority of posts you'll encounter identify range as the measure of progress. They see it as only a factor of kWh capacity. It's sad that miles/kWh is disregarded as important. And that's a factor of EV travel too. It makes discussion of other risk nearly impossible to address. Think about the risk Toyota has taken by not making safety an upgrade package option; instead, they made it standard even on their lowest priced models.

Doing more research into the electrification business, you discover battery chemistries & implementation vary dramatically. Those fundamental choices of approach will have a major impact to outcome. It's an exactly complicated collection of things to learn about. That's why moving ahead cautiously will limited market rollouts isn't such a bad idea. Some people will spin a narrative and spread FUD, but they are the ones who will face eating crow later.

I battled Volt enthusiasts for years, expressing concern about the business choices GM was making. They mocked, belittled, and offended as much as possible to shut me up. Now, there's a long record of my observations confirming the terrible path GM decided to take. That type of vindication isn't rewarding though. It's really a trail of disappointment about so much opportunity being missed. That's why I'm thankful about Toyota's comprehensive exploration of choices and the wisdom to not rush to market.

Waiting is painful. That's why I suggest a deep exploration into the business of electrification. It requires quite a bit of self-educating, doing lots of searching & reading. But it really is a rewarding way to fill the time. You will then be able to shrug off the exclamations of doom and understand the answer why.

- 1-23-2019** **Close-Minded.** Some people just plain don't care: "*Toyota is late to the party...*" To such close-minded individuals, I keep my replies brief. What's the point when they have already made up their mind? After all, the audience they are addressing don't represent the majority of buyers anyway. If you are a participant in an online forum during this initial stage of rollout, there's no possible way to argue otherwise. Ordinary shoppers don't do that. They are the ones who just go over to a dealer and walk around. They talk to friends & family. They do some basic internet search. They may even go to a big autoshow. But that's pretty much the extent of their research. There isn't much study or preparation. In fact, the purchase is pretty close to spontaneous sometimes. The vehicle is the right price. It appeals to variety of wants & needs. And gas is cheap. That's why the short reply is all the more bothersome should get when all they care to do is insult, rather than try to have a constructive discussion. This was mine today: Being late to pre-game activities really doesn't equate to much. Only early-adopters are at the party. That actual game doesn't start until long after the tax-credit (low-hanging fruit) stage is over.
- 1-23-2019** **Basics.** Sometimes, you can actually get someone to listen: "*technology. motors, batteries, chargers, software, and the most difficult; worldwide supercharger network*" Sadly, it doesn't mean they are well informed. But at least there is an effort. If they try, at least you stand a chance. Unfortunately, if they overlook the basics, it can be extremely challenging to get them to notice what they haven't been aware of. This typically comes about from not recognizing how small things can have a major impact. That's because the influence is subtle... which is exactly what you want. The least disruptive (noticeable) to the typical person, the better. Fear of change makes that a necessity. Most resist if they notice. That's why the basics are so important. Lots of small changes really add up. I try to point them out: You are overlooking the basics, which play a role in electrification... like steering. Think about Toyota's advancement in those terms, having phased out the traditional pump by switching to electric... a feat achieved by hybrids, essential for plug-ins. Those little steps make a big difference; yet, you don't acknowledge their importance.
- 1-23-2019** **Ugh.** "*but every day toyota tinkers, tesla advances. all carmakers are already behind the 8-ball. only tesla is prepared for the future.*" That one particular troublemaker who appears to be someone who posts frequently & continuously throughout the day at trolling volumes keeps filling up discussions with substanceless content. It's so annoying when a person just participates for the sake of participating. His "contributions" take away from the value, just cluttering up threads with words lacking any merit or even any substance. They just fill space, making content of value more difficult to find. I try to inform, but providing education without sounding condescending is really a challenge: Know your audience. Please take the time to research what it takes to actually prepare. That post clearly reveals you have not. Toyota is doing exactly what it takes to advance. High-Volume processes cannot be changed quickly. Adaptation works best by taking numerous small steps. That everyday tinkering is evidence of progress forward. Forcing the perspective of Tesla (a limited product start-up) makes absolutely no sense. Claiming otherwise confirms being out of touch with what legacy automakers must do. Only enthusiasts care about the impression of being behind. Ordinary consumers aren't even paying attention to the early-adopter market. When they finally do take notice in a few years, they'll see Toyota was well prepared from all the technology they already rolled out in their hybrids.

1-23-2019 **Trolls.** You follow forums & blogs long enough, eventually you'll notice a pattern. Today, it was: "*tesla technology is way beyond anything else on the market*" That came from a troublemaker who's been getting worse and worse... absolutely refusing to provide anything quantitative. Posts have become vague, to the point of being worthless. Heck, he often doesn't even quote what he's responding to anymore. It's basically a takeover of threads. You know, someone craving attention. For the last 2 years, he's complained about the smaller cargo area in Prime. It never ceased. He just likes to object, perhaps? Following his other posts though, to get a better idea of who I was dealing with, it was obvious he had no actual business or engineering knowledge. All those were lacking substance, closely resembling propaganda. It was really annoying to confirm. Some of it was just pure greenwash too. The complete absence of anything with merit was so frustrating. So, I did more research... know your audience... after all. That was necessary, since my confrontation was replied to with a parrot response and I didn't want to waste anymore more time. The result sounded alarms. Seeing his post count at nearly 75,000 was all it took to become very concerned. He likely turned rogue, the result of disenchantment... which means an endless stream of finding-someone-to-blame posts. Sound familiar? I looked up recent posting activity. 87 posts yesterday. 64 the day before. 153 the day before that. Yup, that was it. Constructive nature is lost when such a magnitude is reached, which was clearly evident by the lack of detail. It was becoming just spin. A troll was born. I always wondered how that attitude came about. It the same thing I've seen several times in the past. History repeats itself with such persistence. Knowing there is no satisfying someone who just plain does not care, I ended his provokes with: It's the same old "*vastly superior*" nonsense again.

1-24-2019 **Moving Parts.** Not understanding is often the root of the problem: "*I don't understand what TGNA is, except more profit for Toyota.*" It's unfortunate someone posting so heavily really doesn't have a clue how all the moving parts interact. It's like throwing a dart randomly, hoping to hit something... hence throwing lots of darts. Eventually, he gets a bite (yes, it's trolling) on something someone else is willing to exchange posts about. Anywho, I was happy to actually get something constructive this time. Hopefully, it provides something worthwhile in return:

This is that paradigm-shift I drew attention to. The industry is being forced to shift to a low-margin approach.... which means what appears to be a profit gain at the moment is really preparation to sustain business in the future. It is that "*tinkering*" you didn't see as progress forward.

Think about how difficult plug-in sales will be without subsidy help. Toyota is taking that situation very serious. They don't have the luxury of \$44,000 base prices as acceptable. Their audience expects much, much lower prices. Rollout of TGNA is to reduce production cost for support of affordably competitive design.

Economics is more important than engineering in the long run. Toyota knows this well. They carefully study how to reach dealer & consumer and plan out their product-cycles accordingly. That provides enthusiasts with lots of material to spin their own narrative... one which you have helped to feed at times. That's why I politely request more detail, pointing out that vague comments unintentionally contribute to their rhetoric.

It's all about understanding the seemingly unrelated moves that contribute to fleet advancement. With so many parts moving, it's very difficult to picture what's happening while in the middle of that plan. As we draw closer to rollout, it will become obvious how each of those steps helped progress along.

1-24-2019 **Consequences.** Rather than expressing concern warning of detrimental outcome, I am now pointing out actual consequences. Those days of arguing risk and defending position are over. Volt was leading a group of followers down a rabbit hole. Those individuals attacked me whenever I tried to get them to look at the big picture. They were convinced the path they were on was what would lead them to happiness. They were wrong, very very very wrong. Making it worse, they now recognize that my concern was sincere... which is an extremely uncomfortable position to be in after countless hostile responses claiming otherwise. No matter what they say, I can turn it on them now. So, they disappear. Quickly approaching the anniversary of their biggest counter-offensive, that defeat appears to have been taken seriously. Volt died a painful death... one of silence. It will be looked back upon as a major failure, technology without support. They were so focused on engineering, the consequences of their business neglect became overwhelming. There's no way to save such a monumental mistake. Dismissing a fundamental aspect of success was foolish... and they all now know that. It's all too clear Volt wasn't a vehicle intended for the masses. This is why I pushed the "Who?" question so much. It was meant to be a wake-up call to draw attention to opportunity being missed. So much focus on their niche was a terrible choice. Oddly, some still try to spin it as not so bad. To that, I say: That narrative here is pretty sad. Several automakers are diversifying with fuel-cell exploration and pursuing EV offerings. Those that engineer with press-release get lots of credit. Those who don't get an "anti" label. No one cried foul about how GM squandered their subsidies on a niche rollout as a distraction from actually electrifying their fleet. It worked well too. That resistance to delivering a plug-in SUV or Pickup went completely unnoticed. In other words, some here really need to reevaluate priorities. The group-think has consequences.

1-25-2019 **Sensibility?** Sometimes there is a glimmer of hope from the noise of chaotic discussion: *"Ultimately, this goes back to coming up with cars that people not only want, but they can afford."* Well, there isn't much to add to that. How many times did the *"nicely under \$30,000"* goal get mentioned over the years? I would remind them of it and then point out why it was so important for the technology to be affordable. You'd think that would be obvious. But then again, some online act as though they are totally brain dead. I never cease to be amazed how many people expect the technology to either be totally free or for there to be a complete payback at some point. That could make sense if they would make an effort to explain why, but they don't even try. It's why I'm often not that hopeful with most discussions. What does "afford" actually mean? For example, if you look at monthly expenses. Put in those terms, a person could see how the reduction of fuel cut has the potential to offset car payments. If the two come close, you stand a chance of keeping the person's attention. They may even become curious and ask you to tell them more. That's the key. Find something they find important. Money out-of-pocket can be a powerful motivator, even if the balance is a bit more than anticipated. Many people just need some sensible conversation to find out what the expenses really are.

1-26-2019 **Extreme Cold.** Weather forecasts state we are in for a blast of cold that will reach an extreme. We will likely break records, seeing temperatures low enough to break daily records. It does get that nasty from time to time in Minnesota, but it has been quite a number of years. In fact, I only remember a few times dealing with such situations in the Prius. Those are distinct memories that really stand out. The engine basically never really warms up, you only get brief opportunities for it to shut off... with previous generations. Knowing of the improvements Prius Prime has implemented, it don't expect as noticeable of an experience. The engine will just run at a high RPM initially, but longer than usual, then stay in that low & off zone. Since I will likely just work from home to avoid the horribly slow commute, that driving experience may not happen. I'd like to get something to share, but wasting so much time behind the wheel when you've got deadlines to meet doesn't make sense. Though less convenient, being able to work remotely is the better choice. Hopefully, after the dangerous part of the system coming through passes, I'll be able to film a commute in the extreme cold. Stay tuned.

1-27-2019 **Jumping Ship.** How would you respond to this: *"Unless Toyota does better to address the range issue on the Prime (Need 60 Miles on Battery) or another Electric or Plugin I am going to defect."* When someone who really wants to be supportive losses patience, you don't want to burn a bridge. Being able to reach out to them later as a friend who ventured out elsewhere is important. They may become an ally supporting the same cause, but with a different automakers. They may return with insight you wouldn't otherwise be able to obtain. They may simply appreciate a supportive goodbye. Whatever the case, it's important to listen to what they have to say. Since that was posted on the big Prius forum with a sense of constructive criticism, I tried to extend a hand of support:

Then, you will get a thank you from us for be willing to pay a premium for a product aimed at a different audience. Breaking out beyond the affordable choices will be helpful at some point. In your case, you'd be paying sooner for that extra capacity and either giving up electric-heating or adding to the price to get it... from a Hyundai that doesn't actually exist yet. Toyota's current focus is to strike a balance that will attract the masses, not what you seek. Diversity is very important. So, you'll get the recognition for breaking other ground.

Keep in mind that GM failed miserably with their attempt to draw buyers to a plug-in hybrid offering that range you deem as necessary. Most people dismissed that as a want, not a need. Someday when cost is much lower and energy-density is much higher, that could be realistic. Currently, it most definitely is not.

Toyota doubled capacity from 4.4 kWh (20 km) to 8.8 kWh (40 km) in their quest to keep Prius targeted at ordinary consumers. Could a 19.6 kWh (80 km) capacity be realistic for the next generation offering? That seems reasonable to expect. It wouldn't satisfy your distance requirement though. So, we must ask what other criteria you deem important for a plug-in hybrid. Tell us, please.

Think about how Toyota has strived to deliver high efficiency for both EV and HV modes, as well as keeping emission-rating for the HV system impressive to all those promoting cleaner air, without forcing a premium to be paid.

1-27-2019 **Priorities.** The death of Volt sure has made it easy to finally discuss matters other than range & power. The obsession with that got so bad, any mention of cost was simply dismissed as an effort to endorse Prius. That ironic twist of recognition to what Prius held as a high priority was quite amusing. To achieve the "*leap frog*" goal, Volt would have to exceed what Prius delivered. Simply disregarding price meant having to overlook failure to actually deliver. The enthusiasts certainly tried too. Problem is, what happened in the United States was only a small play in the big game. In other words, what happens in China really matters, as this post drew attention to: "*I don't think Chinese are incapable of quality manufacturing, I just think there's a huge cultural disconnect. In China, price is king ... and I mean king over all other considerations.*" Discussion of such matters was impossible in the past. That change is quite welcome, which hopefully will become an on-going theme. Even small progress is still progress. One step at a time, keeping priorities clearly in mind:

I had the opportunity to drive an EV from BYD (China automaker) on a closed track along with a number of plug-in offerings available here.

It was truly remarkable to observe firsthand what the cost tradeoffs to achieve a super low price would result in. The electric motor was slow & noisy. The regenerative brakes were rough & noisy. The car itself was utilitarian. Standards in our market would make it a non-starter, even without taking into account the lack of safety features. But if you simply wanted basic electric-only transport, it did indeed deliver.

Sadly, many early-adopters are poor representation of balance, yet they don't recognize that... despite the obvious willingness to spend top-dollar for emerging technology. They gravitate to that opposite extreme, where pricing isn't a priority... which is why Tesla has been so successful. Tesla will continue to be successful too... but not in the same way. Success later this year will depend upon cost-reduction choices. The generous tax-credit phaseout will bring those changes. Sales will drop as a result, settling at sustainable level.

I'm tired of the blatant efforts to stir discussion by bringing up comparisons obviously not relevant to the market changes taking place now. Events of the past don't apply well, or at all, when the audience is different. That's why early-adopter preference may not be applicable to ordinary consumers. Mainstream sales have little in common with the draws of introductory crowds.

Observations of other markets is what helps bring about a better understanding of what we will soon be facing. Looking close at the very large Chinese market with a very different culture and very different priorities will teach us more about what we need to consider.

1-27-2019 **Battery Warming.** There's lots of people posting about the battery-warming feature in Prius Prime. Though my data from last year is limited, it is still something to work with. I captured operational aspects. You can see how the system performs, but there isn't any detail about the battery. Back then, all I had was limited access. Just engine information doesn't tell you enough to really understand what's needed to deal with extreme cold. This generation of battery-pack includes warming technology. It's not complicated. It's basically a carefully thought out plan to take advantage of what essentially is just warming-tape. That simplicity is key. Done right, you have an affordable solution that's really effective. Proving that's what Toyota actually delivered shouldn't be too much of an effort. Complex filming setup can be a problem though. If you breathe too much in a cold car, the windshield will freeze from the moisture you are introducing prior to starting the vehicle. I'm hoping to avoid that situation while trying to get valuable extreme cold data to share. I'll keep the Prius plugged in to take advantage of the warmer. Since my 240-volt charger at home is Wi-Fi enabled, I will be able to capture that data in the form of a graph... hopefully easy enough to see that I could include that detail in a video. The electric draw shown will be exclusively from that of the warmer, since the battery-pack itself will be fully charged prior to the wait. Stay tuned.

1-27-2019 Technology Analogies. It is very interesting when someone brings up a situation to make an analogy, but then totally messes up the concept. For example: *"Phone chargers is a good example of how things develop and progress."* It was obvious he was frustrated by the past from long ago. Remember in the previous decade, when each phone had it's own propriety adaptor? We all do. It was very frustrating to see so much incompatibility. What a waste. We learned from those experiences though. Standards were developed. Sharing & Reuse became a reality. Did the poster forget that? How could so much of this recent history be completely disregarded or overlooked? I was quite curious to find out, so I posted:

Not really. The mini-usb chargers are forward-compatible with usb-c. All you need is a \$2 adapter. I'm still using my S6 charger with my S9 because of that forward-thinking design.

SAE-J1772 protocol for plug-in vehicles is well thought out already. Doubling of our current 3.6 kW charging rate is already supported by most 240-volt chargers, without any need for an adapter. They automatically deliver power based upon the rate requested from the vehicle. Should someone be fortunate enough to take full advantage of that spec and have a high-power vehicle, a 100-amp line will provide 19.2 kW. A charger with that protocol and input capacity covers it already. No adapter needed.

That planning ahead is the result of trying really hard to prevent future capability issues. A standard for household charging benefits everyone involved. Anyone setting up equipment with at least a 40-amp line will be set for many years to come.

Looking at it another way, consider a sustained rate from that 40-amp line. The 7 kW will supply 7 kWh of electricity in 1 hour. Given 8 hours to charge, there would be about 56 kWh delivered. Subtracting charging losses from conversion & transfer, you have roughly 48 kWh added to the battery-pack after that duration. Figuring you'd consume it later at about a rate of 4 mile/kWh, it would provide roughly 190 miles of range... at home from today's technology.

What more do you realistically need?

1-27-2019 Battery Warmer. My hope for extreme cold data has been fulfilled already. It was just something to anticipate, this morning. Now in the evening, I see exactly the activity I was hoping for. To my surprise, I ended up having to drive into work. That certainly wasn't planned, but it was beneficial. Since there's a 240-volt charger there, I could collect some unexpected data. Rather than the Prius being parked in my insulated, but unheated garage, it was exposed to the elements in the parking lot. That's the kind of real-world information which tells us a lot. The battery-warmer kept it at 39°F while parked outside for 9 hours with the outside temperature at 5°F. Slightly above freezing is the goal, since freezing is the point at which efficiency drops significantly. That warmth really makes a difference. Remember decades ago when people routinely plugged in their vehicles to power an engine warming? Now, we're doing the same thing for battery warming... but the reason is quite different. In the past, that was to ensure the car would start. Now, it's just to squeeze out remarkable efficiency and significantly improve emissions.

- 1-28-2019** **Encouraging.** It's amazing how many don't notice, or even look for, clues. They are all around. It's just an endless & senseless attack on Prius. Even though the potential for this new RAV4 hybrid rolling out right now is enormous, it gets totally ignored. That's because an affordable large hybrid that squashes the competition doesn't fit their narrative. They have nothing to fight that with, so they choose to pretend it isn't there. That's where Corolla hybrid comes in. It is the vehicle which will push Prius to become plug-in only. With the world's most popular car of all time finally offering a hybrid option here, the game is over. You can see the entire fleet embracing hybrids, simply because it has become an undeniable endorsement from the automaker. For them to offer the technology on that scale (models & quantity), the decision becomes a no-brainer. I shared that wisdom this way: We've known about the plan for a while. Sadly, that information was drowned out by cries of the "*laggard*" narrative. Far too many don't understand the complexity of a massive legacy automaker. So when they don't find the simple answer they seek, it leaves them vulnerable to being misled... which the antagonists have been exploiting lately. Toyota tends to be very quiet, the opposite extreme of what online venues thrive on. So. It's easy for the vitals to be overlooked, like this. You won't find much, even when you look. Those who get caught misleading will spin the situation to appear that Toyota has finally woke up and is now scrambling to catch up. Those of us who were paying attention know that's not the case.
- 1-29-2019** **Choices.** This is a great example of someone basing judgment on anecdotal evidence: "*If the Prime is any indication, Toyota can make a good BEV, they just choose not to.*" Rather than actually taking the time to research the entire business, they make the mistake of focusing on just what they see with a single vehicle at that time. Ugh. Worse though is the reality that those individuals making that assessment don't place any value on quality. It's a focus almost entirely on market presence. No BEV offering is bad, period. That disregard for what's truly important is disturbing. Of course, it's nothing new. We've seen that for decades. Remember how the SUV was pushed as the safest choice for your family? It clearly wasn't. So, even the feature being promoted as most important didn't deliver. Ugh. I deal with that nonsense on a regular basis. Today's volley back was: Good is not enough. They feel no pressure to rush. Taking their time to do it right... deliver something great.. is why PiP was just a mid-cycle upgrade to a limited market, then halted all together. They waited with Prime, and even then moved slowly... seeing the market had issues. It should be obvious that the tax-credit dependencies the other automakers were struggling with is what Toyota is trying to avoid. Simply waiting is an easy solution. Having to wait annoys some and results in rhetoric being stirred. Overall, it's still worth it though ...and that's the way Toyota chooses to operate.

1-29-2019 **Damage Control.** Things fell apart to such an extreme for GM, there isn't really much to save anymore. A few are trying though. I keep hitting back, reminding them of how that mess came about what when they did to downplay & distract from what was important. Looking back at the terrible decisions. With so many warning signs, it wasn't worth risk. They now know that all too well. You don't put all your eggs in one basket, especially when that basket is so small. Volt had such a small audience, it made no sense continuing with that approach. Moving the technology to a vehicle appealing to a wider audience never happened though. Volt remained a compact hatchback among a fleet of SUV choices. That never made any sense. Yet, there are some still defending it. I'm happy to point out the problem that invites: Damage control is the stage Volt is in now. Many pointed out right from the very beginning that the goals were unrealistic. How could a profitable vehicle with specs so high be achieved so quickly? When the bankruptcy recovery plan was put in place, the task-force assigned to that expressed a "*too little, too slowly*" concern for that very reason. Sure enough, Volt-1 struggled with sales. But rather than spread the technology to another platform, GM decided to make Volt-2 even more in the image Lutz envisioned... which had proven a terrible choice. The design approach is expensive & inefficient. What to do with it at this point is a very big problem, especially now that tax-credit phaseout had been triggered.

1-29-2019 **Game Playing.** Getting early-adopters to recognize their own enthusiast perspective is very difficult. They don't see how intimidating new technology appears compared to commonplace approach. When a person doesn't understand or even have the background, they don't bother. Change requires effort. People are busy with other aspects of their lives. How green a vehicle is doesn't matter. They don't deem that important. What we do is looked upon as a game, actions with an outcome inconsequential regardless of what happens. They'll never be a part of what's happening the industry now. Years later, they'll look upon whatever spoils the victor gained. There is nothing at stake for them. In other words, all the posts now are just rhetoric from everyone. It doesn't matter to them. I can't stress that enough either. Enthusiasts refuse to accept that reality. So, all you can really do is point out the situation: Toyota isn't anti-BEV, they are just avoiding the early-adopter mess. That slowness rubs some people the wrong way. So what if the EV model of CH-R doesn't rollout until next year and only in China at first? It makes no difference with respect to high-volume sales. GM got too much attention from Volt. It was clearly only a niche, never targeting mainstream consumers. Toyota doesn't play that game.

- 1-29-2019** **Halo.** When reality finally comes crashing down, then what? Only now are discussions emerging. It's far too late to be constructive. They are looking back long after anything can actually be done. We see that Prius was able to weather the storm. All the craziness Volt introduced didn't amount to much. So many promises were broken. It comes down to a lot of the effort being expended upon image, rather than actually moving the fleet forward. Reading this now as a result of all that is strange: *"Probably the biggest flaw in all of it was that GM always and only saw value in the Volt as a halo car."* To think, how many times was I attacked for pointing out Volt wasn't actually achieving anything? I'd point out wasted opportunity, miss after miss with nothing to show for. They built up hope without substance to support it and completely losing sight of goals. That mess would only get worse as more time passed... and it did. All that happened when the difference between want & need became so obscured, they couldn't tell the difference. It's sad to win this way. So what if I get vindicated. My own goal was to forge an alliance, to find friends from other automakers. Instead, they chose to fight. Oh well. At least the lessons to be learned will be difficult to deny this time around. I closed the discussion with: That's how enthusiasts became such a problem, pushing mainstream hope with a niche vehicle. It was a conflict of goals they absolutely refused to accept. This is why the *"too little, too slowly"* concern grew. GM didn't show any interest toward spreading technology to a popular vehicle, like Equinox. So much loyal customer opportunity was missed, while wasting tax-credits on conquest sales for the sake of that halo.
- 1-29-2019** **Not True.** Spreading FUD will never end. In this case, it was the "U" for uncertainty: *"With one exception, all other PHEVs have an electric range below 30 miles and will switch to the gasoline engine under strong acceleration."* When I posted a rebut to that, I knew there would be quite a backlash. Enthusiasts don't like to be called out when wrong, especially on a pivotal point. This was definitely one that really hurt. Volt was supposed to be the only plug-in hybrid with such behavior. This is what the current definition of EREV had mutated to. Getting confirmation that a PHEV with the name Prius behaved the same was beyond reproach. My contradiction would stir anger. I didn't care. The truth cannot be silenced. After all, this is a fact, nothing a topic of debate. Ugh. I fired back with: NOT TRUE. Even with the pedal dropped all the way to the floor in Prius Prime, the engine will *NOT* start when in "EV" mode. Reviewers often mistake "EV Auto" mode to mean pure electric-only operation. Their mix-up is understandable. Spreading that confusion here is not.

1-29-2019

Adoption. One way is the only way. Ugh. That mindset goes so deep, many won't accept the idea that problems can be solved by other means. There usually isn't just one approach. That really messes up rhetoric though. Narratives are based upon a single-mindedness. For example: *"Toyota is worse, they try to burnish their fading green credentials and gaslight us into thinking they care about the environment more than sacrificing a bit of profit to speed up the adoption of electric vehicles."* It all comes back to approach. So many think the way GM pursued the challenges of electrification is the only means possible. Problems like this come about from not being aware of all the factors at play. This is why all the engineers get confused when their obvious brilliance is rejected. Regardless of how amazing the results actually were of whatever project was delivered, there's a mystery as to the reason people didn't embrace it. This is where I bridge to the other world, that thing called *"mainstream"*. It is so different, confusion is the norm. Adoption of technology includes obstacles that have nothing to do with science or mathematics. Appealing to emotion or justifying a comfort is beyond quantification. It is still very important though. But how do you sell *"green"* as a feature? This is where approach comes into play. Not everyone comes to terms with a problem the same way. That's why the solution won't be the same for everyone either. Whether or not enthusiasts ever figure this out is their own reality to accept. Meanwhile, I share what I observe: Belief that the only means of electric-vehicle adoption must be a top-down approach is a very common problem among early-adopters. Not recognizing how effective bottom-up can be will be a painful lesson to learn... which is the ambivalence we are witnessing now from those who had high hopes for Volt. It's too bad that understanding of economics is absent from discussions like this.

1-30-2019 **Top / Bottom.** I have no idea if the request I got to provide more information about approach will be understood or taken seriously. It isn't everyday that someone actually responds back with a question. Most of the time, it's just a head-in-the-sand reply... in other words, a down-vote. Never taking the time to find out what is meant harms credibility. That's why the daily blog fell apart. They embrace group-think to the extreme that the venue became nothing but a brainless chanting website. If you didn't agree, you were wrong. Ugh. I try my best to be constructive. In this case, it was this response as an answer to explain those differences:

GM decided to use the TOP-DOWN approach. That meant delivering their vision of the final product configuration, which required a premium price as a result. Selling a Chevy compact hatchback with such a high sticker made no sense. Only early-adopters were interested, hence focus on conquest sales.

GM figured production-cost would fall rapidly, allowing the automaker to take advantage of the technology within just a few years. That expectation was grossly miscalculated. GM was stuck with an expensive halo, rather than something for the masses.

Toyota took the opposite approach, choosing BOTTOM-UP instead. That meant delivering a design through a series of generational upgrades. The results was a highly flexible vehicle that was affordable immediate. Tradeoff was range & power would improve over time... hence starting from the bottom.

Toyota's approach enabled the ability to adapt on-the-fly. For example, the advanced heat-pump could be deployed when it became affordable to do so. Waiting for the rest of the industry to catch up wasn't necessary, which is how Gen-2 got it. That is also how the carbon-fiber hatch and the aero-glass window was rolled out.

Those 2 fundamentally different approaches have demonstrate profoundly different paths to mainstream acceptance, the economics of which are rarely understood in online discussions.

1-31-2019 **Engine Cycling.** Back to the basics, just explaining various aspects of how the hybrid system in Prius operates. Right now, there are many questions being asked about how the engine runs in the extreme cold.... which is very much what I will experience when I head out to work in a little bit. Sharing of those firsthand experiences goes a long way. The words of an owner really taking the time to explain what happens while driving are very powerful. That's what really sways those uncertain about a purchase. We convince them by simply providing everyday information. The detail really matters. It is why I'm compelled to film whenever the situation can add to the understanding of goals & results. With the question about engine cycling, that was easy to answer in the form of setting an expectation... since we have collected so much information, it has been confirmed as fact: When the air-intake temp drops to 11°F, the engine will provide primary heat. It warms the coolant to a threshold you set (based on cabin temperature), then shuts off when reached. It starts off until it cools down. At that point, the engine will repeat that same on/off cycle. Note that the minimum threshold will become greater as the entire vehicle warms. So, you'll see more and more EV the longer you drive.

- 1-31-2019** **Cold Commute.** I did indeed film my drive to work today. That data is priceless. Having so much detail to share about a single experience effectively conveys an understanding while also avoids overwhelming. That's a difficult result to achieve. Lots of feedback makes striking that balance easier. People will provide guidance, if you listen for it carefully. What they pull out and share from observing what you share gives something to build upon. That's how my videos have evolved. It starts with a basic description. I summarized the experience this morning as follows: Commute to work today. Prime hadn't been driven for 3 days. Was plugged in to keep the battery-pack warm. 41°F is what the OBD-II reader stated the battery-pack was at. Outside temperature was -5°F. I drove 18.7 miles. 32% of the drive was EV based on engine-off duration. 61.7 MPG overall result.
- 2-01-2019** **Serious?** Remember the "*do no wrong*" attitude toward GM and Volt? Things got confusing when Bolt was introduced. It contradicted much of what enthusiasts had praised GM for. That got worse and worse as time proceeded, finally coming to this today: "*...if they were really serious/pushing this EV. Right?*" Questioning motive was one thing. Questioning interest is entirely another. I happily jumped in with: Wrong, since we know that GM wasn't really ever serious. From an automaker who heavily favors SUV and Pickup choices instead of cars, it never made any sense to make their premiere offerings a compact hatchback and compact wagon. Talking about a colossal customer mismatch. Also, we know that January (the dead of winter) is terrible for sales of most vehicles anyway. Combine that with having to wait an entire year to wait for getting a tax-credit, there's simply no incentive. Might as well just wait to see what others in the market will be offering. That being said, there is basically no inventory of Volt's antithesis still. There are only 150 Prius Prime 2019 models available for the entire country right now. That lack of inventory seems to be in line with Toyota preparing to take advantage of GM's downfall. Timing of GM phaseout dropping to 50% is perfect for a mid-cycle upgrade reveal, exactly the right timing for Earth Day. Imagine a 2020 model rolled out shortly afterward. It's good reason not to build up much new inventory. This is that opportunity missed a chorus of us raised concern about. Wasting time & credits on conquest achieved what?

2-01-2019 **Realistic Expectations.** It is intriguing to have a discussion with someone who abandoned Volt in favor of Clarity. He use to fight me on a regular basis. It wasn't pretty. My frustration paid off though. He recognizes that my concerns of the past were valid, that I really wasn't just a troll trying to undermine GM. Today's discussion was a reflection on January sales. He wondered why Toyota's green offerings were all low. I pointed out the opportunity approaching. There was intrigue. That's quite an improvement upon confrontation of the past. His comments ended with: *"What I don't understand is why Toyota is using up all their tax credits with it. Seems like a PHEV Rav4 with 20 kW battery or something would be a better way to use it (or what I would rather have)."* With GM sales so low now and the tax-credit reduction rapidly approaching, there's opportunity for constructive exchanges. So, I replied with:

The intended purpose of the tax-credits was for each automaker to use them to establish high-volume profitable sales which could be sustained without any subsidy. In other words, it was to fortify the everyday expectation of seeing a plug-in vehicle on the showroom floor. Whatever it would be, that vehicle needed to be able to compete directly with traditional offerings there at the dealer.

This is why I got so frustrated with GM. Watching great engineering go to waste from stupid management decisions was sad. Enthusiasts made excuses, knowing in the end a compact hatchback would never appeal to GM shoppers. It's really unfortunate Voltec wasn't ever deployed in a vehicle like Equinox.

Since Toyota customers still embrace cars, using up tax-credits on Prius makes sense. There's simply no possible way for the next-gen RAV4 hybrid just rolling out now using the TNGA platform to be established long enough to take advantage of whatever upgrade Toyota has been working on. It would just cannibalize itself. Prius, on the other hand, would be able to take full advantage of an Prime upgrade.

Just like you stated, it's easy to see Toyota treating Prime as a regular car. With some clever repackaging of the battery stack, exploiting the tax-credit to stir market interest and build up a following of non-enthusiasts would push it into the mainstream. The key is appealing to non-enthusiasts. That means reaching beyond early-adopters, which requires word-of-mouth endorsements and routine road-sightings.

200,000 is a very small quantity when you consider how many sales are required for a vehicle to be one that provides business-sustaining profit. That is absolutely essential when you consider the necessity of appealing to salespeople to encourage those sales. Remember, they work on commission and selling anything with a plug requires extra effort. Focusing on Prius jump-start dealerships makes sense.

2-02-2019 **Video: Extreme Cold (commute home).** I was able to film my drive in both directions today. This was the commute home, from work after a long day in the office: Extreme Cold brings about lots of questions. Prius Prime owners ask for detail about how their plug-in hybrid system operations in conditions with the temperature well below freezing. This is a commute home that I filmed when the mercury dipped down to -1°F. Watch the temperature reading of the engine coolant. You can see how the engine shuts off when it reaches a warmed state. It will then remain off for a little while, using that warmth to supply heat for the cabin. Though that electric-only driving doesn't last long, it does contribute quite a bit to overall efficiency. As an expected bonus in this video, you get to see how well the defroster works too. I accidentally bumped the blanket covering the lower camera used to film my commute to work. It slipped down the dashboard, covering the vent... which caused that section of windshield to frost directly in front of the upper camera. Oops! Overall, the EV driving ratio came to 37%. That resulted in a 60.0 MPG average for the 19.1 mile trip in the extreme cold, complete with travel while it was lightly snowing... [Extreme Cold \(commute home\)](#)

2-02-2019 **Spot Blocking.** I couldn't believe it. The guy in front of me pulled right into the charging-spot and sat there with his engine running. I sent a brief honk his way. Nothing. So, then I got out and said: *"I would like to park here to plug in."* He looked at me and said: *"Why don't you park over there?"* Annoyed, but unwilling to give him an emotional excuse to lash out at, I calmly said: *"I would need to drive all the way around, then have to back in to reach the cord."* He got angry, but stayed quiet, rolled up his window, backed out of the parking spot, then drove away. With all the snow we got recently, he was hoping to take advantage of the charging area and not get called out for blocking. I wanted that spot and was polite about my request. It was a very effective means of telling him to leave and never try that again. With only those 2 chargers there, filling one with a non-plug vehicle with its engine running is totally inappropriate. More and more I am seeing both being used at the same time. Why did he think he had the right to prevent what the lot's owner intended that location to be used for?

2-03-2019 **Timing.** If you study carefully, you will uncover clues about what really happens. The key is to do that digging actively while those events are playing out. Looking back, after the fact, they may not be visible. It's that lack of certainty which makes certain things stand out. In other words, those are the decision points. Following whatever choice was made, it may not be obvious what happened any why. That's how blogs like this become so valuable. They document history as it is unfolds, during that moment to capture whatever was relevant & important at that particular time. That's why stuff like this becomes annoying: *"My theory is cost. Toyota needed a bigger battery for Prime and it didn't fit the existing Prius well so they just raised the trunk floor up till it fit. Toyota did keep the Prime cost down."* Looking back years later, it's very easy to miss something vital. While things are taking place gives you sight no one else will ever have. I take advantage of that... and later try to relay my documentation:

We already know that's what happened, no theory necessary. Prime was originally intended with a smaller pack. Flexibility of the design allowed a larger one to be used instead. It didn't fit well... physically, but it was a better fit for the emerging market and still fit within the affordable goal. So, Toyota felt it was fitting.

That responsiveness to market is what we saw with Prius PHV. Back in 2010, the prototype had a raised floor... exactly like we have now. I drove one around for a short span and didn't see any issues with it. When the 2012 was finally rolled out, they decided to scale back from the 5.2 kWh capacity to 4.4 kWh for a better fit. Since it was just a mid-cycle upgrade, no big deal. We'd find out what the first true generation would offer "soon" anyway, not realizing how just how complicated the resistance to change would become.

The problems GM had forced Toyota to be responsive to market uncertainty, of which Volt enthusiasts created. Choosing to rollout Prime into limited areas only to test the waters with a larger pack, while waiting for that fallout to take place made sense... but made enthusiasts crazy, despite the obvious benefit from waiting. Now, we see tax-credit reduction just weeks away, as well as the discontinuation of Volt... a path cleared for Toyota to launch an assault.

This topic addresses the possibility of Toyota going all out, by killing the regular Prius. A logical step to preparing for such a move would be to rollout a mid-cycle update to align Prime according. Lack of 2019 model inventory seems to be setting the stage for an early 2020. Think of the opportunity Toyota has from having waited until the timing was right.

- 2-04-2019** **Video: Extreme Cold (commute to work).** That cold drive to work looked great on each of the capture devices. I couldn't wait to assemble the pieces to something comprehensive to share. It turned out really nice after lots of sizing & cropping, then the long series of renders. Here's what I published: Polar Vortex blast of cold remained for several days, keeping temperatures well into the negatives. That meant no driving. I stayed at home and the Prius Prime stayed plugged in. This was the ideal opportunity to collect data showing how the battery-pack was warmed by electricity from the cord. Its purpose is to allow as much use of power from the battery as possible, despite extreme cold outside. Watch the variety of instruments showing how the system operates when it is so cold. There's quite a bit that takes place, most of which drivers don't usually notice... [Extreme Cold \(commute to work\)](#)
- 2-04-2019** **Complaints.** There are some who will never be happy. Like today: "*Ah, I'm not the only one who realized toyota blew it with battery placement.*" I would like to figuratively slap some sense into him sometimes. This was such an occasion: You are the only one who constantly complains about it. The rest of us acknowledge the upgrade process and the tradeoff decision. Drawing conclusions during pregame simply doesn't make any sense. Wait at least until the tax-credit stage has passed. Real players of the game (mainstream consumers) haven't even arrived at the field yet. Keep in mind that the market is still emerging, that we are only in a very early stage still. In other words, there is no "*blew it*" to claim... that's far too premature. Everyone is only testing the water. There is lots of opportunity to adjust. Also, don't overlook the barriers you create toward technology acceptance but distracting with complaints. Though valid, they are far less important than proving the battery is robust enough to withstand the extremes owners encounter.

2-04-2019 **Priorities.** Follow up to that online slapping was motivating. He actually responded. Most of the time, comments are just blown off. I was pleased to get this: *"Toyota's problem is that they don't listen. There was plenty of talk about the miserable range on the pip for 5 years."* He remains clueless, but at least lurkers will have something to recognize a pattern of denial with. It's intriguing how some people don't like the answer, so they keep asking the question over and over again hoping to finally get something different in return. Refusal to accept is quite common. Resistance on this scale, especially when there isn't anything to gain anyway, makes no sense. He keeps fighting though, hoping for an outcome to change. That's the same nonsense I dealt with for years with the Volt enthusiasts. They absolutely refused to accept what was happening, belligerent to the very end. It was a defeat so comprehensive, there wasn't anything left. Giving up on the idea of GM rolling out any type of plug-in hybrid anymore wasn't an outcome any of them ever saw as a possibility. The remote chance I could possibly be correct was never entertained. They had no clue how bad the situation for GM really was, despite all the evidence I supported. Seeing that automaker's stance change so drastically is a victory for whom? I wasn't even expecting such terrible management decisions to cause such a dramatic setback. Yet, that's what happened. All GM now has is Bolt, which barely sells anymore... even with the \$7,500 tax-credit. That's why Toyota staying true to priorities is so important. That's why I admire any automaker who presents such clear plans for their future. It's not loyalty. It's common sense. Duh! He doesn't get it though, no matter how hard I try to convey that message: Toyota listens, just not to you. Far more people weighed in saying they wanted a more powerful EV drive with electric heating that was still affordable. Toyota delivered that. It's all about managing priorities.

2-04-2019 **Big Problem.** I figured the following message I posted would generate a large number of negative votes: *"You are mixing up RANGE with EFFICIENCY. There's a profound difference, a factor many supporting plug-in vehicles don't recognize the importance of. That's a big problem. MILES/KWH is a measure everyone participating here should learn & understand."* That was a testament to the lack of education related to everyday posters... you know, those who oppose without substance... aka: enthusiasts. Ugh. They blindly follow the mantra of more being better. In the minds of many of them, they belief is a tipping point toward acceptance will be reached simply by delivering enough battery-capacity. Talk of how the electricity is consumed simply doesn't happen. Rather than improve how a heater operates, you just add to the pack enough to compensate. That's an awful approach. Don't deal with the actual problem, just find a better way to compensate for it. Ugh, again. It's maddening at times how poorly informed some people are. But what really makes it troublesome is when they resist any effort to become better informed. They just plain don't care. They've had it with oil & pollution. Green is all about plugging in. How much electricity they actually consume doesn't matter to them, as long as it isn't gas. That's such a let down. They don't even recognize the true issue at hand. It's about the triangle. You know... reduce, reuse, recycle. The effort is to minimize, not just switch to another fuel and waste that instead. Needless to say, it was very disappointing to see that lack of understanding. I've heard from several other leaders recently dealing with that same big problem. Any suggestions?

- 2-04-2019** **The Game.** This seems reasonable, at face value: *"I started to wonder if Toyota might try to up their game by putting in a larger capacity battery-pack."* But when you start wondering about detail, questions emerge about purpose... as I pointed out: If the *"game"* is to sell more, what data is there to show larger capacity would raise demand? I envision Toyota rolling out a mid-cycle update with cell/stack arrangement for the pack altered to provide a better fit in the hatch area for greater cargo space. That may not increase capacity, but it wouldn't cause a price increase either. What if the *"game"* is to prepare Prius for a plug-in only approach instead? In that case, the smaller battery-pack would be better. Think about what people have in their garage for charging. If only a single circuit is available and it must be shared, the rate may be limited to 8-amp draw... which could require 8 hours for a full recharge. More and more, it looks like Toyota is aiming for the masses, where their high-volume profitable seller is something in that regard. Prius would be a "prime" candidate for that. (I know, bad pun.) Reaching mainstream consumers is far more difficult than appealing to early-adopters.
- 2-05-2019** **Video Collection.** Continued refinement of video presentation is rendering some of my older content less useful. More detail and improved quality made that inevitable. Adding value is the goal though, so that's ok. It's interesting to look at those old captures from years ago. A lot has changed with the technologies involved, both car & camera. It's rewarding too, when you have that content to share for education & debunking. So as time progresses, I'll just recapture some of the most referred to video with new footage containing a lot more information. Sadly, some of the locations & circumstances cannot be recreated, but at least it all reflects real-world driving. That's just me behind the wheel doing what I normally do... nothing special... just drive it. More to come as I get better with the editing too. The effort to assemble the variety of feeds and insert commentary is rewarding. I enjoy that build process.

2-05-2019 **Damage Control.** Virtually all the Volt enthusiasts have vanished, gone without a trace. Rather than showing up elsewhere with a revised purpose, there is nothing. It's exactly the pattern observed in the past. Those who cheered & antagonized disappear entirely upon recognition of having failed. Acknowledgement never happens, they simply don't exist anymore. The few who remain don't even speak of them. It's as if that history was just a bad dream. So, all the rhetoric is over. However, those individuals remaining feel the need for damage control. Today, it was an effort to make things look like Toyota was in the situation: "*OMG, even Toyota's doing it.*" Quickly after posting my reply, there was a response to spin what was really intended by that. It was too late though. Even more damage had been done. Making it worse is evidence of still having not learned their lesson. Oh well. It's their loss, which I'm happy to point out: That attempt at damage-control is pretty lame. The advertisement for RAV4 hybrid features the second-generation now being rolled out, not the first as you imply. I have been talking about a "*Prime*" upgrade to that platform for years, just add a one-way clutch and more battery the same way Prius was augmented. It's a simple & affordable way to offer a plug option. Each time I brought up the larger and more powerful hybrid, I got attacked. In fact, I expect the same with this post... especially when I remind everyone of how GM recently chose to offer Equinox as a diesel, rather than a hybrid. See, with the RAV4 hybrid becoming a popular choice, due to the regular RAV4 being Toyota's top-seller and the hybrid being so affordable, taking the next step by offering a plug in a no-brainer. Those loyal showroom shoppers will see the plug-in and seriously consider the purchase, simply by association. All the senseless efforts to undermine Prius and attack me were in vain. Enthusiasts here failed to heed the warning, despite being told hundreds of times GM must diversify their plug-in hybrid technology. It was never spread to a SUV... and clearly should have.

2-06-2019 **40% Loss.** The topic of Winter's impact was exclusively in the domain of enthusiasts, until now. Of course, even then there was little discussion of heater type. That has finally changed. An article published by AAA is the reason. What it says really doesn't matter much yet. The point was to raise awareness. Most notable of that new found attention is the 40% figure sighted. With so much of a range-loss claimed, there was obvious outcry. If you have to deal with lots of weather-related traffic and have the heater set on high, there will indeed be that much of a reduction. But under ordinary circumstances, that's not the case. I wear my coat while driving and use the heated seat. That means nowhere near the amount of electricity for warming is needed through the vents. So just like the problems with MPG rating and the setting of realistic expectations, there's the same YMMV disclaimer. Question is, will readers actually understand that. Sadly, that is not likely. Detail is lost in the shuffle, when it is provided. But most people won't recognize there is a difference between a heat-pump and a resistance-heater. So trying to get any type of awareness related to the type of heat-pump... the regular kind verse one that's vapor-injected... is basically impossible. Long story put short, it's an uphill battle. Required education to better understand purchase choices... or even knowing what to look for... will remain quite a challenge for years to come.

2-07-2019 **Perfect Timing.** A constructive question from an audience genuinely interested in feedback: *"What are you basing the likely mid-cycle refresh on? And when do you think those cars are coming? I am in the market for a Prime right now and I don't want to regret not having waited a few more months."* I always hope replies result in an on-going dialog. After all, we don't have answers. We only have research & observations. Those serve as clues, but nothing definitive. This was my contribution to the hope for more discussion:

Waiting is a challenge. Some people don't like the idea that Prius is morphing into more of an affordable sport/luxury design, rather than remaining the family-mover it started as. That's the reality of a changing market though. RAV4 is quickly becoming the hybrid of choice for that family audience. So, have some realistic of expectations of what adaptations could be offered.

Knowing the shift is underway, it makes you question the direction Prius really will take. From Toyota's extensive history of pushing affordable emission & consumption reduction for Prius, it makes sense that they use the second-half of this product-cycle for Prius Prime as the staging opportunity to make it a plug-in only. Can Toyota attract enough buyers that way for the next-gen to be a high-volume profitable seller? I say: *"Yes!"*

Evidence supporting that builds upon more awareness of history. Toyota likes to do mid-cycle updates. Prius PHV (gen-1 Prime) was in fact that. It was also a limited rollout as a result of carefully watching market change. In that case, it was the disaster GM was dealing with trying to figure out how to configure Volt. All these years later, we see that GM failed to deliver something for the masses... as confirmed by production ending and the tax-credit reduction taking place. The timing is a great happenstance for Toyota, exactly when a 2020 model with a mid-cycle update could be revealed.

Notice how 2018 inventory was burned down and 2019 inventory has been almost non-existent? Though it could all be an amazing set of unplanned circumstances, this certainly looks like far more than just a coincidence. Think of how perfect an Earth Day announcement it could be, especially if rollout follows shortly afterward.

Want more to consider? Think about the timing of rollout for Corolla hybrid. It's just a little too much to dismiss as just dumb luck that everything is falling into place so nicely.

2-08-2019 **Next Step.** Thoughtful questions are nice: *"So you are thinking they might go to a full EV rather than Plug-in hybrid... ?"* This was an easy one to provide an answer for: No, we are looking at the paradigm-shift from hybrid to plug-in hybrid. There's strong potential for them in the mainstream, even without next-gen battery advancement, like to solid-state. EV market development is still its infancy. Dependency on tax-credit subsidies and early-adopters for sales makes that reality all too clear. Hybrids, on the other hand, are a mature market, at the ready to advance to plug-in models as the next natural step. That's vital for reaching ordinary consumers.

- 2-08-2019** **Lacks Vision.** This question wasn't as nice, but it was still an expression of thought: "*Toyota lacks vision?*" I found that one easy to answer too: Reality is, Toyota sees something different. They are looking at the mass market, trying to find a way to affordably fulfill the wants & needs of their 10 million customers per year. In other words, you are looking at something different... which is quite common from the eyes of an enthusiast. Appealing to a Corolla or RAV4 shopper is very challenging. They won't be forgiving like early-adopters and they won't be as willing to pay as much to get a plug. There won't be any tax-credits available for them either. In other words, know your audience. An electric future for those of us here is a reality already. For the masses, it's still a number of years off.
- 2-09-2019** **53 City, 52 Highway.** That's the official EPA rating for the 2020 Corolla hybrid. With MPG being basically the same as Prius (slightly lower City and slightly higher Highway), it marks the end of every possible argument against the hatchback... since this is an affordable sedan instead, a very popular one at that. Nothing can be said about looks anymore. That's the beauty (ironically) of diversification. Toyota is providing a variety of hybrid choices. That spread of new technology is a vital step early-adopters don't understand, since they focus only on what it takes to prove the technology worthy of being a successor. Very few actually take the time to study what comes next. That's why they are enthusiasts, rather than supporters. Phasing out an old technology requires a great deal of effort getting everyone to accept it as a replacement. Seeing it implemented in several different configurations shows that the automaker is committed to it, in addition to proving the design is well thought out by witnessing it being used on a regular basis. Think about how quickly the Corolla hybrid will become a common sight on roads. People buying them tend to be more conscious of efficiency anyway. Having a hybrid choice makes it even more compelling.
- 2-10-2019** **Extremes.** Sighting them is a common practice. Taking the time to determine whether or not that was a good idea is not. For example: "*iirc, the pip won't run ev mode that low whereas the soon-to-be-no-longer-produced 2019 Volt will run EV mode until it's cold soaked to around -13°F.*" How often does it really get that cold? What's wrong with running the engine for those few times per year it happens? Isn't the point of having an engine to use it from time to time? Don't forget, it needs to for routine upkeep anyway. I was annoyed. So, I shot back this: Exaggeration serves no purpose. Here's PiP driving in EV without engine warm-up at -2°F: [Prius PHV - No Heater](#) Remember, the purpose of using the engine is for the best balance of available resources... something Volt did not do. Why carry an engine, then go to extremes to avoid ever using it? In other words, EV driving is possible, just not the best overall choice.

- 2-11-2019** **50, 42, 97, 48.** Checking the post counts for that new troublemaker revealed those numbers. He only posts a sentence or two and rarely includes the quote he's making a comment about. They basically come off as a nuisance to the well informed. But to the casual reader, they could be a source of confusion. I worry because that can be misleading, since it is often quite vague. He doesn't care though. It seems to have become his pastime activity as a retiree... which is unfortunate for us. Having to deal with someone treating the forum as a source of entertainment, rather than being a helpful resource is a loss for everyone. He is basically a friendly troll. There is no intent to cause harm or confusion; nonetheless, that's the result of his ways. No group is perfect. It's not always worth the effort to address each and every problem though. You choose your battles. In this case, I'll just let it go.
- 2-11-2019** **Blog Bias.** We are starting to see some serious purity problems emerge on the EV forum. Back when it was founded many years ago, the thought was that it would cover the advancement of electric-only vehicles. The idea of also providing news coverage & commentary opportunity for plug-in hybrids wasn't even a consideration. That simply didn't make any sense. If it had an engine, it wasn't important. Turns out, that wasn't a good idea. The transition to electricity would very much include that interim stage. The realities of business & infrastructure made it all too clear. Some still see that domain as one of purity though. So, we see insulting & belittling posts on a regular basis. Any of that sound familiar? Needless to say, I recognize the symptoms of the problem. Sadly, I haven't found a source of resolution yet. The moderators have been quite. They are at a loss about what the next steps should be. I appreciate their modest efforts to stir feedback, but I wish they were more forthcoming. The possibility of their blog becoming too bias to appeal to a wide audience is quite real. You get a feeling of unwelcome every now and then. It's quite a contrast to the open expression of acceptance I witness from our local plug-in owners group. Change is difficult. I hope they deal with it appropriately.
- 2-12-2019** **Cannibalize.** What do dropping sales of the regular Prius actually mean? Quite often, the comment is new hybrid offerings from Toyota will continue to erode Prius interest. From a macro perspective, I could see that. But from a micro, not a chance. Prius was always what ushered in new technology to the masses. We are far from complete with the rollout of technology. There is quite a bit of advancement opportunity remaining. Why not just push Prius into the new category of offerings? Why is there always a doom & gloom portrayal of the future? I suspect many people simply thrive on drama. Fortunately, sustainable business is pretty boring. That's how Prius has sneaked through barriers in the past. Such a soft push goes unnoticed... until the count grows to such a scale that you discover the stage has changed. In other words, no cannibalizing is expected. It will be business as usual. I put it this way in my reply to the stir of that topic today: "*Know your audience*" is a fundamental which has served Toyota well. They don't pander to enthusiasts like some others do. Their focus is on how to appeal to their own loyal customers, finding ways for long-time Corolla or RAV4 buyers to go hybrid next time around. Prius doesn't even fit in that market category.

2-13-2019 Corolla Replacement? Now we are really starting to get some constructive questions. I like this simple and to-the-point query: "*What does Prius have to top that?*" It was an easy one to provide a reasonably acceptable-to-many response too: Sedans are rapidly vanishing. Corolla will survive that changing market simply due to it being the world's best-selling vehicle. After so many generations, the choice is a no-brainer for the basics. Prius has always offered more than the basics. So, it makes sense that it will continue to hold that position in the fleet, especially with it being a hatchback. Camry is what see taking more of a sales it, proportionally. That's due to the rise of RAV4, which is extremely well positioned for SUV demand. Keep in mind that Toyota is a 10-million-per-year automaker. They don't cater to the allure early-adopters seek. Their target has always been ordinary consumers. So, there has always been a perception issue when it comes to the appeal of Prius, an image never properly portrayed based on claims from those trying to interpret history long afterward... which always made the understanding of how it sells so well a mystery. The direction of Prius taking on a plug-in only role seems the obvious next step. Battery advancement combined with some emerging clarity of what mainstream consumers will actually purchase... now that we are finally starting to see the confusion caused by enthusiasts & subsidies fade... makes a high-volume profitable approach realistic in the not-too-distant future.

2-13-2019 Attack Ad. First thing this morning, an assault was launched on Toyota. It was the typical "*anti-EV*" nonsense. Not understanding how to reach the masses or understanding how their hybrid technology is actually designed causes all kinds of problems. They focus on only key factors, not everything as a whole. That's why there are claims of me shifting focus. When I mention emissions, profit, sales, and production, an enthusiast will inevitably choose just one to respond to. That's how you end up with spin. They just plain don't want to look at the big picture. In this case, it was how to reach ordinary consumers. The blinders have been on the "*EV market*" for so long, many have completely lost touch with purchase priorities of ordinary people. That's why engineering has changed to advertising. Whatever reality they had based original goals on is gone. That's why the impact of tax-credits loss really hasn't sunk in yet. Enthusiasts are focused on subsidized sales so much, they have no idea how difficult the real-world of direct competition with traditional vehicles will actually be. Plug-In choices don't stand a chance in that aggressive market. This is why they were living in their own world. In made sense, at first, to establish reputation by proving the technology worthy. Unfortunately, many forgot that was only a stage. So now with Toyota advertising Corolla hybrid, they feel the need to attack. Since it doesn't have a plug, they believe it is the enemy rather than a bridge. Ugh. I launched my counter-offensive to that with: We have seen quite a bit of advertising by press-release lately, to the degree that "*over promise, under deliver*" has become common across the industry. Yet, there's no outcry about that. The fact that Toyota made an undeniable subtle comment about the current state of our infrastructure is good reason to self-reflect. In other words, why is there still so much forgiveness in buying guzzling ICE vehicles while we wait for promises of years to come?

2-13-2019 **Large-Scale Change.** Constructive discussion is gone. The death of Volt has opened up the automotive market to explore new offerings. That nasty precedent GM was so counter-productive, it's basically impossible to argue otherwise. Evidence of that approach being unrealistic for the masses was overwhelmingly proven... to the extreme that those saying GM was never committed to the technology go unchallenged. It's over. With that niche no longer being a barrier, a lot of attention is turning toward Toyota with an expectation of it leading the way. Problem is, many at this stage don't agree that leadership is best when targeting mainstream consumers. Want for standout vehicles is the theme, not something to become so common it goes unnoticed. Well, too bad. That's what needs to happen. I let them know it too: Distracting from the challenges of infrastructure and turning a blind-eye on subsidies by crying "*anti-EV*" is constructive how? Reality is, that's an excuse drawing attention away from how the masses will embrace electrification. What is the plan from other automakers for their entire fleet? Taking the hybrid step to plug-ins is a solid means of quickly phasing out a wide variety of ICE choices, as well as overcoming change intimidation.

2-13-2019 **Bon Voyage.** There are hints of trying to be constructive from some, even former antagonists: "*one should at least acknowledge that the cruise ship's bon voyage horn is about to go off - one would think.*" They don't get it though. When you want to attract ordinary consumers, you can't do something symbolic. To get their sales, you have to be persistent, yet subtle. Sending a clear & concise message without actually advertising is a challenge though. People must have enough clues to recognize the paradigm-shift without any question of its takeover. Things like having Wi-Fi at home. Setting up a wireless network was only the domain of technical savvy individuals ages ago. Ask yourself how it became normalized. Think about that. It was due to encountering those free Wi-Fi signs all over the place. Routine sightings make a profound difference. This is how and why Prius became the symbol of hybrids. There was a lot of work set forth to make a colossal, yet seemingly invisible change. That's what will happen with plug-ins. You'll just notice them more and more. I pointed this change out by posting: The first ship of hundreds is basically just symbolic.... very important.... but nothing that will affect the masses for a generation or two still. Remember the first cell phones or digital cameras? They were a sign of great things to come, but totally unrealistic for mass-adoption in those early years... which is exactly where we are now with plug-ins. It's tiring to hear early-adopter impatience, but that's actually how potential is gauged. They feel opportunity is being missed, but are too out of touch with ordinary showroom shoppers to understand why such a different path must be taken to appeal to them.

2-13-2019 **No More Spin.** It's nice to see the arguments are over. We're just seeing a lot of summaries at this point, like: "*Then Toyota will either be left behind or just play more catch up with the rest of the industry.*" It came from someone who sometimes serves as a devil's advocate. So, it was worthwhile providing a well thought out response:

Toyota continues to refine their EV tech. The efficiency from both Prius Prime's traction-motor & heat-pump is impressive already. That will be offered in a plug-in model of Corolla hybrid in the not-to-distance future. Next year, an EV model of C-HR will be offered in China. Meanwhile, the next-gen RAV4 hybrid is being rolled out. What aspect of "*behind*" is there with respect to reaching mainstream consumers?

With respect to cost-reduction of those non-battery components, where is the rest of the industry? Think about how well positioned Toyota will be with RAV4 hybrid in this market when an affordable battery (no tax-credit dependency) becomes realistic for the masses. Having that already established puts them in a very good place.

When I see claims of needing to catch up, it makes me wonder how far reaching the rhetoric has become. There are far too many engineers claiming to be well versed in marketing & economics. It's the problem GM had with Volt now playing out on a larger scale. Knowing your audience means understanding how to appeal to them.

So what if a point-in-time advertisement doesn't embrace the future if it still gets the consumer to take a step forward. You worry about the next step after the baggage holding you back is gone. In this case, Toyota is trying to rid itself of traditional vehicles far faster than other automakers.

Look at it this way, other automakers will have a premiere electric vehicle and a large selection of traditional vehicles. Meanwhile, Toyota will have a wide selection of hybrids and a few plug-in hybrids, to go along with their premiere electric vehicle. No more high-volume traditional vehicles would put them ahead.

2-13-2019 Leadership & Payback. Someone brought up the analogy of this being the age of "*Horse & Buggy*". That was about a century ago when the switch from almost all horses and a few cars reversed to only a few horses and almost all cars. It seemed like overnight, but in reality took roughly 2 decades. Back then, the benefit of switching was profound. Switching from a high maintenance form of transport for one or two to a means of moving more people and cargo a greater distance at greater convenience was obvious. What is there with a switch from guzzler to green? Most people look at it as an expensive sacrifice. How do you sell that? Apparently, the leader is the one who offers the most range... even though you get less miles and less convenient from plugging in rather than pumping gas. Ugh. That comes from our simple-minded approach to everything. When a complex issue comes up, people in general think there is always a simple answer somewhere... that we just need to find it. Ugh, again. The hard work it took to even get the buggy to take over for the horse is over-simplified. It took a lot of work to setup infrastructure and to train people. Whether or not the answer is obvious doesn't mean it will be easy. In this case, we are dealing with a society obsessed with size & power. They will sacrifice quite a bit to have that, but won't consider even a penny toward being green. So many ask about "*payback*" duration, you don't stand any chance of getting them to contribute anything toward environmental benefit. They absolutely refuse to put any value on lower emissions & consumption. It's all about getting something for nothing. Thankfully, there are a few true leaders who see the actual problem. Toyota is pushing Corolla as that something-for-nothing solution. Payback is so obvious, that question won't even get asked. It should become a "*no brainer*" purchase decision. You want a Corolla, why not get the hybrid model? My response to the issue doesn't get such an elaborate explanation though. Heck, I don't even bring up purpose. I keep it very simple: 329,196 sold last year in just the United States... a land of SUV crazed consumers. Not a single one of them had the influence/dependency of a tax-credit and the result was a tidy profit for automaker & dealers. Whether or not that's called "*leadership*", it is an example of solid business... which is exactly what's needed to position the entire fleet for motor & battery use.

2-13-2019 **Smug.** Ever wonder how the smug respond to the logic of a sensible business approach? This was a great example: "*And in Toyota's case it's head in the sand and fingers in the ears, while loudly screaming lalalalalala I can't hear you.*" That's how they perceive the choice to ignore rhetoric. That never ceases to amaze me. Their own hypocrisy goes totally unnoticed. The very comments they make about the situation are their own version of lalalala. Yet, they don't see it. Pushing ahead blindly with nothing but the hope of "*if you build it, they will buy it*" has failed dramatically. Studying the market and staying true to goals is meaningless. They have a group-think idea and believe everyone else will follow, even when there's nothing to support that belief. I find the lack of understanding quite troubling. They simply dismiss what they don't like, rather than addressing the issue. How does that fix a problem? This was my response to the nonsense they stirred today: Hear who? GM made the mistake of listening to enthusiasts. Volt-1 failed to attract their own loyal customers as a result. Volt-2 repeated that same mistake, delivering even more of a niche product. Targeting the wrong audience cost GM immensely. They now have a plug-in hybrid about end production with no successor. It was a huge waste of tax-credits. Toyota isn't concerned about the opinions of those screaming "*anti-EV*" because they don't represent their showroom shoppers. Profitable high-volume don't come from listening to those not interested in what mainstream consumers will actually purchase. Why would Toyota put so much hope on dealers serving a complacent market? Setting the stage for plug-in offerings by shifting a large chunk of their fleet over to hybrids is a sensible next step. Meanwhile, other automakers are making a lot of noise but delivering very little. It's quite hypocritical to pretend not to see that taking place by aiming a spotlight on Toyota. Those of us paying attention see what's really happening. Think about how easy it will be to sell Corolla plug-in hybrid when Corolla hybrid is a common sight on roads and in parking lots. It will be that silent sucker-punch to those enthusiasts here in denial about how to appeal to ordinary people... in high-volume... for a profit.

2-13-2019 **Facts.** Don't you love how people throw around facts, but fail to include any detail to actually support what they claim the fact represents: "*The fact people are abandoning Toyota hybrids in droves for the model3 says it all.*" I wasn't about to let that nonsense attract any thoughtless response: That "*fact*" omits vital information, providing a distorted perspective of the bigger picture. True, some owners of Prius are indeed trading up for Model 3. That's a very small percentage though, and they'd be really missing out on the opportunity by not taking advantage of the tax-credit. It's a low-hanging fruit situation, quite short-sighted. What happens when that \$7,500 incentive is gone? RAV4 hybrid (second-generation is just rolling out now) shows a great deal of growth potential. What does that say? It's a compelling choice at an affordable price. That's what mainstream sales are all about. Corolla hybrid is in a similar strong growth position. For anyone who didn't like the look of Prius, there's no excuse not to seriously consider it. That's what product diversity is all about. Within the fleet, there will be a hybrid choice to your liking... and each is designed to take the step of offering a plug very easily. Remember, Toyota is investing heavily in battery advancement. So what if those plug-ins aren't offered for a few more years still. In the meantime, the platform to take advantage of the new tech will be establishing itself on a massive scale. Dealers & Salespeople will grow familiar with the system ahead of demand from showroom shoppers. So, what does that "*fact*" really tell us about the upcoming market?

2-14-2019 **Direction & Patience.** The smug is growing. Purity is changing to intolerance. It's getting ugly. Statements like this indicate a turning point: "*They reduce emission sure, but not enough, they are always burning fuel, that's not sufficient.*" Remember how Volt had an engine, but everything was done to avoid actually using it? That never made any sense to anyone other than enthusiasts, but it did serve as a bridge to reach ordinary consumers. That failed, but the reasoning of it appealing to mainstream consumers was an obvious point. They'd sell the idea of the engine only being used as an emergency backup, but promote the fact that it performed without sacrifice to power or speed when you used it. That mixing of messages is what ultimately killed Volt. Lack of agreement of purpose is even worse than not fulfilling a goal. Advancement in any direction is impossible without consensus. GM found that out the hard way by trying to please everyone with a one-size-fits-all solution. Thankfully, we can clearly see Toyota isn't doing that. We get a wide variety of hybrids for their wide variety of customers. That makes the direction to take with the technology very easy to agree upon. I pointed that out in my attempt to deal with today's smug post: A plug-in hybrid will dramatically reduce consumption & emissions. My Prime averages 80% EV driving, despite numerous long highway trips per year without a place to recharge. It's a technology we can deploy immediately, due to its affordable design. GM failed miserably with Volt due to the cold, hard reality that it was too expensive to produce. That made it very unattractive to dealers and made the sticker-price unreachable for ordinary people. Your "*not enough*" isn't constructive in 2019. You know quite well next-gen offerings will take battery-tech the next step to being realistic for the masses. In the meantime, the much needed infrastructure will be improved too. Most businesses don't have any chargers at all. The few that do only have a couple. How does that help anyone beyond early-adopters? Show some patience.

2-14-2019 **All-Caps Rant.** Wow! The response to Toyota's advancement of Corolla got intense. It's obvious why. Prius was an easy target. Enthusiasts will dismiss it as slow & fugly, then move on. They saw no reason to take it seriously. Even though sales were strong, it was easy to dismiss as just being a green statement. People were only buying it to show off their care for the environment, to portray an image of caring for all things green... as far as they were concerned. That served enthusiasts well too. It was their excuse to deny. Seeing the same technology rolled out to Corolla without any sacrifice whatsoever derails their avoidance tactics. How does one fight such a popular vehicle offering so much benefit for so little cost? MPG combined rating equal to Prius in a stylish body already proven very popular is a death blow so extreme, they have no logical response. So without any sensible next step, the inevitable happened. Someone posted a rant in all capital letters. It was hysterically long too, just a single run-on sentence a large paragraph in length. You can't help but to be amused by such desperation. It didn't work though. I posed the following to address the nonsense: Wanting it done quickly rather than done right has consequences. Look at GM's rush to market with Volt. It's production will soon end with no successor. That proved a massive waste of tax-credits. Toyota's plug-in approach is slower, but stands much greater chance of reaching mainstream consumers affordably and in large quantity.

2-15-2019 **6 Weeks Left.** Remember the hell some of those enthusiasts put me through? They fought for years in favor of a plug-in hybrid with no compromise, one that only used the gas-engine as an unnecessary emergency backup. They coined "EREV" to displace the original purpose of addressing "range anxiety". It supposedly worked so well, there was no reason to even discuss anything other than EV driving. That was how they chose to fight Prius PHV and Ford's Energi. That kind of worked, until BMW came along with i3. That exceeded performance & purpose of Volt to such an extreme, enthusiasts lost their way. That's what ultimately pushed them to all focus on EV competition instead. Nissan was the victim of that. Leaf's lack of an active thermal-management system left it vulnerable to spin attacks. To the dismay of Volt enthusiasts, that didn't work. They were losing the fight regardless of what seemed sound logic. It was the dismissal of facts they didn't like which caused their downfall. Every time vehicle price was brought up, they'd brush it aside, saying that was of no importance. Having a \$7,500 subsidy to disguise that problem helped tremendously. They could shield attacks with that artificial barrier... which has since expired. Seeing that phaseout coming and the consequences there of, enthusiasts of Volt almost unanimously shifted loyalty over to Bolt instead. Remember how I pointed out the "olt" part of the name could later be exploited to mislead? That's exactly what we saw. The confusion was accepted as a misunderstanding, as if that's what everyone had been talking about all along. We saw that mantra spread like wild fire. As if overnight, Volt enthusiasts began saying the path to Bolt was planned all along. As soon as EV became "*affordable*", the switch would happen. Halting production mid-cycle was supposedly an expectation, even the part about people losing jobs in the process. Ugh. I reminded them of the rhetoric on what's left of the daily blog, pointing out no progress has actually been made in that regard: GM press-release October 2, 2017 stated: "*In the next 18 months, GM will introduce two new all-electric vehicles based off learnings from the Chevrolet Bolt EV.*"

2-16-2019 **Constructive Coexistence?** Fuel-Cell technology gets brought up a lot as a form of diversion. Rather than deal with issues at hand, they attack Toyota with that nonsense. Pretending GM, Honda, and Hyundai don't have fuel-cell programs of their own is key. All you need is just enough to make people lose focus. It's like yelling "*Squirrel!*" with the hope it makes the person talking stop long enough for someone else to fill in the silence. It doesn't matter what is said next, just as long as topic changes. On rare occasions, I get to actually point out some facts with the hope of constructive feedback. It should be obvious that there will be a co-exist situation with hydrogen. That means of energy storage & transfer is practical for certain application. Getting people to consider the possibility of particular situations being more advantageous is a challenge. I keep trying though: Keep in mind that hydrogen will have a place in our society, but that will almost entirely be on the commercial side. The reach out via passenger vehicles right now is to stimulate support for that. Think about how practical they would be for large business fleets and the certain types of cargo trucks. Educating those who will fund those programs is difficult. Rollouts like this do a great job providing that information. Plug-In vehicles face serious challenges in the meantime. High-Speed charging is basically non-existent when you consider how rare those stations actually are. There cost for equipment and the physical space they occupy makes them a monumental effort to rollout. A variety of vehicles supporting a minimum rate of 150kW simply aren't going to be realistic for a number of years still. We are very much in the earliest stages of rollout. In other words, the doom & gloom and conclusions people are already drawing are complete nonsense. There's no reason to take any of that seriously. One thing you can count on though is there will not be a single solution. We are embarking on a multi-technology age where there will be a variety of approaches taken. The one-size-fits-all mindset is not constructive.

2-16-2019 **Charging Cost.** A problem most plug-in advocates tend to avoid is the cost to charge. Under some circumstances, it can be a good deal. Heck, at my local grocery store, it's free. Unfortunately, sometimes it can be really expensive. So, you need to consider all the factors a play. The very high-speed is where you have to be really attentive. A friend of mine tried it with his BMW i3 using a DC Fast Combo charger. He got 17.07 kWh over the course of 45 minutes. A slower charge (2.5 hours) for me overnight (for the off-peak discount) with my Prime is 6 kWh. That comes to \$0.42 for the total cost of that electricity. My friend had pay \$15.75 for his charging. That much faster speed at a more expensive rate (due to the higher draw during peak hours) made it far more expensive for him. Was that worth it? Depending upon the situation, perhaps. In terms of what that electricity equates to for distance, it's typical to get efficiency of around 4 miles/kWh on average for this time of year in the south. That's about 68 miles of travel. At 50 MPG using \$2.50 per gallon gas, that would be equivalent to paying \$3.40 for the same distance. So on the road if you really need electricity, it might be rather expensive for a rapid recharge. Less convenient is usually a better idea. For my commute, electricity is by far the better choice. For my long-distance trips, I'm much better off with just using gas. Eventually, infrastructure will make electricity favorable in far more conditions. That doesn't mean you should wait though. The choice of fuel available to plug-in hybrids can provide the best-of-both-worlds experience... if you pay attention to charging cost.

2-16-2019 **Attacking Others.** It's one thing when a troll becomes an antagonist who lashes out at you. But seeing it happens to others makes the effort to attack anything in opposition obvious. What do you do then? Today, it was this which brought the newest problem to my attention: *"I'm just really not understanding all this effort you're going through to point out the superiority of BEVs and the (frankly) marginal improvements in oil savings when tons of people are moving to hugely less efficient vehicles. You're practically preaching to the choir while (to extend the analogy) the church burns down all around you."* It was directed at a long-time troublemaker, a person who would spread FUD for the sake of keeping conclusions from every being draw. Raising doubt can be an effective means of undermining. Fortunately, you can point out the pattern of repetition after a while. That's what stirred this anger. The other being attacked recognized the intent and wasn't about to put up with any more of it. I joined in with this to help out:

Oddly, preaching to the choir does have its place. It teaches everyone about goals.

I was called a *"troll"* for years due to my pestering of Volt enthusiasts for them to get their priorities straight. Individuals, like our troublemaker here, obsessed with range & power to such an extreme, they lost touch with purpose. It was all about fighting the other plug-in vehicles for superiority. What an embarrassment for those of us really trying to make a difference.

My mantra was repeating the *"too little, too slowly"* concern the GM bankruptcy recovery task force stated. They were worried the technology in Volt wouldn't result in the profitable high-volume offering GM was claiming it would become. So when I asked *"Who is the market for Volt?"* over and over and over again to point out GM wasn't doing anything to spread that technology to vehicles their own loyal customers would actually purchase, I got personally attacked by the *"vastly superior"* crowd.

It was brutal, a test of character remaining true to goals. But it paid off. We now see that all the rhetoric against Prius from those Volt enthusiasts really was an effort to satisfy want, rather than to fulfill need. GM was actually the laggard. They rested on their laurels and fell into the innovator's dilemma trap, despite so many warnings. Now Volt production is about to come to an end without any successor. All those tax-credits with the intention of establishing a mainstream vehicle were wasted. So much opportunity was missed... and they enthusiasts now recognize my concern was sincere all along.

Ironically, this topic of *"EV Mode in Cold Weather"* is what started all the rhetoric. Precisely 1 year before rollout of gen-1 Volt began, back when little was known about plug-in vehicle performance, I brought up this very topic. Armed with some Nissan Leaf mule testing data, I pointed out how much of an impact to range use of the heater had. Volt enthusiasts immediately got angry, claiming my effort was to undermine the *"40 mile"* range goal GM had set by making up FUD about electricity use. Now, we all see that couldn't have been further from the true. I was objectively stating a reality.

Recent rhetoric has turned to the state of panic GM enthusiasts are now dealing with. The abandonment of Volt came with the understanding that Bolt would be the replacement, that GM would aggressively deliver EV choices. It was all based on a press-release from October 2, 2017 stating the following: *"In the next 18 months, GM*

will introduce two new all-electric vehicles based off learnings from the Chevrolet Bolt EV." There are only 6 weeks left of that self-imposed deadline... and we still haven't heard anything from GM.

That terrible mindset of doing it quickly instead is something we must remind ourselves of and make a concerted effort to avoid. Toyota's approach of staying true to goals and taking the time to do it right is proving their wisdom of understanding the market. They know their audience. They study the entire system, carefully noting impact to every step of the production, delivery, and support process.

2-16-2019 **Enthusiast Hope.** The spin keeps coming: *"Can't wait to see all the EV's GM has claimed are in the pipeline."* Seeing that, I was happy to point out the GM press-release October 2, 2017 on that thread. Including those words of *"In the next 18 months, GM will introduce two new all-electric vehicles based off learnings from the Chevrolet Bolt EV"* will obviously still. I also pointed out that April 1, 2019 is rapidly approaching and we still haven't heard a peep. Then I really let those enthusiasts attempting to stir hope with this additional bit of cold, hard reality: *"Following those two, at least 18 more EVs will launch by 2023. GM has already said that it expects to launch 10 electrified vehicles in China by 2020. The 10 for 2020 included plug-hybrids like the Cadillac CT6 Plug-in and the Buick Velite 5 range-extended EV, but some of those ten China-only models will likely be among the 20 EVs that are part of the announcement."* Needless to say, I'm on the offensive now. They must present substance, something of merit. Their attempts to stir blind hope have had costly consequences. Allowing that to continue is unacceptable. They must acknowledge how the path they chose didn't work, they choose a new one. There's nothing wrong with a correction measure. You learn from mistakes, they try something else.

2-17-2019 **Closure.** We've come full circle. I got this in reply: "*You don't need to be an insignificant mosquito looking for a satiating blood meal.*" It was followed by a few personal insults. That invited me to post what I have been waiting a very, very long time for. In other words, patience does pay off:

You think analyzing a situation, sharing observations, then waiting 18 months for it to come to fruition is that? Talking about a complete loss of objectivity. After having to tolerate so many personal attacks, I am very much allowed to point out the hypocrisy unfolding.

This group went from spinning a term called "*EREV*" to set their favored technology apart, without substance to actually support any clear difference, to abandoning it entirely when those efforts fell apart. The choice at that point was to embrace EV and promote how rapidly GM would deliver upon new promises.

This group heavily endorsed those promises, pushing the belief that GM would build upon what Bolt achieved to bring about 2 new all-electric choices. The timeline was firmly established. We had to accept what was promised blindly. We were told to just patiently wait. That time is about to run out and we still haven't heard anything.

GM's reputation for "*over promise, under deliver*" is undeniable. The fact that it stings to find out it happened again is no reason to blame me for your decision to believe what was promised. I was sharing as much history as possible to get you to notice the pattern, to take a more objective view of what could actually be delivered.

The blood is yours and I am not the cause. I'm the one standing next to you with ointment hoping to finally get what I came here for all those years ago... an ally, someone else who understands what it really takes to get each legacy automaker to end production of their traditional vehicles.

GM's fleet is highly dependent upon vehicles which return a very large profit. That means a very large sticker-price, a situation that doesn't work in the age of electrification. Adding the cost of batteries is a very real challenge this group is only now coming to realize. 12 years later isn't too late, but there certainly is a lot of excess baggage to deal with.

What really stings though is the reality that Toyota doesn't have anywhere near the baggage. With Corolla, RAV4, and C-HR hybrids becoming well established in various markets, their preparation for introducing plugs to those particular hybrids is becoming an obvious opportunity... something GM has totally missed.

That lack of diversification effort is what will likely cause the very idea of Volt to be abandoned entirely. Most of the early-adopters have already written off GM as having failed in that market. Remember all those requests for GM to finally deliver the Saturn VUE plug-in hybrid SUV they promised? Over the years, that turned into a focus on Chevy Equinox as the recipient of Voltec instead. Yet, people called me a Toyota troll, despite the blatant effort to push GM to capitalize on their own technology.

Ugh.

- 2-18-2019** **GM Hybrids.** Seeing the shift back to usual levels of rhetoric is interesting. This morning, it was yet again GM getting attention. It's the reason so much blogging focus is on GM, spin emanates from their social-media hubs. In this case, it was an article asking: "*Ford Escape Hybrid On The Way, How About A Chevy Equinox Hybrid?*" That obviously caught my attention. Would there be any mention of RAV4 hybrid? Turns out, the answer was a glaring no. The only mention of RAV4 was to combine sales numbers of both Equinox & Terrain together, then compare them to sales of only RAV4. How is that the slightest bit objective? What was most telling is when you look up the actual count for RAV4, which was suspiciously missing. It was 427,170 for last year. The count for both Equinox & Terrain together was 446,932. It was a blatant greenwashing attempt. The difference is tiny, only 4%. Imagine if they would have also included the count for Highlander to make it fair. Those extra 224,511 units make the difference massive. Instead, all we got was a compare of Ford engines with speculation of what a GM system could deliver. Pretending RAV4 hybrid doesn't exist is an dishonest effort to feed a narrative. RAV4 hybrid is now on its second generation. There is no excuse whatsoever for a claimed journalistic source to misrepresent the market like that.
- 2-19-2019** **Too Early.** It's both intriguing & annoying to have witnessed such an attitude shift. Volt was vastly superior, period. All others were "*laggards*" and Toyota was so far behind it would never catch up to GM. I heard that same sentiment for years. Prius Prime was getting attacked in every possible way. Then GM confirmed Volt production would come to an end sooner than anyone expected and without an successor. All of a sudden, the attitude changed. Rather than spinning the perception of a market Volt alone occupied, it was a new consideration that judging now was far too early. Really? I had been saying that for years! Subsidized sales don't represent mainstream demand, so all of the tax-credit related interest is nothing but early-adopter rhetoric. What that audience feels is in no way a reflection of what ordinary people will feel. That's why enthusiasts have gatherings and participate online. They are a small bunch of specialists... who unfortunately suffer from group-think. They have a very difficult time understanding how different the perspective of an uniformed showroom shopper. They simply cannot relate. Hearing so many finally comes to the realization that the situation they experienced is not the same in some way as what the masses will encounter is somewhat encouraging... though, very hypocritical. There's that frustration of having been accused of trying to undermine their efforts, then having them abruptly change their stance and agree with what I had been saying all along. Ugh. At least I have extensive documentation pointing out my observations of the time. That level detail is quite valuable. With it, more accurate predictions about market response can be made. So, it's not wasted effort... however, the fact that I get attacked on a regular basis for staying true to goals and not giving into the temptation to draw conclusions too early is quite a mix of emotion. I guess being strong and remaining polite through even the most hostile of personal strikes is a credit to my character. I never gave them the satisfaction of fighting back on their terms. I just kept researching and publishing videos to counter their attempts to create misconceptions and spread undermine narratives.

- 2-19-2019 Break-Even Point.** How many times in the past have we encountered someone "*doing the math*" to attempt to figure out the break-even point? It is always looked upon as the technology having to pay for itself entirely, and in terms of nothing but a saving in gas expenses. No value whatsoever is given in regard to reducing dependence on oil or reducing impact to the environment. There isn't ever consideration for those other factors, period. Whether that is appropriate or not, that is the reality we have to deal with. I obviously object to the blatant lack of objectivity, but I deal with it nonetheless... as does Toyota. Remember when RAV4 was first introduced? The hybrid option was only \$800. That made the choice a no-brainer. Who wouldn't want an SUV that used less gas, whether the math worked out or not. With gas so cheap, it's much more difficult of an equation than one would expect. Toyota has embraced that reality too. This new generation of RAV4 is now offered in a variety of packages, making the math more of a "*value added*" situation rather than just a matter of saving gas. That's quite obvious when you consider the top package offering, which is hybrid-only. You want the best? It only comes as a hybrid. I'm not sure if Avalon will be taking that same approach, but that seems rather likely. The new-gen upgrade this year jumps from 40 to 44 MPG. An article featuring the hybrid naturally focused on ROI. That return-on-investment perspective is annoying, but the writer knows his audience. He simply stated the pricing difference was only \$1,000 more. He also pointed out the real-world MPG results were observed higher than the EPA rating.
- 2-20-2019 Temperature Influence.** It's not as simple as one would think. There are tolerances & circumstances to consider and most anecdotal observations don't provide enough information to establish a pattern. You can guess, but the detail can be illusive. This is what new owners find: "*The manual, and my experience says continuous < 14 degrees F will trigger auto HV start... The car has its own mind some days.*" That is inevitably followed up with a post online asking why that situation isn't always clear cut. Sometimes, the observed rule doesn't apply. They want to understand what else is happening. Even for me with detail, every scenario may not be accounted for and experiencing a specific temperature a specific way is very difficult. So, all we can do is share as much knowledge as we can. Today, from me, it was: Outside temperature alone is not what determines the behavior of when the engine runs. Most importantly, the battery-pack must be warm. If you didn't have it plugged in and the temperature within is below freezing, the engine will start regardless of degrees outside the car. The initial trigger is 11°F for outside temperature, with a warm battery-pack (above freezing). That's very easy to confirm if you have an OBD-II reader with aftermarket software (like "Hybrid Assistant" for Android). Following engine warm-up, that threshold changes to 14°F (after power off) or when coolant drops below the threshold you set (while driving), which is controlled by the cabin-heater temperature setting. That threshold for the coolant will drop too, as the vehicle warms up. Knowing all those factors at play and having a means to monitor them, it's easy to understand the car's mind.

2-21-2019

Single Solution. An interesting new bit of insight emerged from the endless attacks on Toyota for supposedly being anti-EV. Turns out, if you take a step back to look at the big picture, you see the self-deprecating approach GM took as a mindset of expectation. There's a group-think at play telling the narrative that all automakers must have a one-solution-for-all approach. The idea of diversification goes no further than whether you want a car or a truck. We've been brainwashed to the point that we aren't aware are choices have been limited. It's effective marketing when you lose sight of what could be offered. They have been forcing a belief that everyone embraced. In this case, it's that a single solution is all we have available. That's why the expectation for an automaker to commit to just one choice is so deep in our psyche. We aren't using our brains. We just follow that credence without question. Since when does such a position make sense? For example, why would a trait of a pickup have to also apply to a car? That sounds absurd, until you notice the pattern. This is why GM has gravitated toward only offering the SUV as a choice for mainstream consumers. They can't handle two entirely different audiences... in other words, show favor toward the strengths only a car can deliver. Understand the problem? It's so subtle, you don't realize you're being manipulated. Why did you give up the comfort of a large sedan to pay a premium for a far less efficient and less safe SUV? Put an entirely different way, how can an automaker promote the benefits of a hybrid while also promoting the benefits of a plug-in? Enthusiasts aren't open-minded enough to embrace a co-exist approach. We have overwhelmingly seen evidence of that with EV and FCV clashes. The problem with this is there's this thing called a plug-in hybrid. That represents the best of both worlds, for Prime... since it offers top-efficiency in both EV and HV modes without compromising affordability. Volt was quite the opposite, neither EV nor HV mode was efficient. To compensate for the shortcomings, GM added battery-capacity... which made the vehicle extremely expensive. Resulting from that came an army of enthusiasts spinning a narrative to persuade us that was the best solution available. Problem is, both Nissan and Tesla proved otherwise. They showed the choice could be EV, as well as the PHV from Toyota. And now that Toyota is also striving to offer a competitive EV, there's a chaotic mess for those attempting to market a single-solution perspective. How can Toyota show favor for both choices? This is where "*know your audience*" comes in. Toyota is marketing to entirely different customers. One type shows interest for hybrids. One type shows interest for electric-only. Either may consider a plug-in hybrid. That's called smart business. When you have over 10 million sales each year to consider, you must offer a variety of choices.

- 2-21-2019** **Tax-Credit Intentions.** I certainly enjoyed taking offense on this play: *"It has almost completely done what it was intended to do, jump start an EV renaissance. Don't reward the laggards..."* The opportunity to choose a fight with a well-known antagonist, spelling out his mistake with such simplicity, was a delight. I'm tired of the insults and there's no reason to allow such blatant attempts to mislead. So, I don't put up with that nonsense anymore: That was not the intent. It's easy to prove too. Had it been, there would have been an industry-wide limit instead of it being for each automaker. What those tax-credits were actually intended to do was help each of those automakers establish a viable (profitable & high-volume) product of their own, something appealing to their particular customers. GM squandered that opportunity, wasting their allocation of tax-credits on conquest... vehicles clearly not targeted at their own particular customers. Why would someone loyal to GM switch from their beloved SUV to a compact hatchback or wagon? Intent was not fulfilled. In other words, the label of *"laggard"* is grossly inaccurate and it distracts from the true problem. We shouldn't have to deal with rhetoric people spread without giving thought to origin or purpose. Automakers who saved their tax-credits for something they believed would become a product that could compete with their own vehicles on the same showroom floor should not be misrepresented like that.
- 2-22-2019** **Fanboy Instructions.** Volt production will be coming to an end soon and we still haven't heard anything at all from GM. No one has any what's in store. Heck, even the most hopeful have moved on... or so I thought. That old daily blog turned into a place for this & that posting. There would comments about the political stage and some environmental tech exchanges. It was pretty blah. What could they bring up that hasn't been beaten to death already? Turns out, I got an answer to that this morning. One of the troublemakers, a particularly nasty one known for posting lies about other automakers, started a *"how to"* for dealing with trolls. I was intrigued, since he chose Tesla as the automaker to attack this time. The quote that caught my attention the most was: *"Trolls are jealous about GM's thorough technical quality, even though they don't understand any part of it. So they undercut anyone that does treasure it and easily explains it."* That ultimately revealed what was really being posted. It was really instructions for preserving that fanboy site. It was the final refuge for anyone still hanging on to the belief that an expensive solution would prevail. Volt never made any sense. They didn't want to hear that. For years, the denial persisted. They wouldn't give up, regardless of how evidence stacked against that. GM wasn't interested in pursuing something so unprofitable. Poorly designed for efficiency... resulting in low Miles/kWh for EV driving and low MPG for HV driving... there was no possible way to compete. Other automakers would deliver better plug-in choices and GM's own traditional choices would be a better buy. Heck, even the early-adopters showed their true colors as the \$7,500 subsidy end drew near. No one is interested anymore. This is where that *"too little, too slowly"* concern seals the coffin on the technology. GM made no effort to diversify. The technology should have been spread to a more appealing vehicle years ago. Volt-2 should have been a small SUV, not another compact hatchback. Of course, that inefficient drive still would have presented challenges. But at least it would have been a step forward. Instead, GM will just let it be buried... and the fanboys know it.

2-23-2019 Game Changer. Yesterday, we found out production of Volt had actually ended already, the week before. No one knew the "March" target would come so much sooner. But then again, Volt was doomed right from the start. I had proof of that too, in a blog I had written way back then. It seemed very fitting to post that in the discussion topic on the EV site about this news. So with a short introduction, that's exactly what I did: People seem to forget the mess Volt was right from the start. Shortly after rollout began, that's over 8 years ago, I posted this reminder of how expectations didn't match what GM ended up delivering: Hype vs. Reality. What was revealed to us 4 years ago is quite different from what we actually got. Most just want to move on at this point, especially those who were responsible for allowing unrealistic hope to continue for so long. Anyone who studied the EV knew very well that demands of the heater reduce available range significantly. But enthusiasts absolutely insisted the "40 mile" promise took that into consideration. It obviously didn't... and they know that well, now. It's a harsh reality they're finally coming to terms with. Too bad they didn't listen to those sharing that information all along. Oh well. It's like the price target. That was totally unrealistic too. Yet, that hype remained right up to the price announcement. As for MPG after depletion, that approach never made any sense. So, Volt now faces a market rapidly filling with choices. It's a plug-in hybrid competing against both pure EVs and other plug-in hybrids... not the "*game changer*" they wanted.

2-23-2019 **Missing The Point.** Death of Volt has brought about a flurry of posts looking backward about mistakes (which were denied until very recently) and complaints about the tax-credits. That monetary incentive is now looked upon as a major disadvantage, even though other automakers don't actually have that many left. Think about how quickly they could be used up when ramp-up takes place. A sustainable approach must be established before expiration, something GM did not take seriously. For that matter, GM didn't even bother. They just let Volt die, shifting favor to Bolt... the very antithesis of what Volt was designed to compete against. Remember all that "*range anxiety*" nonsense? That's the problem with the single-minded belief. An automaker offering a variety of choices is unacceptable. Enthusiasts shot themselves in the foot... a problem originating from not understanding the point of the technology, as I continue to try to convey:

GM competitors? You've completely missed the point.

Volt's competition has always been other GM offerings, those vehicles sharing the same showroom floor.

I asked the question "*Who is the market for Volt?*" hundreds of times over the past decade. Enthusiasts didn't get it. Their contributions to a false hope helped to make Volt fail. They were their own worst enemy and never figured that out. It was always an effort to divert attention to other automakers, rather than taking any time to self-reflect. That's why "*Know your audience*" is what the mantra has changed to.

Early adopter purchases didn't lead to anything. Those owners were absolutely delighted with their choice, focusing so much on factors unimportant to ordinary consumers, their endorsements made the chance of GM diversifying the technology less and less likely. Volt became a modern example of "*Innovator's Dilemma*". It's a trap that could have easily been avoided by putting the same components into an Equinox or Cruze.

Instead, GM focused made diesel their recent focus for an efficiency choice in their popular vehicles. Both Equinox and Cruze got that instead. Meanwhile we see the "*competition*" offering their equivalent as full hybrids. Notice how Toyota, Honda, and Hyundai/Kia are all spreading their affordable choices to a variety of vehicle shapes & sizes?

Meanwhile, we see efforts to offer some hybrids with a plug too. None sacrifice cost (resulting in a very uncompetitive sticker-price) for the sake of range like GM did with Volt. What does that tell us?

2-23-2019 **Placing Blame.** There's a lot of that going around right now. Dependency on tax-credits still isn't being taken seriously either. You'd think after all that has already played out, that lesson would have been learned. Clearly, that isn't the case: "*Badly written legislation killed the Volt.*" Seeing the blame placed on government subsidies, rather than the automaker is pretty bad. Volt wasn't a good product. It targeted the wrong audience. No amount of artificial price manipulation will fix that. Correcting the problem means actually addressing the issue. Pretending the source of the trouble isn't the automaker is hypocritical too. I'm still seeing GM supporters attack Toyota on a regular basis for that very reason. Automaker choices is the problem GM chose to deliver a niche, not a vehicle for mainstream buyers. Their own loyal customers never expressed any interest. And after 8 years of denying that, it's time for the message to finally be acknowledged. Get over it. Stop placing blame elsewhere. Anywho, this is how I responded to that particular comment: Volt wasn't selling well even with the \$7,500 tax-credit available. Looking at GM sales of their other vehicles overwhelmingly confirms that. Intended purpose of the tax-credit was to make that automaker's choice of technology competitive with its own traditional offerings, a means of moving beyond their product-line of just guzzlers. The belief of it to be a tool used for conquest sales against other automakers is a terrible misrepresentation of what such a subsidy was meant to achieve.

2-23-2019 Unprofitable & Uninteresting. That discussion topic addressing end-of-production for Volt sure has stirred a lot of opinion. Posting activity usually dies the following day. That's the nature of blogs. This one is different. Lots of people have lots to say. I homed in on this particular comment: "*Chevy has lost their minds. I have a Volt, it is a great car.*" Could you blame me, especially after having dealt with an attitude of "*just trust GM*" for so many years? That blind faith has cost enthusiasts dearly. They lost the war. No matter how many battles they won in the past, this final outcome says it all. Having endured so many insults along the way, it's quite vindicated for having remain polite and true to purpose. I let them know that in my own way too, keeping focus on what needed to be achieved:

Being so unprofitable for GM and so uninteresting to GM's own customers was good reason for ending production.

GM needed a popular vehicle using that technology, not a "*halo*" that only ever achieved subsidized conquest sales.

We all know GM shoppers want SUV choices. That is why GM introduced both Trax & Blazer to their product-line, neither of which with a plug or even as a hybrid. That disregard for the technology Volt demonstrated so much potential for was just completely abandoned. What a waste of opportunity, as well as tax-credits.

Think of how loyal customers shopping the showroom floor of a GM dealer will feel walking around looking for an efficient SUV choice. GM has nothing. Whether or not that person who has purchased many GM vehicles in the past is aware of what other automakers may be offering doesn't matter. They will be stuck with gas SUV choices of a 28 MPG Equinox, 28 MPG Trax, 24 MPG Blazer, 22 MPG Traverse, or 18 MPG Tahoe.

Think of how popular a SUV choice with a plug could have been.

2-23-2019 **Loss of Trust.** Consequence is becoming evident already: "*But I really don't believe much of anything from GM anymore.*" Everything related to Volt hinged on the belief that GM was committed to the technology. Evidence that GM was not became abundant. That's why I ended up blogging so much about the situation. Enthusiasts were expending an enormous amount of effort defending GM by attacking those who raised concern. That level of defense with basically no offense whatsoever meant the best outcome would be not losing any ground. Problem was, everything else was advancing. Even that Prius they loved to attack was drawing more and more near to the hearts of mainstream consumers. It was a simple matter of battery-technology improvement. Being able to deliver the same for less was that needed step forward. More range or power isn't necessary. Cost reduction was of the greatest importance... and a smaller capacity makes that easier. Neither GM, nor their enthusiasts, ever learned that lesson. Obsession with range & power blinded them from being constructive. And now that their gamble has proven a terrible choice, there's a loss of trust. Being able to take on new risk will be much harder. Virtually all of those holding the line have vanished. Whatever GM announces going forward will require new support. Those defenders of the past are gone. I still see some of them posting. Their attitudes have changed though. That quote above is a good example. To that, I responded in dismay about him being so out of touch: Any more? It's bad enough words of warning about how Two-Mode was handled and concern expressed from the bankruptcy recovery task-force wasn't taken seriously. But then GM disregarded advice about how to make the second Volt appeal to a wider audience. How many times will GM be given a free pass? Remember, it was enthusiasts who encouraged the disastrous course that was taken. Those of us who pointed out those details, noting observations to confirm the terrible choices being made were treated poorly (to put it politely) for our effort. And we were correct! It really did all fall apart... and for the reasons stated way back when it was playing out!

2-23-2019 **When Things Go Bad.** At the point an enthusiast realizes there is nothing constructive to post, they revert to personal attacks and name calling. This evening, discussion turned to "*anti EV*" for Toyota. That seems to make them feel about GM's struggle... and on a thread about Volt's death, such a turn was inevitable. Right away, I fired back: That narrative of an automaker only being able to sell a single choice is what messed up GM. Remember all their "*range anxiety*" nonsense? They embraced the one-solution-for-all approach, which resulted in abandonment of Volt mid-cycle in favor of Bolt. GM is missing so much opportunity. Reality is, a large automaker needs offer a variety of choices. That means they don't need to send a unified message in their advertisements. One can show strengths of an EV and the next can show strengths of a Hybrid. That's why a Plug-In Hybrid fits so well into the mix. Portraying Toyota... a 10-million-per-year automaker ...as a business that must choose only one solution to sell is just plain stupid. Diversity is an essential key to high-volume sales. Anyway, we know for a fact that there's a Corolla PHV coming later this year and a C-HR EV next year. More choices with a plug will follow. So, you can stop with the "*anti EV*" greenwash and show a little patience. Put it this way, because GM wasted tax-credits on conquest rather than focusing on delivery of a product their own customers would be drawn to, you shouldn't be diverting attention to what happens with Toyota. It should be obvious GM needs to regain the support they lost.

2-24-2019 **Silence.** It is amazing to look back and see how much worthless noise Volt was actually making... all bark... no bite. Those declarations of leadership lacked substance at the time. Now, we see there was no merit to those claims. None are coming forward to fill the void. It is somewhat bizarre for such silence to come so quickly. Production ended. Without a successor, the technology is dead. Whatever "EREV" was supposed to represent, it doesn't anymore. The long-predicted collapse upon triggering of tax-credit phaseout happened. To have brought of concern of dependency on those subsidies, been attacked for doing so, then getting vindication afterward for proving to be correct. I was polite. The message was sincere. Reaction was to get attacked. They made it personal. What a waste... or so it would seem. Reality is, that history is documented in great detail. Their denial of facts and spin of news was noted while it was playing out. No level of recall afterward can compare to study of what was written during the time those events were unfolding. There will be claims now of how market change could have never been predicted. Evidence proving otherwise is here. That is what has shut them up. It all turns to silence when you finally recognize your mistake. No amount of "*my bad*" will change this lesson learned, especially after seeing history repeat. I will use the knowledge gained from witnessing their errors firsthand to remind them.. Remember Two-Mode? Remember Volt?

2-25-2019 **Not Posted.** The blog about Volt's production coming to an end came to an end with a brief post about the terrible mistake GM is making. It came from an owner of 2 Volts, blinded by the technology. All he provided was praise for the vehicle. There was nothing else. That lack of consideration for the rest of GM's fleet perfectly illustrates how I knew of this demise so many years ago. I knew the early-adopter would obsess with the range & power, showing no care whatsoever to affordability or profitability. That's what turns a supporter into an enthusiasts. The attack anything unwilling to express praise for only their choice. That's why bringing up the topic of a second model of Volt long ago and an Equinox using that technology in recent years fell on deaf ears. They truly believed any type of diversification would dilute what "EREV" meant... which was only just a vague marketing term anyway. They didn't care about anything else GM could or should offer. They didn't care about dependency on tax-credits. They didn't even care about using electricity in an efficient manner. It was all just treated as a big joke, with Prius as the object of ridicule. Eventually, I pointed out how the situation resembled the story of the Tortoise and the Hare. They just laughed... which I found quite ironic... now that the Hare is no longer in the race. So, it doesn't matter how long the slow of the turtle takes... a winner is a winner, regardless of duration. The knowledge of pacing yourself and taking the entire race into consideration is a very important one to understand. They didn't care. So, I just stopped typing this response mid-thought, since it wasn't worth posting a reply to that blog message: Big mistake was not spreading the technology. That's what the "*too little, too slowly*" concern was all about. Worry was that GM would waste tax-credit opportunity on conquest sales, rather than focusing on actual change for their own customer base. Not having a plug-in hybrid choice in their product-line, like Equinox or Trax, meant nothing dealers would be interested in stocking.

- 2-26-2019 Pricing.** We are getting very close to debut of the long-awaited Corolla hybrid. Detail is finally coming out. Though, this summary is all that most people will focus on, in addition to the 52 MPG rating: "*The 2020 Corolla LE Hybrid starts at \$23,880 with destination, or \$3,000 more than the non-hybrid LE.*" 46 Million Corolla have been purchased globally since introduction in 1966. That makes it the most popular vehicle of all time. So it being rolled out worldwide now as a hybrid marks a turning point in automotive history. There is nothing anyone can say anymore about hybrid potential... since that's as mainstream as you can possibly get. All those attacks on Prius based upon appearance didn't change the outcome. Joining Camry, Avalon, RAV4, and Highlander hybrids is now an even more familiar nameplate... with pricing to play a major role in the effort toward bringing traditional vehicle production to an end.
- 2-26-2019 Omitting Detail.** This is the most effective means of being dishonest. You just leave out an important detail. That omission is quite often overlooked, allowing the person trying to persuade you of something an opportunity to deceive. Today, I heard a senator defending the president by leaving out the vital fact of duration. He claimed the president offered the democrats what they wanted by referring to it by title only. The reality that it was only an extension for 3 years, rather than the permanent change they were asking for was conveniently omitted. Not mentioning that bit of detail changes meaning dramatically. 3 years versus the rest of your life is how significant of a point? Ugh. That's the same kind of thing we've been dealing with in regard to green technologies since the very beginning. Heck, a decade into them, we got tax-credits... limited to just 60,000 per automaker. How can that possibly compare to the subsidizing of gas prices since before everyone reading this blog entry was born? Examples like that are disheartening. Just imagine how far a teeny, tiny increase in the price of gas could contribute to the building of infrastructure for charging cars. It's a transportation tax used specifically for transportation use. That's how investment in the future should happen. Sadly, we never get to talk about choices like that. The discussions never start... since even in just casual conversation, there's a bias from omitting detail. Whether it is intentional or not, it has a very big impact on outcome.

2-27-2019 **Incorrect Assumptions.** I found this comment quite intriguing: "*This is the linchpin: GM simply couldn't make a profit on the Volt, and so there was no incentive to advertise or sell it.*" The poster continued on, providing insight about how PHEV systems were "*designed to significantly increase MPG*". That really got my attention. Where would his thoughts take us? Sadly, it fell apart in the very next sentence: "*Volt on the other had was designed to be a full-time EV around town, and an ICE on the road. These are almost two different animals.*" My guess was that he really didn't understand what a plug-in hybrid actually was. That seemed odd, based upon his opening of: "*just about every plug-in PHEV out there has a very small battery and a very low EV range*". I wondered what the heck "*full-time*" really referred to. Thinking about the past, I recalled how antagonists would lead people to believe EV from all other plug-in hybrids except Volt would start their engine upon demands for high power. That isn't true for gen-2 of Prius PHV and was never true for BMW i3. Others make the distinction rather confusing to pinpoint if you don't know what to look for in the first place. That's how the deception works. Someone presents a misconception as fact, then it becomes an assumption without ever being questioned. Ironically, that is what helped to kill Volt. Never being well understood is good reason to avoid purchases. People won't embrace something they aren't quite certain about, especially with such a high sticker-price. Some of us knew the influence of enthusiasts could be that significant. They laughed off those words of warning. Who's laughing now?

2-27-2019 **Rule of Thumb.** This basic knowledge seems to be a really useful way to summarize need: "*8 hours on a 40-amp line will deliver 200 miles. More is nice, but not necessary. Remember, you'll be wanting to add additional chargers at some point... one for each vehicle in the household. So, consideration of maximum capacity from your service-panel is a factor.*" It's the type of simplification required to reach mainstream consumers. They need a clear & concise message. Understanding those terms is difficult when the concept is new. I'm hoping something that basic will catch on.... hence my push to repeat it over and over. Again, I see a need and a pattern. Let's hope this one sticks. Remember how "*stealth mode*" became an expected success? I didn't even realize the importance of such identification of operation back then. Now, it's rather obvious. We need clear understanding to get strong acceptance.

2-28-2019 **How We Got Here.** All I can say is: Wow! There are so many different spins on history at this point, it's easy to see how mistakes get repeated. Most online participants don't bother to research or even check the "facts" they do have. Recent posts have been a complete disaster from any historical perspective. They basically don't have a clue how we got here. Sadly, that's all too common of a problem. Making decisions based upon limited anecdotal evidence has become the norm. It is a consequence of letting anyone express an opinion online. They expect instant validation and will settle upon any source that will provide it. Whether or not that information is accurate doesn't matter. Heck, it doesn't even need to resemble anything truthful. We created a mess and haven't really come to recognize the situation yet. That makes dealing with it pretty much impossible. Hopefully, a glimmer of hope will emerge from Volt fallout. To learn from efforts being made and advance forward, something must be acknowledged as not good enough. You can't just assume more is better... the very problem Volt experienced. Adding range & power didn't help deal with the problem of being too small and too expensive. It was an act of pure hope that such a senseless effort would provide the necessary fix. Optimism, rather than logic, is not a good way to run a business. GM really messed up and no amount of damage-control now will make it better. That's why looking back upon history cannot be a perspective built upon incorrect claims. Remember, there are some who spread misconceptions intentionally, so due diligence is absolutely essential. Any change of moving in the right direction requires careful consideration of how we got to where we are now.

3-01-2019 **\$35,000 Tesla.** It has finally happened, but not really in a good way. The reveal of this "affordable" choice of Model 3 comes at the penalty of reducing overhead expenses. Many of the galleries will be closed. (Those were the "stores" where you could test-drive a Tesla vehicle, but not actually purchase one. They just served as delivery & service locations, not anything resembling an actual dealership). Employees at the remaining locations will not get bonuses and there is an expectation of salaries being reduced. It's an ugly form of attrition... a sour-the-milk approach to cutting cost. Knowing that Tesla's tax-credit has already been lowered by 50% (to \$3,750) and that another reduction of 50% (to \$1,875) is coming at the start of July, it's a step we all saw coming. But year-end, the tax-credit will be eliminated entirely. That \$35,000 price must be enough of a draw to keep sales strong, all on its own, while also providing enough of a profit to sustain the business. Remember, the introduction of Model Y is still pending. Turning that into a rollout to grow the market won't exactly be easy, especially with legacy automakers struggling to find their own means of selling plug-in choices. While all that is happening, there is still the reality of battery technology evolving. Tesla uses cylindrical shaped cells. Pretty much everyone else uses prismatic. All still rely upon a liquid electrolyte. How packaging & solid-state changes will influence the upcoming market is anyone's guess still. We just plain don't know, especially on the scale of gigawatt production.

- 3-01-2019** **Extended Range.** It looks like BMW i3 will offer a 44.2 kWh pack for 2019. That translates to an electric-only range of 126 miles for the range-extended model. This is why GM's marketing of an "*extended range*" vehicle, or as the enthusiasts used the "*EREV*" identifier, never made any sense. How could Volt's range of 53 miles be considered the market leader compared to that? Nothing the enthusiast did to spin favor toward Volt worked anymore. All of their greenwash efforts fell apart, without any successor. It's the "*doom & gloom*" that was predicted from such heavy dependency on tax-credits. BMW understands their audience. That's why the REx model offered an ample supply of electricity, then supplemented by a small engine (2-cylinder 647cc) for power following depletion. It was the design for Volt that GM never actually delivered. BMW did. That's why enthusiasts focused so much attention of Toyota. That diversion of thought prevented readers from noticing what Volt really was, a plug-in hybrid. The definition of "*extended range*" never worked for Volt. It was a deception they worked hard to convince others to embrace. That's why I battled them so often, knowing that misleading wouldn't be enough for the war to be won. All they could do was hold a line for awhile. Fighting is over now. Volt has become a footnote in history, an example of what not to do.
- 3-02-2019** **Speculation.** It is always interesting to hear from someone who has no background whatsoever. Their history of Prius and knowledge of Toyota is limited to recent observations only. Knowing they were just introduced to this world I've known for over 20 years adds an element of fascination. It's all new to them. That adds a somewhat magical feeling to their perspective... that overnight success impression people get. You know, like when a musician achieves a smash hit and most people think "instant success" without ever coming to realize they worked hard on that for decades. That's simply a reality of working with mainstream consumers. They consider the product, not the history. So naturally, there's a look of guessing & assumptions. Today, I saw this: "*Just offering an opinion.*" It was in regard to what Toyota might have decided about Prius. The absence of history was obvious; so much so, I wanted to make sure my reply to that was to the point. It's easy to come across as insulting or condescending when you have extensive knowledge of a situation and the other person has no background. Hopefully, this did the trick: No need. Cosmetic changes are a very common practice for mid-cycle updates. We saw that with both gen-2 and gen-3 Prius, though on the subtle side. The gen-1 mid-cycle update was more like gen-4, rather obvious.

3-02-2019 Sales Numbers. They were always a contributor to trouble, especially when broken down by month. That helped to feed narratives. Rather than looking at the bigger picture, you could select specific data to present. Volt enthusiasts were notorious for choosing to focus on just the "*EV Market*" to allow them to completely disregard incentives & distribution. In that regard, anyone taking the time would notice that 200,000 is really a very small count. The same is true for availability limitations. They'd fight to make sure no one took the time to do that though. It was always an effort to mislead. I have hundreds and hundreds of examples documenting their attempts too. Some of those quotes are truly remarkable. Looking back, now that Volt is dead, you can see lack of objectivity rather easily. GM set a self-deprecating course. They were in denial. Automakers require diversity. Lack of choice was an obvious flaw for any long-term (big picture) expectation of profit & sustainability. Somewhat annoyed by their denial, but not in a teachable moment situation, I posted this on the thread discussing Volt's final sales:

Epitaphs for Volt have been interesting to read. They all tend to follow the same pattern. Praise is given, then there's a comment that follows about what GM should have done. When that very same comment was provided in the past, it wasn't treated as a suggestion though. The response was a narrative about how GM knew what it was doing and that comment was really just an effort to undermine GM progress.

Now, we all see the situation clearly. Concern expressed as "*too little, too slowly*" to draw attention about how GM still had not spread Voltec to ordinary loyal GM shopper choices, like Equinox, should have been looked upon as constructive discussion. Shooting the messenger was just plain wrong.

Volt has become a modern example of innovator's dilemma. GM focused on the wrong audience, accepting the voice of early-adopters to be that of mainstream consumers. That group-think contribution sent a message approval to continue on with what we all recognize after production has ended as a niche. It was a terrible path to follow. Warnings should not have been so easily dismissed.

Consequences of that are obvious. Tax-Credits were wasted on a very limited market. Rather than using those subsidies as a means of establishing dealer change, making the showroom a means of reaching GM's own customers, that opportunity was lost.

- 3-03-2019** **Used Import Purchase.** Every now and then, we'll get a post on the big Prius forum from someone who purchased a used import of a Japanese model Prius. Since their own country doesn't offer them, that's the best they can do. So when help is needed, we try to provide it. That's a challenge when English isn't their native language and photos or video are almost never provided. We just have to make a best guess at what they are asking. This one in particular was really difficult. The question was asked repeatedly, in a variety of different ways to help convey what was going on. This was the most understandable of what I could use to quote the situation: "*The button should lit up and turn off the EV icon on the screen, which it doesn't even do all the time under 5kph as well (Sometimes I press it will turn on or off the EV icon other times nothing). But above 5kph it doesn't respond like the button is dead or something.*" He wanted to know more about how the HC/EV button should work on a 2012 model PHV from Japan. His location was Pakistan. We really couldn't even figure out why he wanted to use the switch or how well EV mode itself was operating. Basic information, like the number of kilometers the vehicle had already been driven, wasn't ever included. There were also factors, like temperature, missing too. We simply didn't have much to work with, despite his many posts. After a number of others had contributed detail about how the system operates, I jumped into the discussion with: After reading through this entire thread twice, I get the impression you aren't aware of the required warm-up cycle. Once you push that HV/EV button, it will force the engine to start and will continue running until coolant reaches the necessary temperature for emission cleansing. If there is something wrong with your coolant (low, dirty, clogged) or your thermostat (unable to shut), you may not be able to get back into EV mode.
- 3-08-2019** **EPA Deregulation.** This topic just pops up in the news from time to time. Today, it was about yet another rollback. We fought so hard for years to get regulations & restrictions to help guide cleaner and more responsible transportation technology only to have this administration do everything possible to undermine and dismantle. Thank goodness the diesel debacle played out a number of years ago, back when the situation could be dealt with properly. There's so much FUD going on now, it's hard to even notice. People just dismiss without conscience. The efforts to promote consumption have been so constant, perspective has been lost. Goal posts were moved back (our expectations) and that was enabled by our society as a whole (our regulations). It's really sad.

3-08-2019 **Longer?** Ugh. Seeing this from early-adopters is getting annoying: "*How much longer can Toyota wait to start bringing EV models to the markets?*" The reason why is simple... no one else is making the same claim. The mainstream is perfectly content waiting a few years. They know that in the meantime early-adopters are helping to work out any details that need to be refined. It's a sensible view that enthusiasts just plain cannot see. Lack of patience is no surprise. That's a common problem. Today, I dealt with it using the following:

That overall environmental impact approach is the same **BIG PICTURE** mindset Toyota has had since back in 2003, when it was first discovered that the gen-2 Prius could deliver electric-only driving speeds up to 100 km/h (62 mph). I asked the top engineer why a plug wasn't made available. It wasn't due to the extremely low energy-density of the batteries of that time. His direct answer was due to how dirty the electricity was. We would have to patiently wait for cleaner sources.

Think about how much coal we still use for generating power for what we recharge. Thankfully, I live in a state that has seen explosive growth of local solar farms over the past few years. Watching small towns build those vast spans of cells over their otherwise modestly used land is amazing. It's quite a surprise too. That happens with little to no fanfare. It just happens. It's like the ramp I park at for work. All of a sudden, they are installing a massive solar-array on it's sunny side.

I understand the "*How much longer?*" anxiety the full EV supporters are dealing with, but I really don't appreciate the barriers they are erecting for ordinary consumers. My household already has 2 plug-in vehicles, each with their own 40-amp 240-volt charger. So what if both vehicles only average around 1,000 miles per tank of gas? That shift to using more and more electricity is already well supported. We have our infrastructure established and our current plug-in will feed the used market when we upgrade later.

Show some patience and consider the big picture.

3-08-2019 **Looking Back.** Reading through a discussion from 11 months ago was interesting. Quite a bit has changed with regard to plug-in vehicles since then. Think about Model 3 rollout hopes. Think about Volt discontinuation rumors. Think about the continued attacks on Toyota. There was a lot of rhetoric back then, far more than anything even remotely considered trouble now. In that not-so-distant past, you didn't need any evidence to support your claim. In fact, it was very easy to dismiss the post of others simply by taking advantage of group-think. The enthusiast mindset was so focused on an obsession with speed & distance that nothing else mattered. It's interesting to see how that early-adopter push has fallen apart. More and more people are turning attention toward the possibility of an EV being in their future only to become disappointed in the price. Automakers are seeing that. We are hearing about planned rollouts elsewhere with much smaller battery-packs. Why pay for all that capacity when you are only looking for an affordable & reliable commute vehicle? Saving the old guzzler for only the long trips is a heck of a nice tradeoff... especially if you have an old Toyota that still has a number of miles remaining, despite many years of great service already. What's wrong with keeping your high-mileage vehicle for non-commute use? That already seems a sensible choice, even if you are only looking back to compare opinions from just last year.

3-08-2019 **Upcoming Choices.** There have been so many announced recently, spread over the next few years, it's a confusing mess. Just trying to recall what VW alone has revealed as concept and just for their plans in general, the expectations are unclear. How many? For who? Where? When? That in itself is a problem. Attempting to get detail about any particular upcoming choice is a challenge. What source do you go to for accurate, up to date information? We're entering an age that people pay less and less attention now too. Being overwhelmed to facts that are readily available at any time, you have to wonder people know and how it actually reflects on reality. This is why fake news was able to so successfully influence our culture. People just accepted it and passed the damaging claims along. We've lost critical thinking and the slew of recent announcements hasn't helped matters. They are so vague, it all serves to feed narratives. Lack of detail is what stirred hype into hope last time we went through a "revolution" of supposedly new ideas. History really does repeat itself. This is all too familiar. Remember 20 years ago when Prius first rolled out?

- 3-08-2019** **Arguably?** It should be no surprise that I found this something to argue: *"Something I've never liked about the current United States EV Federal Tax-Credit is that it operates in a way that arguably rewards those car makers that are EV laggards."* I look forward to posting responses to such statements: The belief about *"rewarding laggards"* is another way of stating upset about punishing automakers who squandered their opportunity. Watch out for that group-think spin. Here's what was overlooked as a result of such greenwash. GM should have used their 200,000 for changing their own fleet to attract their own customers, rather than wasting effort on conquest sales. The unlimited phaseout period could have been a boom for them. Look at how much was saw Tesla strive to do exactly that, taking full advantage by seriously ramping up production for that time period. The result is continued opportunity for Tesla and the halting of production for GM. Imagine if GM had instead used Volt as the demonstrator of their technology by rolling it out in limited numbers, then saved the bulk of their tax-credit allocation for a plug-in hybrid Equinox. Imagine how effective that use of *"reward"* would have been. Even though GM would also be treated as a *"laggard"* automaker, the money would have been put to good use by helping convert GM's own fleet of guzzlers to being electrified. In other words, forcing all automakers to follow the same schedule would have encouraged sloppy design and taking shortcuts. When is rushing to deliver a better choice than spending the time to do it right ever the better choice?
- 3-09-2019** **Acceleration Speed.** A short video-clip was posted showing Honda Clarity accelerating in both EV and HV modes. It started as an objective discussion. Hoping it would stay that way, I joined in by responding to a query asking how the other PHEV offerings performed: Prime is a little bit faster in EV and a little bit slower in HV. With mine, I simply drop the pedal to the floor (since it is so smoooooth and the engine remains off) and don't give it any other thought. That works fine, even for the from-a-dead-stop corners merging onto a 55 mph road. On my daily commute, maximum draw (68 kW) isn't required. So, acceleration hasn't been much of a topic. I do enjoy the extra torque from stoplights. That boost from the larger battery-pack is quite obvious compared to the regular model Prius.
- 3-09-2019** **The "Slow" Narrative.** This is what the *"behind"* narrative has morphed into: *"A sale is a sale. In the medium term, EV sales will displace conventional ICE Hybrids. Only Toyota and Honda is slow on this and I suspect is their corp. culture. Japanese work culture is job stability and permanence."* I saw that as painting an incomplete picture of what is actually happening: You've been greenwashed if you actually believe that. The current offerings from other big automakers... GM, Ford, Chrysler, VW... are not in meaningful numbers and all have a heavy dependency on tax-credits. The pusher is Nissan, with a respectable mention to Hyundai/Kia Also, getting clean hybrids (SULEV & PZEV) rated immediately is far more impact to the environment. So, that claim is just rhetoric. What's especially bad is how GM continues to be given a free pass, even though they never spread Volt technology to their other vehicles. Notice how they introduced both Trax & Blazer in their line-up, neither of which is even a hybrid? Equinox & Cruze both got diesel models recently too. Why are those actions not being called out? Why does Toyota constantly get negative press, despite their push for the new 39 MPG hybrid RAV4 rollout? That is an undeniable move to phaseout traditional choices, which paves a simple path to choosing a plug later. That first step away from a guzzler is the hardest.

3-09-2019 **Effective Greenwash.** The effort to dodge & divert has become so normalized, any act to draw attention to something outside of that "acceptable" behavior is called out. So when a new thread on the big Prius forum pops up and there's a bigger picture to consider, I usually get an invite as some point. On the daily blog for Volt, that invite was almost immediate. They thrived on the conflict, looking forward to those battles. They lost the war as a result... since I was in for the long-term. I carefully observed & documented. That's how you learn. So, when I got this today, I had to share that: *"This thread will not be PC complete till john1701a enters and tries to pivot the negative Toyota conversation towards GM."* It was a conversation about Toyota's long-term strategy. That made the invite a natural. I didn't hesitate either:

Those lessons learned are a very, very important part of the discussion, something that shouldn't be ignored. GM's propaganda has a disastrous history, over and over again confirming the problems *"over promise, under deliver"* can have on the entire industry. Their rhetoric causes apprehension & confusion, not to mention wasted opportunity.

Look at this thread. Notice how many followed the pivot to hydrogen & fuel-cell discussion? That's effective greenwashing. Without even realizing how, they got off topic. That's what GM enthusiasts spread to take the attention off GM mistakes. They don't want success & failure stories of the past to influence the Toyota narrative.

Why don't you want to talk about the squandering of tax-credits Volt became? Intentions of that money was to help each automaker along with their effort to electrify their own fleet, to offer something with a plug to compel their own loyal customers to change. Instead, those sales were wasted on conquest. Delivering something that only appealed to an outside audience never made any sense.

Feel free to invite me to point out the mistakes GM made anytime. There's lots of detail to share about how those mistakes came about. Preventing others from doing the same is a worthwhile effort.

3-09-2019 **Understanding the Past.** Many don't. That's why I ask questions often and provide lots of exposition. It continues. My question of "*Why don't you want to talk about the squandering of tax-credits Volt became?*" resulted in the following: "*Similar to the E85 capable cars...*" I could see the information that followed related to tax-breaks automakers receive, but couldn't help being quite direct about the outcome:

Is that an ironic reference or were you being facetious?

"*LIVE GREEN, GO YELLOW*" was GM's first disastrous failure attempting to undermine hybrids. Remember that E85 marketing campaign? It was before the Two-Mode, Volt-1, and Volt-2 disasters. With such a well established "*over promise, under deliver*" reputation, I'm really surprised how many simply accept the ambiguous statements without any regard to lack of supporting material. The sharing of lessons learned is an exercise to prevent repetition of it happening yet again.

The wasting of tax-credits, then spinning those who took the time to really think through their decisions as "*laggards*", is a red-flag that there's enough gullible people for the cycle of misleading to continue. History repeats for those who are not wise enough to study what happened in the past and work to prevent.

This is an aspect of "*know your audience*". When the cycle begins again, you observe who participates. When that introductory stage concludes, you observe who's being targeted. For Two-Mode, Volt-1, and Volt-2, there was a clear mismatch between the audience claimed and the actual buyers. That threw goals into chaos. Each of those projects fell apart as a result.

For E85, there was no target... since as you say, there was no supply in many locations. Of course, that's a red-herring. Your reference is from a decade ago. The industry has moved on to a more realistic approach since then, support for E15.

3-09-2019 **Willing to Wait.** Following the ever changing messages from GM is very difficult for some. They usually don't pick up on nuisances or the ambiguous approach. You had to pay attention... in the past. Not anymore though. EV had been the problem to overcome... which is how Volt came about and was heavily promoted... until it became obvious all the low-hanging fruit had been picked. Clearly not part of the plan, that entire concept of engine & motor was abandoned in favor of the antithesis... which how we got Bolt. Lesson learned in this case is you need to recognize an automaker without a well understood purpose. It was always a follow-the-money approach, which can be a huge gamble. GM lost. Toyota is wise enough to hold true to clear goals, which allows them to both be flexible and to diversify.... a business model GM still is unwilling to adopt. Understanding that fundamental difference is vital. Sadly, most people don't even recognize it... hence drawing the quoted conclusion. In short, much can come from having a solid plan and being willing to wait.

3-10-2019 The Wait. I continued on with more:

Waiting is the reason that background was shared, to ensure everyone was on the same page when this next chapter begins.

In just a few weeks, the event enthusiasts tried so desperately hard to avoid at all costs will play out. Tax-Credits for GM will be reduced by 50%. To distract from that ugly reality of Volt not having any plug-in hybrid successor, GM announced they would expand their EV offering by revealing 2 new models based upon the Bolt design. The promise was that would happen within the next 18 months. Our wait is now into the 17th month. Not a peep from GM still. Why is this acceptable for GM but not for Toyota?

It's a double-standard that needs to get proper attention. Engineering by press-release has been a chronic problem that no one seems to take issue with, to the point where that is accepted as legitimate advertising... even though there is no actual product to sell... not so much as the basic detail sometimes.

This is why the "*not selling*" topic shouldn't be taken at face value, which far too many people do. We fall into a group-think and lose perspective on progress & goals.

Toyota is very actively producing & selling components vital for EV deployment, in high-volume for a profit. Refinements to those components and associated software continue on with lots of real-world exposure. So while they wait for that next-gen battery, no time is wasted in the meantime. That setting of the stage also includes drawing of interest away from traditional vehicles. It's a win-win with immediate benefits.

3-08-2019 EPA Deregulation. This topic just pops up in the news from time to time. Today, it was about yet another rollback. We fought so hard for years to get regulations & restrictions to help guide cleaner and more responsible transportation technology only to have this administration do everything possible to undermine and dismantle. Thank goodness the diesel debacle played out a number of years ago, back when the situation could be dealt with properly. There's so much FUD going on now, it's hard to even notice. People just dismiss without conscience. The efforts to promote consumption have been so constant, perspective has been lost. Goal posts were moved back (our expectations) and that was enabled by our society as a whole (our regulations). It's really sad.

3-08-2019 **Longer?** Ugh. Seeing this from early-adopters is getting annoying: "*How much longer can Toyota wait to start bringing EV models to the markets?*" The reason why is simple... no one else is making the same claim. The mainstream is perfectly content waiting a few years. They know that in the meantime early-adopters are helping to work out any details that need to be refined. It's a sensible view that enthusiasts just plain cannot see. Lack of patience is no surprise. That's a common problem. Today, I dealt with it using the following:

3-10-2019 The Wait. I continued on with more:

Waiting is the reason that background was shared, to ensure everyone was on the same page when this next chapter begins.

In just a few weeks, the event enthusiasts tried so desperately hard to avoid at all costs will play out. Tax-Credits for GM will be reduced by 50%. To distract from that ugly reality of Volt not having any plug-in hybrid successor, GM announced they would expand their EV offering by revealing 2 new models based upon the Bolt design. The promise was that would happen within the next 18 months. Our wait is now into the 17th month. Not a peep from GM still. Why is this acceptable for GM but not for Toyota?

It's a double-standard that needs to get proper attention. Engineering by press-release has been a chronic problem that no one seems to take issue with, to the point where that is accepted as legitimate advertising... even though there is no actual product to sell... not so much as the basic detail sometimes.

This is why the "*not selling*" topic shouldn't be taken at face value, which far too many people do. We fall into a group-think and lose perspective on progress & goals.

Toyota is very actively producing & selling components vital for EV deployment, in high-volume for a profit. Refinements to those components and associated software continue on with lots of real-world exposure. So while they wait for that next-gen battery, no time is wasted in the meantime. That setting of the stage also includes drawing of interest away from traditional vehicles. It's a win-win with immediate benefits.

3-11-2019 Rule-Of-Thumb. I keep repeating it: Rule-Of-Thumb is that a 40-amp line will deliver 200 miles in 8 hours.

That basic formula covers the needs for most multi-car households. It's fast enough without becoming too expensive. Taking into account how much the typical service-panel has available for capacity, that idea of a continuous 32-amp draw (7.2 kW rate) of electricity from 2 plug-in vehicles at the same time may actually be pushing it. So, carefully consider plans for the future.

In my household, we installed two 40-amp lines connected each to 100-amp meters for Time-Of-Use discounts. The dedicated hardware makes tracking usage as simple as looking at the monthly bill. They break down the tiered pricing for each meter and show the usage in each category. Also, we choose to use larger-than-needed conduit. So in the future, we could pull higher gauge wire if there was the desire to beef up a charger.

Lastly, keep in mind that some people have their service-panel in or near the garage. That's quite convenient. Some have it clear on the other side of their house. That's quite expensive. So, the ideal may not work out. But even just sharing a 240-volt line works fine, since some chargers will allow you to set a maximum draw.

The key is to consider how many vehicles will need to be plugged in overnight.

3-12-2019 **Melting!** There's a lot of that happening now... to the point of flooding. Spring has arrived. Yeah! Of course, the chance of getting significant snow still is quite realistic. That happened last year in April. What a mess! We had near blizzard conditions. In the meantime, I'm able to take advantage of the warm for some outdoor work, including some cleaning of the car interior. Winter in Minnesota presents challenges at times, fortunately nothing related to the car. It worked fine even in the extremes. It looks awful though. Sprayed with the residue from salt & sand, you can't keep it clean for more than just a single drive. Oh well. Pre-Conditioning from the cord sure is nice. You come out to a warmed vehicle and a full battery that is also warmed. The thing to look forward to now is watching EV range increase. With warmer temperatures comes an increase in efficiency.

3-13-2019 **Apologists.** Now that other automakers are getting attention, as was with this thread about VW, there are GM apologists working hard to protect image: "*GM doesn't belong in your post. GM has been at the forefront with the Chevy Volt, the Chevy Spark EV, Caddy ELR, some other caddy, and the now the Chevy Bolt EV.*" More realistically, that's a damage control effort. Volt may have reached the forefront, but it didn't do anything in that position. Spark, ELR, and Bolt didn't do anything at all; they just rolled out without any type of industry draw. GM had potential, but chose to do nothing with it. I'm making sure that history is not overlooked. Allowing it to repeat without a fight to share information about what happened in the past isn't something I will tolerate. The time to take an position of offense has come. Playing defense made sense in the "fake news" time. But now that tax-credits are about to expire, the early-adopter stage can finally be seen with some clarity. Detail is key to moving forward. It starts though with point out the problem:

GM certainly helped in support of the technology itself, from an engineering standpoint. But the amount of collateral damage caused from their focus on a small & expensive niche pretty much makes their position a wash. Volt most definitely was not targeted at mainstream consumers and nothing became of that plug-in technology. Rather than actually being at the forefront of change, the status quo remained firmly in place.

Try arguing that those tax-credits made a difference in their fleet. Notice all the guzzlers on the showroom floor? There aren't even hybrid choices. Why isn't there a SUV based on Volt after all these years? It's just a wide selection of traditional vehicles still. GM never diversified. Volt was the low-hanging fruit that early-adopters feasted upon, then moved on.

Notice how VW is trying to promote a variety of choices right from the start? Many people don't. After all, people obsess so much with Prius, they don't even notice the other Toyota hybrid choices available. Ironically, that tends to be a good thing if the goal truly is to electrify more with each generation. It's like phasing the variety of past automotive technologies, like the carburetor, power-steering fluid, and incandescent bulbs.

Changing the course of legacy sales requires far more than just token efforts. Those who judge based on just that aren't making an effort to consider consumers beyond the initial early market. Ordinary shoppers are considerably more difficult to appeal to... and it certainly won't happen as fast as you'd like.

- 3-14-2019** **Model Y.** The reveal was quite a let down. Tesla didn't move forward much. Everyone expected more. It's a just hatchback version of Model 3 and won't be available until the end of next year. It won't be affordable either. Looks like the lowest priced configuration will be \$47,000. It's not at all what had been hoped for. The extremely long introduction, which spent quite a bit of time dwelling on Tesla history (about 30 minutes or so), ended up devoted just 4 minutes to Model Y itself. I expected the opposite, a brief overview of how the automaker got to that point, then a deep dive into what the newest vehicle would have to offer. There's seemingly so much more that could have been done, I think. My impression is morphing as I consider the choices available. It feels like that Y should have been rolled out side-by-side with 3. The only apparent difference is seating. What's wrong with that being a choice, like how other automakers deliver packages. You select the interior you want. Wouldn't that reduce cost? Too much variation without obvious benefit is a difficult sell anyway. Needless to say, this evening's reveal didn't stir much promise. The anticipation fizzled quickly.
- 3-14-2019** **Local Production.** Toyota just announced plans to begin production of RAV4 hybrid here in the United States, specifically in Kentucky next January. Capacity will be 100,000 of the RAV4. Starting this year will be 12,000 of the Lexus ES300h. Having both hybrids local is great news for everyone. The increase in employment is an obvious plus. There's the obvious benefit of not having to ship the final product as far too. Several other local investments for production were also in the same announcement. Corolla gets some for the Mississippi plant. Highlander gets some for the Indiana plant. There's the hybrid transaxle production in Virginia getting more money. And engine production in both Alabama & Missouri also get some. Note that Kentucky had a major investment for Camry & Avalon 2 years ago. So, long story short, anyone who calls Toyota a foreign automaker really doesn't have any clue what they are talking about. Toyota has a major presence in the United States. In fact, their commitment to new investment since 2017 will end up reaching nearly \$13 billion in a 5-year span.
- 3-15-2019** **"Losing" Spin.** Now that Volt has been dead for an entire month, it's curious to see what will emerge. I posted this on a topic attempting to keep attention on Toyota: I find it interesting how much "*losing*" spin is being published. It's the standard rhetoric that comes from early-adopters who don't want to look at the big picture or want to distract from it. The recent news of Toyota investing heavily in hybrid production in the United States is good reason for those desperate to undermine to step up their efforts. Reality is, the plan for Toyota to offer a wide variety of hybrid choices is a very effective means to not only bring traditional vehicle production to an end, it also sets the stage nicely for high-volume plug-in demand. Getting a hybrid owner to upgrade to a plug-in hybrid is far easier than convincing someone to go straight to a plug. Other automakers don't have a transition plan. Their attempts to introduce something with a plug have been chaotic and with an uncertain message of commitment.

3-15-2019 **Slowness?** My attention was caught by an article with this title: "*Reasons behind the slowness of EVs adoption in US.*" Sadly, the thread pointing it out was almost immediately joined by our resident problem poster. It was the usual banter: "*30% of Americans polled will say they would consider an EV in their next purchase.*" I was quite annoyed with such lack of substance: What poll was it? How people were questioned? What was the question? Did those being asked understand what an EV could be? Were these people who had access to a plug? And what the heck does "*consider*" actually mean? For that matter, when was the poll taken? That type of vague statement is exactly where "*Know your audience*" came from. It originates with a small sampling and a meritless claim, just like that. Volt enthusiasts spread such rhetoric to the point of creating their own "*fake news*" source, way back before the term had been coined. I got mocked for pointing out the power of what turned out to be propaganda. Those observations shouldn't have been so callously dismissed. Now, it's a grim reality with widespread collateral damage. It's the face-value acceptance of comment without detail that feeds group-think. People endorse the greenwash simply by passing it along without question. Just look at the outcome of Volt. Expectations were set that were based on want, not need. That fundamental disconnect confused the market and prevented progress forward. It's a trap that's easy to fall into, started by spreading a vague statement. Now, we wonder the reasons why there's a slowness to adopt EV here.

3-15-2019 **Trolling, part 1.** There is a well-known antagonist who relentlessly provokes to stir discussion. He just plain doesn't care about the bigger picture or the longer term. It's all about getting attention. He likes to participate. So, the routine post like this is an expectation: "*It's there because the press, market research, and gen1 owners said they wanted a middle seat.*" I rarely respond, but today's was rather enticing. Teaching moments can be useful. So, I took his bait. In this case, it was related to Volt and how the lack of a 5th seat applied to Prius Prime. Pointing out his spin by distorting & misleading the perspective to confuse the topic is something I've had to deal with routinely anyway. Sadly, it's easy to greenwash simply by being selective about the information being shared, especially if it is just vague comment. My sharing of what was learned went like this: Listening to them was a fool's errand... the fundamental mistake "*know your audience*" draws attention to. GM played tax-credits and early-adopters ignored signs. Those wanting to purchase a vehicle for family transport didn't want a compact hatchback anyway. It should have been obvious the technology would need to be in a larger vehicle. That is why Camry hybrid, RAV4 hybrid, and Corolla hybrid are all better PHV choices here. So what happens in Europe, may not be what happens for this market. In other words, understand who you ask.

3-16-2019 Trolling, part 2. I was rather surprised that his response was just a load of greenwash, something very easy to disprove: "*The new Corolla shrank; it has less passenger and cargo space than the Volt*" Why would anyone make a claim with undisputable evidence available to reveal intent to mislead? It only took me a few minutes to look up the specs for each, to confirm every one of the dimensions in question were wrong. He lied, plain & simple. There's no way around it. I caught him in the act. How will others respond to the obvious effort to troll? Causing trouble brings down the integrity of the forum. Yet, there is rarely a moderator response when such posts are spread. Sadly, the proliferation of fake news has become so bad, people may be getting burned out... tired of fighting battles the cannot possibly win, due to the quantity. Stumbling across efforts to mislead is easy. You can find them everywhere; nonetheless, I keep fighting them: 2020 Corolla Hybrid: headroom = 38.3/37.1 in; legroom = 42.3/41.4 in; cargo = 13.0 cu-ft. 2019 Volt: headroom = 37.8/35.8 in; legroom = 42.1/34.7 in; cargo = 10.6 cu-ft. Why are you spreading such blatantly false information?

3-16-2019 Trolling, part 3. That same post with the lie also included this: "*Where, oh where, can one get a PHEV version of a Camry or Rav4?*" He knew the possibility of getting caught should include something to distract with. He'll just attempt to avoid the callout by shifting focus. I wasn't about to let that happen either: You know all too well Toyota has been focused on getting TNGA-based platforms out to as much of their fleet as possible. The goal is to convert roughly 80% by the end of 2023. That's an aggressive pace for such a major undertaking, but the results are enormous... lower cost, improved performance, and reduced emissions. That's a mammoth goal for a 10-million-per-year output. What other automaker is pushing that hard to advance what they produce overall? You also know that Toyota is starting with Corolla PHEV, which is why that was conveniently left off the list. It's the best selling vehicle worldwide, so it makes sense to choose that. And since the new Corolla hybrid is only just this month starting wide-scale rollout, expecting a PHEV already is clearly a lack of patience. Keep in mind, the new RAV4 hybrid is only now just rolling out too. You aren't taking into account the most important part of Toyota's timing either. It's affordability. Everything they do is fundamentally planned around delivering something that will appeal to both dealer & buyer. Both are important customers. Both want a good price.

3-16-2019 The Race. Discussion topics about Toyota falling "*behind*" have a new "*losing*" label. We see various sources attempting to stir online comments, but with mixed success. Posts like this help to obscure the reference: "*I don't think Toyota is losing the BEV race; they're not entering that race!*" They are an effort to get people to think about the bigger picture. The nightmare created by Volt enthusiasts about supporting a niche is beginning to raise awareness. Why did Volt fail? It's a good start to constructive consideration of what really needs to be done. I gladly contributed to that:

The race hasn't even started yet. What has been done so far that would qualify as mainstream penetration? Thinking these warm-up laps taking place now (sales subsidized by tax-credits) are what count as efforts to compete directly with traditional vehicles... the actual race... is just early-adopter rhetoric. How many ordinary consumers are actually that gullible to believe such nonsense?

Media outlets posting such dribble are taking advantage of hype to draw traffic to their publication. The knowledge of "*there's a sucker born every minute*" is just as relevant now as it was when back when that phrase was first coined. Think about how much easier it is to fool people now that anyone can post a comment online.

Look around. We are surrounded by guzzlers running on cheap gas and outright denial of their impact. That harsh reality is something "*EV Market*" spinners don't want you to notice. They direct focus on just the plug-in offerings to avoid addressing what really matters... change of the status quo.

Legacy automakers have a massive undertaking required to get their own loyal customers to embrace greener choices. Focus on the low-hanging fruit people are eating right is such a waste. Whomever wins the warm-up laps doesn't matter. In fact, that competition to follow isn't just a single 500-laps around the track either. There will be many races. Consider how many models of vehicle each automaker must implement battery-powered technology in.

3-17-2019 **Vague, Divert, Dismiss, Restrict.** That troll attack continued. It's like I had to revise my old greenwash-awareness guide. Ugh. Oh well, a refresher for everyone isn't such a bad thing. What he selected for the source of antagonism was interesting anyway. So, I punched back: We all know how this works. It's usually either post a vague reference or divert with a red herring. I'm not the one doing either. The other tactic commonly used is dismiss the issued being raised. People complained about Volt-1 head room. So when GM did nothing about that with Volt-2 (in fact, head room was slightly reduced), the problem was just dropped as no longer a concern. Head & Leg dimensions have overwhelmingly been the focus of seating size discussion, so that's what the response included. With respect to "cargo" discussions, you must list the actual height/length/width to address transport capability properly. Lastly, there's an obvious effort to restrict scope. If it isn't available here or now, it doesn't exist. That's just plain wrong. Toyota's expansion of plug-in offerings by diversifying their "Prime" enhancement is exactly what GM had been pressed to do for years, knew it needed to for business success, but chose not to regardless of the consequences. Toyota choosing to spread their technology to a variety of choices is a wise move. So what if Corolla PHV doesn't fit a family of 5 well. That's what Camry & RAV4 are for. You want a larger interior, you purchase a larger vehicle. That is also why Avalon & Highlander are offered as hybrid models. Toyota is preparing for large-scale electrification. What's happening here is quite different... vague... divert... dismiss... restrict.

3-17-2019 **True Change.** I like when someone helps out by interjecting a constructive comment to take attention away from the troll. This was a great example of that: *"You mean we need to wait for the government to mandate EVs? Good luck with that. Too much oil lobbying for that to happen."* I was delighted to indulge that initiation to discuss what really matters too. So, I added to the topic with:

That's why early-adopter sales shouldn't be taken in any way as representative of mainstream penetration potential. All those heavily subsidized sales do is prove out the technology... which is great... but nothing worthy to gauge demand upon. This discussion of a 5-seat Prime is a highlight of Toyota testing the waters. Just like the intrusion of cargo-space by the battery-pack, it is pre-mainstream real-world study. They have learned the value of research-by-trial.

So when certain people here raise a big stink about a configuration during these early-market rollouts, they need to be reminded about perspective. Toyota is extremely aware that no government funding or mandate should be counted upon for help with sales. It is up to each automaker to find their own way to appeal to their own loyal customers. For Toyota to retain their 10-million-per-year sales, they must do what works for them.

What I find most interesting about a particular thread like this is how newbies are introduced to what those of us with many years of observation have witnessed many times now. Toyota will respond to customer feedback. They take online comments seriously and respond in a constructive manner. Rhetoric is filtered out to find a high-volume solution. Watching the challenge being addressed is fascinating for those who truly want to change the status quo.

3-17-2019 **Antagonism.** Some people have a bridge to burn: "*nah, toyota blew it...*" Basically, he just thrives on the attention. So, choosing to provoke Prius supporters has become a pastime. He seeks out something to argue, then posts a provoke to stir attention. Yes, it's trolling. But as a regular poster and a Prius owner, he just blows off anyone who sights issue with his activity. I don't bother. I do look for opportunities to provide exposition though. The provokes provide an invitation to do exactly that. For example: That's not how the early-adopter market works. This is why you get the "*know your audience*" every time you complain or try to prematurely draw a conclusion. Knowing goals is the second part of that wisdom to share. An automaker can only be losing if they fail to achieve their goal. Notice how others are placing their statements in front of Toyota's to make it appear as though Toyota is struggling? That's how spin works. We have been watching Toyota set the stage for very wide-spread acceptance of electrification, offering a variety of choices across their entire fleet. The dealer's showroom floor will have diversification no other automaker has achieved. Though, we do see Hyundai/Kia working toward that same goal. Kudos to anyone genuinely working toward the phaseout of traditional vehicles. It's not easy and there will be a lot of people who will declare blowing it prior to even having finished the early-adopter phase... which is very clearly defined as the time when government subsidies (both federal & state) are offered to help establish those new choices.

3-17-2019 **Cycle Attack.** Now that plug-in hybrids are getting more attention, constructive discussion is emerging as a result. A big part of this is the death of Volt, since it was always a barrier to progress. That senseless EREV labeled confused the entire industry. It was an obvious effort to obscure PHEV offerings. It was marketed as superior without any explanation why. Details were intentionally suppressed. So, topics like how cycling of the battery-pack in various plug-in vehicles came into play. Efforts to keep focus on only range & speed was the mantra. That is no more, because Volt is no more. Other plug-in hybrids are now getting attention. That's putting the up directly against electric-only vehicles... hence today's attack. It was a misrepresentation of how the battery is used. I was quite annoyed. The thread was filled with blatant attempts to mislead, all by one particular individual. I saw that as a great "teaching moment" opportunity, ignoring him entirely by posting this information stand-alone: Cycle... Cycle... Cycle... Cycle... Notice how many times that reference is used in this discussion and not a single comment uses it correctly? The definition of "*cycle*" is when a battery is fully discharged, then fully recharged. That's not something which actually happens with a PHEV. Avoiding those extremes is what greatly improves the longevity of the pack. Look no further than Toyota for a Prime example (bad pun). A full charge is only 83% capacity, not 100%. A full depletion is only 13% capacity, not 0%. That's very similar to what other automakers do and the advice given to anyone wanting to keep their battery-pack from getting stressed. So when you see a post referring to how many "*cycles*" a battery can handle, keep in mind that doesn't apply to the PHEV systems designed to prevent extremes. The result is a battery-pack that lasts longer.

3-18-2019

The Wait. There's a calm before the storm. GM is approaching their own self-imposed deadline. That promise to deliver news within the next 18 months is nearly 18 months old now... and still not a peep. 2 new vehicles based upon Bolt were supposedly to be announced for our market. With the death of Volt and no successor to the technology, the belief has been that GM will indeed just embrace EV and allow their "EREV" technology to die. Knowing that just 2 weeks from now the \$7,500 tax-credit... which Volt was so heavily dependent upon... will be reduced by 50% is good reason to expect some type of vague announcement. It will be ambiguous, of course. That's who GM operates. They release something lacking detail with the hope that hype will stir interest and distract from their problems. In this case, that reduction of the tax-credit to \$3,750 is good incentive to yell out "Squirrel!" Ugh. This was inevitable. Volt lacked safety features that Toyota offers standard (like dynamic-cruise) and you had to pay extra for the features enthusiasts really want (like faster charging). So, GM waited out the clock, rather than making any type of next move. That's their biggest obvious missed opportunity. Rather than taking advantage of the transition period from quantity-based credits to time-based, GM didn't do anything. Tesla did quite the opposite. When they hit the 200,000 limit, they took full advantage of the unlimited quantity period. It is a 6-month span where the full \$7,500 is available for the automaker to sell as many of their product as possible before hitting the 50% reduction time. Tesla most definitely capitalized on that. GM rested on its laurels, doing nothing at all... just letting Volt die on the vine. All the low-hanging fruit people wanted was picked. The remainder now sit on dealer's lots. No more will ever be delivered and there is no word of anything "EREV" on the way. We have the impression GM will drag its feet, but not "*kicking & screaming*" as Toyota is portrayed by their enthusiasts. Instead, it's silence. We haven't heard any plans. All we have been told is that EV sales from GM aren't expected to be profitable until 2021. That puts the wait of these last 18 months into perspective. No much of anything is hoped for. GM lost its supposed "*leader*" position... exactly as predicted.

3-19-2019 **Success or Failure.** The antagonists certainly are enjoying this time of wait: "*My point is that outsiders, and likely many insiders, can say why the Volt was cancelled, and not knowing the why means we can't call the model itself a success or failure.*" They see it as a chance to spin new history, to distort facts about the past simply by stating their own narrative. Sadly, this is rather effective when a void is left behind... exactly what the death of Volt has created. Stating vague references and misrepresenting timelines is all it really takes. Casual readers of forums & blogs (lurkers) won't have any idea they are being feed fake news. Manipulation of facts has become so common, it is especially difficult to debunk the assumptions emerging. In fact, that's why the mindset of success or failure has become so prevalent. There's a polarization at its peak... thankfully, one that about to fall. We'll see a variety of plug-in hybrid and electric-only configurations hit the market. That diversity of choices will open up some closed minds, reaching those who didn't even realize they had fallen into that trap. That's the goal, to have a narrative so effective people have no idea they are being manipulated. This is why I strive to deliver a collection of detailed videos. That type of simple-to-understand presentation serves as a powerful empowerment tool. You learn more than it would at first seem, simply by paying attention to what was offered without bias. In the meantime, I'm still dealing with this type of crap online: That load of rubbish isn't fooling anyone. We all knew the goal of Volt long before it was even rolled out. By the end of year-2, sales were expected to reach 60,000. For year-3, production capacity would be capable of delivering 120,000 annually. That failed to such a degree, GM scrambled to revive the struggling effort by slashing prices. It didn't work. Focus shifted to what the second-generation could deliver instead. That turned out to be even more of a sales disappointment. Cancelling a product mid-cycle, without any successor, is the epitome of "*over promise, under deliver*" ...something we know GM all too well for. Had a Trax or Equinox been rolled out using Voltec, that would have been a different story. But all we see now is a tree with all the low-hanging fruit picked and an automaker not interested in climbing.

3-20-2019 **\$13.8 Billion.** That level of investment is clearly stirring executive anger. We have been witnessing the president attack GM for plant shutdowns and the loss of jobs. His pride & ego are focused on bringing jobs back to America. Seeing the opposite happen, where production ends here and resumes elsewhere is really bad for him.... especially when Toyota makes it quite clear they are investing heavily in the opportunities here. Toyota sees the profit-based decision making will lead to trouble, again. That's how GM fell into bankruptcy last time. They were desperate for money, which is how the highly-profitable Pickup & SUV focus came about. Watching the production of their sedans come to an end is far more than just coincidence. It is evidence of the same thing happening again, but this time out in the open. It's obvious what they are doing. GM claims that's just a move to align with market demand, but the lack of investment in efficiency offerings says otherwise. Had we seen a Trax with Volt technology, that would have been a different story. Why would a new offering like that not include at least hybrid technology? Claims of leadership make no sense when a small SUV is nothing but a guzzler. That should have been what replaced the plug-in hatchback. Why not? Of course, the all-new Blazer being built in Mexico makes any such argument of "*investment*" difficult. What is being done to retain production here, to prevent bankruptcy and rebuild employment opportunity? Toyota is doing it. Why not GM too? Remember the "*too little, too slowly*" concern?

- 3-20-2019** **Bleeding Cash.** It was intriguing to just finish blogging about the problem GM has created for itself, then stumble across this: "*Sedans a cash bleed*" It was a section of an article published explaining that very problem. It proceeded on to state: "*GM is discontinuing many of the products built at those five plants, which are mostly sedans, saying U.S. consumers prefer SUVs and pickups. But GM has faced a backlash for opting to build other new products, such as the Chevrolet Blazer SUV, in Mexico.*" That is exactly what I said. The link for that article came in a post including this comment: "*So, I am not surprised that GM's lackadaisical support for plug-in sales is evident in their customer lack of demand.*" It was in a thread complaining about GM providing no support for their plug-in vehicles. Exactly as I argued many times in the past, the true customers of GM are their own dealers. That is why I asked the "*Who?*" question so often. It was to point out that Volt buyers were only conquest sales, enthusiasts just taking advantage of a good deal. Evidence of that was the lack of loyalty. They'd just abandon Volt when the next opportunity came along. They didn't care. Most had never owned a GM vehicle prior to that purchase. So, moving on to another automaker later was no big deal. That stems from the dealer they made the sale with never expressing any interest. After all, they don't want to be bleeding cash too. This is why inventory is almost entirely just Pickup and SUV choices. Heck, I see something similar happening at Toyota. The difference is seeing strong growth opportunity for the hybrids, especially the newest choices: RAV4 hybrid & Corolla hybrid. Competitively affordable with traditional counterparts makes them a compelling advancement forward for dealers. They will be willing to carry some inventory like that. It shows Toyota's commitment to them... rather than GM just expecting their dealers to find a way to survive with expensive choices.
- 3-21-2019** **Ford Investment.** Talking about building pressure for GM: "*As part of an \$11.1 Billion investment in emissions-free cars, the Dearborn, Michigan-based company's Flat Rock Assembly Plant will manufacture the next-generation battery electric flexible architecture.*" Hearing from both Ford & Toyota recently about their plans to invest and carry the industry forward makes you wonder when the long awaited announcement from GM will finally come. With the March 31 deadline rapidly approaching, it's getting rather dramatic. Of course, the expectation is the same old game play. GM will have a press-release that tells us virtually nothing. Most are so horribly vague, you don't even have enough detail to sight concern of vaporware. The spin will be obvious. An expectation of "*next-generation*" promotion is a given. There's always some type of "*new & improved*" hype, without anything telling us what that actually means. GM's goal with any type of distraction like this one coming is to build hype. That creates a sense of hope few question the merit of... knowing anyone who questions the absence of clarity will get publicly shamed. The internet continues to be cruel like that. Constructive discussion is still unwelcome. That's sad. As with this announcement from Ford, it will get buried in rhetoric. Ugh.

3-22-2019 **GM Announcement.** Sure enough, we got exactly what had been anticipated: "*This new Chevrolet electric vehicle is another positive step toward our commitment to an all-electric future. GM will continue to invest in our U.S. operations where we see opportunities for growth.*" That was the highlight in the press-release today. It tells us nothing whatsoever... except the fact that 2 new electric vehicles were the expectation GM had set. That only mentioned 1. Sadly, that was literally all we were told about plug-in investment. The statements made primarily focused on GM's investment of \$1.8 Billion to take place. That's a far cry from Toyota's \$13.8 Billion and Ford's \$11.1 Billion. The assuming part, since there is always something, was the mention of and "*advanced version*" of Bolt this new EV will be based upon. Of course anything new will be advanced. What else would it be? Nothing else was stated. It simply concluded with: "*Additional product information and timing for the new Chevrolet EV will be released closer to production.*" Talking about stirring the pot without adding any substance. We literally got nothing. The certainly is an effective means of avoiding the problem of over-promise, under-deliver. Not setting any expectation whatsoever or even hinting at a plan is par for course. We really didn't think substance of any sort would actually be shared. So close to the reveal of Q1 sales and the 50% reduction of tax-credits, the mood is grim. Anything providing a glimmer of hope is welcome. I await the rest of the industry to take advantage of this leadership fall. GM's claim to "*game changer*" was nothing but an exploitation. Evidence of choosing to support the status quo is overwhelming.

3-23-2019 **Server Down.** I posted a brief response to an antagonist yesterday, just as I was packing up to leave work. It was in reply to GM dropping the ball. I wanted to get it out there right away, since the evening was about to be filled with things having nothing to do with the automotive industry... though, our drive there would be with electricity. We watched a performance of a play our good friend's daughter was a part of, both as a performer and writer. It was a great too! She's got a lot of potential, a talent I really admire. Anywho, that was followed by a nice late dinner with my wife. It wasn't until this morning that I attempted to follow up on the many notifies I had received from my post. Unfortunately, the server is down. I suspect routine maintenance, since this is the start of the weekend. That means having no clue what was posted. All I know is several well-known antagonists had something to say. Sadly, I didn't save my own post to quote. It simply as priority. We'll all have to wait. The forecast for today is 58°F. Yeah! Yesterday was the first time we saw a temperature over 50 in over 4 months. Minnesota had a proper Winter. Now, we welcome Spring. That doesn't mean a huge storm with lots of snow won't still happen. It just means the mess afterward will melt quickly, now that most of the ground-cover is gone. This time of year is quite welcome. So, I'll gladly enjoy it. The server will be restored by this evening, after the sun has set. I'll get back to those posts then.

3-23-2019 **Impressive.** That was his assessment of current sales. Unfortunately, such a perspective requires absolutes. I begged to differ by posting my own: "0% purchased without tax-credits is not impressive. Don't be fooled by only paying attention to the low-hanging fruit." That stirred exactly what I anticipated for a response: "*So you really think EV sales will totally go away once the tax credits do?*" That's absurd. There will always be some type of niche market. The point though is to get the technology into the hands of mainstream buyers. This is why I called out his limited scope. It's easy to manipulate be simply cherry-picking data. In this case, it was misrepresenting the market. I provide a does of reality: Absolutes are no way to form a constructive query. We know that there will be some winners and some losers. Dependency on subsidies will confirm weaknesses. For example, today's disappointing announcement from GM (basically no plan and a small investment) seems to indicate a lack of interest. We figured something would happen as the 50% reduction approached.

3-23-2019 Background & Purpose. The timing made attacks like this inevitable: "*Then don't allude to it.*" Those troublemakers of the past will mislead & imply to make their narrative what gets the most attention. That requires a disregard of the past. For those paying attention, it's obvious. For others, you need to directly point out what's really going on:

No amount of "*totally go away*" spin can evade acknowledgement of my years and years of expressing concern that only affordable choices will survive the expiration of tax-credits. There were many short-sighted people who focused exclusively on the tax-credit dependent sales, absolutely refusing to recognize how few 200,000 actually is with respect to ordinary business-sustaining profitable sales. I most definitely was not part of that group-think crowd. I spoke out loudly against them... and you know it.

I was one who said Volt would die if GM didn't spread their plug-in hybrid technology prior to the approach of tax-credit phaseout. I kept posting "*too little, too slowly*" over and over and over again, warning of the consequences of inaction. For that, I got attacked relentlessly. Vindication now from having correctly spelled out that situation is bittersweet. Supposed leadership from GM didn't actually change the status quo. Something not dependent upon tax-credits still needs to be delivered.

Seeing Toyota have to deal with rhetoric for taking their time to do it right is annoying. How is rushing into a money-losing approach going to get dealers to embrace the idea of stocking & selling inventory that necessitates a subsidy? That never made any sense and GM's colossal screw up with Volt overwhelming concerns how terrible of a choice that was. GM violated basic business principles to push an expensive compact hatchback, something that stood no chance of actually appealing to their own Pickup & SUV wanting customers.

You know all too well that Toyota's effort to always focus on affordability and finding a way to spread their technology across the entire fleet at minimal cost has always been the better strategy for a legacy automaker. Is the effort to distribution a hybrid platform capable of plug easy augmentation to a wide variety of vehicles sizes & shapes prior to actually offering a plug that slow? Can you honestly claim that their long-term goal of achieving that diversity by 2020 was a waste of time & resources?

I'm tired of dealing with the nonsense of not taking market reach seriously. That smug from enthusiasts can finally end by us not feeding them with material like "*allude*" when you know quite well that wasn't the case. You are well aware of my background and my purpose.

3-23-2019 Breaking the Deadlock. I'm really starting to push now. There are several individuals who like to play the game. Hitting reset every time they begin to lose influence. They try to keep you from drawing conclusions from pushing a misleading narrative or raising doubt. I get really annoyed by the obvious efforts to divert discussions and the effort to repeat the same questions. They hope whomever challenges them won't have the ability to push back hard enough. I have earned the rank of a senior participant though. After having whether so many battles in the past, resulting in several wars being won, it's time I take advantage of that experience. Turns out, it's very difficult to argue with someone who has an extensive history to share that's so well summed up. I hadn't realized all the blogging would develop the skill to see past rhetoric so well. You learn to keep focus, regardless of how much of an influence the current hype is having. It all comes down to having established concise goals. That clarity is key... exactly like I theorized way back when... but since has been confirmed. Phew! This means I can come down rather intensely on particular individuals, intentionally making it personal. It works when you stay focused on why. It's not vengeance or malice. It's the effort to find allies. You don't try to destroy your enemy. You work to find compromise. Showing them a way forward can be that. Extending a hand to move in a direction unfamiliar, but with a shared objective, can be very effective. I intend to break the deadlock by showing force. Remember how effective that was ages ago, when I directly confronted a diesel antagonist?

3-23-2019 **No Spin.** This came from that antagonist who just kept asking the same question over and over again. Now, he's basically becoming a troll: "*We will have to wait till then to see what John's next spin will be.*" I'm not sure if he's just getting lazy or realizes there's a chance of getting called out. Eventually, others will notice the behavior pattern. That's why they try to put the attention back on you. Anywho, I responded to that with:

You know all too well I was correct about Two-Mode, correct about Volt-1, and correct about Volt-2. Each of those technologies had a fatal shortcoming... being too expensive. Each time the evidence became so abundant that their shortcoming could no longer be denied, something else came about to fill the void. Now for GM, that's Bolt.

In other words, there hasn't been any spin from me. It's the same old argument. I say the technology must be affordable, period. GM is the one providing spin. I could point out some old posts about me getting complaints for repeating the same old argument over and over and over again, like a broken record. You know that isn't necessary though. You too are well aware of my background and purpose.

I want a wide variety of affordable choices for consumers. They must be capable of competing directly with traditional vehicles, so those new clean & efficient choices can become the replacement. That means none of the activity so represents the change needed. It paves the way, but subsidized sales are sustainable... hence the concern about tax-credit dependency.

As for your obvious attempt to divert attention away from discussion of legacy automaker approach, that's disappointing. We need well informed people like you to help with the effort to get those traditional sellers (dealers) to embrace change they can actually influence. They won't ever have a business model like Tesla, so it makes no sense treating them that way. In other words, I reject your spin. Legacy automaker finances & distribution are quite different.

3-23-2019 **Common. Ordinary. Boring.** The transition from niche to ubiquitous is what early-adopters have a terrible time dealing with. Ironically, their exposure & understanding of the technology makes them blind to what mainstream consumer don't see. So neither group recognizes how each is interpreting the situation. What is obvious for the one is often be an unknown for the other. That's why a vehicle like Corolla is pretty much never mentioned by enthusiasts but is the first consideration for someone wandering around on the showroom looking for what to buy. There's the difference between want & need too, seen from perspective that are far from the same in any respect. This is why I face so many barriers getting those early-adopters to recognize what's important for an audience quiet unlike them. Often, they'll just dismiss what I say, claiming I've lost touch with reality. That's another irony, for me to be one of the few forum & blog posters who is more in touch with your typical shopper than any of their own peers online. They still don't realize that even just the basic act of posting participation sets them apart. It's why cars labeled as "*common*" or "*ordinary*" or "*boring*" get so little attention, despite being the top-sellers and the fundamental basis for business sustainability. That necessary profit comes from those vehicles, not the niche they endorse with such praise.

3-23-2019 **Already.** I was annoyed upon getting this: "*What will Toyota do when the \$4,500 federal credit goes away?*" It was a sign that he either wasn't paying attention or simply didn't care, since we had already addressed the topic multiple times. Well... there are some who remain clueless, not wanting to accept information. So, that's a possibility too. Whatever the case, I was annoyed but took the opportunity to explain yet again:

Toyota is doing it already. They are spreading their hybrid technology as widely as possible, striving to establish a customer base readily acceptable to change by offering a variety of affordable choices... each capable of offering a plug later. Making Prius into Prius PHV was basically just a matter of introducing that one-way clutch. We're about to see the same upgrade play out with Corolla PHV.

It's easy to see how RAV4, C-HR, Camry could all follow the same path. That's how successful economy-of-scale cost-reduction is achieved... exactly what's needed to overcome any type of subsidy... which Toyota has already demonstrated with the MSRP for Prius Prime.

The problem with your perspective is that you're treating the market of 2 years from now, when the tax-credits are used up... as if it is still 2018, not acknowledging how much change that's about to happen as a result of seeing so many new plug-ins on the road. It's that big curve upward we are about to hit in the product life-cycle that will introduce a market you are quite unfamiliar with. That's an exciting time to look forward to if you are **NOT** an early-adopter.

Remember that sales in high-volume to ordinary consumers are profoundly different. Far too many here assume mainstream appeal is just a matter of delivering enough capacity at a reasonable price... hence the technology being affordable. If it isn't, all those other purchase priorities people have can't also be delivered. Early-Adopters are willing to compromise. Buyers on the showroom floor are not... which is why Toyota is already working to deliver a variety of choices.

3-24-2019 **Spinning Stance.** The most common response to my posts has been to spin my stance. Someone will either twist what I say, take it out of context, or just totally make something up. I always wonder if that is intentional to provoke online activity or they simply aren't paying attention. For those troublemakers whom I have known years, it's especially bewildering. There are posts where I wonder if they make assumptions based what they can only remember in part or they are actually remembering someone else. That's why I'm taking the forceful stance now. Being very direct eliminates most of the uncertainty. We'll see if the nonsense continues or if I'm able to break the pattern. It stands a chance of progress forward. After all, the market itself is changing.

3-24-2019 **Antagonists.** There are some who are obvious trolls, more politely referred to as antagonists. You get the point. Their purpose is to provoke you to reply: *"I believe john's argument was that batteries are too expensive so small batteries will be better once tax credits end. Of course Nissan and Tesla have already proved this argument completely false."* Options about how to reply are limited. I chose my reply carefully:

You've know me for how many years? That has never been my stance. I have always said we need a variety of affordable choices. Not at any time have I stated a relational between PHEV & EV with respect to tax-credits.

As for Nissan & Tesla proving it, you've lost touch with the big picture... the market as a whole. There haven't been any non-subsidized sales yet. So far, all we have seen is early-adopters taking advantage of tax-credit opportunity. The stage where mainstream consumers make the choice on the showroom floor with traditional, PHEV, and EV all there as part of the decision with none getting special government incentive hasn't even begun yet.

PHEV will have a place for many, many years to come still. Our infrastructure (all locations: home, work, businesses, public locations, and roadways) is only in the earliest stages of building and becoming green for transportation. So, the very idea that all could be served in the near future by just EV isn't constructive in any manner.

It isn't just the expense of batteries either. There's the problem of production-capacity and energy-density as major holdbacks. Overcoming that still leaves us with the liquid-electrolyte limitation. It will all happen, but claiming *"completely false"* already is absurd. What has been proven is being at the *"lots of potential"* point with a great deal of effort required to achieve all those goals.

3-24-2019 **Continued Provokes.** He didn't let up: "*There is a good place for the <40 mile PHEV like the Prime, but these designs are better from the ground up. By the time Toyota gets its battery production together with Panasonic my guess is they will be able to produce 30 mile PHEVs with battery packs that are lighter, smaller, and cost less than the 25 mile one in the current Prime.*" It's interesting to read that, since arguments expire after awhile. You simply cannot use the same reason endlessly, especially when the circumstances change. In this case, the market is rapidly approaching the end of tax-credits... which will dramatically impact the situation. In fact, the death of Volt makes that blatantly obvious. Toyota clearly planned ahead. He just doesn't want to accept the evidence. So, he takes offense by trying to spin perception. I'll have none of that:

Use of "*from the ground up*" doesn't actually mean anything. People have come to recognize it as representing only a first-generation model. Why? Anything built upon with the original intent there from the start is dismissed. Again, why? Upgrades are an expectation with other technologies, why not with automotive design?

Looking at Prius, we see the design way back in 2003 offering up to 100 km/h travel in EV mode. It was pressed for power with battery-technology of the time; nonetheless, it was indeed built from the ground up. Potential from the system has always been limited that way. The most recent generation, we know as "*Prime*", was clearly it was configured to fit 4 stacks nicely inside the cargo area. The choice to add a 5th just prior to rollout for more range & power doesn't change the propulsion system. All it did was cause a loss of interior space.

Toyota's approach of a drop-in battery-pack means they will be able to take advantage of lighter, smaller, lower cost later. No where does it say they have committed to older cells. Newer will be used as the technology improves. Those cells will be arranged in the stacks to create battery-packs for newer models of Prime. Their design is already capable.

3-24-2019 **Yet Another.** The troublemakers are appearing in from all over. You can tell they fear what's to come a week from now: *"Toyota is not even in the game, for some reason....."* In his case, he has chosen to raise doubt. Attempting to get people to second-guess their conclusion is an act of desperation, especially at the last hour like this. But knowing this individual has been a particularly nasty Volt enthusiast who has gone out of his way to spread misconceptions, it was inevitable we'd have to deal with a return on the big Prius forum. With the 50% reduction of that tax-credit Volt was so heavily dependent upon about to become a reality, it's easy to see his motive to divert attention from GM back to Toyota. I wasn't about to let that happen:

What good came from the game GM played? Upon using up their allocation of tax-credits, nothing viable for the masses came about. They have an expensive plug-in hybrid that only appeals to enthusiasts.

Why would Toyota want to do the same? The choice for Toyota to refine their underlying electric-tech while waiting for battery cost to reach a tipping point sure makes a lot of sense. They are setting the stage for high-volume sales to a very wide audience while learning from real-world data they collect. That certainly sounds like a very good reason.

You mention Kia, Hyundai, and Nissan. Notice how none of them have anything in large quantity yet here. For that matter, how many have you ever even seen on the road? Do you consider the *"game"* they play better? If so, how?

Think about where we currently are on the product life-cycle curve for plug-in vehicles.

3-25-2019 **More Attacks.** This was quite predicable: *"Refine?? You mean like the cheap, inadequate TMS workaround that is in the Prime?"* I kept my reply to that short. There's no sense arguing with someone who simply doesn't care, but it can be helpful to lurkers now and the curious later to leave behind evidence explaining what the situation truly was at the time: Understanding the difference between want & need comes from seeking a balance. Your insistence upon the battery-pack requiring liquid-cooling, knowing it will never be DC fast-charged, shows a lack of understanding. Adding expense & complexity to a system that doesn't reveal the need makes no sense. Toyota's observation of real-world data from forced air-cooling will help identify what's truly necessary. It's ironic how some claim Toyota is unwilling to take risks, then turn a blind-eye to them when they do exactly that.

3-25-2019 Forcing Perspective. Rhetoric most common among those attempting to appear constructive comes in a form like that: *"Sure. Build all the PHEVs that you want. But don't pretend it is the fastest or only path to a highly electric future."* They are actually the ones who see the "fastest" and "only" perspective. It's called "projection" when someone accuses you of the very act they are guilty of. It's confirmation they recognize the problem, but mistakenly identify the wrong party of that act. I see it on a regular basis. Reading it gives me a bizarre feeling, every time. Most continue on forcing their message of reversed perspective without ever figuring out their mistake. You become familiar with their aviator after awhile. This is why I often end my response to them with a question: Automakers lived in the present for decades, promoting whatever was big at the moment. Now that there is a need to look forward, why must there be a comprehensive look to the long-term. You're setting a dangerous precedent. Think about how unrealistic that can be. Automakers can spin whatever future they want with no accountability... and some have already exploited that opportunity. We've seen things get very messy in the past. There's reason for caution. What do you really expect from an automaker touting a fully electric future, but still sells millions of guzzlers annually for years to come?

3-25-2019 Limited Perspective. That forcing of perspective can sometimes be broken by presenting options. People sometimes draw incorrect conclusions based upon assumptions due to lack of information. If they simply don't know to what degree something is available, they'll believe options are limited. I try my best to provide that missing information when I notice the problem. This caught my attention in that on-going rant: *"Yes, this makes it easy for the consumer. They can just at home, just using 110v overnight and they need no new infrastructure at all. If they forget to charge, no problem."* That overly simplistic response made me wonder if he just lacked a full understanding of potential. So, I pointed in out:

Evidence of the desire to upgrade after getting a taste of EV is absolutely overwhelming. Whether it is the want to recharge faster or simply the need to plug in a second vehicle in the household, there will be pressure which naturally occurs simply from that first PHEV purchase. The owner will seek options, discovering incentives from local electricity providers for them to use more electricity.

Keep in mind of the potential. SAE-J1772 can deliver a charge-rate as high as 19.2 kW. Most households, even with EVs already touting large battery-packs, don't have anywhere near the 100-amp dedicated service to support that currently. So, there will very likely be upgrades for everyone in the years to come anyway.

Toyota is well aware of this power to build a customer base. Their focus on reliability & affordability now makes sense. Higher capacity can follow without consequence of not being available now or even being promoted now. Upgrades are already an expectation. We have come to expect continued improvement.

Know your audience.

3-26-2019 **Push.** Bouncing between several different attacks all at the same time is interesting. I knew this day would come, when the panic from Volt enthusiasts would stir discussion about topics rarely addressed with anything more than just a brief mention: "*PHEVs do not ever, IMO, push that long term infrastructure...they kick that can down the road.*" That in particular caught my attention. It was an effort to spin perspective. That doesn't work when you've misidentified audience. He kept dwelling on the consumer. Overlooking another player involved is a surprise common problem. We see that all the time with respect to dealers. They are almost never treated as a customer to the automaker, even though that is exactly what they are. They choose how to stock & sell the product. That is a vital bit of knowledge to not notice. With regard to this topic today, it's the lack of recognition from whom the electricity for charging comes. Why would you equate infrastructure to an automaker? Since when are they expected to do things like influence the location & quantity of gas stations? In fact, that's an absurd idea to even suggest. Yet, that's exactly what is being forced. Ugh. I replied to that nonsense with: You're looking at it backward. Again, know your audience. There are electricity providers all around the country gearing up to do the push. As a PHEV owner, it's just a matter of taking them up on the upgrade opportunity. They want you to use more electricity, to get on their time-of-use programs, to want your next vehicle purchase to rely on electricity even more.

3-27-2019 **Push Back.** Eventually, he may catch on. Until then, it's dealing with stuff like this: "*Why would someone install a 19kw charger at home in order to take advantage of time-of-use rates? You are making no sense. The idea of charging at night is that you have 8 or 10 or more hours to charge. With an ~6kW L2 you can add enough miles for 95% of commuters.*" That brings us back to the limited perspective, conclusions drawn upon without having all the necessary information available. My guess is the idea never crossed his mind. Options that aren't ever thought of can sometimes result in a reconsideration when presented. I'm not sure that will work in this case. He seems dead set on incomplete facts being enough. Ugh. I pushed back anyway: You are repeating what I already pointed out, the rule-of-thumb: a 40-amp line will deliver 200 miles in 8 hours. You also sighted a situation when a person with the available capacity could take the most advantage of time-of-use rates. Think about this. It's mid-afternoon and you have a low battery. You want to avoid the dinner-time rate. The fastest charger possible is how you would achieve that. So what if a person has the ability to rapid recharge at home for opportunity charging but also overnight charges. You have the choice of when and how much. For that matter, you can even choose charging speed.

3-27-2019 **First Sighting.** I saw a 2019 mid-cycle refresh Prius this morning. It looked very new, no plates yet. That first sighting caught me by surprise. I hadn't heard much about shipments elsewhere yet. Living in the middle of the country, it's quite normal for reports from the coasts to become common before there's even a chance of it happening locally. So, I was happy to see the dealer-tag while driving by it parked on the road. With the market so screwy right now, it's difficult to set any type of expectations. Once the uncertainty of the tax-credit phaseout passes, then we should return to some sense of normal. For now, I'll just chalk this first sighting up as a moment to remember.

3-28-2019 **Reasons Behind The Slowness.** The discussion topic about EV acceptance & adoption on the big Prius forum has stirred quite a bit of participation. Here's my add to it:

It has been quite helpful to hear from the regular antagonists about EV adoption, especially upon the death of the biggest "*vaporware*" failure in the industry. Remember Volt? That promise of an efficient & affordable plug-in hybrid never materialized.

The biggest shortcoming was price. We were provided with a "*nicely under \$30,000*" target. It made a lot of sense why GM would set a goal like that. Supposedly, it would be achieved upon initial rollout. That didn't happen. We were told to be patient, the wait for gen-2 would address pricing. It was a let down for many, but fine. Unfortunately, the necessary cost reductions weren't taken seriously. That pricing never materialized... hence, the vaporware label... and the confirmation of price importance. Tax-Credit phaseout push so much pressure on that aspect of competition, the effort was abandoned. Volt production ended without a successor established.

Efficiency played an important role as well, but it was far more subtle. A system requiring less electricity to travel the same distance wouldn't require as large of a battery. That would contribute directly to a smaller, lighter, and less expensive pack. That would require reduce the time & electricity to recharge. It was a factor if design rarely focused upon. Importance of electricity consumption was just ignored. Displacement of gas got so much attention, concern for efficiency was recklessly treated as rhetoric without regard to source or quantity. It was evidence the situation would eventually become a clash of image verses truly being green.

Ultimate, it was the "*green*" messaging that caused Volt to be trapped in the early-adopter stage. Dealers had no interest in a "*EREV*" when no one knew what the heck that actually meant. Fights even among Volt enthusiasts made that marketing term a self-destructive concept. The definition continued to change, each time a new plug-in hybrid offering rolled out. That positioned Volt against the entire line of EV choices as well as all of the plug-in hybrids. No one ever really understood what purpose it served. Even the message from GM itself was bewildering. Volt wasn't the intended "*range anxiety*" solution as promised; rather, it was abandoned shortly after gen-2 rollout in favor of Bolt.

Everyone saw what was happening, but enthusiasts fought hard to evade addressing it. We witnessed propaganda efforts all over online to distract & mislead. How is that ever an effective means of promoting a technology? Needless to say, a massive amount of opportunity was missed as result. Nothing came about to help raise awareness about charging infrastructure. You'd think with that much attention and 150,000 vehicles sold, some message about plugging in would have come about.

Toyota saw this coming... as did I. We saw the value of simply continuing to study & refine while waiting for the GM disaster to play out would be a fruitful endeavor. Patience does have merit. Now, just 3 days before the 50% reduction of GM tax-credits and production of Volt having ended 6 weeks ago, there's a wide open field to play in. None of the other plug-in hybrids presented the unrealistic expectations hyped by GM and their fanboys. In fact, they were the ones who spread the "*slow*" narrative.

Stepping back to consider the bigger picture (the legacy automaker market as a whole), what reason is there to claim Toyota as being slow?

3-28-2019 **Distorting Purpose & Timeline.** That's what you do when things go horribly wrong. Here's the spin: "*Volt owners - jumping ship, consider the Chevy Bolt to be the Volt's successor. ie, a Bridge car. Isn't that what we keep saying? A plug-in is just a bridge before getting rid of the ice?*" Comments like that are often looked upon as damage-control. That outcome is clearly not what had been hoped for at this point in time. I responded to it with:

GM's fundamental problem with Volt was failing to attract its own loyal customers. Those who already owned a GM vehicle couldn't care less about a compact hatchback with a plug. They desired a SUV of some sort. That left it to attract only conquest sales, those early-adopters seeking opportunity in the form of incredibly low leases or a substantial tax-credit.

GM made that worse by listening to enthusiasts about how to make the next generation better. It was the classic "*Innovator's Dilemma*" business mistake playing out right before everyone's eye. They listened to the wrong people... hence asking "*Who?*" on a regular basis...which ultimately ended up becoming the lesson learned: "*Know your audience.*"

Volt being abandoned early in its product-cycle is a costly. No automaker ever plans an abrupt stop like that. Calling Bolt a successor makes that already troubled situation even worse. It suffers the same fundamental problem. GM's own loyal customers don't want a compact wagon, especially without tax-credit help.

Toyota gets routinely accused of resisting the EV market by "*kicking & screaming*". We know that's not true, since their push to phaseout traditional vehicles by offering a wide variety of compelling hybrids is on such a large scale. They are undeniably trying to change the status quo. For those watching carefully, they notice those doing damage-control for GM spinning that situation to draw attention away from GM not even going slow anymore. That previous progress has since come to a complete stop.

This discussion thread about EV adoption has been overlooking that history playing out at this very moment. Those reasons are far more important than quibbling about a past long ago or looking beyond the bridge. We must deal with what's unfolding right now.

- 3-29-2019** **Omitting Detail.** Reaction to my distortion callout didn't surprise me at all. It was a typical mislead by omitting detail: "*...but even if we look at recent sales - the Volt / Bolt (w/out the largest incentives any more) & Prime are all pretty close in sales.*" His attempt ultimately had an expectation of taking attention off of GM. I took the bait anyway, figuring his trolling had a motive of stirring discussion. So, asking his point may result in something to derive a construction exchange with. You never know, especially at such a critical junction. So close to that tax-credit reduction none of the Volt enthusiasts ever took seriously is a harsh reality none can escape. The nightmare they tried to dodge will smack them head on... production has already ended and the heavily depended upon subsidy is in the phaseout stage. I hit him with: Wow, that's a pretty lame attempt at whatever you're trying to convince us of. The incentives are still available for Volt & Bolt. That \$7,500 tax-credit doesn't get reduced until next month. So if anything, there should be a jump in sales for those wanting to take advantage of that final opportunity. As for attempting to compare a nationally available vehicle to one with almost non-existent inventory in the center of the country, that reveals the opposite of what was claimed. What was your point? We can speculate endlessly about GM's point, but it always comes down to wanting to out Prius, Prius... something that breaks the status quo... which didn't happen. Realistically, slow is just fine if it gets the job done. That's why it doesn't matter whatever each legacy automaker does, as long as they actually do something to get their own loyal customers to change.
- 3-29-2019** **Charger Upgrades.** This crazy moment in automotive history here isn't all about GM's fall and Tesla's aspiration. We often talk online about establishing infrastructure, but rarely is there mention of improving upon it. But now that so many years have passed since those original efforts began, it is time to address their progress... or lack thereof. In the case of where I park for work, there's very good news. 4 of the 6 chargers there (2 dual-plug units) lost communication with the network. I don't know the detail of what happened, but the decision was made to swap them out with new models. While at it, the 2 other units will be too. Both dated back to 2012. Only one L2 connection was available on each. But since they from long ago, each also had a L1 connection. Neither was ever used (as far as I know), but parking spots were allocated. So, they will now become L2. The newer duals will bump the count that can all L2 charge (usually a 208-volt commercial connection delivering up to 6.6 kW sustained) to 8 vehicles at the same time. That's a nice setup, especially when you consider the really nice location the chargers are at. Sometimes, you get really lucky.

3-30-2019 **Volt Epitaph.** There was a new topic posted on that old daily blog for Volt. It was an attempt to paint a rosy picture using this title: "*With Tax-Credit Cut Looming, GM Promises New Incentives for the Chevrolet Bolt*". I found it especially intriguing, since no other news source I had come across had made that claim. In fact, several of the green websites I frequent had posted quite the opposite topic. Those discussions were stirring quite a bit of participation too. I noted how the usual antagonists were almost entirely absent. They wanted nothing to do with such an obvious admission to mistakes made. I felt quite welcome to post an epitaph for Volt as a result, waiting until yesterday's stir had settled to post the following... on that daily blog, which even after a wait of 23 hours hadn't resulted in a single post:

Back in July 2013, the price of Volt was dropped by \$4,000 to help clear out the 2013 model-year pile up inventory. In August 2013, pricing of both the 2013 & upcoming 2014 model-years were dropped by an additional \$1,000. It was a strategy to stimulate the market. But having a new base-price of \$34,000, it was still far too expensive to be competitive without subsidies against traditional vehicles.

Back then, enthusiasts were confident the target of "*nicely under \$30,000*" could be achieved prior to tax-credit expiration. Many of the meritless claims about sales challenges were difficult to address; so much so, some of it became mindless rhetoric. That's what contributed heavily to mistakes made with the second-generation design. Those enthusiasts became the voice of misleading design suggestion.

Limited initial rollout of that next Volt and the reveal of Bolt prior to it were clues that something had seriously went wrong with the "*Game Changer*" plan GM had committed to. Sales remained a struggle and much greater investment was being made to traditional SUV offerings. As a result, enthusiasts turned a blind-eye to GM's fleet and directed focus entirely on the "*EV Market*" instead.

Now, with only 1 day remaining (0 in states that don't allow sales on Sunday) of the generous \$7,500 tax-credit, we see an abandonment of GM. There's simply nothing to draw attention anymore. Volt production has ended. There's no word whatsoever of an upcoming plug-in hybrid. And the price of Bolt simply isn't competitive with at \$32,870 (the \$36,620 MSRP minus \$3,750 tax-credit). If GM compensates with a \$3,750 price drop, how would that help? Sales will remain far below expectations for an ordinary profitable vehicle on the sales floor.

This outcome was predicted. Concern in the form of "*too little, too slowly*" was expressed countless times, only to be returned with an everything will be fine. GM's own loyal customers were never interested and enthusiasts are moving on to other automakers.

3-30-2019 Game Changer, part 1. My post from the night before was responded to with a link for this article: *"Better Late Than Never: Chevy Volt Sales Finally Hit 100,000 Mark"* It was from a Detroit publication in August 2016, a positive spin on Volt's history to help gen-2 rollout along as its first full year of nationwide availability was about to start. The prior was a strange mix of limited features and distribution to only select states. There was also the uncertainty surrounding gen-4 Prius rollout about to begin, followed by rollout of Bolt. It was an interesting time. This is the opening of that article I was about to comment on: *Chevrolet is marking an important milestone, General Motors' biggest brand taking an order for the 100,000th Volt plug-in hybrid-electric vehicle. The Chevy Volt has been one of the world's top-selling plug-based vehicles ever since its launch in December 2010, but tempering any celebration is the fact that the Volt hasn't come close to meeting the brand's once-ambitious sales targets. At one point, GM officials were hoping to deliver as many as 40,000 of the vehicles annually in the U.S. alone. "Not only is the Volt a class-creator, it serves as the foundation of a Chevrolet electric family that will soon add the first long-range, affordable EV available to customers across the U.S., the Chevrolet Bolt EV" said Steve Majoros, director of marketing Chevrolet Cars and Crossovers, in a statement. Few would argue with the fact that the original Chevy Volt was a game-changer.*

3-30-2019 Game Changer, part 1. This is the comment I posted in response to that *"Few would argue"* claim:

It was that sentence in the article's open which made this thread the one to stir the topic of GM's fall. Today is the very last day (for states that don't allow sales on Sunday) before the tax-credit for GM gets reduced by 50%.

Volt never actually changed the game. Now 6 weeks after its production ended, saying the status quo remains intact should be a statement made without contradiction. Sadly, we see GM's fleet flourishing with traditional SUV choices, including the newly introduced offerings: Trax & Blazer. Their concept of a plug-in hybrid died without a successor. Their contradictory shift to EV instead has floundered to compete. It's a disaster about to get worse.

The reason to bump this particular topic this way was to attract discussion about it. Sales are the measure of change. All we saw come from Volt was subsidized conquest and an impediment to other efforts. The natural progression for Prius to become more and more electrified became a confused message by those hoping to undermine Toyota's long-term effort to transform their entire fleet... the true game-changer.

It's time to argue. What should the next step for GM be to actually deliver something that changes the game?

3-31-2019 **Closure & Record.** I pointed that same epitaph on the big Prius forum. The introduction for it was as follows:

The point of stirring discussion here is both for closure and to leave a record with the hope of history not repeating, yet again. Awareness is key.

Sadly, most people are entirely oblivious to GM's first attempt to seize the efficiency market following their EV1 debacle. Those who know something likely have a distorted history of what actually happened, simply from only hearing about or remembering highlights. It's the detail that really makes a difference. Influences along the way are easy to overlook and dates are commonly incorrect. Lacking such information, those same mistakes can be repeated... and were, as I witnessed firsthand and had to deal with some rather hostile responses when pointing out the pattern recognition.

We saw that repetition with Volt. It was supposed to save GM from their sales disaster with Two-Mode, which ironically, actually had a plug-in prototype... the very solution they should have continued pursuing all along, something clearly needed from them now. Abandoning that technology for large guzzlers made no sense for an automaker who heavily favors SUV offerings; nonetheless, that happened anyway.

Since Volt is basically dead in every regard starting tomorrow, I posted an epitaph elsewhere yesterday, seeking feedback from that audience about what (if any) future the technology itself holds. That reflection of major past events started with the point when the sales struggle became undeniable.

3-31-2019 **Disruption.** Limited scope has become so pervasive, it's an everyday battle. Some have no clue they aren't seeing the market as a whole. For example, today I got: "*For the game changer, they are the only company in the world that has seriously disrupted the fossil fuel personal transportation paradigm.*" It was supposedly a summary of the industry, with Tesla as the "*disruption*" in the simplistic of terms. I disagreed with:

You're missing the bigger picture. It's is the same problem GM enthusiasts had. Watching Tesla support aim in the same direction should be reason for pause, a warning to be taken seriously. That's why I do so much to share history. We don't want a repeat of the same mistakes, yet again.

Volt was also a serious disruption. What it failed to do is the same thing there should be concern about with Tesla now. The influence didn't result in lasting change. Unless that disruption is permanent, people lose interest and move on.

GM failed because the "*know your audience*" suggestion was dismissed. They didn't acknowledge the reality that DEALERS were their customer, not CONSUMERS. That fundamental misunderstanding doomed their cumbersome & confusing technology to challenges unlikely to be overcome. And sure enough, lack of stirring interest to stock & sell that inventory contributed significantly to Volt's death.

In fact, this lesson is a big reason why Toyota is taking its time with the rollout of Prius Prime. Why push a technology with great potential in a market unwilling to accept change yet? Putting that kind of hope on dealers somewhat reluctant to even emphasize hybrid models of Camry, Corolla, and Rav4 simply isn't realistic. Waiting doesn't result in much penalty. Just look at the industry as a whole for that reality check... the bigger picture.

In other words, disruption isn't as simple as it seems.

3-31-2019 **Clueless.** He refused to accept my disagreement: "*Volt was never a serious disruption, and nothing even close to what Tesla has done and is doing.*" It brought me back to the beginning of that GM disaster, remembering how clueless those supporters were. It's hard to believe some stuck with it for over an entire decade... only to discover in the end they had made a fundamental mistake... the same mistake this individual is making now. It's bizarre how simply not understanding what the outcome should be messes how everything plays out; yet, few take the time initially to verify facts. It starts with an assumption, then builds to hype on such a scale they completely lose touch. Seeing it on a regular basis make it easy to recognize. Clearly, they don't pay attention. Oh well, it's not like I don't keep pointing out my observations and ask questions:

There it is, the pattern repeating. That dismissal of the past and looking forward with rose-colored glasses is exactly what I recognized back then... and now see again. The easy confirm is an assessment of the market requiring an assumption of mainstream reaction mimicking subsidized sales to early-adopters. Lack of any clear direction forward validates it.

For Volt, it was the obsession with speed & power. We kept hearing over and over and over again how that technology was "*vastly superior*" even though there was an obvious dismissal of both other purchase priorities and business objectives. Enthusiasts turned a blind-eye and convinced GM to do the same.

All you have to do is ask what the goals are. Lack of clarity is the first red flag. Efforts to evade is a dead giveaway. Seeing an effort to direct focus away from legacy automakers by vaguely claiming Tesla is responsible for changing something but not stating what or how is good reason to call for clarification.

What specific expectations are you trying to set? What should the goals be?

4-01-2019 **Nothing Constructive.** The start of a new stage, one that's difficult to accept, is unfolding right before our eyes. That misguided tax-credit with unintended consequences has triggered phaseout and the 50% reduction is in place. GM exploited the opportunity with Volt and now that supposed "*vastly superior*" technology is facing the reality of not actually being the leader it was portrayed to be. It clearly wasn't a "*game changer*" as hoped. That's very, very easy to see now. People are buying more guzzlers than ever. GM is thriving on their SUV sales, having introduced 2 new vehicle choices to their showroom floor. The outcome federal subsidized purchase was nothing. That technology just died. It had a focus so heavy on niche preference, there wasn't anything to appeal to ordinary consumers. GM's own loyal customers replaced their aged traditional vehicle with a brand new guzzler. Sadly, posts online don't want to address that outcome. I'm not seeing anything constructive. Today clearly marks the end to that particular rhetoric. To think, we had to endure all that nonsense about how GM's plug-in hybrid technology... with that meaningless "*EREV*" label... for it to result in a morbid fizzle. The worse nightmare of those terrible antagonists is playing out today. This is an intriguing time to witness.

4-02-2019 Reality. That reputation of "*over promise, under deliver*" has moved to a whole new level of disappointment. Enthusiasts of Volt who had moved onto Bolt were anticipating an 11th hour announcement. They dismissed warnings of GM ambiguity, a problem arising from intentionally vague press-releases. That practice of lacking clarity allowed the automaker to mislead about intentions and evade being held accountable later. That was definitely the case this time. Supposedly their announcement from 1.5 years ago with a deadline of yesterday was about here, this market in the United States. It was implied that the new vehicles would be something those reading the press-release would actually be able to purchase. Now, we are being told that was just to keep us informed about activity overall, that we may never get some of the GM vehicles offering elsewhere in the world. That worldwide perspective is crushed when hope of even an export the other direction becomes impossible. Nothing will be available here, end of story. It's a bitter pill for some to swallow. Being let down on that scale is going to have some interesting fallout. I have no idea what to expect. I suspect silence at first, denial so bad, no one wants to talk about it. That may result in new hope & hype, the way Two-Mode's collapse resulted in Volt... or perhaps not. GM may have burned too many bridges. The automakers heralded as legacy leader just 6 months ago may be facing abandonment, with literally nothing of appeal. It's not easy being green, especially when you don't heed warnings about the challenges to come. I summed up the situation this way: Try some prescriptive, something actually appealing for this market. It's time for a dose of cold, hard reality. GM promised we would be told about 2 new vehicles based on Bolt for this market within the next 18 months. That was 18 months and 1 day ago. 25 miles is amazing compared to the nothing we got from GM. All they did was kill Volt without a successor.

4-02-2019 Toyota Patents. A lesson learned long ago, forgotten by pretty much everyone, is the necessity of having allies. In fact, that wisdom is what compelled me to seek partnership with those supporting Ford and GM. With recognition of shared purpose, you can advance beyond the enthusiast market. That's the key to extending reach outside of a niche. It was quite ironic when I pointed out such a requirement to the "*vastly superior*" attitudes for Volt and they pushed even harder to resist exactly that. Today, we got an announcement from Toyota that a large collection of their hybrid-related patents would be offered for use royalty free. Obviously, there's a financial benefit to the spreading of technology when your push effort is to make it ubiquitous. This is especially true when the underlying control is retained in an open manner. Think of other standards, like USB and JPG. They have become open use, but how they implementation is applied remains that of individual businesses. They simply share the technology without restraint to approach. Toyota will be the owner, but does that matter? It ensures a strong standard, like Apple did for decades. Heck, it's what Tesla hoped to achieve in some manner with their superchargers. Some sort of share is how you advance to whatever comes next, as well as growing the market itself. This is a clear effort to move forward; however, there's no good way to really predict how the rest of the industry will respond. We'll see.

- 4-03-2019 Promises.** There are some voices of reason beginning to emerge: *"GM isn't the only company to make promises on press releases and hope people forget about them when they come to fruition."* Most will never remember the big promise Ford made about changing their fleet, the big promise to embrace hybrids. When the deadline was reached, overall efficiency had actually gone backward. MPG averages were worse. All the hype we are getting from VW now resembles that meritless hype. The potential seems real, based on technology available. It's quite feasible what's being promised. But the automaker making those assertions is not one to trust. So what if Toyota gives the impression of moving slowly? At least you know there is movement forward on a massive scale. We see little with regard to changing the status quo from others. Each rollout is basically just a demonstration of potential, not any actual progress forward... since the back end never changes. Basically, it can be thought of as a dog on a rope. The stake never moves. All we get is really loud barking at times and an impressive display of running & jumping. The dog never gets anywhere. Watching from the sidewalk, nothing ever happens for you... from automakers like GM. Considering a dog analogy about Toyota, it is instead on a leash, the owner walks right by you with a pleasant welcome, and you are offered the opportunity to pet. That's quite a difference.
- 4-03-2019 Expected Announcements.** Just like Toyota, we see that Ford was waiting for GM to fall before making any type of statement. It makes sense. Why risk getting pulled into what could be a massive wake from that sinking ship? I didn't realize the wait would be so brief for expected announcements. My anticipation was subdued, a sense of patience strengthened by the knowledge change was inevitable. The industry was an entity with a chronic impediment about to become just a really bad memory. Sure enough, it happened. Today brought about a reveal of the upcoming new hybrids we've known about for quite awhile, but never had any detail. There was only a sense that Ford was working on big change. That is indeed the case. We learned there will be an all new Escape (known as "Kuga" in Europe) which will be offered in mild, full, and plug-in hybrid models. That's exciting news. The plug-in battery-pack is expected to deliver 50 km (31 miles) of EV range from it's 14.4 kWh capacity. Not much else was revealed, though the addition of charge-mode was nice to hear about. Ford is finally making its move... or at least announcing production intentions. It's far more than the nothing we have heard from GM. To think, the technology in Volt could have been rolled out years ago to Equinox or Trax. Instead, there was just a lot of barking. Ugh.
- 4-03-2019 Denial.** Sure enough, someone stated exactly what I had just blogged: *"I still can't believe that GM has had this technology for a DECADE and is going to let Ford beat them to market? Crazy."* I knew that would happen, but wondered how long it would take. Turns out, things can happen very fast. All those claims of leadership have fallen apart and the dogs barking suddenly gone. That vanish effect is remarkable. When trying to be constructive, you get attacked relentlessly from those blinded by hope. It goes on for what seems an eternity. Day after day, they endorse a technology with questionable potential. Nothing ever happens though. You express out *"too little, too slowly"* concern and get attacked for your trouble. Then one day, those in deep denial just vanish. Not a single Volt enthusiast from that nasty daily blog can be found anymore. It's almost surreal. Their absence isn't the slightest bit missed though. Ford is capitalizing on that predicted outcome. Reaction to their announcements have been very well received. News like that is a very, very welcome change.

4-04-2019 **Hybrids.** Speaking of denial, this particular comment caught my eye: "*I can't see any way but down for Toyota sales if they carry on like this.*" It's that one-size-fits-all mentality having transform to a narrative passed along so well, most have completely lost perspective. The technology used for hybrids has become so well proven, it is dismissed as obsolete. That's an interesting place to be when you realize that's confirmation of having arrived at a mature status. It works well... so well, it isn't given any thought anymore. That's great! The advance of combustion engines reaching that point took how long? Remember how unreliable they were in your youth? Look at how that approach become so well accepted, we think nothing of using the technology. It's everywhere and works remarkably well. That's exactly where Toyota strived to get hybrids. Unfortunately, the rest of the industry wasn't able get to the same point... hence the absence of royalties now. The lifting of that aspect of a patent means opportunity for those interested. Not everyone will want to embrace that level of diversity though. Simply offering Traditional and EV choices may be a logistical challenge maxing out their resources. The idea of hybrid or plug-in hybrid models added to the mix is simply too much for those unable to take on that much variety... so, they dismiss it as realistic. That presents serious challenge for legacy adaptation to a world necessitating change. Taking a major step all at once means taking on a whole lot of risk, something automakers will find very difficult for their dealers to accept. That's a very real problem. Seeing hybrids bridge the gap was a realistic solution many automakers decided to avoid. Not embracing the obvious next step could have serious consequences. How will they address the fear? I pointed out the situation by asking a loaded question: The one-solution-only narrative from those afraid to address diversity is falling apart. Show us proof that people beyond the group-think here actually care. It simply makes no sense to not offer a variety of choices. When you see a truck commercial, do you really believe that automaker is sending a message that is all they care about?

4-05-2019 **Ramblings About PHEV.** Discussions of plug-in hybrids are rapidly growing. Despite limited availability of Prius Prime still, it's a sales leader in the category. That's getting attention of everyone. More are looking at the technology as something to co-exist with EV. That narrative from Volt enthusiasts... which is now easy to see as a damage-control effort... was that PHEV was only a bridge to be abandoned as quickly as possible. It's the their way of explaining GM losses. So much was gambled upon a niche offering somehow becoming a strong seller. It never made any sense. Although that helped to prove the technology viable, the approach itself was terrible. More finally see that. It's a bittersweet reality though. Hope was put upon cost falling far faster than it actually did. Hope was also put on the belief that an automaker staunchly endorsing SUV growth would somehow embrace a compact hatchback without sacrificing either of their premiere sport cars.... Camaro or Corvette. It never made any sense. Volt was doomed from the start... hence "*vaporware*" concerns. That lack of desire to truly commit made the lofty goals difficult to accept. So now, after all that time wasted and so much intentional diversion, we are finally getting so proper attention. Phew! That was a painful journey.

4-06-2019 **More Ramblings.** This was a collection of thoughts I ended up posting in one of those recent discussions about PHEV: In terms of appealing to both the wallet of consumers and the inventory of dealers, much lower MSRP is key. That vital purchase-priority is how automakers will be able to reach beyond the early-adopter stage (tax-credits available) to achieve sustainable high-volume sales for a profit. Toyota has that aspect nailed. Transitioning from Prius from no plug to plug would inevitably cause a disturbance in demand. The important part is that it's happening, not the means it took to get there. Keep the goal in mind. Toyota is pushing to electrify without causing chaos for their dealers.

4-06-2019 **Doing It Right.** There's a lot of rhetoric still being stirred. Expiration of tax-credits for GM resulted in the disaster predicted an entire decade ago. There was a dependence on subsidies to such a degree, the technology could not survive without. And sure enough, that's exactly what happened with Volt. That concern for "*too little, too slowly*" was dead on. The situation wasn't taken seriously. All those hostile responses, attacking the messenger relentlessly, become a collateral waste. Now, it's time to finally address the problem. Some are trying. I chimed in today with:

The tax-credit didn't include criteria requiring the vehicle to be something that would actually force phaseout of that automakers traditional vehicles. In other words, there was no clear goal. It was just a vague endorsement of electrification.

We all witnessed GM take advantage of that legislative shortcoming. Volt was not a vehicle targeting its own loyal customers. In fact, GM eventually confirmed they had only delivered a niche for conquest. Had there been intent to change the status quo, those 200K sales would have had an end result of a technology the automaker could utilize for profitable sales throughout their fleet.

This is why a "*STAGE 2*" recommendation is the next move our government should take. To qualify for a secondary round of tax-credits, the automaker must achieve more demanding criteria.

For example, GM clearly didn't care about making their choices affordable. Had they, there would have been an effort to deliver a second model of Volt or Bolt that actually had an affordably sized battery-pack, rather than trying to persuade us that more range is truly necessary. The narrative was spun that smaller capacity was seen as the automaker being a laggard... and much of the EV community got suckered into believing it.

Taking the time to do it right, by delivering a technology which could easily be spread to a variety of vehicle choices in a profitable manner, should be rewarded. Carelessly offering more subsidies without forcing the automaker to reap the appeal of their own guzzlers in the process would be such a waste.

4-07-2019 **Toyota vs Tesla.** The mighty GM has fallen so fast, it's like dieselgate was to VW. All of sudden, no one cares what happens to GM. It will be interesting to see what attention Ford gets in the meantime, since they won't have anything to actually purchase for awhile. Their new offerings are 2020 models. Toyota on the other hand is aggressively working to get their hybrid fleet in place. I rarely mention Avalon hybrid & Highlander hybrid or any of the Lexus hybrids. Already having them in place means focus on the premiere 5 offerings is realistic. That long-term goal of offering the choice across their product-line is progressing well. That schedule played out nicely. So, it should be undeniable Toyota carefully plans out their moves well in advance. That's a fantastic example of preparing the stage for significant change. Anywho, there are some well known antagonists who strongly disagree... which made the topic of Toyota verses Tesla an irresistible draw. I posted the following right away, quite curious how it will be responded to:

Comparing Toyota to Tesla doesn't really tell us much. One is a well funded start-up that made the tax-credit opportunity an impressive means of gaining an audience. The other is a legacy seller required to take a dramatically different path & timeline to get to the same destination. Think about how an entire fleet can be converted, offering a wide range of choices.

Comparing Toyota to GM is far more telling and clearly the constructive means of judging that market they share. Toyota watched GM squander their tax-credits, wasting precious opportunity in conquest rather than focusing on their own customers. That resulted in a disastrous dependency on government subsidy. Volt died as a result without a successor established.

It simply makes no sense for Toyota to not put a lot of effort toward diversification while they wait for the market to settle. So, that's exactly what they are doing. RAV4 hybrid, Corolla hybrid, Camry hybrid, C-HR hybrid are all well positioned for plug augmentation. Each can undergo that upgrade and still be profitable. Isn't that the point?

4-07-2019 **Some Perspective.** This new chapter we have just begun requires reminders that the past is the past. Some are treating the "*game*" as if nothing has changed. It's the drawing a conclusion problem. They don't want to start over with findings, even though so much is now different. That's why knowing audience is so important. Toyota's newest hybrid offerings are now targeted at the same consumers as in the past. So, treating them that way isn't constructive. In fact, it could be considered misleading if you try. I provided some information to hopefully enlighten those who actually take the time to consider it: Look at the sales of RAV4 hybrid and Corolla hybrid for some perspective. Toyota simply sells them with a brief mention that a hybrid model is also available. The subtle approach is working well too, just enough to point out there's another choice offered. The meaning & reputation of "*hybrid*" from Toyota is so well established, the idea of inducing fear or uncertainty doesn't hold much... if any... merit anymore. It's become so ubiquitous, Toyota will be able to quietly phaseout their traditional models without disruption to their true customers... dealers who stock & sale that inventory. In other words, look beyond the misconceptions fading away, toward the plan to get the entire fleet electrified in some manner. Hybrids like RAV4 and Corolla are key to making that happen. Reaching mainstream consumers is far more difficult than the early-adopter (tax-credit dependent) market most are still focusing on.

- 4-07-2019** **Omission Misleading.** We've seen this before, lumping everything into all one category: "*Hybrids are losing share to BEVs...*" I remember having to argue "*not the same*" countless times about hybrids, but that was more of a technical/operational topic. In this case, it's whether or not the hybrid has a plug... which makes a profound difference. Yet, that is blown off as inconsequential. Grrr. Not wanting to listen is bad enough. But this forced narrative is frustrating. I made that clear by posting information to show everyone else his intent to mislead: Omitting the category of plug-in hybrids create a perception that doesn't reflect the actual market. In other words, it endorses the narrative of polarization. In reality, the PHEV is a great bridge to EV that will co-exist for many, many years to come. In fact, we're seeing strong growth potential for them. Those commuting to work in a Prius Prime enjoy the full EV experience. So what if the engine gets used from time to time. A technology which dramatically reduces oil consumption without disruption to consumer or business is a win-win outcome right away. The fact that it also sets the stage for more EV later is an extra win. It's ironic how some portray "*disruption*" as the desired state right now without taking into consideration the negative impact that would have to the current market. We don't want to encourage that by sending the message of it being the desired immediate state. Rapid transition away from traditional vehicles won't happen if EV is the only choice available.
- 4-07-2019** **Disagree.** I found the response to my post rather amusing. He disagreed. That's all I got, a contradictory stance without anything else. That total absence of any substance made my reply quite simple: You cannot disagree without stating a position of your own. A statement of "*continually improving*" doesn't actually tell us anything. Being vague about what you expect to happen leaves a massive gap of uncertainty. Toyota sells over 10 million new vehicles every year.
- 4-07-2019** **Osborne Effect.** Most discussions don't take the bigger picture into consideration. Arguments are worse, forcing the scope to just a single vehicle within a specific span of time. There is some change though. The recent stir from tax-credit loss is breaking the grip on narratives. We don't get much for answers though... not even speculation anymore. The fallout is rather obvious. So, I just keep posting information to keep everyone aware of the situation and asking about what comes next: Volt was an expensive compact hatchback. With Trax, Equinox, Blazer, and Traverse all starting at prices under \$30K, there was simply no possibility of overlap for GM post tax-credit availability. They would remain mutually exclusive. Any announcement of a plug-in hybrid SUV though, even at a more expensive price, would get their customers to take notice. They are willing to pay extra for the pointlessly large vehicle. They would delay their purchase for that choice. Sales would drop in the meantime. At least with Toyota, they are already offering a 219 hp SUV hybrid that delivers 40 MPG. Build up of its reputation, combined with the proven reliability of what the "*Prime*" model of Prius is establishing, makes the choice of a plug-in model much easier to accommodate. It's not a profound redesign like an EV requires. Toyota's design only requires the addition of a one-way along with an increase of battery-capacity and the plug itself. That's it. Having a clear path to the future is vital. Detriment of the Osborne effect is something to take very seriously. How will the other legacy automakers, like GM, handle that situation?

4-07-2019 **Disappointment.** Whenever an argument goes bad or the poster gets called out for misleading, the response ultimately becomes a pivot. We've seen the antagonist change the subject to hydrogen and fuel-cells. It's happened so many times, it's basically pointless. The act of trying to divert attention has become even more obvious with the debate of tax-credits becoming so intense. You know they are desperate when they attempt to treat them as the same. They have virtually nothing in common. The timeline & objectives are so different, it makes no sense in any type of comparison. But being objective is not how online exchanges work. They hit hard & fast, hoping for reward from being quick & clever... rather than thinking things out and providing detail to support the claim. Oh well, that's how it goes. Fortunately, the lack of critical thinking on their part ultimately catches them in the end. We saw that with the extremely drawn out "*vastly superior*" hype for Volt. We'll see more of the same from others later. Some people never learn. I try to provide guidance though, sharing wisdom with the hope some will take it into consideration: Fuel-Cell will co-exist with EV, a reality that some simply refuse to accept. With both, there are applications which it makes sense and applications it does not. Starting with personal vehicles is the easiest and most flexible way to evolve the technology, in addition to having a wider source of real-world data to collect from. It wouldn't be as effective starting with commercial vehicles. Just look at Tesla, who also started with personal vehicles. In the meantime, refinements to electric drive benefit both in the long-term. Heck, we have even seen the tech trickle down to Prius already. Basically, the reason there's so much resentment toward Toyota is a combined lack of patience and the mentality that one solution must fit all. It's a recipe for disappointment.

4-08-2019 **Damage.** It is interesting how some double-standards never get challenged. Whether there is a true similarity or not, the choice to disregard without consideration is obvious. For example: "*When they finally produce an EV, I will remember the damage to the BEV transition and avoid buying or leasing their vehicles.*" This is where knowing your audience pays off. First, it is basically pointless arguing with someone who's poorly informed. Second, understand that anything they argue in third-person will likely not come to fruition anyway. It's that old idiom of "*garbage in, garbage out*". If what they are claiming has weak or no evidence supporting it, odds are quite good their prediction will be inaccurate. We've seen that outcome far too many times now. Noticing that pattern is easy. I don't even have to provide an analogy anymore. I have the real-thing to sight as an example now: So all the "*range anxiety*" campaigning from GM, their anti-EV efforts to promote Volt didn't cause damage? Realistically, GM caused so much harm to the plug-in hybrid market, you have to question the impact it had to EV. Think about the confusing & contradictory messages they sent. Now consider how there has been basically zero influence on mainstream consumers. Those ordinary showroom shoppers that most legacy automakers depend upon for business sustaining profit won't know of this history playing out now. For that matter, they have an expectation of continuous improvement anyway. Look at the studies about consumer awareness. They overwhelmingly confirm the point-in-time advertisements are limited scope and have a very small influence on future sales. There are much bigger issues... like bankruptcies & safety... that people pay attention to.

- 4-08-2019** **The "Behind" Narrative.** We haven't even emerged from the early-adopter yet and we are still far from a tipping point. So, the attitude toward Toyota doesn't hold much merit. Pointing that out is... well, pointless. All you get in return is: "*The idea that they can "leap" into BEV is foolish.*" They see the current narrative of being "*behind*" isn't working, so there's a re-emergence of the leap-frog mentality again. Rather than focusing on mainstream buyers, it's always that attitude of more. Faster, further, and fiercer is that same old push we got from enthusiasts long before the emission & efficiency revolution began. Simply offering something modest & affordable is so unacceptable, all you get is a maniacal response. Returning your attempt at constructive discussion with such callous disdain is quite telling. Some people just plain don't care. That's why it can be best to keep replies to that short & revealing, as I did today: Prius Prime already delivers a massive amount of real-world data, clearly showing how to best squeeze out speed (84 mph) and power from a smaller battery-pack. Mirai already delivers a massive amount of real-world data, clearly showing how to best squeeze an EV drive from a 113 kW (152 hp) electric traction-motor.
- 4-08-2019** **Uncaring Attitude.** From time to time, you'll encounter someone who outright lies. In this case, it was so untrue, that quote isn't worth including. They aren't worth that. I will post my response to the desperation to undermine: Greenwash at it's best, just making stuff up that can easily be disproven. Ugh. As for protecting Toyota, against what? All this early-adopter bickering is simply an effort to divert attention away from the struggle to advance beyond the subsidy-dependent stage. The supposedly "*vastly superior*" Volt wasn't able achieve any type of volume sales, the obvious necessity for growth beyond being stuck in a niche. Hope that speed & power would appeal to the masses failed. So what, move on. Focus on another priority instead. The obvious is that target GM set all those years ago, back when Volt was first being developed... a price "*nicely under \$30,000*". Attacking Toyota for having focused on price from the start is pretty bad, but to mislead about the other development Toyota is also pursuing at the same time reveals an effort to undermine. Notice how most here are fiercely against Mirai but absolutely refuse to acknowledge the 152 horsepower EV drive it provides? That's because they fear the same setup could be delivered in a future electric-only model of Prius. Think about what that sales scorecard really tells us about the uphill battle legacy automakers still face. Shooting the messenger is an act of denial.

4-09-2019 **Online Death.** All posting activity for that old daily blog halted a week and a half ago. It was quite abrupt. The only posters left were the antagonists looking for trouble to stir. I watched as a lurker, wondering what they would come up with undeterred. Without an audience though, that was going nowhere. Topics weren't about Volt anymore anyway. It was just random content at random intervals. A new discussion finally popped up, it was about GM's fate with the tax-credit cut looming and supposed promises of what was to come. My post to that has been in a "*waiting for moderation*" status ever since. Clearly, the website is advancing its prolonged death. Online entities like this can persist for a long time though, even with the homepage feed being abandoned over a year ago and now the blogging no longer allowing posts. There's a small forum there that never really caught on. The old-school format of daily blogging with an anonymous avatar and no accountability beyond just a few days, this death was a long time coming. Reputable websites wishing to retain any type of integrity stopping allowing such activity awhile ago. This one simply lived on because it was an inexpensive branch of a much larger parent entity that would just repost the same content. Becoming a source for fake news was what convinced many to leave on their own. They didn't want to be associated with greenwashing that's so obvious to recognize now. Back in its day though, most didn't have a clue they were contributing to an effort to mislead. They became enablers and didn't even realize the greenwash endorsement they were contributing to. I'm sure glad that ugly chapter in emission & efficiency history is finally over. What a relief!

4-10-2019 **New Tax-Credits.** Efforts continue for some type of renewal. I don't see how something so vague, counter to the rollback efforts of this administration, could ever stand a chance of getting approval... or even recognition. There are some who keep trying. In the meantime, I keep pushing for improvement. New tax-credits should come with improved requirements, as I stated today: It's the response that's flawed. Discussing the point of tax-credits is far more effective than name calling. Each automaker was given an allocation to come up with a means of making their product reach a state that where subsidies were no longer needed. Extending poorly written legislation isn't a good idea. Requirements to be eligible for the tax-credit should be addressed. In the past, they were exploited because the goal was so vague. Why would we want to renew that? Eligibility for the additional quantity shouldn't just be based on participation alone. There should be qualification spelled out. In other competitions you must qualify. That next level of subsidies should be earned. Reward those that push hard to actually reach ordinary consumers.

4-10-2019 **Growing Trouble.** Watching the greenwash grow worse is troubling. His simple-minded view of the world, clearly expressed in his abundant very short posts, resembles that of a troll now. It was just annoying in the past, making constructive posts difficult to find. You know, just innocently diluting content and taking attention away from those who usually don't participate much. Anywho, today it was this: *"I would prefer to see one total number of credits, and first come first serve, instead of wasting 200,000 each on mfgs that don't care, or may show up some time in the future."* That was frustrating to read, but understandable how someone could take that stance. The sentence that followed, concluding his statement, was not: *"But this is better than nothing."* When some posts that often, yet claims to not know of any alternative, it's the sign of not even trying. He's just there to give himself some sense of purpose. Really annoyed, I fired back with: Advocating for a rush to market, rather than show support for taking time to do it right... Ugh. It's really unfortunate that narrative of "faster is better" has penetrated our society so much, most people don't even realize there is a worthy alternative available. Other markets are aware; sadly, we still haven't learned that yet. Think about the example no can deny anymore, Volt. That turned out to be a huge waste. Why invest so much toward plug-in hybrid technology only to abandon it entirely midway through its second generation? GM didn't care enough to implement what they originally pursued, with the aid of that subsidy money, on a platform their own customers would be interested in. Punishing automakers who avoid rhetoric and take some time to rollout something with wider appeal and greater potential in the future is quite backward. Allowing that to go unchallenged is a terrible next step. Your preference has been called out. What do you now suggest instead?

4-11-2019 **Round Two.** Talk of an extension of the tax-credit for plug-in vehicles is heating up. There have been several, but this newest one seems to be drawing more attention than the others. It's not because there's anything impressive about the proposal. It's simply the only one with one Republican and one Democrat. That's all. No committee. No well thought out plan. Nothing more than just a suggestion to extend from a representative of each side. With such a weak approach, it's no surprise the rhetoric has stirred. We almost immediately fell into that same old nonsense again. I sounded off about it, which should be no surprise: It's the response that's flawed. Discussing the point of tax-credits is far more effective than name calling. Each automaker was given an allocation to come up with a means of making their product reach a state that where subsidies were no longer needed. Extending poorly written legislation isn't a good idea. Requirements to be eligible for the tax-credit should be addressed. In the past, they were exploited because the goal was so vague. Why would we want to renew that? Eligibility for the additional quantity shouldn't just be based on participation alone. There should be qualification spelled out. In other competitions you must qualify. That next level of subsidies should be earned. Reward those that push hard to actually reach ordinary consumers.

- 4-11-2019** **Stage Two.** At least I'm getting some kind of dialog: "*So would a car that hundreds of thousands pre-order without seeing it qualify as having appeal? What is your criteria?*" It's really unfortunate though that after so many years, all that comes from this topic is a generic question. Never really giving the topic any thought is no surprise. Many make assumptions without bothering to consider anything beyond a basic anecdotal observation... hence the advice to know your audience. Somewhat annoyed, while at the same time a little encouraged, I posted a lead into my stage-two suggestion: This is basic economics, the 101 first-day intro stuff. Toyota sells over 10 million vehicles annually. Those subsidized sales of "*hundreds of thousands*" only equates to less the 4% of their production alone. Worldwide, the total comes to almost 60 million. That perspective clearly shows us the initial sales are only low-hanging fruit... especially when you try to consider what they would have been without tax-credits through legacy channels.
- 4-11-2019** **Progress?** I'm not sure how well that went. This was the response after a number of short exchanges: "*Define ordinary.*" Not recognizing how early-adopters differ from ordinary consumers is troubling. You'd think that would be obvious, especially when there's a tax-credit involved. My guess is some people never really give the process of purchasing a vehicle much thought. So, you have to start at the beginning and see how productive some exchanges are. Perhaps I'll make some progress with this: That also is basic economics. It's whatever represents a majority of customers. In this case, that's people who go to the dealership of their favorite brand and simply just shop around. They have a general idea what they would like and want if from the source they've grown to trust. Looking at inventory & sales numbers, it's easy to see the outcome. Whatever plug-in is offered should target that same pattern. This is why each automaker was given the discretion of how their tax-credit allocation could be used.
- 4-11-2019** **No Cap.** In the middle of my attempt to invoke some critical thinking, a well known troll jumped into the topic and posted: "*There shouldn't be a cap. Just a set date on when the incentive starts declining for everyone.*" It was only a matter of time before that happened. Those mindless, vague suggestions only serve to stir trouble. It is especially bad when the individual knows the reasons why such a generalized approach is a bad idea. But that is how he provokes posts and fulfills his need for attention. That's unfortunate. Oh well, at least it gives me a chance to slip in a little background information: Turn a blind-eye to what has already played out and just allow the exploit of tax-credits to continue. Ugh. We all witnessed GM miss opportunity after opportunity. Rather than using the knowledge & experience they gained from subsidy aided sales of Volt by rolling out that technology to vehicle types & styles their own loyal customers would prefer, it was wasted on appealing to enthusiasts. That lack of effort to actually change what legacy automakers sell should not be encouraged and you know it.

- 4-11-2019** **Understanding Purpose.** This could be promising: "*Without specifically designing and picking winners it allows a diversity of solutions to be tried...*" It shows an effort to recognize need. The problem is, it doesn't serve as any type of encouragement. Incentivizing a goal requirements stating some type of desired outcome. How do you know who wins? For that matter, is it a pass/fail situation or will the result be graded? There are consequences of being vague. We have witnessed missed opportunity and wasted resources. That's why I propose some type of next step. Now that introduction has been achieved (the first round of tax-credits), what should the next step deliver? Some type of threshold should be defined. Leaving it open-ended is like telling someone to "make it better" without explaining what you had in mind. What do you hope will be accomplished? Needless to say, I get quite frustrated with the lack of critical thinking. Maybe this will be helpful: That's great for stage 1, but offers no suggestion or justification for stage 2. GM never rolled out their plug-in hybrid technology to anything beyond Volt. Their approach died, no successor. Missed opportunity is what the next round of tax-credits should address; otherwise, there's more waste appealing to niche interest. Remember, the goal is to find a way to reach beyond just early-adopters.
- 4-11-2019** **Not Paying Attention.** The effort fell apart: "*Not every company is going to pick a stage 1 technology that leads directly to a stage 2... they may need to backup and try again.*" I've posted the idea of secondary requirements several times now. Clearly, that isn't being recognized as such. This twisted perspective back on the automaker though, forgetting the topic was about tax-credit renewal. I was concerned that the entire effort would fall apart, that the topic was too complicated to address properly online. I hoped for the best anyway, with this response: Please read posts carefully. That's not what stage referred to. Try again. STAGE 1 is the first allocation of tax-credits, that initial 200,000 for each automaker. STAGE 2 would be the next level, which would require meeting new criteria to be eligible for. In other words, if you waste opportunity with the first, you'll have to find another means of qualifying for the second.

4-11-2019 **Across The Fleet.** It's very difficult to assess progress of a discussion, especially when you encounter something like this: "*And the average mpg is dropping. This is basic economics. They are going the wrong direction.*" It implies a step back, attempting to consider the larger problem. But then again, that's what you would do to undermine a specific point. Whatever the case, it did present the opportunity to share more information about how to interpret data of that nature:

Basic economics must include a timeline. You cannot just disregard that part of the equation. Ironically, that "*Losing Ground*" article is a great example of feeding the narrative of shortsightedness. People read something like that and take the contents at face value, without bothering to consider the larger picture and the time involved.

For those who do bother to research, they'll discover Toyota is taking the time to do it right. They are striving to offer hybrids across their entire fleet. Despite the slipping popularity and small profit-margins of sedans, we get a Avalon, Camry, and Corolla hybrids. At the same time, they upgraded both Prius and Prius PHV, while also rolling out a RAV4 mid-cycle update to introduce it as a hybrid. Then just 2 years later, we get a full generational upgrade to both RAV4 and Camry hybrids. Next year, there will be a generational upgrade to Highlander too. Don't forget about the variety of Lexus hybrids either.

Think about how cost-effective it will be for Toyota to augment their RAV4 & C-HR hybrids to also offer a plug. Like Prius, it's basically just a matter of adding that one-way clutch, since the hybrid system in place already has everything else it needs. This is the stage Toyota is setting as they wait for battery prices to reach an affordable point. They are carefully using their tax-credits, while learning from other automakers along the way about what not to do.

So what if there's a slip backward on that journey? Toyota still remains well in front of the old Big-3 automakers, with lots of potential to come from already being well into their effort to phaseout non-electrified vehicles across the fleet.

4-11-2019 **Expectations.** Nope, things fell apart. He reverted back to trying to judge the progress of legacy automakers to Tesla: *"And yet the last 10 years of incentives gave us what, model X and...and...what?"* They have so little in common with one and other, it would be hard to believe anyone would take such a comparison seriously... until you reflect upon hybrid history. Remember how the 2-seat, all-aluminum, manual-transmission Insight was considered direct competition with Prius? Even without taking into consideration how fundamentally different the 2 types of hybrids were, it should have been obvious how drastically different the vehicles themselves were. Yet, we got countless direct comparisons anyway. That's the same problem with this situation now... lack of anything else to compare. That mindset limitation leads to all kinds of trouble. It's how the hope for Volt transformed into hype. Group-Think thrives on absence of critical thinking just like that. Expectations grow out of control without any means of validating information. Meritless claims become facts... hence, fake news. Seeing beyond that rhetoric is quite a challenge. I keep trying to push online readers beyond the crazy though, attempting to interject some sense into the chaos: Toyota, Nissan, and Hyundai are all pursuing affordable choices with variety prior to reaching tax-credit phaseout. Assigning an arbitrary deadline serves what purpose? Again, forcing doing it fast rather than doing it right doesn't make sense for legacy automakers. That's more economics 101. Think about how long it takes for other changes that actually altered the status quo. That history informs us a lot about setting realistic expectations.

4-12-2019 **They Don't Listen.** It got worse, rather than better. Comments like this are how you know the audience has given up: *"Just few years ago hydrogen was the future. And flying cars before that."* Signs of really never having paid attention are confirmed when you read that. It wasn't just a few years ago. It was 15 and that was never what the industry stated. It was GM attempting to divert attention away from hybrids. Remember that bizarre State-Of-The-Union address making the hydrogen claim? Even then, most people were scratching their heads trying to figure out what such a vague statement actually meant. There was no detail whatsoever. Lack of any substance made it nothing but greenwash... and we certainly knew that audience. The administration was strongly opposed to hybrids, going to the extreme of pushing guzzlers. Remember that *"good for the economy"* nonsense and the \$10,000 tax-credit available for Hummer? I was definitely annoyed by having such a comment to reply to. When they don't listen to anything leading up to that point, how do you find a way to reach such an audience? I keep trying: If you listened to the rhetoric... In reality, hydrogen was always a complimentary tech. There are some applications in certain localities where it would work well. Starting with small test vehicles with a diverse set of users still makes sense. The narrative of one solution for all never did. This is why looking at the bigger picture is necessary. EV and FCEV will co-exist, just like other tech of the past... for example, diesel was primarily for commercial use and gas for personal transportation.

4-13-2019 Discussion Distractions. If you stick with a topic long enough, and the trolls to undermine its purpose, the distractions will eventually fade. In most cases related to plug-in vehicles, those distractions are Telsa and Fuel-Cells. With the discussion related to raising the eligible quantity of tax-credits per automaker, we finally got this: "*These are the vehicles that consume the most fuel, so improvements there save the most fuel.*" Comments like that bring us back to fundamentals. That's how you become constructive. It offers material to build upon, rather than distract. I was delighted to respond in detail:

That is how "*Know Your Audience*" came about, from similar statements 14 years ago... way back when Two-Mode emerged as a technology promoted as far superior to Prius... complete with a plug-in hybrid model planned for 2009.

When Two-Mode was finally rolled out, the targeted audience didn't care. Mainstream consumers were not impressed. Large savings of gas in terms of a few MPG improvement wasn't a priority for them. Sales floundered from the very beginning. Rollout was such a disaster, the next-generation design intended for a small car platform was disassociated with the one for large vehicles, showcased as a fresh start. Despite that, it turned out to be a sales disaster for the very same reason. Volt didn't appeal to mainstream consumers either.

Knowing your audience means understanding how to appeal to them. Lesson learned was selling the idea of "*most fuel*" to someone who drives a guzzler with no concern for guzzling simply won't be interested. Gas is cheap and they are unwilling to try something new.

This is exactly why some of us knew from the start tax-credits would be wasted by a legacy automaker like GM. We saw from the early days of development that Volt was being created for the wrong reason. Those that wanted to save the most fuel were not their own loyal customers. That compact plug-in hybrid hatchback didn't target the right audience. It was opportunity missed, intentionally.

It was obvious that a smaller battery-pack would reduce cost, weight, and complexity of Volt without much of an overall loss of MPG. That electric-only drive could reach a much larger audience and could more easily be ported to other vehicle platforms. GM simply wasn't interested. Whether GM was just resting on its laurels or being afraid of the paradigm-shift, outcome is undeniable... tax-credits didn't result in a shift of their basic offerings at dealerships.

That's why this topic of raising the limit for tax-credits is such a hot discussion. Why would we want more of the same?

4-14-2019 **Greater Than 50%.** That magic point of hybrid interest was reached in the first quarter of 2019 for Europe. 51% of the 279,000 sales for Toyota (that's 143,300 vehicles) were hybrid there. This was a goal targeted for 2020. Meeting that already, prior to anticipated by an entire year, is fantastic. Unfortunately, not everyone sees it that way. The spin today was "*Over 50% Of Toyota Sales In Europe Are Hybrids: PHEVs Not Even 1%*". That's the rhetoric I've come to expect. Rather than looking at the market as a whole, they chose to cherry-pick by focusing exclusively on the plug-in vehicles. That selection of only a specific choice is blatant misleading, which I strongly resent. That's exactly how Volt got on its course toward disaster. Enthusiasts couldn't care less about tax-credit dependency or mainstream interest. All they had any interest in was conquest. I'm so glad I took time to document that attitude, as it played out. It's a history of short-sightedness and focus on want, rather than need. I asked "*Who is the market for Volt?*" over and over and over again to draw attention to their own self-destructive nature. They destroyed themselves anyway, shooting the messenger as much as possible to feel better about their mistakes. It all came down to market reach. You don't endorse something with such a limited market potential. So what if Toyota's technology doesn't get a "*vastly superior*" label? That's not the point. You want the masses to purchase the new technology. They are the ones who couldn't care less what happens under the hood. They just want something reliable, practical, and affordable. That's why Toyota's recent emphasis on safety doesn't get much attention, yet helps ensure strong sales. The same is now proving true for efficiency & emissions too.

4-14-2019 **More Rhetoric.** I don't even need to quote the post anymore. Their desperation has become so extreme, there's no denying it. Volt is dead. Tax-Credit dependency is obvious. Toyota's choice to take the time to address the status quo, making an effort for real change, is starting to show. It never ceases to amaze me how people get drawn into hype & hope. They lose common sense. They become out of touch with their own surroundings. It's a dangerous disconnect they just plain don't see. That's why more and more of my posts focus on the bigger picture now. Being trapped on spin is a thing of the past now. What a relief. Phew! I'll take this over that any day: Know your audience. Claiming "*defect*" is rather disingenuous. They are early-adopters taking advantage of the tax-credit opportunity. Why now? It's a good deal and that has no bearing on whether or not their next purchase will go the same direction. Toyota is in it for the long-term. That loyalty isn't being challenged, it's actually helping to establish the industry. We need customers all over for the next stage to take place. Alone doesn't work. Toyota needs allies. Toyota is well aware of this and working to appeal to their future shoppers, not early-adopters. Notice how affordable Prius Prime is, even without any government subsidy? As for claiming under-powered, my Prius Prime merges just fine onto the highway using EV mode. You want more power, you buy something like the RAV4 instead. Heck, even Mirai with its 152 hp motor would make for a nice all-electric model of Prius.

- 4-15-2019** **New York City.** I arrived today for a conference, taking a cab from JFK to Times Square. What an unusual experience. Traffic really was as bad as the stereotypical description would lead you to believe. It was bumper-to-bumper with some very tight & aggressive lane changes. Whoa! I certainly wouldn't want to deal with that, especially on a regular basis like I driver did. He handled that chaos just fine. Stranger though was the sea of SUV within that flow. They are all over the place! With such tight conditions and so much waiting in stopped traffic, it was surreal seeing so many giant guzzlers like that. People who don't understand the draw of size & power really need a wake-up call like that. The supposed logic I have to deal with on a regular basis shows being out-of-touch with what's realistic. That doesn't hold any comparison to what's unrealistic, what I'm seeing right now. The craziness looking down on those streets below is truly amazing. It's remarkable to see how disregard for environment or resources can take you.
- 4-16-2019** **Highlander Hybrid.** Exactly as anticipated, the reveal of next-gen Highlander coming late this year was a short & sweet announcement. 34 MPG from such a massive vehicle is incredible. With such a massive interior and lots of power, this will be the hybrid SUV that quietly crushes other automakers. RAV4 hybrid will get lots of attention, but this is the one to cause fear in the hearts of Detroit backers... especially since it will be produced here in the United States. It's nice to see such efforts to offer a diverse set of choices. This is what both GM & Ford were expected to do ages ago. Remember, it was well over a decade in that they were gloating about how Toyota would be crushed by their high-efficiency monsters. That never happened. They just kept making larger guzzlers without any concern for oil dependency, clean air, or environment impact. For that matter, they weren't even concerned about their own long-term survival. That live-in-the-now attitude can be quite detrimental... and sad. Thank goodness some of that is finally changing, with Toyota setting a good example of what can be achieved. Ironically, I'm reading news of this coming from the New York International Autoshow while being in New York City... a place where SUV traffic is abundant. It's amazing how such vehicles became people movers in a place where their off-road & power abilities are completely worthless.

4-16-2019 **C-HR EV.** Exactly as anticipated, there was a reveal of an EV model of C-HR for the market in China. It's becoming more and more difficult for the die-hard enthusiasts to portray a narrative of Toyota being anti-EV. Being compelled to seek out an enemy is normal. It's commonly how troops are rallied and teams pepped up. It's needs some sort of basis in reality though. For early-adopters who took advantage of tax-credits, but denied that was a primary motivator, are now challenged with explaining how their choice will be appealing to a topic consumer without that generous incentive. Toyota never catered to that audience. GM thrived on it, milking that opportunity without regard for consequence of missing others. Now, we see GM struggling with no audience and Toyota setting the stage for wide-spread appeal. The difference is so drastic, I'm fascinated to find out what comments will result from this reveal. There will be some outright hate, but that's easy to look past. There will be some efforts to undermine, but those are the same old tired posts that stir very little feedback. There will be some sense of optimism. That's what I'll be looking for. Detail will be scarce though, especially since this isn't for the United States and Toyota tends to withhold reveals until close to rollout... quite the opposite of GM. My guess is focus will be on the one-size-fits all narrative. That claim of anti-EV belief feeds on the "*self-charging*" advertisement. I find that quite telling. These same people turn a blind-eye to all the SUV promoting we get from GM on a very regular basis. They desperately attempt to lead you to believe an automaker must only represent one offering, that focus on a diverse set of choices involving a wide variety of appeals is impossible. It's so hypocritical, it's embarrassing at times. The rest of the world wonders how bad complacency of people here will become. It's sad. Fortunately, we have Toyota doing their rollouts elsewhere and well disguised. C-HR is getting attention now, but hiding their EV tech in plain view here is what really blows my mind. Mirai is right there for all too analyze; yet, most only notice the fuel-cell part. The electric-only drivetrain part is getting quite the real-world testing & refinement without anyone taking notice.

4-17-2019 **Air Cooled.** Final efforts from antagonists don't seem to be making any difference. I'm watching their influence fade. Much of that comes from a new chorus of interest, people who were never part of that past rhetoric speaking out with messages of their own to share: "*Toyota said in the past they use batteries in the Prime designed specifically for heat...*" When they make the same information conveyed in the past part of their own statement of fact, it really makes a difference. Antagonists attacking me relentlessly as a scapegoat makes no difference when someone else passes on the same message. There's where knowing your audience makes a difference. Breaking the problem of group-think only takes a few individuals to stop listening. I'm happy to contribute to that, by providing other detail for them to consider: Better chemistry & design is the preferred approach. Necessity of liquid cooling is a complexity & cost that doesn't make sense beyond early-adopter sales. Remember, the sales pitch for EV is simplicity. Avoiding coolant, piping, a radiator, and maintenance is a vital step toward ending the reign of traditional vehicles.

- 4-17-2019** **What Data?** It's quite vindicating when you see something like this posted: "*Sure, it's cheaper to build a car that only attempts to cool by hot air, but the industry's history already shows...*" I know what the real-world data shows. You can manipulate the message of history by cherry-picking, to present a false narrative. But when looking at the bigger picture and taking realistic goals into account, the story changes. This is especially easy to confirm when dealing with data that becomes outdated quickly. I know that. They know that. The hope is to not be called out on it. This is why I ask for detail... and rarely ever get any. Not getting it is an implied confirm that they really didn't have anything of substance to make their claim with. This time, I asked: Shows what? Where is there data with newer chemistry and forced A/C cooling? Think about how primitive the chargers themselves were back then too. You couldn't sustain a 7.2 kW draw, but that is now becoming realistic.
- 4-18-2019** **Recent?** This was a delight to read: "*...and that's where the market has headed recently*" Most people don't pay close attention to the automotive industry. In fact, even when they make a purchase, it only represents a tiny research effort. There's no extensive study or on-going monitor. The typical mainstream consumer is just an ordinary person who wanders into a dealer and starts looking. They do some basic looking at specifications and do some simple calculations. That's it. There's no big picture. There's no waiting. There's only a consideration of immediate impact... usually in the form of, can I afford gas & payments? Hope that consideration for environmental or politic impact is a futile expectation. It doesn't happen. That's why we have had a endless growth of vehicle size & power for decades. It's not recent in any regard. So reading about someone commenting with regard to the shrinking sedan market is maddening... though, quite understandable. Know your audience. Don't get on them about not being attentive. Don't make them feel bad in any regard. However, do let them off the hook either. Ignorance is not an excuse. Make sure you convey a clear message of the true situation, especially when you confirm they really didn't notice what has been happening over all those years: That's the history I'm referring to. Some of saw the "*recent*" trend begin back in 1994, then a massive push into the mainstream back in 2004. What is happening now is that has become the norm, with everything else now an exception or holdback.
- 4-18-2019** **Central Park.** I got to spend some quality time with my wife today. We took a stroll through Central Park. What an amazing part of a truly unique urban environment. It's quite beautiful. We really, really lucked out with weather too. There was a light rain in the morning, which provided a nice sense of exclusiveness. Most people weren't out wandering around. We got to enjoy the sections & trails mostly alone. Early spring made it even more inviting. Anywho, it provides a great opportunity to reflect. The clouds parted. We saw others come out. In fact, after a nice lunch at a local restaurant, there were lots of people to share that great setting with. By the time we got to the other end, crossing somewhat in a diagonal manner, we got to see where the nice location was to watch a sunset on the massive building from that tranquil jungle of trees. To my surprise, right there at the southeast corner was a long line of plug-in vehicles, plugged in. They had setup chargers for city vehicles along the roadway. It was a sweet sight... in a quite unexpected location. There was about a dozen vehicle there... all with charge-ports on the wrong side, requiring the cord to stick out into the street. Fortunately, Prius Prime has its access on the passenger side... but I digress.

- 4-19-2019** **Prius Taxi.** We got a taxi from Times Square to JFK for our flight home yesterday. What a crazy experience... in a Prius V cab. The cab trip my wife had in Rome a number of years ago is no longer her favorite cab story to share. This driver was all over the place. If anyone ever questions the driving dynamics of that car, just express an interest in wanting to get to the airport quickly! The weaving through traffic was remarkable. I would not have been thrilled about seeing him approach in my mirror or watching him merge into the lane opening I wanted. Whoa! It sure was a testament to how well the lower gear-ratio for the bigger Prius combined with the power of an electric-motor can really make a difference for providing small boosts of thrust. What a contrast to the next taxi we got a few hours later. It was a guy with an Iconic model. His Prius had a little over 209K miles on it and had been working great as a cab. Since it was his vehicle, rather than a commercial service as before, the driving & conversation was quite different. He was intrigued that we were both Prius owners and had never heard of the plug-in model. So, we indulged upon arriving at home. I actually showed him my wife's Prime, demonstrating how it was plugged in. That blew his mind. It was an incredible confirmation of how even a well-informed owner who uses his Prius to earn a living, knew virtually nothing of the technology. He simply trusted Toyota's reputation for affordable, reliable, and responsible transportation choices. btw, while in New York City, we saw quite a few Camry & RAV4 hybrids used for taxi service too. It's obviously an excellent choice for that type of driving.
- 4-19-2019** **Posting Comments, change.** It will be changing on the website that has become the authority on all things plug-in. It was starting to become a troll creator, where points-of-view could thrive as propaganda. Moderators were well aware of the growing problem. The owner electing to change the posting format, but remain within the rheum of blogging. That obviously didn't work. People could still hide their identity and easily cover their tracks along the way. As a result, topics would die quickly and construction follow-up remain hopeless. Change was needed, something significant enough to sour the milk. And sure enough, right after today's announcements we got some goodbyes. It was always quite clear that enthusiasts were diligently working to retain the status quo. Fighting efforts to grow beyond the initial rollout stage (early-adopter, which was identified by subsidized sales) became increasingly more difficult... because they stopped caring about being constructive. More and more activity recognized as trolling emerged. Thankfully, they drew the line. In few days, yet another resource online will attempt to establish a voice of integrity by pushing out those who were just enjoying a moment in time at the cost of others.

4-20-2019 Posting Comments, perspective. I was quite happy to join into the discussion topic addressing the way comments will be posted. That website was really struggling for awhile there, not having a good idea how to objectively promote both EV and PHEV for both start-up and legacy automakers. The idea of diversity is compelling. Actually achieving it is quite a struggle though. Fighting to retain the status quo comes from some you would hope would be more open minded. Discovering they really didn't care about the greater good is disheartening... and also a difficult barrier to overcome. I added some perspective with a post of my own: Understand that this next step is necessary as the reach of plug-in offerings grow beside the obvious enthusiast group currently active here. Though many don't see the group-think that's rather blatant from the perspective of someone who just happened to stumble across this site, but it's there and a very real problem to address. Continued improvement efforts like this, are a clear attempt to ensure integrity of postings. Over the years, I have watched the pattern of attacks meant to enforce a narrative. Wanting to witness it for yourself, watch what happens when affordability (discussion of vehicle pricing without tax-credits available) with regard to high-volume and profitability is brought up. You'll see the usual bunch of individuals promote their rhetoric of power & range attempt to undermine those who simply want everyday plug-in... nothing special... just basic electric travel for their daily driving. I welcome this step they are taking to overcome rhetoric and provide a most useful tool for discussion participation. Features like ignore & notify will be improvements many will really appreciate.

4-20-2019 Posting Comments, resistance. I should have expected a gross over-reaction to my post. There's a sense of panic about how comments will be changing, one stirring fear... Recognition of the situation's magnitude should have clued me into the nature tendency for FUD to be used. Responding with Fear, Uncertainty, or Doubt is extremely common. Rather than rationalize or trust, they revert to instinct. Ugh. Anyone, in this case in was in the fear of suppression. To the individual I responded, there was a belief that adding controls will create limitations. It's easy to see how that assumption comes about, but it simply isn't true. I know this well already simply from having observed the same thing already play out elsewhere. It's not even pattern recognition this time. It's a repeat of the same issue. I kept reply to that on the shorter side: Empowering people by giving them a means of discussion participation with expanded abilities is quite the opposite of limiting freedom of speech. Notice how people can currently hide behind just label? Putting a control in place to prevent that lack of accountability is a benefit to everyone. Notice how websites unwilling to require some type of identity have disappeared over time? They lacked integrity by allowing an anything-goes policy and they lost their audience as a result.

4-21-2019 Dishonesty & Misdirection. That's the description rising to the topic of that report about our president's activity coming from his own party. Sound familiar? That's exactly what I dealt with on a regular basis coming from the Volt enthusiasts. It's what set them apart from being true supporters. They'd think anything of saying whatever they thought sounded convincing. That's how I got so detailed with my blogs & video. Their acts to deceive were relentless. They simply didn't care. It was all about feeding hope with hype. Stunning is how I can best describe my thoughts of how blindly optimistic they became. With only a vague press-release, they would spin an incredible wave of false expectation. It was so obvious too. Without any supporting material, they'd make too-good-too-be-claims. It was on a regular basis too... to the point where people would lose touch with reality. The narrative took over, becoming what would be perceived as normal... a con job on an enormous scale. They know at some point the dishonesty & misdirection will eventually catch up with them. That doesn't matter, since their want is to do as much damage along the way as possible. It's an effort to undermine, to keep the status quo from actually changing. Seeing parallels between business & politics is saddening, but not at all a surprise. Power corrupts. That's why I give so much respect for Toyota not giving in to the temptation. They remain true to their values of focus on the mainstream. They build reliable, affordable products that are also responsible.

4-21-2019 **Continued Attacks.** I read through a forum thread about the now completely dead daily blog. Comments posted there included a variety of thoughts. Most have simply moved on, not caring about it no longer allowing posts, despite new articles being published. What I found intriguing were the attempts to stir rhetoric. It was obviously a venue attempts to cultivate attack approach... because sure enough, one of the individuals there jumped on the chance to try out his material on the big Prius forum today: *"What's your new ride going to be? Probably not an EV, because Toyota is now poo-pooing that idea. (probably because they are so far behind the ball on that tech...)"* His choice of where and how made that interesting. It was on an innocent thread where people were posting comments about what they owned prior to purchasing a Prius. I decided to go all out in response. My post was as follows, complete with a nice photo of each of my Prius selected from my album:

That rhetoric is becoming shallow & desperate. We all know Toyota has chosen to avoid the tax-credit game, deciding instead to focus on delivery of choices capable of reaching a very wide audience in a manner not disruptive to their true customers, the dealers. That's why claims of enthusiasts don't matter. They simply feed innovator's dilemma, making the challenge of profitable high-volume sales more difficult. Not only do I applaud that sensible business approach, I also support it.

My first Prius was a Classic model, among the initial rollout here in the United States way back in September 2000.

I traded it in to be among the first to get the next generation, the Iconic model. It was a pioneer package too, so I could easily identify it (in addition to the very unique dent I put on it). And sure enough, I saw it in a parking lot a few months ago, after all these years!

That was the Prius I owned for the longest duration. I had it 118K miles for 5.5 years. It got traded to again be among the first to get a next-gen upgrade. This one, like the others, demonstrated a strong commitment to refining the technology.

That 2010 model got replaced less than 3 years later with a mid-cycle update, the first offering here to include a plug. Since I had driven a prototype of for a few days years before, it was solid assurance that Toyota was striving to deliver a product for the masses.

That first Prius PHV was a great opportunity for Toyota to explore the market, choosing to rollout mid-cycle to limited regions. Seeing how effective that approach was at avoiding the tax-credit game, Toyota continued with the limited rollout. I jumped on board yet again.

This latest Prius confirms Toyota is striving for that wide appeal target. The technology in Prime is an adaptation to the hybrid system allowing it to enjoy the battery-pack with a full EV driving experience, one that China will be seeing as a Corolla PHV. China will also be seeing Toyota first EV offering, a new model of CH-R. Meanwhile, watch how Toyota is quietly road-testing their 152hp full-electric system in Mirai. Wouldn't that make a nice battery-only setup for a next-gen model of Prius? I need something to set my sights on for another upgrade opportunity.

- 4-21-2019** **Label Arguments.** I was pleased to see that the forum isn't able to fuel the fire of labels. A few tried to renew efforts to push "EREV" as an indication of superiority, but it all fell on deaf ears. Things like "*top speed*" and "*certain threshold*" were used to no avail. The even more generic "*extending the range*" reference made no difference. Ultimately, the attempts to stir ended with: "*Describing the difference between a EREV and a PHEV seems pointless.*" That was all nice to see. But what I found most informative was this statement: "*But this is NOT how the Volt works.*" When you encounter that on a Volt forum, odds are quite good they know even less about the supposed competition. I ran into that a lot over time... hence all the videos. They served as proof the label arguments were questionable. They'd attack me claiming I'm bias. I'd reply back pointing that making it personal doesn't change the fact that their information is wrong. Ultimately, it always came down to Volt enthusiasts trying to portray me as anti-GM, when in reality I was just against the approach. It made them absolutely crazy that I would endorse parts of the design stating a new configuration could appeal to a wide-array of GM customers. The idea of diversification messed up their vague definition of EREV. That label wouldn't mean as much spread onto a second model of Volt and an Equinox that could also use both gas & electricity. Most learned from their mistakes and moved on. The few that remain have lost their audience. Remember asking: "*Who is the market for Volt?*" They didn't understand who EREV appealed to. Know your audience.
- 4-21-2019** **Spinning Lies.** Our new resident troll is pushing harder and harder. After attempting to mislead about profit by pretending there's no tax-credit dependency and volume doesn't matter, he moved on to: "*While I generally agree with this statement, it doesn't justify lying to try to persuade 'who'? I'm not quite sure who Toyota is trying to convince.*" It was an obvious effort to disrupt the discussion any way he could, to the point of even frustrating the moderator. Seeing an end coming from such desperate acts, I summed up the situation with: Know your audience. The perception of lying comes from listening to spin and not recognizing who is being targeted. We saw this done extensively by Volt enthusiasts attempting to portray their vehicle as something for the mainstream, a high-volume profitable seller intended for a GM's own loyal customers. That couldn't have been further from the truth; yet, it was the mantra accepted by those spreading a message of change. That was a false hope, just like the demise of Toyota. Reality is, this publication is exploiting the opportunity to draw attention to itself by milking the spin. They directly benefit from the online activity their articles stir. If you take the time to really consider what buyers of each automakers own vehicles seek, you'll see that Toyota is doing exactly what they should to deliver a reliable, affordable, and responsible platform in large quantity... without disruption to dealers... a vital component to change of the status quo most enthusiasts refuse to address. Again, it's important to understand who.

4-21-2019 **Intelligent Debate.** The moderator stepped in when bait from that troll got out of hand. He posts so frequently, often without actually quoting what he's responding too. Sadly, many of his claims are misinformation derived from snap conclusions drawn on little to no actual data. Like most trolls, that identification comes about simply from the desire for attention. That's why facts make no difference. It's act of participation he seeks, not constructive dialog. So, I have to carefully watch what the moderator desires for next steps, to get us back on track. In this case, it was spin about lies. He never bothered to do any research or even try to derive how the quoted value came about. I immediately understood what the "*average*" comment was referring to and how it translated to a monetary value. I shared that detail:

Intelligent debates would require actually reading for context. In the case of that quote, notice how everyone just blew past the word "*average*" without even bothering to consider what it actually represented?

Think about the capacities for an "*average*" vehicle. They have a 15 gallon gas tank and deliver about 30 MPG. That's a range expectation of 450 miles... which most of us would recognize as quite typical. More of a guzzler would have a larger capacity to compensate, to deliver roughly the same range.

Think about how big the battery-pack would have to be to match that expectation of 450 miles. Knowing the "*average*" vehicle is much heavier and much less aerodynamic than a Prius, you have to use something like Outlander as a somewhat practical measure of EV efficiency. Ratings of 45 kWh/100mi are about what a vehicle like that would deliver. Anyone else see the problem?

$$45 \text{ kWh} * (450/100) = 202.5 \text{ kWh}$$

$$202.5 \text{ kWh} * \$150 \text{ per kWh} = \$30,375$$

Then when you add in the longevity capacity buffer, since you won't be stressing the battery-pack by charging to 100% and discharging to 0% to achieve that 450-mile range expectation, the value easily matches up with what had previously seemed a wild estimate of \$34,000.

So much for intelligent debate.

- 4-22-2019** **Ask Again.** One effective way of confirming you really are dealing with a troll and just not someone poorly informed is to watch other thread. If you provide an answer on one thread, then they ask again on another, you have your confirmation. That repetition of questioning the same thing over and over is a dead giveaway. They don't like what they got in return and hope somehow stirring the same pot again will result in a different outcome. Yes, that's the definition of insanity... but online posts can resemble that type of being out of touch. I find the repetition annoying, but it can be tolerated. You find ways of being short with responses and getting others to participate in something constructive. In other words, don't feed the troll by denying them an audience. Remember that daily blog? Loss of an audience helped kill it. That website went from being a premiere "*fake news*" source to a collection of mistakes which had a profound influence on a history most people won't ever be aware of... hence not ever allowing questions to be asked again and again. Those lessons learned should be shared, once you've confirmed you really are dealing with a troll. Take advantage of those teaching moments.
- 4-23-2019** **Not Realistic.** It's somewhat bizarre how the death of Volt has turned into what is basically a push of the reset button. It failed to move beyond niche. No successor means something else will fill the void. What that will be isn't obvious though. My pointing out of the "*450 mile*" expectation has blown some people's mind. Their attempts to explain why such a large range isn't necessary has fallen on deaf ears. Mainstream consumers have come to expect more, period. Not realistic isn't a consideration. They have that much now and see absolutely no reason to settle for less. That's how we got into this mess with the SUV obsession. More was always promoted as better. Whether that makes sense or not is irrelevant. Vehicle purchases are more often than not based on emotion. It's that want verses need problem. That never goes away. Denying it only makes the situation worse... as the Volt enthusiasts learned in a very painful manner. They dismissed clues, refusing to take the situation seriously. It cost them dearly. Now, the rest of us try to figure out how to overcome collateral damage caused by that denial. Conveying the situation is a challenge. I'm keeping my effort to that affect short & sweet: Agreed; however, that's the way it is. Automakers could easily save money & weight by simply using a smaller gas tank. They don't though. Explaining why less is better won't change that. You're fighting the status quo, which isn't always logical.

4-24-2019 **Who?** Watching the lack of excitement for Earth Day this year has been compelling. Financial struggle for Tesla and the absurd self-inflicted problems GM now faces has setup the market for lots of uncertainty. Supposedly, we'll be getting a variety of plug-in choices from both VW and Ford within the next few years, but all that's been shared are snippets of plans without any detail. It's all so vague, there's no real sense of progress actually being made. That's not stopping those who see Toyota's actual progress as a force to fight though, which we do our best to counter: *"No matter what Toyota produces some people will still see negatives: "CVT gearbox, "self charging" hybrid nonsense, not fun to drive."* Unfortunately, most rebuttal posts are long and drown out. They tend to go no where as a result. Much of that struggle in the past was due to the trolls forcing a Prius narrative. No matter what you posted, they'd spin it to be about Prius. I got quite a kick out of that. Post after post would be nothing but GM. Someone would inevitably change the topic to Toyota and blame me. I always found that desperation both reaffirming and tantalizing. It validated their lack of evidence to actually prove their point. Mine was always simple. I asked who. Knowing that a business could not thrive on a single product, the doom GM would face with Volt was only a matter of time. No diversification prior to tax-credit phaseout being triggered meant it would die... and, that's exactly what happened. Seeing Toyota strive to deliver a variety of choices means a very different outcome. They know their audience. Who is their entire fleet, that large collection of very different buyers are pleased with their own particular purchase. It's not just about Prius. It never was. They refused to accept that. I keep reminding them: With the Corolla and RAV4 hybrids so non-Prius like, who would that be?

4-25-2019 **Tesla Trouble.** Yesterday's financial report painted the picture most fanboys feared. Tesla's gamble to stay in front of the massive risk being taken isn't working. Profitable quarters turned into the most recent posting a massive loss. The planned 35 GWh capacity from the Gigafactory in Nevada is only at 24 GWh. Ramp-Up isn't financially realistic either. It looks like a deal with Panasonic to ship cells from Japan is the plan now being explored. That compromises the *"Made in America"* promotion and faces possible import tariffs barriers. Ugh. Another possibility for elevating production bottlenecks is to move vehicle production elsewhere. Building a Gigafactory in Germany is an option now being explored and construction of the one in China continues. Negative net of \$702 million for the first quarter of this year makes those efforts easier. Pain of growing beyond niche is a sign of progress for Tesla that will either establish a true foothold in the industry or bring about surprises. Acceptance of EV is an achievement we all benefit from already regardless. This is yet another reason why Toyota sees no reason to rush to market. Rough times from having to grow beyond initial market are never easy. Trouble confirms you are still in the game.

4-26-2019 Ford Announcements. It was interesting to hear Ford strike an partnership agreement with electric truck startup Rivian... after finding out GM turned down the chance. Ford was happy to provide a \$500 Million equity investment to make that happen. It will add to the growing portfolio Ford has for new choices on the way. It's odd to hear there will be 16 full EV vehicles and 40 electrified vehicles coming worldwide through 2022. Many could be limited market and limited volume; nonetheless, Ford is being given a nod of approval while Toyota is getting attacked. So what if Toyota is planning fewer choices? They stand a better chance of being widely available and more affordably priced. Enthusiasts don't want to hear that. They are enthusiasts because that are not mainstreamists. Endorsing something for the common person goes against the very nature of being a fanboy... which none of them will admit to being. It's a fundamental flaw in their approach... which they hope no one will ever call them out on. Thank goodness Ford has been able to avoid most of that rhetoric. We're expecting to see some new hybrid and plug-in hybrid choices. That will be great... and not "*late*" as so many attempt to spin. Timing & Technology is coming to a point where the choice will be realistic for the masses. I'd say, that's just right. So, these announcements we are getting now seem to be a good plan.

4-27-2019

New Audience. Realization of just how much of a barrier enthusiasts of Volt had created is becoming quite clear. As the dust settles from the end of its production, that death reveals an entirely new audience. These are the smaller, quieter voices of mainstream consumers... which are drawn to Prius Prime, exactly as Toyota had predicted. In fact, we even now have evidence of just how closely they were monitoring that early-adopter market. I always said the replacement of the unused-by-most middle seat in back with a nice armrest & bucket seats was to test appeal. It's undeniable now that the shift to SUV platforms as family-mover vehicles is well into the final stages. Sedans are vanishing and hatchbacks are needing to evolve. What did that mean for Prius Prime, which is now a bit more upscale to keep it relevant? Not much, apparently. That middle-seat will be coming back. Toyota took the risk, quite contrary to claims of antagonists. The 2020 model will bring that layout back, along with the much hoped for (including by me) visor-extenders. I simply bought a set online. Next year's will have them built in. Switches for the seat-heaters will be moved to a more predominate location as well. It's all about listening to potential customers, not enthusiasts. Toyota isn't dumb enough to fall into the trap GM did. Innovator's dilemma is a well known business conundrum that a legacy automaker as experienced as GM should have been able to avoid. That's why Toyota was willing to also take risk with the battery. The original gen-3 prototype had a 5.2 kWh capacity. That pack size was large, making the floor taller... exactly as it is now with Prius Prime. The decision back then was to reduce it to 4.4 kWh to make it fit better. Toyota decided with gen-4 to try the larger. Since a mid-cycle update provides opportunity for change, we may be seeing that floor drop to provide more cargo capacity. That would keep Toyota's mission true to staying affordable and targeting mainstream consumers... who may prefer that over increased capacity. That's why so much real-world data is collected during the first 2 years of rollout... giving Toyota key insight to what the more favorable configuration would be for the new audience... the one that much more be profitable without tax-credit dependency able to achieve high-volume sales competing directly with traditional vehicles. That's a tall order, but realistic if you understand who. Based on my observations of recent posts from new Prius Prime owners, we seem to have reached the point of non-enthusiast interest. I had no idea the problems Volt had created for market interest would fade so quickly upon its death.

- 4-28-2019 Co-Exist.** Every time an article comes up about the delay of EV rollout, someone brings up conspiracy theories about fuel-cell vehicles. They absolutely refuse to acknowledge the reality of economics; instead, it's always turn a blind-eye to token efforts giving them unending forgiveness for selling at a loss. It's no wonder that their short-sightedness would stir cries of lobbying and market manipulation for the sake of killing EV efforts. They just plain don't want to accept a world where many clean solutions could exist side-by-side. It's really sad when so many lose sight of goals. Have they really forgotten what we want to achieve, for who, and when? Unwilling to put up with more of this nonsense... the endless bickering that doesn't achieve anything... I just punched right back with: Are you so naive to think that the oil industry could simply be shut down, that battery-only vehicles will dramatically just end our need for them? That's as gullible as the one-solution-for-all chats we keep hearing. It's not going to happen. Breaking the status quo on that magnitude requires compromise. Deal with it. The best way to get them to stopping fighting change is to give them something else to produce. Taking advantage of the infrastructure they have in place is key. So what if the conversion to hydrogen isn't as efficient as storing electricity in massive battery-banks? At least it is both carbon neutral and clean. Fleet & Commercial vehicles can exploit that opportunity to get us off the dirty, non-renewable fuels. Why do you have a problem with your Amazon delivery coming from a truck using fuel cells?
- 4-28-2019 Dead.** Sentiment over the circumstances was posted as follows today: "*Volt is dead and they don't seem to care much about maintaining a good relationship with Volt buyers anymore.*" That turn on GM from enthusiasts was found on the dedicated forum for Volt. I have been watching the shift take place, observing change as the final sales wrap up. There's a limited quantity available and no hope whatsoever for a future plug-in hybrid offering. Even the future of the Volt antithesis... Bolt... remains uncertain. It was always a strange offering. Gross overkill for speed & power from a compact wagon certainly was out of character for anything normally offered by GM. It's easy to see how some dealers simply didn't want to bother. What message did it send about GM's future or their commitment? This is why Toyota's dedication to hybrids was so important. So what if it wasn't bleeding-edge technology? Mainstream consumers don't want that anyway. Their interest is something of good value, meaning it was safe, comfortable, and reliable for an affordable price. Volt died because it failed with that vital criteria of being affordable. It was far too expensive... but didn't need to be. Remember all that suggestion made by so many all those years ago? It was to offer a configuration of Volt that had a significantly smaller battery-pack. That would have greatly reduced cost, while at the same time free up interior space and lighten the weight. It was a viable solution. Sadly, what seemed a winning combination was never tried. GM never tried to spread the technology to an ordinary vehicle either, something their customers would actually purchase, in Equinox. Remember all that same suggestion for Prius? Remember how Toyota did exactly that, rolling out both Highlander & Camry models using the hybrid system? That later got spread to quite a variety of other vehicles too. It was a winning formula that proved successful. Yet, GM never tried. Many now feel that lack of effort in their sentiment. Why didn't GM try?

4-29-2019 **Compliance Car.** Attacks from within continue. It's been a persistent message for years, passed along by a few Prius owners who absolutely refuse to accept the idea that time isn't vital. So, we get: "*Prime is a compliance car.*" It comes from the mindset of having to deliver something as fast as possible. That message our society sends of needing to be first as the measure of success can have terrible consequences. You are being taught that not being first means you lost. Second place is not a winner as far as our highly superficial beliefs instill. That's really unfortunate. Taking the time to do it right should be the mantra; instead, the need to rush is perceived as necessary. Ugh. That makes drawing conclusions, like compliance, difficult to avoid. Many don't see any other option. You either go all out or you don't. When balance is no longer viewed as essential, problems arise. That's why the crazy attitude toward Volt was accepted as normal. Enthusiasts didn't see themselves as pushing an extreme. GM sacrificed too much to deliver something that wouldn't be looked upon as a compliance car. It proved a disastrous choice. Just imagine how much better things could have proceeded if an incremental approach had been taken instead. Small steps forward is progress. So what if it appears to just be an act of complying at first? I stated the method of advancement this way: That's just spin for those who don't like the concept of phased rollouts. Toyota tests the market by rolling out small allocations to limited areas. That real-world data they collect provides a powerful means of product alignment. The fact that it also meets California requirements is a benefit to the approach, a win-win situation for both.

4-29-2019 **Stop!** It continued. There's a strong feeling of anger coming from certain individuals. This highlights their view: "*Stop studying on it and make fully electric vehicles.*" That belief of having to deliver something right away is a theme we'll always have to deal with. If they don't see the entire vehicle, none of the technology exists. That's sad... and quite impractical. There's no effective means of achieving a rollout of that nature without extreme risk. Successful business requires sensible steps. You improve components, then implement using existing platforms. For example, that's how Prius got its two-speed hybrid system. It started in Camry hybrid. Another example is the AWD for Prius. Same thing, it started elsewhere. Not everything is offered immediately either. The fact that Mirai is using an all-electric propulsion system that would make for a great Prius EV later is further proof of doing things in stages. Imagine how expensive and how challenging it would be to provide that configuration now. Battery technology isn't up to the challenge yet. Facing the expectation of prices directly competitive with traditional vehicles simply isn't realistic yet. In a few years time, when the liquid electrolyte barrier is overcome, things could be profoundly different. That dramatic reduction of heat & fire exposures will really change the reach of fully electric vehicles... hence the value of studying. In the meantime, it's not like the rest of the vehicle isn't taking shape. Sadly, certain individuals are blind to that progress. Ugh. I tried to state the situation in terms immediately understandable. It probably won't to any good though. Some people just like to argue. We'll see: What other legacy automaker is making fully electric vehicles that are profitable, without dependency on tax-credits? Toyota's fully electric platform currently used in Mirai will make a nice EV platform, when battery cost drops to the level of realistic high-volume production. In the meantime, there's continued refinement and the spread of hybrid choices. Remember, that diversification is essential for plug-in offerings... something all the other legacy automakers must also address. In other words, Toyota is not sitting idle as the narrative portrays.

- 4-30-2019 Full-Size Pickup.** Quite vague, though impressionable, announcements about the intent to produce full-size electric pickups really shook the industry yesterday and today. Ford revealed their joint-venture with new partner and GM immediately countered with plans of their own. It was the usual substanceless rhetoric feed. You know, those ambiguous releases that really don't tell you anything. That complete absence of detail is so much a part of our normal approach to accepting plans, no one seems to care anymore. Merit is just freely given out without any expectation to actually be held accountable. That's why all the plans for VW shouldn't be taken seriously until something is delivered in quantity. Right now, it's all just empty hope. There's lot of potential and substantial investment, but that in no way equates to success. It will happen, eventually. Rushing out press-releases doesn't speed up the process. Yet, that's what we are getting.
- 4-30-2019 Blinded.** Sometimes, the hate runs so deep nothing else is seen. In this case, it was yet another attack on Toyota. Rather than actually discuss the topic at hand, there was an obvious diversion of attention. That effort to evade is a undeniable sign they really don't care. All they want is for you to stop posting information related to the discussion. They'll do anything to change the subject. Ugh. I fired back to today's "*Fool Cell*" nonsense attempting to distract from the plug-in hybrid posts with: Really? So blinded by a resistance to diversity that you don't actually see the plug-in advancements taking place? With just an output of 68 kW, we already have a vehicle from Toyota able to drive as an EV. From just that small 8.8 kWh battery-pack, my daily commute in a Prius Prime is entirely electric. Complete with both electric A/C and the industry's most efficient heat-pump, it's a rewarding experience at an affordable price. Toyota simply isn't interested in playing the games you want. They are refining their technology as the market progresses beyond the early-adopter stage. Mirai is a great example; the platform delivers 113 kW of EV power. So what if the current power supply comes from a fuel-cell? Within the next year, a plug-in hybrid Corolla and an EV model of C-HR will be rolled out in China taking advantage of what they learned from Mirai. So what if they also pursue fuel-cell offerings? There's quite a bit of opportunity available for fleet & commercial sales. Are you so blinded by rhetoric of one-solution-for-all that you can't see the value of a business offering a variety of choices?
- 4-30-2019 Attacker Info.** Now that post history is available, the circumstances have changed rather dramatically. You can follow the activity of each participant. That lack of accountability was terrible. Certain individuals would hide behind an avatar. You'd never know who they really were or even what & where they were posting. That's why that awful daily blog for Volt thrived for so long. It attracted those who just wanted to win battles on a regular basis with no concern for winning the war. They only cared about small victories. Since the discussion threads usually died the very next day, it was easy to post the same rhetoric endlessly to achieve exactly that. They'd do everything possible to retain the status quo, learning how to prevent conclusions from being drawn. That type of behavior is what brings down the integrity of a venue. Some of those websites falling victim to such activity clean up their overall message by upgrading software to deter those determined to undermine. It works well. This is the latest example. Moderators made it quite clear there would be no compromise. Either you accept the effort to make people be responsible for their actions or don't participate anymore. Phew! It sure is nice to have improvements like that take place.

5-01-2019 **Trolling Pattern.** It is sad to report that although websites hosting blogs are improving the political environmental is not. In fact, that particular venue is getting worse. The very activity I used to witness and deal with on a regular basis is now playing out in the daily news. We get sound bites of politicians outright lying over and over again. We get the same deceptive messages so often, you lose touch with purpose & direction. The same old nonsense is now repeating there. In other words, the pattern of trolls is easily recognizable in politics. Some simply don't care. They figure if enough join into that group-think, accountability won't be necessary... everyone will agree what is "*truth*" and what is "*fanboy*". In other words, they work really hard to enable dismissal. There's no need to justify your claim. You only have to refer to the next person saying the same thing. Thankfully, there's always a day-of-reckoning at some point. Catch is, a lot of collateral damage can occur along the way. Cleaning up that mess afterward can be a monumental effort. Look no further than Volt for a great example of that. What in the world will GM do now? There's no path forward. Preventing that from happening again with some other efforts starts by addressing shortcomings that allow trolls to thrive.

5-01-2019 **Ice Spin.** Witnessing the anticipation of bad news is always interesting. We should be getting news of April sales today. That's the first month GM faced with a 50% reduction of tax-credits. Everyone knew Volt was doomed, but few enthusiasts were willing to acknowledge the destructive path it was on until the outcome was undeniable. Their hope of a miracle was far too much of a gamble to help with the ultimate goal of change anyway. GM had already reversed course by embracing the very approach they had worked so hard to fight. EREV was to be the "*range anxiety*" solution to EV capacity shortcomings. That never made any sense. Enthusiasts claim this outcome was inevitable, that it was the plan all along... despite overwhelming evidence to the contrary. That's why I documented history as it was occurring. Details written while events are playing out is how you find out what the true story was. There's no other good way to assess what expectations were after the fact. That makes the spin about ICE vehicles taking place right now a great topic to blog about. Who knows, that announcement I'm expecting from Toyota about a mid-cycle upgrade shouldn't too far away. All the signs are pointing to stage setup going well. This is how I stated the reaction to what's happening right now, in the moment, before we actually get the news: Using Toyota as a distraction to draw attention away from the automakers who haven't actually delivered anything affordable... Makes sense. There are many who refuse to acknowledge tax-credit dependency, who treat the early-adopters as representative of mainstream consumer demand. Reality is, even a small battery-pack will offer a dramatic reduction in consumption & emissions... and will make far more of an impact to changing the status quo than a few expensive token offerings. Camry, Corolla, C-HR, RAV4 all provide a means of reaching a wide variety of customers being offered as a hybrid with a plug. What other automaker has such diverse choices available? Toyota is setting that stage and you refuse to acknowledge it.

5-02-2019 **Real Change?** Raising doubt is standard practice for when attempting to undermine. When successful, that sentiment will be passed along by others. For example: *"I am beginning to wonder if these vehicles aren't a publicity stunt or an attempt to carefully impact overall fleet mpg rather than a true vehicle marketing attempt."* This is especially easy to see as the approach of an announcement nears. In this case, we just cleared the fallout related to Volt & Bolt. That first month of phaseout sales were just reported. With the tax-credit no longer an option GM could exploit, it cleared the way for Toyota to take a turn. In simply made no sense getting involved with those actions of the past which clearly didn't pursue real change. Toyota's choice to avoid that is one I wholeheartedly welcome. I spelled out the situation with:

That narrative is making the rounds. It's easy to get sucked into the belief of that being the case too... if you aren't familiar with Toyota's history.

The practice of intentionally limiting rollout is what we saw with Prius even before it rolled out here in the United States. That extremely limited offering, only available in Japan, actually had a plug. It was quickly dropped, since battery-tech of the time offered very little capacity to take advantage of. In fact, the rollout in the United States was came with an entirely new pack... so significant of an upgrade, it should have been called a full generation. Switching from D-cell packaging to prismatic was a really big deal. But back then, no one cared. It was just labeled as a mid-cycle update, despite the pack change, the screen changing from button to touch, the engine gaining more power, and the look itself changing.

That's not even the point of the story either. It was that Toyota continued to hold back. Cruise-Control was intentionally not included, a way of deterring those who weren't absolutely interested in purchasing a Prius. After all, there was no tax-credit back then. You could only get a tax-deduction, which equated to about \$350 for most people. It was a blatant effort to attract only the devoted. We proved it too, by confirming cruise-control was part of the system already, only the stalk with interface buttons was left off... which you could have the dealer add later, if you were so inclined.

Toyota wasn't targeting mainstream consumers yet. They used early rollout as an opportunity to collect real-world data. This is why they felt free to experiment with Prius Prime. Knowing that it would only be offered in specific areas, feedback from those markets could be studied without having to re-educate later, should big changes be offered in a mid-cycle update. After all, Toyota knew GM was using Volt as a publicity stunt by attracting conquest sales with tax-credits, not even trying to draw interest from their own loyal customers. That meant Toyota has lots of time available. So, we saw this first half of Prime's product-cycle with a middle-seat swapped out for an arm-rest with storage and the cargo-area raised to offer more capacity.

That choice resulted in valuable real-world data. All that telematic activity provided a vital understanding of how the system would operate in true driving conditions, but without interfering with upgrade & diversification efforts underway at their dealers. Remember, it's about changing the entire fleet, the whole product-line, not just offering a token vehicle. That has gone well, as we see the upgrades to Camry & RAV4 hybrids and the introduction of Corolla hybrid taking place. At the same time, there's some tweaks to Prius Prime on the way.

In other words, taking the time to consider the bigger picture along a larger timeline, you can see what Toyota is really doing.

5-02-2019 **Expectations.** Sadly, the reply back was one of little substance: "*I do think Toyota's position as the acknowledged pioneer and industry leader in this technology has been diminished by their own doing - to my disappointment.*" This is where knowing your audience is necessary. Posting online among enthusiasts who border on crazy-fanboys from time to time, you really need to be aware how little they represent mainstream consumers. So when supposed controversy comes up, remind yourself how the typical consumer most likely will never be part of any of that. In fact, most what even understand what the supposed problem was. They'll just simply see the outcome as what was an obvious step forward. In reality, it's never that clear. This is why expectations must be set. No clarity about that path forward, no progress can be made. For this, we must define what "*success*" is. That's why I always ask for goals. It helps identify scope & timeline. The topic of "*leader*" is so vague, it could mean anything. We see that too. Different people have different definitions. So, what they expect differs. I made sure it was quite clear from my perspective: How leadership is defined is based upon product life-cycle. Upon the early stages (low volume, high cost), it is a reasonable expectation for a large manufacturer to be a pioneer. But as the product matures (several generations later), the expectation changes. Upon that later stage, it switches (high volume, low cost). Toyota is very much pushing to be the leader in that regard.

5-02-2019 **Change.** Most people simply don't pay close enough attention to notice how change actually takes place. It occurs over a long course of time, but they don't notice it until something grabs their attention. In other words, they don't seek it out. That quest would reveal the components at play, leading to an understanding of influences & barriers. Instead, it is usually something like this: *"Afterwards, when I had time to reflect, I realized at least for me that was a ridiculous adventure to go through to buy a car. One I will never consider again."* That was the comment posted following a chaotic hunt to find a Prime to purchase. It's what happens when you jump without any preparation. I sounded off, knowing he had already made up his mind, but to properly follow up with the on-going discussion and to give others something to consider:

Having mainstream expectations during this early-adopter stage will inevitably lead to disappointment. You need to be realistic about timeline. Paradigm shifts do not happen overnight. The industry is still just introducing first choices, experimenting with configurations while very much depending upon subsidies to get established. We are many years away from the ordinary customer shopping experience.

With the case of Prius Prime specifically, we know there's a mid-cycle update on the way for 2020. That means there's no benefit to ramping up inventory of the outgoing model... especially when you take the Osborne Effect into account. Making matters worse, the industry itself is faced with having to deal with fallout from Innovator's Dilemma... specifically the problem GM created by making Volt too specialized, causing market confusion in the process.

Think about what it takes to build vehicles requiring large quantities of product not scaled-up yet for high-volume. (Toyota sells over 10 Million new vehicles annually.) Think about what it takes to ensure salespeople & mechanics are well informed about the new product you are rolling out. That's a monumental challenge to do it right. Also making it both competitive and profitable requires a lot of time.

That everyday shopping experience you hope for will happen, eventually. Look at what happened with hybrids. You can now go to a Toyota dealer and choose between several different choices. Deciding between a hatchback (Prius), 3 different sizes of sedan (Corolla, Camry, Avalon), and 2 different sizes of SUV (RAV4 & Highlander) is now totally realistic. We will likely be getting the C-HR hybrid here in the not-too-distant future as well. All that took awhile though. The same will be the case for plug-in hybrids.

What other legacy automakers will be offering anything in quantity anytime soon?

5-02-2019 **2020 Prime.** To my delight, the announcements of the mid-cycle upgrade for Prime came right on schedule. Summation of what was to come and when was dead on. That shows I am carefully & comprehensively observing the factors at play and have correctly recognized the patterns. After 20 years, I should have a clear understanding of Toyota business practices and how they reflect upon the industry as a whole. Influence of other automakers' actions plays a big role in Toyota decisions. Unlike what enthusiasts expect, Toyota does not operate in isolation. That's why "EV Market" reference should not be taken seriously. What happens on the larger scale is what matters, not the motivation of enthusiasts. That's why I posted this in reaction to the press-release we got from Toyota just an hour ago: Commuting in mine is entirely electric. I enjoy the EV driving experience and see how Toyota's effort will appeal to the masses. No tax-credits or gimmicks. It's just the next-gen advancement of their hybrid system. 1,259 miles from my current tank, with a 1/3 of it still left. That works out to 198 MPG. In other words, the feelings expressed from a few uptight enthusiasts unwilling to accept Toyota's focus toward offering an affordable solution for their own loyal customers and showroom shoppers really don't have any impact. Toyota is targeting the mainstream market. Prius Prime clearly for that audience. Think of how Corolla and RAV4 hybrids also offering a plug will change the landscape, as well as the posting here.

5-02-2019 **Press Release.** This is what we got from Toyota today: *"New upgrades for 2020 include: New 5th seat for even more room. Standard Apple CarPlay, SiriusXM and Amazon Alexa compatibility. Two additional 2.1A USB ports for the rear passengers. Black interior accents to replace previous white accents for a more premium feel. A new sun visor extender. A relocation of seat heater buttons for front seat passengers for easier usability. New grade strategy that offers LE, XLE, and Limited Grades."* That collection of refinements is exactly what I had expected to hear about. What I don't expect to be told is a change to the battery-pack. There's no reason to draw any attention to cell/stack arrangement. It should go without saying that continuous revision takes place. That's a reasonable expectation. On-Going improvement is how progress occurs, not profound overnight change. Toyota tests the market with limited rollout. Knowing the entire industry is shifting to SUV, where the preference for larger vehicles has already taken hold even though there is still some denial, Toyota took the risk to find out if a change to interior layout would be embraced. It wasn't, so they adjusted accordingly. It's ironic how antagonists claim Toyota is unwilling to try anything new, yet turn a blind-eye when evidence to the contrary is presented. This is why change is perceived so differently for different people. If they don't pay close enough attention, they'll never notice something like the 4-seat arrangement was tried. For that matter, they'll never know that Toyota took the risk with a raised cargo floor either. That's annoying, but quite understandable.

5-03-2019 **Clues.** Some people simply won't ever get it: *"The nutty thing is that they could increase the size of the battery and range at -no cost- to the customer. The federal tax rebate is partially based on the battery capacity..."* Of course, some of that could come from calling it a rebate. That implies everyone will get one. In reality, you must have enough tax-liability to collect the full tax-credit. Some people won't. Consequently, they'll only be able to claim a partial amount or none at all. The passing along of such misleading information is a clue that purpose may not be understood. I watch for clues like that... and pass along my observations: GM proved that gaming the system for short-term gain was a terrible idea. Volt ended up becoming a vehicle for conquest sales as a result, never actually changing the status quo. Loyal GM customers kept purchasing the same traditional vehicles and Volt died without a successor when the tax-credits were used up. Remember, intention of that subsidy is to help each automaker alter their own fleet, making it greener for their own customers. That's why each automaker got their own allocation of 200,000 to use on their own timeline. Adding capacity wouldn't do that. It would simply make Prius Prime too expensive after that 200,000 limit is reached. With a starting price of \$27,600 and that base model loaded with a surprising number of features, Toyota has a long-term winner in the works. It's a design we are already seeing carry over to Corolla hybrid. The same could easily happen with RAV4 hybrid too.

5-03-2019 **Long Term.** Dealing with enthusiasts always meant a forced short-term perspective. They simply didn't care what happened next. It was all about establishing a foothold. Cost of doing so wasn't a concern. That was their downfall. In addition to the obvious monetary sacrifices, they were giving up chances to do more along the way. Most notably was their dismissal of the importance of having an ally. Pride got in the way, causing the loss of purpose. They really would lose sight of what was truly important. That's why I pushed on a regular basis for goals. From time to time, I'd get an answer to my question. Sadly, the objective stated always varied. It was a moving target without any clear progress forward. This summed it up well: *"The Volt was the best-selling EV in US history until it was cancelled. On what basis do you claim that the Prime is a "long-term winner" with even worse sales than the "terrible" Volt?"* Looking backward without anything truly being achieved (measured by the lack of any actual change) makes it all too clear there wasn't any real understanding of what the technology would or should deliver. What were the plans? Not having a vision for the future is a very real problem. In terms of business, that's a warning. Something of substance must be accomplished. All the efforts we saw ended up just being for show. When the tax-credits hit phaseout, GM simply reverted back to old practices. We have a nice selection of guzzling SUVs now and a mid-engine sports car on the way. What kind of long-term plan is that? I'm growing tired of the rhetoric, but fortunately don't have to deal with it too much longer. This nonsense is coming to an end. The voices of enthusiasts are fading and the queries of newbies being to sound like a chorus. I certainly welcome that change. But there's still some reflecting upon what happened to do: Volt never attracted GM's own showroom shoppers, had a MSRP far too high to survive without subsidies, and wasn't able to diversify prior to tax-credit phaseout. Toyota is clearly making efforts to avoid each of those mistakes.

5-04-2019 **Victory.** Sadly, there are a few who keep pushing that narrative of early-adopter sales representing what mainstream consumers will buy. That's because they only see the numbers. The cost of dependency or value of loyalty simply doesn't come into play. They don't consider that an factor to measure. So, comments like this continue to persist: *"Again, Toyota has fewer sales of a less-expensive car in a more crowded market. I don't see how that's a victory."* It makes you wonder how long that will continue. With the audience for Volt now gone, asking *"Who?"* isn't necessary. The vehicle, nor its technology, is being produced anymore. It died... exactly as predicted. GM's obsession with conquest handed victory to whomever was willing to stay true to purpose. Toyota set goals that didn't depend upon subsidies and didn't depend upon attracting outside buyers. Starting with hybrid technology, there was a persistent effort to change their fleet. What could be found on their dealers' lots would transform over time... which is now quite apparent with so many highly efficient, affordable choices available. We'll see them become more and more electrified over time. It will make the decision for carrying more of them and fewer of the traditional choices easy. That's how it should be done. That is what we are now witnessing. Yet, some refuse to see it. I'm happy to point that out: There it is. The same mistake so many others made... not recognizing who the market is.

5-04-2019 **Doing It Right.** That didn't take long. I wondered if the wait for an incoherent argument in defense of Volt would come soon. There simply isn't anything left to support a plan that made no progress after all those years. With every possible excuse exhausted, a feeling of defeat is taking over. Phew! What a waste of opportunity. So much could have been accomplished. Oh well. Now it is time for true leadership, not conquest. I was happy to provide the detail:

Timing & Circumstances tell us the real story.

Volt-1 failed. Hope had been that it would become a huge sales success, a technology to "*leap frog*" the leader, Prius. Sales just barely scraped along (averaging 1,600 to 1,700 monthly). So, effort to postpone that victory began. Volt-2 fizzled too. Sales remained flat. Reach never grew beyond early-adopters. GM's own loyal customers simply weren't interested.

Hope to become a technology to replace traditional offerings faded quickly. Spin was that GM remained a leader, despite heavy dependence on tax-credits and an abrupt change of strategy. All that work to promote "*EREV*" as a solution was abandoned in favor of its own antithesis. Bolt never achieved that needed growth either.

Since way back when the Two-Mode plug-in prototype was being promoted, we had expected GM to diversify their technology to offer it on a platform they could actually sell in high-volume. That would be an Equinox or Trax using Voltec. It never happened. The government subsidy for that very purpose was squandered on conquest instead.

This is why the approach Toyota used to transform Prius to plug-in Prius is so important. It's an affordable design that can be easily applied to its other hybrid offerings. In fact, later this year, it will happen for Corolla hybrid. So, it's reasonable to expect we'll get a RAV4 hybrid with a plug in the not-too-distant future... which would indeed draw interest from Toyota's own loyal customers.

Toyota is taking the time to do it right.

- 5-05-2019** **Leapfrog.** It's remarkable how many times you see someone make a statement like this without any follow up: *"So instead of barely, almost, kind of catching up Toyota should have leapfrogged."* I posted my response just 12 minutes after it had been posted. So, I'm quite curious if I'll get anything constructive in reply. In this circumstance, the comment was about Toyota's choices related to the infotainment system. It could have been anything. We see examples all of the place routinely. I posted: That term *"leapfrog"* has become meaningless rhetoric. It's easy to understand why too. Just ask anyone who's serious about improvement what improvement actually means. That absence of detail and lack of agreement make it all too clear the path to an upgrade is a very real problem. Want a different example of the same problem? Look at the mess we have with public charging-stations. After all these years, there is consolidated message about how they should be used and who should use them. You'd think the answer to that would be obvious. Digging for information, you end up with many conflicting messages. Please tell us with a level of clarity, as if you were funding the effort, what you would like. As a software engineer, I've discovered asking that question tends to end complaints. The user comes to realize they don't actually have solid requirements for me to program. This is why partnership with business customers is so vital. You need an ongoing exchange of information. With the case of Toyota, this is why they have employed a phased rollout. That approach really irritates some enthusiasts... to the point of them acting in frustration like trolls... but it is a proven method for achieving actual progress. Watch for detail and try to pass it along.
- 5-05-2019** **Facetious.** I was really hoping this new member on the big Prius forum was just being facetious. That kind of obnoxious behavior, showing no interest to consider what others are sharing, is frustrating to deal with. When I got this, I was done: *"You expect the customer to write the spec for you?"* He simply didn't care. I posted and moved on: To complain without providing any constructive feedback is a waste of everyone's time. Ever notice how the act of asking what a consumer actually wants will often result in something that isn't well articulated? It simply makes no sense for you to assume the provider will be able to accurately guess what you expect. That's why extensive study of consumer behavior takes place. Toyota, just like other providers, will collect and carefully observes massive amounts of real-world data with the hope of figuring out what you don't bother to take the time to explain. With over 25 years of experience trying to understand what the user actually wants, verses what they claim to want, I can tell you that anyone who makes an effort to describe what their need actually is will get taken seriously. Those who don't are just looking for an audience to vent upon.
- 5-05-2019** **Listen.** Even though some new voices are obnoxious, far more are simply looking for somewhere to share thoughts: *"It sounds like Toyota is betting that they can quickly turn something like a Prius Prime into a full electric quickly rather than investing in all-electric design now."* Stuff like that is welcome. They tend to stay open-minded, asking for more information so they can draw their own conclusions. For them, I'm happy to contribute little nuggets of detail to help that process along. In this case, I could even do in with respect to the sound theme: Listen to the whisper, not the rhetoric. That all-electric 152 hp drive system already in use by Mirai would make a nice setup for the next-gen Prius.

- 5-06-2019** **2020 Timing.** Accurate predictions come from careful & meticulous study. Both the 2001 & 2012 rollouts were mid-cycle upgrades, though they could easily be labeled as generations. People don't recognize change easily, so that's a rather pointless debate. I was an active participant with both though, so my perspective is quite different. I recognize how Toyota performs their study and what they look for. Knowing their goal of sustainable high-volume profitability being of major importance, it's easy to see beyond rhetoric. They don't find disruption to dealers acceptable. Dumping a profoundly new technology without any clear direction, as GM did with Volt, upon them is totally against what they've demonstrated over the past 20 years. That's why I saw a mid-cycle upgrade as a very realistic expectation to set. Limiting availability and the obvious burn down of inventory should have made it obvious to everyone watching, or at least those actively participating online. Instead, I got quite a bit of pushback from sharing my observations and declaring a prediction of a very short 2019. It made sense that Toyota would stay clear of GM fallout, being well aware of tax-credit dependency and the long-term damage that results. 1 day after 1 month of phaseout sales, we get news of the upgrade. Today, we got news that the path is wide open for what looks to be a wait of just a little over 1 month until 2020 deliveries begin. Sweet!
- 5-07-2019** **Opportunity Missed.** Some people just never learn. Ugh. It's not even worth quoting the nonsense anymore. Here's my reply: Yes, repeating the same mistakes... Volt was never targeted at the masses, even though it was marketed that way. The configuration was too expensive, overkill for what was actually needed. Hope was the "*it's worth it*" reasoning would catch on. Affordability is a requirement that enthusiasts turned a blind-eye to, hence so many problems... notably, the way to market Volt. The nonsense of EREV really screwed up the message to consumers. Simply sticking with "*plug-in hybrid*" would have been a wise move. It's over now. Voltec didn't get diversified prior to tax-credit phaseout being triggered. That opportunity was missed.
- 5-07-2019** **Superior.** There's a small amount of rhetoric still, but not much. Overly generalized claims like this are all that's left: "*Volt proved GM could make a superior Prius.*" Watching the endgame play out has been interesting. It was undeniable that they long hoped for miracle wouldn't happen. Rather than actually change the status quo, the outlook of enthusiasts was conquest. Their focus on bragging-rights was shallow and self-deprecating. Such a perspective cannot be sustained. Realities of business eventually become too much to evade. It's like building up debt. You can really enjoy yourself for awhile, but at some point it all falls apart. Some take much longer to learn that lesson than others, as I was happy to point out: That definition of "*superior*" is one of only enthusiasts. Checking with the true customer, GM dealers, you get a very different reply. They'll point out importance of the vehicle having a competitive cost. Volt was never affordable, period. GM's pricing goal of "*nicely under \$30,000*" was never reached. Toyota, on the other hand, nailed it with Prius Prime at \$27,600 nicely loaded for the base 2020 model.

5-08-2019 **Reminder.** Stuff like this reveals how little effort is made to look at the bigger picture: *"Don't worry, it will run out eventually as more and more Prius owners get converted to other brands."* It comes from the mindset of conquest. The early-adopter perspective is that automakers are competing with each other. They absolutely refuse to look at the situation from the point-of-view where tax-credits have all been used up and those offerings are then competing with other choices on the dealer's showroom floor. That idea of competing directly with traditional vehicles had been fought against with such intensity, it was truly remarkable. Volt enthusiasts were the worst, absolutely refusing to acknowledge a market where Equinox was their greatest foe. That level of denial was amazing. They have been paid the price. Seeing them welcome their own destruction was an interesting experience. I patiently observed, reminding them along the way of goals. What mattered was shrugged off though, sometimes intensely fought, never taken seriously. I asked a lot of questions along the way... and still do: Which will other brands offer to compete with plug-in model of RAV4 hybrid? Remember, it's all about diversifying the technology. Spreading it to other vehicles, like Toyota giving Corolla hybrid the PHV treatment, is already underway. That's the fundamental mistake GM made with Volt. Success requires rollout to other choices... like a SUV. Again, what can we expect from automakers to compete with that?

5-08-2019 **Tidbits.** Reaching new audiences means dealing with a hodgepodge of information. Often, a fact will be sighted incorrectly. That misunderstanding can spin out of control at some point, if not properly addressed. When it comes to efficiency, that's common. Many make the easy assumption that greater battery-capacity equates to greater efficiency. In reality, the reverse can actually be the case. If that range isn't actually utilized, you're carrying around unnecessary weight. How the electricity is consumed is what matters... which is why *"gas consumption"* was always a hot topic. People would misunderstand MPG as a result. That's why MPG isn't used as a measure of efficiency in most of the rest of the world; instead, others elsewhere state consumptions in terms of how much fuel is consumed to travel a specific distance. Our own EPA introduced that approach for electricity, but the market is far too premature to recognize the importance. So for now, we are stuck on the MPGe rating. That stands for "Miles Per Gallon Equivalent". Few understand how it works either. Making matters worse is when the two get confused with each other, as it was today. I pointed out the error: Mixing up MPG with MPGe is a common problem. Prime's 133 MPGe wins hands down over Clarity's 110 MPGe. Being more efficient with EV drive is a big deal in the overall equation of both production cost and ownership cost. Remember overall goals. For Clarity to deliver higher MPG results, you have to drive further routinely between charges. Otherwise, you'll end up with a Prime that's difficult to compete with. Mine is at 1,529 miles with the current tank, resulting in an average of 189 MPG. Also, you don't seem to be aware that Prime became a 5-seater a few days ago. Production of the 2020 just began and shipments are expected to begin in a little over a month.

5-08-2019 **Schooled.** Sometimes posts are so confusing, you wonder if the person has any clue how the system actually works. Of course, some wanting to undermine will intentionally confuse matters by posting outdated information and facts unrelated to the subject of discussion. It's all fairly maddening. That's why many online are either lurkers or pushers after awhile. You end up forming an opinion of some sort if you hang around long enough. This is what brings about turnover, especially when a new generation rolls out. So, I provide background from time to time. Never really knowing who you are dealing with necessitates reminders. Though on some occasions, you know you are dealing with a person hell-bent on stirring trouble. That was today, when I punched back with some education: Toyota's approach is clear evidence of planning well ahead, establishing a design that can easily be augmented without requiring major changes. To make Prius into Prius Prime, a one-way clutch was added. This allows MG1 (which is normally used as a generator) to be used for propulsion, adding to the output from MG2. Combined with the larger battery-pack, far more EV power becomes available. It really is that simple. Each of the hybrids, like RAV4, will be able to take advantage of the same approach. It's a cost-effective means of reaching a very large & diverse audience.

5-08-2019 **Desperate.** Watching a troll become desperate is interesting. They all eventually back themselves into a corner. Some figure out how to wiggle out of that situation. Some end up losing attention to the point of giving up. Whatever the situation, you just need to remain true to goals and never lash out. I enjoy the effort to find constructive rebuttal material. They push you to searching for clues where you wouldn't ever consider usual. For example, the relentless attacks on Toyota's fuel-cell program overlooked what is now so obvious. Mirai is an EV platform that would provide a great template for a Prius without a gas engine. The size of its electric propulsion system would be ideal for that. It's just the right balance of power & cost, when you connect it to a battery-pack. Antagonists quickly recognized that fact when I discovered & shared that information. It was an oops on their part on a colossal scale. No one had bothered to step back far enough to notice. Being the one to point it out was a delight. For the most part though, I don't need to pull out argument material on that scale. It's still effective to keep focus on hybrids: With the mid-cycle update a little over a month from first delivery, it's pretty clear the old narrative has fallen apart and new spin doesn't have an audience. Toyota's larger hybrids offering more power and more space for batteries demonstrate it's a waste of time bothering to respond. We all see Toyota setting the stage for a major push away from their traditional choices by providing a variety of hybrid options that will all easily transition to plug-in hybrid. It's a simple path for dealer & consumer to follow... something all the other automakers are scrambling to also deliver... hence the obvious attempts by some to distract & confuse. Yup, desperate.

- 5-09-2019** **Non-Hybrid Plug-Ins.** This was wonderful to read: *"The only narrative is the one spun by a Toyota fanboy who makes up story about how Toyota would extend its non-hybrid plugins to PHEV."* The post came from not just an antagonist, this was an outright hater. He just plain doesn't care. Posting anything possible to undermine Prius is his goal. It's quite obvious too. I wonder how much longer he'll survive with the new discussion approach. That structure makes attacks easy to avoid and trolls easy to ignore. For me personally, I was amazed at his level of anger. That confused message made that a very real problem to retract. It made no sense. He backed himself into a corner and revealed desperation... which I called him out on: Your own spin of *"non-hybrid plugin"* is truly bizarre, worthy of being such a blatant attempt to undermine PHEV progress, it should be bubbled up to the top of the discussion thread rather than buried in a long string of replies. Toyota already offers Camry, Corolla, Avalon, RAV4, and Highlander as hybrids in this market. That's a large portion of what you find on dealers lots here in the United States with hybrid models. C-HR is also available as a hybrid in other markets. Prius got the PHEV treatment 2.5 years ago and it is already getting a mid-cycle upgrade. Corolla will become available as a PHEV later this year in China. Right before our eyes, we are seeing the progress forward with greater electrification taking place. The most recent tank in my Prius PHEV (aka Prime) is almost complete. That 1,573 miles so far equates to 190 MPG. Spinning that to whatever you want won't change the outcome. We are seeing Toyota's fleet advance forward in a way no other legacy automaker has been able to achieve.
- 5-09-2019** **Observation.** This type of assessment of market potential is quite common: *"It's great that the 47-mile electric range Clarity PHEV is giving the 25-mile electric range Prius Prime a run for its money..."* It comes from just watching sales. No study or understanding of the larger market is a very, very common problem. People just report what they see, making the assumption that pattern will apply to everyone. It's a grave mistake... one that played out entirely with Volt. Remember all those *"Who?"* asks. Each time I posed that question, there was a flurry of rhetoric attack as an answer. That was a dead giveaway their stance was or soon would experience trouble. And sure enough, GM killed Volt. That premiere technology expected to become a choice for many never reached beyond niche buyers. Those early-adopters taking advantage of tax-credit opportunities were never a reflection of the market to come. Mainstream shoppers are very, very different. That's why offerings like Clarity must be carefully studied for potential, looking beyond the configuration available today for what is clearly a limited market. How will the technology reach ordinary consumers? I put it this way: Anecdotal observation doesn't equate to much. While the tax-credits are still in play, all we are really seeing is just pre-game trials against other new entries. The real game starts when plug-in offerings must compete directly against the true competition... traditional vehicles. Once the showroom floor of a legacy automaker, it boils down to the price on the sticker. Without any subsidy available, you quickly find out who prepared well and who was just working the crowd. Toyota is clearly setting the stage for mass acceptance. That low MSRP for Prius Prime and the affordable means of also making the other Toyota hybrids plug-in models is a formula for success with a great deal of potential. We'll see Corolla hybrid become a Corolla PHV this year. Following that could be RAV4. Few will care about more range when an entry-level choice can deliver so much. Don't forget how incredibly efficient the hybrid system is following depletion of the plug-supplied electricity... and how well proven the reliability is.

5-10-2019

Spoiled Market. When Volt was first revealed, people feared that reception of delight would turn into an introduction of disaster. Reason for that was simple... but an easy lessoned-learned to forget or overlook. It's origin was not a subject of debate. Decades back, GM had rolled out their solution to the gas-price crisis. Rather than focus on small cars to compete, they went all out on diesel. Trouble was, their diesel engines were horribly unreliable... so much so, it spoiled the market. That appeal was soured so bad, other automakers abandoned their own diesel plans. That's why there was a concern from the beginning that GM would do the same with Volt. I saw that trouble brewing immediately. That's how the "*vaporware*" posts ended up with me providing contributions. Seeing that goals were set well above what was realistic for that calendar and well above what cost would reasonably justify, there was to possible was to deliver so much in such a short amount of time. It was the "*over promise, under deliver*" problem ramped up to a whole new level rhetoric. It was if nothing had been learned from the Two-Mode disaster. We now have evidence the Volt disaster has indeed risen beyond that, to the scale of diesel fallout from decades back. Evidence of that is undeniable. VW will not be offering their first from-the-ground-up EV here in the United States. They see this market as disinterested in the technology, not worth the bother. GM failing to achieve a successor to Volt is a big factor in that decision. It was regarded as the prominent technology for legacy automakers. Being able to diversify the offering for high-volume profitable sales would have opened the door to opportunity for others; instead, Volt was discontinued without a successor. The supposed replacement of Bolt as withered on the vine, a fitting cliché for expectations of fruitful growth. This is why Toyota worked so hard to avoid fallout. I'm quite thankful it worked. After so much rhetoric, there was risk of collapse across the board... especially with the magnitude of political influence. Being left to build up our own market isn't so bad either. It's not like Prius supporters don't have a history of that to provide a guide to doing it again.

5-11-2019 Bird Crap. Discussion of a constructive nature is emerging. To watch things fall into place after so long having to deal with online nonsense is rewarding. Of course, that's what I've done at work for decades. You don't build great software overnight. It takes an enormous amount of study to get it right. But after countless upgrades and lots of feedback, you achieve that long-term goal. That's why I felt so fulfilled upon reading this: *"Spending most of my days at a dealership, I can firsthand tell you that Prius' in general are nothing more than bird crap collectors right now..."* It was objective comment inserted into a thread about 2020 inventory. The upgrade to Prime is getting serious attention from outside the group-thinkers already. That's the sign I've been looking for. Those unfamiliar voices are wonderful. The same old spin from the same old daily posters is just a waste of time and a distraction. Comments like this one today confirm the landscape is changing. Toyota is reaching a new audience. Yeah! Anywho, this is what I posted in reply:

We've known about Toyota's intent to transition Prius to a plug-only offering for an entire decade.

Back with the gen-2 prototype, it demonstrated battery technology was simply not there yet. Even though the system could deliver 100 km/h (62 mph), the return simply wasn't realistic. Capacity was too low and cost was too high.

The gen-3 offering was the first to actually be offered as a choice to consumers. Toyota intentionally limited it to very select markets though, knowing it would be best to stay as a real-world data-collection vehicle rather than something for the masses. That's why there was no reason for high-volume production yet. After all, it was rolled out mid-cycle.

Prius Prime (the gen-4 plug-in model) is the first with potential for the masses; however, Toyota kept it limited too. The goal was to get feedback about what it would take to drop most of the regular Prius models so the plug could be favored instead. That's why quantity & scope was limited... until this mid-cycle update.

Notice how we have no information whatsoever about how the 2020 battery-pack fits? What are the odds that Toyota didn't allow their engineers to indulge. Restacking the pack for a cell arrangement capable of fitting better while at the same time squeaking out a little bit more profit was quite realistic.

Key to that success though was to invest heavily in the rest of the fleet in the meantime. Getting Camry, Corolla, RAV4, and Highlander all upgraded was an essential part of the bigger equation. Allowing non-plug Prius choice to be reduced to AWD and Limited Edition models pave the way for Prime. You want a regular hybrid, just choose one of the others instead.

You'd think those plans would be obvious. Turns out, that's not the case. Most people only have a basic understanding of micro economics and have no idea what macro economics even is. So, we have to deal with a lot of incorrect assumptions and even more rhetoric about Toyota intentions.

Keep in mind, dealers are Toyota's true customer, not consumers. When you start to see

that picture, it becomes easier to understand the relationship regions & country have on supply & demand. This is why there was a burndown of 2018 inventory and 2019 inventory was so limited. In fact, some of us recognized that pattern and stated there would be a mid-cycle upgrade this year with potential for a very short 2019 offering. After all, late Spring rollout for mid-cycle is nothing new. That's how I got my 2012 Prius PHV.

Being able to compete directly against other vehicles on the showroom floor is a massive undertaking. Don't fall for any claims that don't take that essential component to successful business into account. We aren't dealing with an "EV market" only. That terrible early-adopter perspective has proven a grave mistake... quite literally, since Volt is now dead. For a plug-in hybrid to sell in high-volume without any dependency on subsidies, it must appeal to the casual shopper. Prime's design with heavy attention to low MSRP wasn't easy for Toyota to achieve.

Watch how interest is stirred for the 2020 Prime. Expect that paradigm-shift intent to finally get noticed.

5-12-2019 **Acceptance & Balance.** The ability to fail quickly and move on (the "Agile" method) is not something certain enthusiasts will ever embrace. They fight and fight and fight for a cause that sounds good, but doesn't actually have a viable business path. That's what sets them apart from supporters. If something doesn't work, you acknowledge the lesson learned and confirm goals are still sensible. Instead, we get excuses & blame. Ugh. That's still what a few are doing as damage-control for Volt. They just plain don't want to accept what happened... the very thing that sets them up to repeat the same mistake, yet again. In this case, it was refusing to acknowledge this comment on a discussion about Honda's effort to offer a plug-in hybrid: "*How is/was the Volt in any way better than the Clarity? Volt is too small, cramped.*" I was obviously annoyed. So, I jumped in with: It doesn't matter. The problem with Volt was always GM's attitude toward the technology. Configuring a niche was fine for initial rollout, but betting the farm on it becoming the source of sustainable high-volume profitable sales with a recipe for disaster. GM never planned to diversify. That's an essential next step in any type of effort to change the status quo. Initially, constructive feedback was to simply offer a second model with a more affordable configuration. Enthusiast pushback turned that into the suggestion to offer that technology in Volt on a more appealing platform for GM's own customers, like Equinox. Instead, GM focused on making Volt even more appealing to enthusiasts. They ended up rolling out a next-gen Volt, which clearly emphasized traits showroom shoppers would have no interest in paying a premium for. They also rolled out ELR, an even more expensive version of Volt. It was the problem of "*Innovator's Dilemma*" playing out exactly as supporters expressed concern about. Thankfully, other automakers didn't follow GM. Seeing Honda favor a layout that isn't cramped is great. The potential for Toyota to do the same with their Camry or RAV4 hybrids adds to that sentiment of balance. What did GM's choice to push an enthusiast favored niche accomplish?

- 5-13-2019** **Subaru Hybrid.** Spotting a new purchase (no plates yet) of a Crosstrek on the road today left me wondering. I couldn't for the life of me remember at that moment if there was a hybrid model prior to the plug-in and what to look for on the upcoming plug-in model? Fortunately, I was able to capture the moment with my dashcam. Afterward, I looked up badging on internet. Turns out, it wasn't the Subaru with Prime's tech in it. So, I still haven't seen one yet. From such a small automaker, that's no surprise... though, I have noticed quite a number of Crosstreks on the road. It's only a matter of time... and I now know exactly what to look for.
- 5-14-2019** **\$1,000 Fee.** Imagine getting hit with that each year when renewing registration for your vehicle. That's what owners in the state of Illinois are now facing. It's an extreme for collecting funds in place of what would ordinarily be accounted for simply through gas-tax. The logic of EV miles not paying for road repair & replace is sensible. But with an amount so massive, that's nuts. What makes such a huge amount realistic? A traditional vehicle getting 35 MPG over an annual travel distance of 15,000 miles will consume 429 gallons of gas. If the typical tax is \$0.25 per gallon, that only comes to \$107.25 for the entire year. How can nearly 10 times that amount be justified for an electric-only vehicle? That's absolutely absurd to think it could be looked upon as reasonable. Talking about extreme overkill. Why not a fee of \$125 instead? Such a proposed effort to provide proceeds for maintenance... which are very difficult to account... is clearly a move to discourage the switch to electricity. You can easily imagine some type of oil-industry lobbying to influence a political proposal do drastic
- 5-12-2019** **EV Support in Japan.** We get comments like this on a regular basis: *"Ironically, Japan is way-low on that list, because of their insistence upon developing FCEVs over BEVs."* That often comes from jumping to conclusions using limited to no actual data to support them. Many only see references to hydrogen support and have no idea what actually takes place behind the scenes in technical decisions and public releases. It's very easy to cherry-pick information too. Simply filtering what's shared is how misconceptions are intentionally spread. In other words, some people feed narratives. Whether that is done with purpose or unknowingly doesn't matter. It's all about making sure specific facts aren't ever shared. For example, not having 240-volt service available for most homes in Japan is a vital tidbits never mentioned. That would obviously impact decisions related to the size of a battery-pack offering. What benefit is there to a capacity larger than what an owner can reasonably recharge overnight. With standard voltage lower in Japan than our lowest here in the United States is a really big deal... yet, rarely acknowledged or even known. I kept my response to the misconception feeding short: That would be an anecdotal observation leading you to decision based upon incomplete information. Most households in Japan only have 100-volt lines available. Imagine how inconvenient it would be to have that as your only means of recharging an EV. It would take forever. That shortcoming is why Prime over there has CHAdeMO as an option.

5-16-2019 **Short-Sightedness.** If you pay close attention to the rhetoric, sometimes a shortcoming to their line of argument will be exposed. In the case of constantly trying to push a narrative portraying Toyota as unwilling to embrace EV... which is long-term... I came to realize no one was addressing mid-term. It only takes a moment of thought about what those plans could be when you recognize the importance. Toyota has a clear path to get from here to there. GM never did. Watching Volt trapped in the past, never advancing forward eventually got noticed. That's how Bolt name about. In fact, that's how the similar sounding aspect was derived. It was obvious right from that moment it was announced confusion with those similar names would help conceal the dramatic change of plans for GM. Failing to have anything capable of achieving the next step in terms of spreading Volt technology to some mainstream vehicle with the intent of competing directly against traditional vehicles (the undeniable next stage for any initial rollout) meant giving up and trying something else. Abandoning that technology was a rather drastic move, one that does not have any path forward. It's incredibly risky to expect customers to embrace something so unfamiliar. Sure, early-adopters don't mind. But for ordinary people who no little to nothing about how their current vehicle operates means a world of unexpected consequences to deal with. There's simply no way to set realistic expectations. Fortunately, not all automakers are that short-sighted. Hopefully, most of the enthusiasts will wake up to reality too. There are consequences. Leading by example is the most effective means of change. Perhaps this will help: People who complain about "*self-charging*" are not acknowledging or recognizing Toyota's effort to phaseout traditional vehicles. When that is achieved, there will be two fundamentally different types of hybrids available. Use of the "*self-charging*" label makes it very clear it is different from the "*plug-in*" model. Planning ahead like that is good business. Contributing to confusion by fueling enthusiast rhetoric is unfortunate.

5-16-2019 EV Owners Meeting. This evening's (here in Minnesota, where our group is quite large and quite diverse) was quite informative. I wasn't aware that the effort to provide a state-level tax-credit was still active. \$2,500 for each new purchase would be great. Unfortunately, that is being fought against really hard. Making matters even worse with respect to political lobbying is a proposed \$200 fee per charging-station. Imagine owners of a store or resort facing that payment each year for each charging their offer for their patrons. How is that even being considered? For what purpose? There's no benefit to what will clearly be looked upon as a discouragement. Sadly, our group is keenly in tune to how much the general public is oblivious to these happenings. The year's legislative session will end this week without them being any the wiser. Most people still know very little about electric vehicles or charging. Even fewer know anything about the detail related to politics. Fortunately, we recognize the potential. That's what we are trying to teach others about. For example, I routinely hear that our grid is incapable of serving a large number of vehicles for charging. That's pure nonsense. We already see that type of demand each summer. A/C power is readily available. We manage just fine. That same load can be provided for homes needing overnight vehicle charging. It's not a big deal. Our infrastructure already supports it... no upgrade needed. In fact, that provides opportunity rural areas are hoping to exploit. Those co-ops know they'll have a very difficult time getting local businesses to offer chargers. But in homes, there's a great deal of potential. So, we get many exchanges with their representatives about how to achieve that. Appealing to customers is a win-win situation. They'll get to sell more electricity, even for those with solar. Our effort now is to spread the word about things to come. In the meantime, we're establishing relationships with those who can spread the word. For me, I have an interview scheduled with a national representative and I'll be organizing a discussion panel at a local library. I'm also looking forward to starting up gatherings again, now that availability of Prime is looking to ramp up. In other words, it's all about being proactive. Finding a group of supporters to make that happen is great.

5-17-2019 GM Progress? Remember all those claims of "*vastly superior*" to that resulted in a position of supposed leadership? I heard so many "*behind*" insults it was truly remarkable... and never made any sense. GM demonstrated you could have a great performing electric-vehicle if you brushed aside concerns of cost and just squeezed in as much battery-capacity as possible. What did that accomplish? It certainly didn't result in any progress with regard to changing the status quo. Just go to a GM dealership. Do you see any difference Volt or Bolt made? How can Toyota be so far behind when their hybrid technology has become so prolific? The new RAV4 hybrid is extremely popular. It's a platform that can inexpensively support plug augmentation. How is that in any way "*laggard*" indication? It's undeniable effort to avoid the Osborne Effect. When the market nears mainstream interest toward plugging in, transition away from traditional vehicles across the fleet will be well underway. This isn't manipulation of attitude via press-release. It's a solid business plan. As for GM making progress, there we spy-shots of a supposed plug-in SUV posted online today. What was most interesting about that was the lack of interest. In the past, we'd get enthusiast hype stirred to an extreme. Now, there's barely a whisper. People have clearly moved on, given up on GM. The reputation of "*over promise, under deliver*" has become a burn for so many, there simply isn't an audience anymore. This is why I kept asking the "Who?" question... knowing someday this would be the outcome. Sustainable business cannot survive on conquest alone.

- 5-17-2019** **Attacking Imports.** During that long series of rhetoric for Volt, there was often a lot of flag-waving propaganda. We'd get claims of "*American*" vehicle support for a car that was nearly two-thirds foreign. So much was imported from Korea, it was difficult to have any type of constructive response. Nothing was effective to those who simply dismiss facts. The same problem persisted with Bolt until recently, when everyone stopped paying attention to GM. Focus was has become directed to Tesla, which isn't as American built as thought. There are some essential components coming from China manufacturers... which makes it subject to tariffs. The recent application for exemption from that was rejected too. Cost to American consumers is skyrocketing overall with so many sources now faced with higher prices. How do you deal with a self-imposed problem that ultimately will cause harm? Our president just plain doesn't care about the consequences. Today's announcement made that behavior even worse. The idea of superiority is reaching a scary level. There was an executive proclamation that declared a 25% tariff will be imposed on imports from Europe & Japan. Making things worse, he's attacking the brand not the product. I suspect news of fallout from this will be fresh online first thing tomorrow morning.
- 5-18-2019** **It's Getting Ugly.** This was the opening sentence on the first article I came across: "*President Donald Trump on Friday declared that imported cars represented a threat to U.S. national security...*" It's truly disturbing to see fear used in such a way. That type of manipulation of people, making them feel insecure when there isn't actually anything to fear, is a practice those well informed know all too well. You appeal to emotion, telling them what they want to hear. That version of reality is fake news. It's a narrative used to undermine... and is often effective for those who simply don't pay attention or don't want to get involved. It's group-think with terrible consequences. Needless to say, there was a press-release from Toyota about the attack. This was how they responded: "*Toyota has been deeply engrained in the U.S. for over 60 years. Between our R&D centers, 10 manufacturing plants, 1,500-strong dealer network, extensive supply chain and other operations, we directly and indirectly employ over 475,000 in the U.S., and have invested over \$60 billion in this country, including over \$1 billion in philanthropic and community-outreach efforts.*" In addition to all those American paychecks, there are over 36,000,000 vehicles from Toyota/Lexus on our roads still. What a mess. Consumers here will end up with fewer choices and those choices will be more expensive. How is that helping American families? How is that helping anything related to improved security? Think about how much better the country would be with imports helping to change infrastructure, encouraging the move away from imported oil? It's an attack on the wrong industry. How stupid can this supposed leader of ours really be?

- 5-18-2019** **Climate Denial.** I stumbled across an article today about a giant coal company filing for bankruptcy. It was Chapter 11, so there will be some type of reorganization effort. That process is revealing. Much can be learned about how the business got into that situation. That's key to understanding what the future holds. What should you expect? What will actually happen? How long will it take. This is what I had to say with regard to this particular situation: It's interesting when you have some family that actually lives in Gillette. Driving around there with my Blue Magnetism Prime, especially when back on the dirt roads, sure provides an acute awareness of how much certain areas of the country fight to retain the status quo. You see signs there proudly supporting that industry... which is extra poignant during the holiday, when you see one reminding you that coal in your stocking is the ultimate gift. There's opportunity to embrace change. The potential is obvious. Just imagine how such unfarmable land that's always windy could take advantage of turbines. Generating lots of electricity to supply other areas of the country seems like something they'd seek out, knowing that coal is doomed. Perhaps this bankruptcy file will serve as a wake-up call. It certainly has revealed that some have been well aware of the problem. At some point, they need to finally address it. Soon would be nice. So many resources have been wasted on the denial. Evidence of how it impacts climate is obvious. Solutions to that are too. It's so reminiscent of tobacco. Their fight to prevent the inevitable was remarkable.
- 5-19-2019** **Charging Questions.** We are getting a lot of them now. For example: "*40A (overkill for Prime) EVSE. Plugs to 40A 240v circuit. Charges the Prime from 0 to 34 miles (reported) in 2 hours flat.*" There is a lot to contribute. Basically, any information is a good means of getting constructive discussion. Many people have little to no background. So, even just sharing personal experience stories is helpful... which is precisely what I did today: We have 2, both the Wi-Fi enabled model. They work great for our Primes. Being able to check status, adjust settings (like maximum draw and maximum charge), and view history is really nice. A full recharge takes us 1-hour 50-minutes. Keep in mind that a 40-amp line (sustained delivery of 32 amps) will provide 200 miles of range in 8 hours. So, a 40A setup is really overkill for most of your need is overnight charging. Remember, you'll almost certainly want a second charger for your household at some point. That means taking into account now how much your service-panel can provide for capacity overall. You'll also want to consider how to take advantage of your local electricity discount opportunities. In our case, we were the very first customers for our Co-Op to request dual time-of-use lines. With that, our billing lists activity from each vehicle individually, showing the quantity of kWh usage for each pricing category (based on timing when electricity is drawn). It's quite nice. All we needed to do was pay for the extra meter (\$75) and can (\$70) during installation of the line. Another thing to be aware of is the 240-volt outlet type. Having such a standard outlet is important when shopping for a charger (adapters are available). NEMA 14-50 is by far the most common for new installs. But that's likely not what you have currently for other appliances, like a clothes dryer. It can support a maximum capacity of 50-amp, but the line doesn't need to be that powerful. In our case, we have 8-gauge wire connected to 40-amp breakers. There isn't much else to consider technically. All you really need to know are those basics. The electrician providing an estimate for cost for running line(s) is the only thing that will vary for individual homes, since service-panel access and where you would like to physically locate the charger will obviously differ.

5-20-2019 **Local Trolls.** His posting have grown so bad, it has really become a problem. Today, we got this: "*my ev estimate always goes down after driving hv. no idea why.*" It's just a flurry of worthless posting. Everything is lowercase without ever referring back to any specific message. He doesn't quote what he's referring to. There's just interjections of brainless posts without any context. There's clearly no thought involved. No one could be so active for so long and still not have any clue. I pointed that out too, as well as provide constructive comment: After nearly 78,000 posts here and 14 years of participation... let's try to use that experience to help us all advance to the next level. It's really important at this stage to engage in the more informative discussion. We are the ones who make that progress forward happen, by posting messages that are constructive. Think about how poor of a job salespeople at the dealership do for actually selling the technology. We all get frustrated by their "*no idea why*" responses. Doing the same here puts us at the same level of disinterest. The more we share our understanding with others, the better off everyone else will be. In this case, the answer to why is simple. The system takes an average based on the outcome of how the battery was recently used. Electricity shared with HV is less efficient than just using it with EV. The traction motor (along with associated components) isn't being used to its full potential, which is optimized for efficiency.

5-20-2019 **The Bigger Picture.** I found my own quote from a little over 4 years ago which applied well to the topic: "*25 miles (40 km) is a worthy goal.*" It was a prediction that turned out to be remarkably accurate. I posted this on the long-dead thread it had originated, hoping to stir renewed discussion on the topic: I was looking for a recent comment about the wish that Toyota had made the mid-cycle upgrade of Prime to deliver more EV mile, so I could point out the importance of looking forward... seeing the bigger picture. I couldn't find it, but did stumble across this look forward from the past... which never lost sight of the bigger picture. For example, there have been quite a number of complaints related to Toyota's use of the "*self charging*" label in their hybrid advertisements. Anyone notice how not a single one of those posts mentioned Toyota quest to phase out traditional vehicles? Having established that "*self charging*" identifier makes the identifier of "*plug in*" so unambiguous, there's no uncertainty what the difference is. Look forward, not backward... as my own quote above did from 4 years ago. Notice how I nailed the expectation for Prime long before anyone else had any idea why Toyota would do such a thing? Back then, there was quite a stir that Toyota was giving up plug-in support entirely as a result of PHV production ending. Those were the words of some spinning their own narrative. Don't listen. Pay attention by looking forward. In this case, I'd like point out an important reason why the capacity for Prime wasn't increased mid-cycle. It's quite simple. Toyota places a very high value on the used market. They go out of their way to appeal to the early-adopters, making the upgrade so compelling some trade-in for the newer model. They provides inventory for the used market. An important aspect of that used market is support. Changing capacity would have resulted in a loss of value in 2 regards. One is obviously less EV miles. The other is simply replacement coverage. If you want a vehicle to last a freakishly long time, don't make it's parts so unique they become difficult & expense to replace. That leads us to the next look forward. Would it be cost-effective to have the engineers restack the cells to make them fit better? Resulting increase in cargo area without any change to operational specs would be a benefit to both new & used sales. Doesn't that seem a worthy goal for mid-cycle?

5-21-2019 **Confusion.** The topic of marketing confusion for Volt came up today. Needless to say, I had much to contribute in that discussion:

Depends upon the audience. GM catered to enthusiasts, thriving on the attention from their early-adopter niche. Toyota is focused entirely on mainstream buyers. That fundamental difference means very, very different messages.

With the case of Toyota, the forward-thinking aspect tends to get overlooked by everyone. They're effort to phaseout traditional vehicles requires setting the stage long in advance to avoid confusion when that final happens. The first part is what antagonists absolutely love to spin, the "*self-charging*" promotion. That marketing taken out of context can be used as undermining material. But when you come to realize that "*plug-in*" is the second part, their approach makes sense. That's how they will distinguish between the two very different types of hybrid offered.

On the other extreme is GM. There is no message or even a clear plan. Heavy investment was made into refinement of their plug-in hybrid tech. But rather than rollout what Volt demonstrated into a popular GM vehicle, like Equinox, the effort was just abandoned in favor of Volt's own antithesis: a full EV. Sending such mixed messages to their customers without any obvious next-step forward explains why investors are now so upset.

Knowing that business-sustaining sales (profitable & high-volume) require appeal to shoppers on the showroom floor, advertising detail of how a system operates is pointless. It comes down to the basics... size, price, features, power, handling, etc. The means of propulsion isn't really ever primary purchase criteria. Dealers (the true customer for automakers) simply weren't interested in what early-adopters wanted.

5-21-2019 **Campaign?** As expected, the discussion got rather heated quickly. This really stirred things up: "*GM campaigned on range anxiety.*" It was the result of the enthusiast claiming hybrid owners were the target for Volt, which makes no sense for an audience already quite familiar with dual-powered systems. Why wouldn't you reach out to those who have been waiting for an EV instead? The arguments had little substance. It was just more of the usual rhetoric. I chimed back in with: No, the problem was GM had a solution looking for a problem. Reality is, there's a huge PHEV market in the waiting and Toyota is prepping for it with deploys of a wide variety of hybrid choices. Each is which is setting the stage by replacing their traditional counterpart and making way for a plug-in model. Your own reply repeated the same mistaken message by focusing solely on Prius owners and conquest. Deciding to completely ignore the large sedan and SUV market was a profound error by GM repeated by enthusiasts. Looking now, it should be obvious how much GM messed up by not marketing Volt as a platform for other vehicles to adopt. Just imagine what that message had sent. People would be expecting an Equinox or Trax with that technology. Instead, loyal GM customers just replace their old GM guzzler with a new GM guzzler. What will GM campaign on now?

- 5-21-2019** **No Market.** The effort to avoid anything constructive continued: The major mistake made by Volt enthusiasts was to treat the technology as a competitor with other automakers, rather than GM's transition away from its own traditional offerings. That made conquest sales the focus. It wasted the limited supply of tax-credits, achieving nothing in returns. GM's status quo remained intact. This prevented the benefits of plug-in hybrids from ever being addressed. Attention was constantly directed to minor conquest. Volt won a few battles, but lost the war. Enthusiasts enabled GM to fall into the innovator's dilemma trap. So, no amount of advertising would overcome the misdirection. Volt became a product without a market.
- 5-21-2019** **Futile.** They say hate blinds. They are right. When a person makes up their mind you have an agenda, they stop listening. That's especially problematic if they assume incorrectly about what it is. For example: *"It (Volt) failed because people in EV community like you who hated it just because it is a PHEV from GM."* That sentiment of not being able to be supportive of more than a single automaker is a difficult self-created barrier to overcome. Some people believe cooperation is impossible. That's absurd. We have shared goals for many things. Why couldn't electrification be among them? Ugh. I asked: The point is to change the status quo, right? Targeting EV supporters was a fundamental mistake. Yet, it continues. That *"wrong audience"* lesson was not learned. The goal of appealing to showroom shoppers wasn't taken seriously. It failed because enthusiasts didn't understand who the market for Volt was. Trying to sell a performance compact to loyal GM customers interested in a SUV was a waste of time & money. It was doomed to fail. Looking back, it's amazing to recall how hard certain people truly believed that would work and to what extremes they'd go to defend that risky hope. Reality is, the path forward for GM will require finally acknowledging need over want. Priorities for ordinary consumers don't view the divide between PHEV and EV the same way. Treating the situation as such is futile.
- 5-22-2019** **KISS.** The arguing about how marketing was or should have been continued. Distortion of history is rampant at this point. Not remembering the timeline correctly and simply just forgetting all that influenced decisions is an all too familiar problem. That's why I documented that history as it was playing out, capturing as much as I could while it was happening, to properly represent it all these years later. I just look back through the blogs to get an accurate picture of the situation at the time. It's far too easy to look back with bias once you know the outcome. Not knowing is what leads to the behavior that unfolded. In a way, it's not so bad that they forget. It can sometimes present an opportunity to reintroduce an idea which had been brushed aside in the past. For example: *"I drove over 1,600 miles with my most recent tank of gas."* That was my marketing suggestion to the discussion. I further added: What more can be effectively said when you have the attention of a random person for just 30 seconds? That simple sentence addresses all concern without getting into an detail. It's marketing that actually works. Ironically, GM teased that very idea. Enthusiasts fought it though, not wanting to acknowledge the reality of Volt not actually being vastly superior. Other PHEV would be able to deliver the same thing. That's how the self-destructive EREV identifier came about. KISS really is the best approach.

- 5-22-2019 Competition.** The best word to describe today's situation is "Ugh". It was a staged competition to compare the MPGe of an AWD Prius to that of a Tesla Model 3 AWD. See the problem yet? If you've read my blogs from the past, you'll recognize the MPG issue. Yup, just like that coast to coast drive of Jetta against Prius, it was a measure designed to focus specifically on just a single trait and dismiss all else. The video repeated that mantra over and over again, as if that's all that ever matters in terms of understanding the ownership equation. To be unbiased, you avoid ever doing such a thing. This is why those trying to honestly represent true usage always report their lifetime value. That measurement takes everything into account... daily driving... seasonal changes... vacation trips... running errands... holiday shopping... family gatherings... entertainment stops... you name it. To attempt to make a specific test representative of true performance is a common undermining technique we've seen all too well. So whether the video posted was intended to be bias, that's what it ended up being. Perhaps if they follow up with a variety of other drives, then it would balance out. But this first one was not appropriate as presented. And I didn't even mention the huge price difference. Since when is comparing vehicles with such a large price difference a reasonable representation of competition? Ugh.
- 5-22-2019 Cry Spin.** Attack is the theme. Rather than deal with the issue at hand (effective marketing and a path forward), it's better to declare the messenger the real problem. Ugh. Fortunately, I don't have to put up with that nonsense anymore. Toyota's plan to diversify has been going really well. Progress of that goal is obvious. Sweet! This is how I responded to the troublemaker who clearly isn't ready to face reality yet: 6,556 RAV4 hybrid; 2,128 Camry hybrid; 1,403 Corolla hybrid; 1,104 Highlander hybrid (next-gen coming later this year). All are examples of popular vehicles adopting the hybrid technology and selling well. Those numbers are just from April alone. Think about what that's doing to interest in their traditional counterparts. That's a solid path forward... non-disruptive... an approach dealers will embrace... exactly what's needed for electrification to reach the masses. As the hybrid models become more popular, a plug-in variant will be added. Cry spin all you want. It won't change the reality that we still don't see any fleet plan from GM.
- 5-23-2019 Evade & Bash.** Feelings related to defending GM are still quite high. With a loss so blatant, the damage-control effort is daunting. Those few still holding on to unwarranted hope have literally nothing to work with. Tax-Credit phaseout is underway and there isn't any path forward. Stubborn resistance from dealers is as strong as ever. Why change? Bolt is simply far too different from ordinary inventory that's stocked for salespeople to bother. This is why it was so important to get a clear message of purpose. After an entire decade, we still don't have that from GM. What is their next step? Needless to say, there's no interest in actually addressing that issue. Instead, the response is to evade & bash. Doing everything possible to change the topic. Where have I encountered that? Anywho, this is how I dealt with that nonsense: Toyota is demonstrating a clear path forward that is proving to be very successful. Dealers are pleased with the results and there's a great deal of potential for growth. That wide variety of hybrids, each on a platform that can affordably & profitably offer a plug, is the solution GM had always hoped for.

- 5-23-2019 Marketing.** This is how the long string of posts about how GM messed up with Volt came to an end: "...*marketing strategy aimed at the general public.*" Since it was something I had blogged (and complained) about for an entire decade, it should be no surprised that I sounded off about price. Way back in 2007, it sounded quite unrealistic to set a target so low for a return so high. That proved quite true too. Concern about that was blown off though. Criticism was twisted as claims of undermining attempts. Enthusiasts just plain did not want to hear anything constructive. Question is, now that those enthusiasts are all gone, what do those participating online at this point think? With Volt dead and the possibility of that technology containing unlikely, it's an interesting thing to ponder. I didn't. I just posted: GM should have stuck with its own strategy. That "*nicely under \$30,000*" goal still stands true for appeal to the masses.
- 5-23-2019 Entertainment.** I'm tired of certain individuals who use the forum for their own entertainment. In this case, it's a retired person who apparently has nothing better to do. It wouldn't be so bad if his many scores of posts each day (sometimes even exceeding 100) actually included some study. They don't though. In fact, we see repeats of the same thing frequently. There is no progress, despite such active participation. Posts never included a quote, are always all lowercase, and rarely haven't anything of substance. That's the same thing a troll does. For example: "*toyota can barely sell 2,000 a month at the current pricing.*" It wasn't even on topic. It was an comment completely out of context. We were discussing what brought about GM's most recent disaster. Like a troll, his purpose is to provoke. You know, anything to get someone to provide entertainment. Being engaged in discussion is all he desires. Progress is never made. I see the pattern repeat over and over. Sometimes, I do actually push back to draw attention to his activity. Vague posts are what tend to do that. Today, I kept it brief: That's highly misleading. Toyota has clearly been delaying both promotion & rollout until the mid-cycle. Toyota has also done all it could to avoid getting caught up in GM's fallout.
- 5-24-2019 Tradeoff.** Another thing I find annoying is when luxury vehicles are compared to ordinary mainstream offerings. How is that constructive? Like other pointless efforts, it happens all the time. That can be an effective means of undermining a discussion. Again, this is something we often find coming from one of those individuals who use the forum for their own personal entertainment. Today, it was: "*The 2019 BMW 330e loses 105 liters (3.7 cubic feet) for its 12 kwh liquid cooled battery.*" Even though this topic presents the option to expand upon the topic being discussed, it really wasn't helpful... since the topic has been beaten to death already. They like to repeat. That's key to their entertainment. Preventing progress is something they work hard at. After all, not many have a domain like that at their disposal. We can do much to prevent their posting. Their distractions continue, endlessly. Like usual, I keep my replies to such individuals brief: Liquid cooling adds cost & weight. To be a mass-market leader, doing the same as a luxury brand doesn't make sense. GM learned that lesson the hard way. The tradeoff isn't worth it.

- 5-24-2019** **Priorities.** This is why I so often say "ugh" to some of the stuff posted in the forum threads: "Yes, yes, exactly..." That was a vague agreement just for the sake of moving on to a preferred topic. It's what happens when you nail down an element of importance. Those efforts to keep things active can't be interrupted by a logical point. The last thing they want you to do is draw a conclusion, since it will end their entertainment. Annoyed, as usual, I still took the time to reply with something constructive: With all that, you completely evaded the topic of MASS-MARKET sales. That means MSRP near the consumer mean (not average) without subsidies, since it must be able to compete directly with traditional offerings. The goal is mainstream volume with several models for each automaker. Remember, the ability to achieve both profitable & sustainable requires a balance of priorities.
- 5-24-2019** **New Audience.** It never ends. Spin from long-time antagonists always emerges as some point. I was actually a bit surprised it took so long this time: *"It shows that GM is serious enough about making a long-term commitment to electric vehicles to cast aside the Volt, GM's most successful electrified vehicle to date, and embark on an uncertain all-electric future even if it means some near term sacrifice."* That was amusing to read... since there hasn't been any long-term commitment actually made. GM simply abandoned Volt when the tax-credits were used up. It ended up being a waste of opportunity. What was the point of joining an engine to a motor, especially with gen-2 refinements in hybrid efficiency, if the goal all along was an all-electric future? Why not just do what Nissan did instead, just start with the preferred approach? There is no justification to spend so much, then cast it aside. Sacrificing such a massive engineering investment doesn't make sense if there's nothing to switch to. GM itself told use profitable EV sales are still several years away. Cutting losses is one thing. But when you know that technology would work great in a Trax, why wouldn't you offer it? Think about the size of that particular SUV. Think about the convenient height for adding batteries. Think about the propulsion configuration. Trax uses a 1.4-liter turbocharged 4-cylinder engine to deliver 138 horsepower. Volt used a 1.5-liter 4-cylinder engine to deliver 149 horsepower. Doesn't that seem an ideal platform for the propulsion system to have been transferred to, rather than just abandon? Anywho, the Volt enthusiasts have a new audience now. They are trying to somehow convince them that's a terrible idea, that simply endorsing only Bolt makes more sense than leveraging all that refinement GM already delivered. Huh?

5-24-2019 **Jumping Ship.** There aren't many Volt enthusiasts remaining. Yet another just revealed he's jumping ship: *"I'll be trading my 2017 Volt for a M3 in the coming months."* The hypocrisy is amazing. They absolutely insisted conquest wasn't a problem, that GM was building loyalty with their commitment to EREV technology. That fell apart to such an extreme, they cannot distance themselves fast enough. Remember all those attacks I got on the EV blog, when I started posting there after the Volt blog died? Even those came to an end. It was futile defending a technology that had been "*cast aside*" without even so much as a tear. To be told this would never happen... Looking back at the nonsense I had to endure. What was the point? They fought and fought and fought without ever doing what I asked, to state goals. I was about winning something, not actually getting the status quo to change. I saw that from the start. My question changed to "*Who?*" when it became apparent their was no interest in mainstream sales. Appealing to ordinary consumers wasn't of any interest to them. Just about all of them have jumped ship at this point. Many followed glory, hoping to find it elsewhere. The rest faded into nothing. It's a strange victory.

5-24-2019 **Sales Graph.** Someone animated the sales chart for the United States over the past 7 years. It shows month-by-month changes, allowing for a rather clever means of representing progress of the market. It doesn't actually show progress of the industry though. That limited scope is very misleading. The fact that it also divided gen-1 and gen-2 of the plug-in Prius into two separate categories was rather blatant misleading too. Enthusiasts would have screamed bloody murder if that had been done for Volt, but it wasn't. Worldwide sales were completely omitted too. It was obvious cherry-picking; nonetheless, it did stir some constructive discussion. People are avoiding the topic of GM progress though and this was yet another example. Playing the victim card for Volt isn't even happening anymore. Bolt is just there, but nothing is happening with it. Tesla was the rising star in that animation, but there's a gray cloud growing over its future. With the final reduction to 25% just 5 weeks away now, that dependency on tax-credit for sales is obvious. No one seems to want to discuss that though, just like what we saw with GM. So, I reminded everyone of that recent history to be ready for some type of change on the horizon: GM's heavy dependence on tax-credits only resulted in trivial sales with respect to the true competition, traditional vehicles. That meant it was doomed once phaseout was triggered. GM should have diversified long before reaching that obvious cliff. No Trax or Equinox with tech from Volt was a terrible executive decision.

5-25-2019 **Cattle Cliché.** I hadn't ever actually heard this one, but it fit well into the sale graph discussion. So, I added more in response to it: That "*all hat and no cattle*" is an excellent way of describing the situation. It doesn't matter though. The first stage of rollout doesn't represent what will happen later anyway. That graph is rather misleading too. The separation of Toyota PHV gen-1 from gen-2 is rather blatant misrepresentation, since the same was not done for Volt. But then again, the graph only tells the early-adopter story, since all the sale were subsidized. That's a lot of low-hanging fruit, which is pretty much all gone now. It's time for the cattle. Think about how the market will look once those tax-credits are completely phased out. After all, that quantity of 200,000 vehicles is much when you consider annual sales in the United States is still somewhere around 17,000,000. Consider the extremes. We have Tesla who strived to establish a profitable foothold prior to expiration and GM who simply exploited the conquest opportunity. As a result, one built up some rather fierce loyalty and the other struggles to retain attention. Realistically, it's how the dealers embrace change, not those who end up owning the vehicles. Showroom shoppers are what bring in the sustainable profit. That market has yet to be tapped. There's a lot of potential, but a graph like the one provided doesn't represent how that entirely different audience will respond.

5-25-2019 **One Solution.** Most people have little background in business and pay attention to the market even less. That absence of understanding makes seeing the bigger picture a hopeless battle. All you can really do is provide information when that unknown is detected. For example: *"What I don't understand, though, is why they are spending so much on developing fuel cell cars..."* It makes sense that to be so uncertain. After all, look at how few EV owners actually really understand the EV market. There's just so much to be aware of and the perspective of United States information sources has undeniable bias... a narrative of what is hoped for, rather than what actually is. Some of that comes from the aforementioned lack of understanding. Unfortunately, some also comes from the political efforts to misrepresent. With the hope of providing some useful view, I posted:

One solution for all, especially with so many markets to serve, doesn't make sense. Hydrogen won't be everywhere, but commercial fleet use has strong market potential. The electric drive system can be shared anyway. So, there's a win-win. Heck, even battery advances can be used by both. So, delay with full EV and maturing the FCV tech in the meantime isn't a futile waste as many spin it to be. We reap the benefits for PHV use along the way too.

Basically, it's Toyota thinking long-term & high-volume facing critics obsessed with limited scope returns. After all, who's to say all the investment VW is doing will put them anymore ahead? Look at Tesla, so much spending in charging infrastructure has left them very short on sales & support infrastructure. Balance of risk necessitates diversity. Notice how little Volt accomplished for GM. That major investment in plug-in hybrid tech was just abandoned. Was it good to cut-bait like that?

The answer to that GM conundrum comes from whatever the next step delivers. If their learning experience results in profitable & sustainable sales from whatever Bolt becomes, then yes, it was good. If GM just flounders and is unable to fortify their foothold in the plug-in market, then no, it was a waste. That same logic can be applied to Toyota.

It all boils down to market impact. What really affects the status quo? Most of the hype garners much praise, but really doesn't achieve any real change.

5-26-2019 **Change Precedent.** It is especially intriguing when someone with a constructive demeanor posts something like this: *"The Volt was not abandoned. GM is selling it in China under the name Buick Elite -- they have a new model this year and an electric model (based off the Bolt) called the Velite 6 MAV."* His message was clear & concise. It didn't play by the rules of engagement though. That approach of logic without context can be brutal, as I pointed out with the hope of some constructive feedback:

Volt enthusiasts established the precedent of separate markets, absolutely refusing to acknowledge worldwide efforts. They fought and fought and fought for over a decade, fiercely attacking anyone who attempted to include Japan or China in activity that took place in the United States. Now, they must reap what they sowed. Making matters worse, some got to the point of hostility (offensive online posting) to divide the market here in the United States. They fortified the narrative that *"EV market"* was all that mattered, that *"mainstream consumers"* would simply follow suit following expiration of tax-credit.

That was a brutal history I will continuously remind people here of... because we've seen that cycle repeat. It started with attacks on Toyota's hybrid system with Two-Mode. That went on for years and years, then finally collapsed when the technology proved unworthy to compete with traditional vehicles. Sound familiar? The very same thing played out with Volt, despite all the reminders and the *"too little, too slowly"* concern expressed over the bankruptcy recovery about the technology.

And sure enough, failure to spread the technology from Volt to something capable of sustainably returning profit is undeniable. The opportunity to use tax-credits as intended (to help with the spread) was wasted. Now, if GM really hasn't abandoned Volt for this market, the technology will have to compete directly against GM's own traditional vehicles (the true competition) without subsidies.

Remember, the point is to change what is offered at dealers, here. Take a look around. Each automaker faces their own set of challenges to change purchase choices for their own customers. Notice how Toyota is doing an absolutely incredible job of pushing out traditional vehicles? RAV4 hybrid is proving extremely popular. That's paving the way for plug-in models.

So what if the narrative that *"Toyota is still balking on EVs"* is what you hear from enthusiasts? They set a terrible precedent that is now coming back to haunt them. Anyone who takes the time to look for true change will find it on Toyota dealers' lots. It may not be the speed or approach that's excited, but it is an undeniable large-scale shift away from traditional vehicles setting the stage for more change.

5-27-2019 **Yawn.** The emoji response was pretty lame. I shoot back with:

That yawn response is an excellent example of a passive-aggressive enthusiast. Showing indifference to such a serious situation is how we identify enabler activity. That's what becomes a part of group-think, the very problem that contributed heavily to Volt's downfall. Those sharing that attitude invited innovator's dilemma. Essentially, they sabotaged GM's efforts by encouraging the niche. It was progress, but the wrong direction and no one was willing to call out the mistake.

It was an error on a monumental scale. All that money invested went to what? Remember, the intent with Volt was to be a high-volume seller. It's not like Toyota's investment in Mirai that is produced at low-volume with clear intention to only sell at that small number and only in limited markets. It's kind of like Tesla back when Roadster served as a real-world research vehicle. Toyota has stated there is no mainstream intention yet with that generation. Decisions will come later, exactly as their all-electric rollout has been presented.

So what if you don't care about the well-being of an automaker? Very few actually do. Most focus on what they see at auto shows, which has little reflection of what they end up purchasing. Tesla offers premium vehicles. Whether or not you want to call them a "luxury" automaker makes no difference anyway. Each automaker has their own audience. Toyota's is much more reflective of mainstream consumers. Their vehicles are ordinary... something most enthusiasts would yawn at.

5-27-2019 Warm Up. It took quite a bit of posting from a number of active constructive posters to finally get this: *"If 'warm up' is a thing in the past, then the term 'warm up' should not even be mentioned anywhere in the manual."* The new Prime owner wants to have a engine-startup remote installed, but not for the sake of either warming up the cabin or warming up the engine. It was bizarre. Why? That quote became the missing clue. He read that *"warm up"* was necessary. I was revealed to provide the final puzzle piece:

Now, we are finally getting somewhere. You made the assumption that *"warm up"* for a traditional vehicle is the same thing as *"warm up"* is for a hybrid. It is not.

For a traditional vehicle, the term *"warm up"* means to get the engine up to a temperature with enough heat so that the output of the propulsion system is normal. A cold system will be sluggish. Engine oil, engine coolant, and steering fluid all work better when there's some radiant heat energy circulating through the propulsion system.

That same definition most definitely doesn't apply to a hybrid like Prius. It uses 0W-20 synthetic oil in an engine designed for rapid heat distribution. The steering doesn't even have fluid, since it's electric. Most power provided during the initial operation of the engine comes from the electric traction-motor too. In other words, none of that heat is needed for driving.

The *"warm up"* with respect to Prius is related to the emission system. For the catalytic-converter to cleanse emissions thoroughly, it must have heat to make the chemical conversion to take place... hence *"gasoline engine may not stop"* mentioned in the manual. Remember, cleaner emissions than traditional vehicles is a priority for Toyota's hybrid system. Engine warmth is used for that, but is clearly not necessary for propulsion.

So, what you see in the manual is a misunderstanding. For Prius to be cleaner than traditional vehicles, it requires heat from the engine... hence the *"warm up"* mention.

5-27-2019 Too Soon. I liked this particular question: *"How is the Volt being 'Canceled' a way to rationalize that it's too soon for Toyota - when in fact plug-in's growth has been at a much faster rate then hybrids market begin to grow?"* Since it was the obvious cherry-picking to limit scope, answering was easy; As mentioned countless times by me, the *"EV market"* narrative is not representative of what we will see once this early-adopter stage (clearly defined by tax-credit availability) comes to a close. Statistical misrepresentation is a really easy trap to fall into, especially with generous subsidies involved and an ample amount of low-hanging fruit. That next stage in rollout process is far more difficult and Toyota much better positioned to address that. Anyone can build an expense electric-drive system. Making it affordable and available on a wide variety of platforms is an entirely different matter. Toyota's distribution of HSD is an undeniable example of that. Remember, the upgrade to deliver the full EV driving experience only requires the adding of a one-way clutch. Having the rest already in place provides a simple next-step forward. Since there is no other platform using Volt technology available, Volt itself is no longer being produced, and no hybrid version of any SUV offered, whatever term you want can be used to describe situation GM customers now face. Semantics is a moot point. It is obviously *"too soon"* for GM.

5-27-2019 **Someone Asked.** I responded to inquiry with: Once upon a time, there was a blog for Volt. It innocently started out as a fan website, but over time became a source for fake news. This was long before the term had ever been coined or the understanding of how much damage such a entity could cause. It was a group of enthusiasts who became masters of hype. Making ambiguous automaker releases into unrealistic expectations people would believe became a daily ritual. They would fight anyone who questioned their ways. The ability to hide behind an anonymous posts made it especially inviting for those who just plain didn't care about integrity. Fortunately, it was doomed to ultimately fail... and finally did.

5-28-2019 **Marketing.** This is difficult to understand: *"Perhaps if Toyota made some sort of effort to sell their hybrids?? What would happen if the Toyota marketers got with some of us here on PC and we could coach them on these amazing cars?"* So, providing the response got a little involved.

They are! This is why *"know your audience"* is so vital.

2019 brings about 4 new hybrids. Prius AWD was introduced early in the year, but has a focus on winter driving... which won't arrive until late in the year. RAV4 is a next-gen rollout, so it's facing sold-delivery & back-order situations. Corolla is a brand new hybrid for this market, so there's a lot to address simply from the dynamic that introduces. Highlander next-gen won't be available until later this year.

With all that going on, in addition to the mid-cycle upgrade of Prime and the introduction of the new look for Prius, we can see that Toyota's effort to sell is well underway with dealers... who are their primary audience, since they are the ones who actually purchase Toyota vehicles. The dealers will be working to get their salesperson trained to handle marketing later done by us... who are the secondary audience, since we'll be doing a bulk of the promotion.

Near year end, we'll very likely be getting ordinary advertising. Getting all that in place in the meantime is a major undertaking, to even just properly address the final audience... who will be driving home in one of those new hybrids.

Remember, there's a major shake-up in the EV sector right now. That will most definitely impact the rest of the automotive market. So, steering clear of that... simply by doing other stuff (like dealer prep) in the meantime... is a wise use of that beneficial delay.

- 5-28-2019** **Paradigm Shift.** This troll just keeps at it: "*yes, but the sales weasels don't. they only see the bottom line*". His style was reflected well with that... never change. It's quite annoying, as is his approach of all lowercase, never quoting, and being exceptionally vague. This is one of those situations where anything different is unwelcome. In other words, he just likes to complain. You know the type. Fortunately, the world around him is changing. This time, it's going to be rather big too. The pattern of stereotypes & misconceptions only lasts so long. I pointed out: That misconception of "tough sell with little to gain" needs to finally be squashed. RAV4 hybrid is proving the very assumption you just contributed to incorrect... hence the next class. Far too often, we see discussions online focus entirely on micro-economics with no regard to macro-economics. They focus on doings of the automaker only with respect to a very narrow scope... like a single vehicle for a limited audience. At this stage, that's harmful. It holds back the work needed to grow the market. In other words, don't be an enabler of the status quo. We now need to move beyond the stage you had been part of. This next one... mainstream acceptance... is very, very different. That means really making an effort to understand the new situation, known as a paradigm shift.
- 5-29-2019** **Ford Escape 2020.** We actually got a little detail today. This new upcoming hybrid from Ford will use a 2.5 liter four-cylinder engine and will have a starting price of \$29,350. The estimated efficiency is 39 MPG combined. Sounds like they'll have a popular choice. Hearing that is on the way provides a glimmer of hope. Such silence from Ford was painful. Nothing seemed to be happening. It made sense though. Why do anything that resembles GM behavior? Not having anything green whatsoever in the SUV category was an indication of trouble to come. There's simply nothing to argue about. No attempt to change the status quo is a very real problem. Something at some point will give. This is good news.
- 5-31-2019** **C-HR EV.** There was an unveil today. That ended rumor, speculation, and doubt. It leaves antagonists in a pickle. Of course, they'll come up with something else to complain about. Losing their favorite scapegoat leaves damage-control efforts a mess. It's all about setting realistic expectations. They don't... hence being enthusiasts. A true supporter won't do that. They'll make a sincere effort to really understand the market. They don't operate on hype & hope. Toyota doesn't either. We'll eventually get that C-HR or something similar here. That's the way Prius started. In a less fickle market, shaking out refinements takes time. There are tradeoffs which need to be measured in real-world driving. Both engineering & management have choices to make based upon that feedback. It's how you reach the wider audience, beyond just enthusiasts. Toyota doesn't want a niche disaster that GM had with the now dead Volt and still has with Bolt. In other words, we're in that limited rollout stage. Think about how much that did for Prius PHV, since it was just a mid-cycle offering and only made available in 15 states. We're witnessing the same now with Prius Prime. Toyota limited rollout to select regions, without any real push. It was clearly an effort to collect real-world data for the mid-cycle upgrade. Once that is in place (the 2020 model), we should see it nationwide and in much greater quantity. Patience pays off. Unfortunately, few online are willing to practice such waiting. They want it now. Gain in the short-term is an unfortunate expectation with sometimes terrible consequences. Thankfully, Toyota doesn't play that game. Being "*late*" to a party you don't actually want to be part of isn't so bad.

6-01-2019 **Uncertain Future, part 1.** Constant attacks on Toyota make it obvious those enthusiasts lost without that daily blog are struggling without a plan. Having been caught in lies to cover up reality crashing down on them clearly had the long-awaited impact it should. Each time a goal was missed, there was downplay & deception. It was nasty at times. Focus on just engineering alone was a flawed approach. Combined with the overkill attitude, precedent was set. Failure to deliver business need was inevitable. I was annoyed from the start. There was such an obsession with speed & power, the claim of leadership was nothing but vanity. I coined it the "*trophy mentality*" problem. Want clouded judgment. Their desire to project beliefs they had were actually needs for everyone never had merit. That doom took a very long time to play out though. GM milked it for all they time they could drag it out. 200,000 sales is quite small, especially for such a large automaker. I still remember Toyota setting their annual hybrid goal for 300,000. It was for 2005, which was 8 years after rollout. That was not only achieved, it was exceeded. There was no tax-credit available here in the United States back then either. For the 10-year anniversary, the goal was bumped up 40%, to a level 430,000 annual. It seemed quite realistic, since 2006 sales actually reached 315,000. When the goal for 2007 was achieved in late 2007, we were told by Toyota about their next goal: 1,000,000 by 2012. Well, you know how the story goes from there. That goal was achieved and annual sales continued to grow. Now, we have a vast array of hybrid choices and a stage set well for plug-in hybrid opportunity. Meanwhile, we haven't heard anything at all from GM. Even the enthusiasts are dead quiet. The daily blog has resumed posting too. So, I'm going to find out what's going on by attempting a post myself. It's difficult to tell if that will be allowed. There are only 4 messages and those were from hard-core participants. We'll see.

6-01-2019 **Uncertain Future, part 2.** Here is that post:

Rewind to the end of 2008, back when GM was preparing their bankruptcy recovery plans. At that point, the Volt concept was 2 years old and this blog was quite active. I was among the top participants (as listed on the homepage statistics) and was known for my concern about GM not actually following through with their intent to deliver a high-volume profitable plug-in technology. In fact, I shared the same sentiment later expressed by the bankruptcy recovery task-force: *"too little, too slowly"*.

Enthusiasts of Volt assured me there was nothing to worry about, GM was investing heavily in Volt and believed strongly their approach would squash both HV and EV offerings. It was to be the industry leader, that technology would grow to levels of acceptance yet to be imagined. I continued to push concern, raising issues over the years about the absence of diversification and catering to niche interest.

There was only a finite quantity of tax-credits available, opportunity was being lost. So reason for the push to move forward was genuine. Volt rollout proved to be a disastrous misalignment of priorities. It was impressive technology poorly implemented. The form & function didn't appeal to GM's own loyal customers. That path to sustainable sales for their dealerships has been jeopardized for the sake of image.

The promise of that push to develop a portfolio beyond Volt wasn't going to happen. That was overwhelmingly confirmed upon learning what gen-2 of the technology would deliver. GM followed the path of praise rather than taking the business situation seriously. No variant in a form similar to their current fleet was to be delivered. Status quo would remain unchanged.

8 years following rollout, word was shared that Volt production would come to an end without any successor. No progress would be made by GM to advance their plug-in hybrid technology. It was to be abandoned in favor of the antithesis they had promoted so hard against, full electric vehicles.

Say what you want about this summary, from a participant who was their on the front lines from long before Volt's concept reveal. Call it online spin. Claim it is a narrative. There is no hiding the reality that a plan forward from GM is still needed. How will the automaker quickly transform a bulk of their fleet to something other than guzzlers without any type of battery-pack?

After all these years, the efforts to electrify haven't resulted in actual change on the showroom floor. Loyal GM customers go to dealers to replace their aged traditional vehicle with a new traditional vehicle. No hybrid. No plug. Nothing by the same old guzzlers.

- 6-03-2019** **11-20 Years.** I found this quote today intriguing: "*People now care much more about reliability & resale value for years 11-20 of a car's life.*" It is pretty much just a moot point though, as I explained: There's an interesting twist to that. Yes, they do indeed care. But when it plays out, they don't actually keep the vehicle that long. It is statically extremely low (at least here in a northern state) for vehicles to survive that long. The seasonal changes age the vehicle to the point where upkeep to keep a guzzler going simply isn't worth the expense. There's also the reality of human nature. Desire for something newer compels many to replace, even if there are a few years left on the vehicle. Those end up in the used market, skewing the ownership trail. Dealers will sometimes dump those vehicles on buyers who purchase in bulk for resale elsewhere.
- 6-03-2019** **Real Change.** This was another that caught my attention: "*Dead-cat bounce? Follow the number back a decade or so, hasn't it slowed appreciably.*" People look at sales from various perspectives. I'm often dealing with the difference between micro & macro. That, in itself, represents enormous variance. Each has its place, yet still related, while telling stories of outcome that conflict. Since most online don't ever bother to take the time to really understand and even fewer make an effort to be clear & concise, it's basically a hopeless battle. Opening eyes to see what could be requires that. Most don't see the problem until it's too late though. Volt was the ideal example. Enthusiasts fought and fought and fought, claiming I was making up stuff with the intent to undermine. That took an monumental amount of denial. They worked so hard not to see what was obvious to so many. Oh well. That's over now. GM failed and will hopefully move on. The effort to actually make an impact isn't just a matter of squeezing in a much battery as possible. Did they really think that would actually work? Anywho, I posted this as my reply, pointing out a great example of progress: Very, very, very different market back then makes direct comparisons impossible. The measure of success is based on the progress of traditional vehicle phaseout. RAV4 hybrid is reaching a new audience. That impacts the status quo. Real change is happening.
- 6-03-2019** **Nonsense.** This closing statement was a real head-scratcher: "*...and a lot of the advantages of a pure EV are lost.*" It was supposedly a rant about PHEV being nothing but a short-term bridge to the future. Remember all that "*stop gap*" nonsense years ago? I wondered if that was more of this. Unfortunately, none of the paragraph preceding it provided any clarity. What could possibly be a strong argument point? It eluded to nothing and Volt enthusiasts worked hard to demonstrate there was nothing lost. So, I really wanted to know what in the world he was referring too. The answer to follow my post was a big disappointment though. Turns out, he had mixed up the two terms and not even noticed. That left me wondering about context. Something still wasn't right. But like many who get caught posting something misunderstood or in error, you rarely ever get constructive follow up. So, I didn't bother. This is what I originally posted: My entire commute in my PHEV is entirely electric. I enjoy the silent cruise on the highway in total comfort without using any gas. Advantages of the all-electric drive is quite obvious. Claims about that EV experience somehow lacking something is nonsense.

- 6-04-2019** **Between?** On that same thread as the nonsense post, we got this: "*Now that the Volt is all but gone, it is a greater separation between EV and PHEV.*" It was apparently an effort to push the two apart, kind of like the failed effort to define EREV. Posts on that topic were both vague and contradictory. They changed over time too. So, any lack of clarity on it now meant future replies would be even weaker. It's yet another attempt to market by clever wording rather than clever engineering. Ugh. When you look at deal, even if vague, those categories will stir discussion to reveal shortcomings. I started my rebuttal with: That's just nonsense. PHEV like Prius Prime have EV up to 84 mph, electric heat-pump, electric A/C... what more do you need? Reality is, the PHEV has a much smaller capacity battery with charging that isn't a fast. The driving experience is no difference.
- 6-04-2019** **Codependent.** What happens when 2 automakers become dependent upon each other? Turns out, that has been playing out right in front of us. I questioned how Tesla was able to keep funding new builds. It seemed bizarre that so much capital remained available. How many stock was actually being purchased? Similar suspicions came about for GM. What had the automaker been ok with the abrupt abandonment of plug-in efforts? It seemed bizarre that emission requirements were somehow still being fulfilled. Remember all the clamoring of Volt related to HOV stickers? Each sale resulted in some carbon credits. Without those sales now, how was GM getting enough? Bolt certainly wasn't going to deliver and there aren't any hybrids for that. Guess what. Tesla has an abundance and was more than will to exchange them for money from GM. Eek! That's not a sustainable business model, knowing Tesla is still investing heavily and Model 3 is starting to see hints of market saturation at its current pricing. It's a relationship likely to be strained and with no guarantees. This situation is bound to get interesting.
- 6-05-2019** **May Sales.** That fall I had been talking about for years is now playing out before our eyes. Every time a Volt enthusiast brought up affordability, they would always include the tax-credit. Portraying it as a guarantee for everyone with no expiration was a doomed approach. If somehow the price of batteries ever dropped so low it would make Volt competitive with traditional vehicles, the benefit would also be true for EV offerings. It was a lose-lose situation. That's why Toyota's effort to squeeze out as much efficiency as possible from both HV and EV operation was so important. That was a win-win. In other words, it could compete. We're seeing evidence of that stage being set now. It's all about preparation. You don't gloat & promote. You quietly get everything in place. I keep telling them to get ready. May sales just brought about more rhetoric though. They don't want to hear this: 2020 model-year brings about a mid-cycle upgrade. That should open up availability to the whole country. The current limitation to just selected regions has demonstrated the potential for significant growth. 917 miles on my current tank. Only used 1/8 of the gas so far (about 1.25 gallons). That's 90% of the driving EV. Works great, highly efficient, no effort.

6-06-2019 **Terrible Mistake.** Seeing this was rather vindicating: *"It's brand loyalty...nothing more. If they had a Prius before they don't even check to see what else is out there."* That type of generalized assumption without any actual data to support the claim is a clue they don't really have any idea what they are talking about. At least with others, you get some sort of anecdotal observation. In this case, I knew there was nothing... because the discussion leading up to it was completely absent of any history. Watch for clues like that. In the meantime, consider how I responded:

What you carelessly dismiss about Toyota has been a very hard lesson learned for GM.

The disastrous end to Volt came about because GM didn't understand the power of loyalty. Rather than create a plug-in hybrid targeting its own customers, focus was entirely on conquest instead. That's why so many abandoned their Volt when the leases expired and traded up for a Tesla. Those tax-credits were supposed to be used to establish a technology for dealers to embrace, something to appeal to showroom shoppers. In other words, GM did nothing to build loyalty.

All these years later, Toyota has built up a reputation that contributes heavily to both the millions of Prius owners considering the purchase of a new Prius along with a massive armada of Toyota shoppers considering the purchase of a RAV4 hybrid.

Note how easy & obvious the next step for Toyota is. They have a clear path laid out. RAV4 hybrid with a plug is quite realistic. Meanwhile, GM has no expectations set. Neither dealers nor consumers have any idea what GM will do next. In other words, dismissing loyalty is a terrible mistake.

6-06-2019 **Timing.** Toyota announced a partnership with Subaru. The joint venture is expected to result in an EV platform to share. Since Toyota is the biggest stakeholder in Subaru (17% holding), it's a sensible step. There's a mutual benefit for the emerging plug-in market. Of course, some feel the effort is never fast enough: *"Would have liked to see this announcement 5 years ago."* Naturally, those comments are coming from the same crowd who praised GM not too long ago for being so far ahead of all others, showing leadership among the automotive industry beyond anything we could ever imagine. Well, that certainly wasn't true. GM has fallen to still being roughly 4 years away from having something competitive with traditional vehicles. Ugh. It never ceases to amaze me how some cling to meritless hope, wishing for miracle instead of being practical. Oh well. They can look back at this announcement 5 years from now and wonder how Toyota managed to get everything in place. In other words, you won't see much... since there is no specific "time" to really attribute the word. Preparation is quiet & subtle without ever ceasing. In fact, sometimes so much must happen on such a wide scale, the state of those continuous & numerous small improvements go unnoticed. I put it this way: Other automakers have made announcements and come up way short. So, the timing is a wash. Toyota already has lots of experience to leverage. So not only is the likelihood higher, the probability of it being profitable and competitive with the true competition (traditional vehicles) is quite realistic.

6-07-2019 **Competition & Goals.** There are a lot of clueless people who participate in discussions online. For example: *"It is not just Tesla cars. Other cars like I-Pace, E-Tron and Taycan will be in their second, maybe third generation by then. That means they will be facing a lot of competition..."* That seems innocent enough, until you did for detail. There's nothing of substance. That's literally all some have to contribute. Not having any idea how that is actually achieved is a very big problem. That's why I start by asking *"Who?"* When you discover they don't even have an answer to such a fundamental question, the lack of understanding intent is revealed as a major barrier unlikely to be overcome. Think about what that *"generation"* reference actually means. What must an automaker do for the next step? For that matter, what is the purpose of that next step? Most of the time, you confirm they really don't have any clue... because they have neither the background nor make an effort to find information. It's just a gibberish of guessing and gut reaction. Ugh. I kept trying to get them to think these things through. I rarely makes any impression though: Toyota will be using well proven technology, heavily real-world tested for many years before rollout. Mirai already has great 151 hp traction-motor that would work well in a the shared C-HR/Prius platform. Prime already has an extremely efficient heat-pump. Prime also great use of carbon-fiber. There's also the work done with the variety of hybrids to refine their lithium chemistry. Lots taking place behind the scenes positions Toyota well for competing with the true competition, their own traditional vehicles. So what if other automakers offer different configurations? Conquest isn't the goal.

6-08-2019 **Taking the Bait.** I found this quite amusing: "*His point whizzed right over your head.*" That's when you really know your audience. Someone tried to set me up and another tried to take me down. Both end up disappointed. I don't play that game. It's all about the bigger picture, winning that overall war, not battling online for a tiny victory. In other words, they really don't take the matter seriously. It's just like the daily blog. Many find it satisfying to be part of something, even if it really doesn't accomplish the goal they had hoped for. That's why we see participants disappear. They give up upon discovering a mistake had been made. How is that constructive? Why not just course correct instead? You are supposed to learn from mistakes. I always hope some lone individual will heed the advice & observations:

That's called not taking the bait.

Going forward, there will be multiple types of electrified vehicle, one with a plug and one without. Using the term "*hybrid*" simply doesn't make sense anymore; the technology has changed too much over the past 2 decades. So, Toyota being well ahead of everyone else in the hybrid category, coined a new name for the non-plug hybrids.

Ironically, the more you post about the "*self-charging*" category, the more you are doing to help promote it. Drawing attention is exactly with Toyota wants. It's a page right out of the negative-publicity handbook Microsoft so successfully used. Your contribution is appreciated.

Think about how meaningless "*hybrid*" is now. There are so many different types, coming up with a new identifier is a wise move for the entire industry. After all, other industries do that as the technology advances. For example, the Wi-Fi successor to "*ac*" has been named "*6*". The need was there, just as it is for "*hybrid*".

If you still don't like "*self-charging*", start promoting something else instead. Otherwise, you'll be stuck with it to differentiate between non-plug hybrids and those referred to as "*plug-in*".

6-08-2019 **Bandwagon.** Hearing that Toyota officially has plans to deliver EV offerings is taking some aback. They are spinning it as if there is now a rush to jump on the bandwagon. One individual trying to help bring some sense to the wild discussion stated it this way: "*People seem to think that it just finally occurred to Toyota that electric is a thing.*" My statements that there was an effort already underway in China to target an EV model of C-HR for next year basically fell on deaf ears. Acknowledging that meant nothing more to complain about, that they'd have to admit their scapegoat no longer exists. It makes them feel better being able to say the entire industry could have been much further ahead if Toyota had made such an announcement (actually a 45-page presentation released today, with some video) years ago instead. They never want to recognize the reality that there's far more to just increasing production capacity for battery cells. The reality of the market not being ready and Toyota striving to rollout both platform & technology upgrades in the meantime is just ignored. They don't see all that extra work required to actually setup the business part of the infrastructure as anything more than an apologist attempting to distract from the actual issue. Ugh. Needless to say, I expect the posts to spin out of control. Enthusiasts don't deal with change well. For that matter, enthusiasts don't recognize it. That activity can take place for years and the best they'll do is deny it has any relevance to their demands. I simply stated the situation as: It's like the musician who gets praised for being an "*overnight success*" even though they worked hard for decades to achieve their goal.

6-08-2019 **Desperate Spin.** I suspect the discussion is already spinning out of control, that no aspect of being constructive can be stirred at this point. It's what happens with most of these blog topics. They simply become a venue for self-validation and spreading rhetoric. That mantra of Toyota being cast as a "*laggard*" helps them deal with the reality now crashing down as a result of tax-credit expiration marking the death of Volt. That expensive niche was far too dependent on government incentives. Not rolling out the technology to other platforms... any SUV model... market its death long ago. That is what the investment in Gen-2 should have been. Making their niche hatchback even more of a niche was an obvious sign that interest to continue had faded. In fact, that would have been the ideal endorsement for Volt. Dealers would take carrying it in stock with the knowledge that another offering would be on the way. That would have been a great way to prepare salespeople for an upcoming SUV with a plug. Experience with the technology prior to wide scale rollout is essential. Does that approach sound familiar? It's exactly what Toyota is doing... which is exactly why those in favor of GM are against it. They don't believe in cooperation. There isn't even a spirit of shared goals. All they do is desperately spin the situation. It's really sad. I pointed out that situation will the cold reality of being a for-profit business: Bottom line is none of those BEVs have demonstrated the ability to sell well with subsidies. In fact, most didn't even sell well with subsidies. The claimed growth is still far under what's needed for those businesses to achieve & sustain profit. Treating early-adopter outcome as if it is representative of how ordinary consumers will respond is a grave error... as GM just showed us with failure of the technology from Volt to achieve & sustain profit.

- 6-08-2019 Behavior Repetition, Whoa!** I had no idea that same behavior of enthusiasts on the daily blog for Volt would emerge on the large general audience EV blog. It is virtually an exact match. My assumption of that audience taking the time to be open-minded and being better informed due to the wider variety of content was quite incorrect. I was wrong. Gasp! They are making the very same mistakes. These are basic errors you'd think they'd be aware of. Clearly, that's not the case. Ugh. It's just like whenever I'd point out to the Volt enthusiasts how I recognized the response pattern as frighteningly similar to what Two-Mode enthusiasts did. Their reactions were a match too. It was amazing. Now, it's happening again! People who don't learn from history really are doomed to repeat it. This blog spanning nearly 20 years of that activity overwhelmingly confirms it. Whoa! Anywho, after a day of crazy posting, I started a new thread with on that blog topic with this: It has been interesting to read the opinions of early-adopters who don't have an understanding how much change is needed to appeal to mainstream consumers. They look at the situation through a micro economics lens not realizing how different macro will be. They also turn a blind-eye to history, remembering only that fits their preferred approach. Well, too bad you don't like the reality that Toyota isn't taking a different path to the same future. The market is plenty big for that diversity.
- 6-08-2019 Behavior Repetition, Obsolete.** My post was quickly responded to with an attempt to undermine the sales growth of hybrids: Rhetoric claims of hybrids fast becoming obsolete are rather desperate at this point. We're seeing very strong demand for the new RAV4 hybrid. 40 MPG from such a large AWD vehicle with a base MSRP of \$27,850 is all Toyota customers need to know. They are placing orders and waiting for delivery. It's quite impressive to see such excitement. Meanwhile, there's the new Corolla hybrid. Well loaded with safety features and with a starting price of \$22,950 it is also a compelling draw for those shopping for a well-balance purchase from a Toyota dealer. There is a next-gen Highlander hybrid coming later this year. 34 MPG from a 240 horsepower system will make people take notice, especially with such a competitive market in that size category. Obsolete, not a chance.

6-08-2019 Behavior Repetition, Business. It never ceases to amaze me how narrow the scope of focus is on discussions like this. Participants will obsess with a particular aspect of the technology and disregard the rest of the business. That's such a fundamental mistake, I cannot believe it happens so frequently. They either don't understand or don't even recognize how the rest of the business works. It's not about engineering alone! Ugh. Failing to grasp the reality that legacy automakers must maintain a continuous and reliable flow of revenue is apparently beyond their grasp. Simple matter of accounting boggle their minds. Why? It's not that complicated. Dealers must purchase inventory they know their salespeople will easily be able to sell. Each sale must return enough money for that cycle to continue. These are all people expecting to be paid. They aren't motivated by doing what's better for our world. So, extra effort to make the purchase happen or a reduction to the monetary return is a major deterrent. That shouldn't be difficult to acknowledge. Yet, it happens all the time. Those online fighting me fiercely resist any type of acceptance for that aspect of the automotive business. They just plain don't care. It's sad. The result is a lot of spin. The most comment is to portray Toyota as being "*late to the game*". Ironically, their treatment of the situation as a game shows it isn't being taken seriously. This isn't a game. This is a for-profit business. Even the engineering itself is far more involved than they'll even admit. Knowing that, I kept my reply to the latest response short: Toyota is already producing motors, invertors, pumps, etc. for electric drive in high volume. So what if they associated battery-packs are smaller? Instead, there are the same cells stacked together as a longer range vehicle. "*Late*" doesn't hold much merit, especially when you add in profitability to the equation.

6-08-2019 Behavior Repetition, Audience. The truly remarkable aspect of some of the nonsense I have to deal with online is the obsession with more being better. There's no sense of balance. The vehicle must deliver more distance and more power, period. That's absurd. You don't attract ordinary consumers that way. They look for a variety of purchase priorities. In fact, this is why the popularity of online comments posted about products has become such a powerful means of solidifying demand. Remember all those years ago how Toyota got ridiculed for doing little to promote Prius? It was all about empowering their own consumers. Toyota knew long ago that owner endorsements were far more influential than anything they could do. That's precisely why they reached out to that group online leaders. We each had captured & maintained an audience they didn't have the means of effectively tapping. It was the key to growth... something that became a fundamental barrier to Volt. Those enthusiasts always reverted back to GM, never actually taking an action to promote as owners. It was strange to watch such great opportunity passed by. They obsessed with the daily blog, not even bothering to explore what the forum venue had to offer. Ironically, I got attacked routinely for hosting my own personal website to share my experiences. Taking about not understanding audience. Ugh. Needless to say, that same nonsense continued in today's post. I kept my next reply to it short too: Who are you trying to convince about Prius Prime range & performance? Enthusiasts here is the wrong audience. When people hear that I effortlessly drive for many, many weeks without refilling the tank, they want to be told more. When I tell them that equates to over 200 MPG, they ask if charging at home is difficult. I tell them the 25 miles of EV can be achieved with nothing but an ordinary 120-volt outlet. In other words, you don't stand a chance when I finally mention the base MSRP of just \$27,600.

6-08-2019 Behavior Repetition, Naming. Confusion for the naming of Bolt, being mixed up with Volt, was no accident. It was clearly an intentional act to provide damage-control ahead of time. GM already knew Volt was in trouble. Calling attention to their abrupt and rather drastic objective was something to be avoided at all costs. Bolt was the antithesis of what Volt had been designed to compete against. Promotion of Volt shows that extremely well. Remember all that "*range anxiety*" advertising? The discussion today certainly didn't. In fact, someone attempted to take advantage of that damage-control mechanism by trying to mix up my reference. My focus has been entirely on Volt; yet, he claimed I had referred to Bolt. The hope was that slip would go unnoticed. It didn't. I called him out on it too: Interesting how even you mixed up a Bolt and Volt reference. Some of us called that problem out right away, seeing that GM would benefit from the confusion later. And sure enough... As for what I actually did say, I did indeed point out the mistake GM made with Volt. They fell into the innovator's dilemma trap by catering to enthusiast want rather than striving to understand mainstream need. It was the very same mistake they made with Two-Mode. Had GM really wanted to "*out Prius, Prius*" the approach would have been different. Gambling with an overkill design set to an expectation of achieving high-volume profitable sales by mid-cycle was nuts. That simply was never realistic. Pushing out the expectation to gen-2 could have worked if the design had been altered to appeal to their own showroom shoppers. GM didn't do that though. As for the abrupt decision to abandon the technology in Volt to pursue its antithesis instead, that doesn't make sense. There is clearly a market emerging for a Trax or Equinox as a plug-in hybrid.

6-08-2019 Behavior Repetition, Forest. Much of the conflict I deal with online is those participants tend to only see a single tree. When you're in a forest, that's a very bad problem. Ignoring everything else around you is a terrible mistake. Yet, that's what they do. In fact, they argue it's all that's important. Ugh. It's that single-mindedness I keep referring to. They refuse to acknowledge more exists. I do my best to point out there is far more to recognize & consider: Looking at just the hatchback market creates a very distorted view. The next-gen RAV4 hybrid is selling remarkably well and the newly introduced Corolla hybrid is showing lots of potential. As Prius transforms from predominantly being a hybrid to just a Limited and AWD offering with the rest PHEV, we'll see those others sour appeal for their traditional counterparts. Have you noticed how nice the 52 MPG Camry hybrid? Right now, effort is being focused on Toyota's primary customer, their dealers. Those are the ones who need to be convinced the automaker is committed to wide scale change. Toyota is a for-profit business after all. Enthusiast obsession with conquest is not a wise path to follow. GM learned that lesson the hard way with Volt. Rather than diversifying their technology as Toyota has done, they catered to niche interest. That was a terrible mistake. That midsize electric sedan you predict will be shipping at 500K per year isn't a realistic forecast. The market will be saturated and the tax-credits used up. It will make that expectation of continued market growth far more of a challenge... even without taking into consideration offerings from legacy automakers. Tesla sales will plateau or even fall at some point in the not too distant future. In other words, the time will be right in a few years. In the meantime, there is a very hard push coming from Toyota to phaseout traditional models. Getting their dealers to favor hybrid choices will give Toyota a major advantage over the other legacy automakers hoping to skip that step. Think about how each automaker will need to entice consumers to purchase a plug-in. There's a lot more to it than just rushing out a one-size-fits-all solution.

6-09-2019 Behavior Repetition, Oblivious. The situation is not only dismissed, it's claimed as an extreme: *"If you read the Innovator's Dilemma, you would realize Toyota's approach is 100% wrong."* That was the response to the ongoing discussion about Toyota's announcement 2 days ago. There are a few who will deny what they witness, doing everything they can to distort reality. It's quite an act of resistance to observe. They'll never admit to not recognizing something. When an important aspect of a situation is overlooked, they'll just outright dismiss it. If I push the issue, I get personally attacked. Their purpose is to win arguments, not to actually address the topic. Ugh. This is how I dealt with that dilemma claim:

Toyota has diversified their technology. We now see it taking 3 paths. RAV4 hybrid, Camry hybrid, Corolla hybrid are all successful implementations of the original Prius offering. Each is contributing to the goal of traditional vehicle phaseout. Prius Prime demonstrates how effectively (simple & profitable) each can be upgraded to offer a plug. C-HR hybrid is a raised Prius platform, offering the height required for more battery-capacity.

None of that shows any sign of innovator's dilemma. Toyota carefully studied their dealers & consumers, then responded accordingly to serve that extremely wide audience.

You want an example of a legacy automaker who did the opposite, look at the disaster Volt became for GM. It started out as a risky approach, one that didn't make sense for the business. How could such an expensive design, one that clearly exceeded requirements, attract & sustain profitable sales? Gen-1 didn't even remotely achieve that goal. GM made the problem worse with Gen-2 by listening to enthusiasts (their own early-adopter customers) rather than finding out what people on their dealers showroom floors would be interested in... hence, falling into the trap. Taking even more risk resulted in a production abruptly ending midway through its product cycle. That's a very expensive problem. The technology died without a successor. All that promoting of EREV as the solution rather than EV fell apart as a costly mistake.

Toyota has a clear electrification path, as the 45-page presentation spells out. They are striving to appeal to dealer & consumer every step of the way, which is very appealing to stockholders. Everyone will see a strong commitment to phasing out traditional vehicles by offering a variety of electrified choices.

Again, none of that resembles being 100% wrong.

6-09-2019 Behavior Repetition, Silly. This is what I got when in reply to the audience post: *"That's a really silly argument. The charge time is related to actual battery consumption. The only reason the Prius Prime can be recharged overnight is because it has a pathetically small battery."* It was the typical type of rhetoric I had dealt with for years from Volt enthusiasts. Some just plain don't care about mainstream sales. Their niche was "vastly superior" and any less was a target of insult & ridicule. Ugh. I was annoyed, if you couldn't tell: You're calling Toyota's effort to appeal to ordinary consumers silly? \$5,920 lower base MSRP for Prius Prime than Volt is clear evidence of striving to do that. No dependency on tax-credits, which is very much what contributed heavily to Volt's death and no EREV successor. It's a sound business approach, especially when embracing change on such a large scale. As for claiming "pathetic" to the size of that battery, that's a obvious effort to conceal the reality that Volt's is too large to be practical for a 120-volt connection. 13 hours for a full recharge is a very real problem. If you start recharging at 6 PM, you'll be good to go at 7 AM for the morning commute. That means you'd have to charge during peak load and wouldn't have a car available for going anywhere after dinner. Remember, adding a 240-volt charger and line to your garage add to both cost & complexity. People want an affordable plug-in choice that's simple to purchase. Know your audience.

6-09-2019 Behavior Repetition, Vague. Typical response to getting cornered is to change the topic, being extremely vague in the process: *"The problem with Toyota's analysis is that once supply of BEVs is sufficient there is going to be a wave of government regulation essentially banning the sale of IC engines for everyday use. The health impacts and the environmental impacts will force their hands."* I'm quite familiar with that tactic. It usually doesn't equate to much. That basically just serves as confirmation to me that they have nothing to argue with about my point and have given up. Despite that, I do ask for detail: Who? When? Where? If you think other legacy automakers have a more comprehensive and faster plan, dish up. Let's here about GM's plan to rollout hybrid, plug-in hybrid, or EV offerings for their primary product: SUV. Toyota is already deep into RAV4 hybrid (which is easily adaptable to offer a plug) and the new Highlander hybrid is coming later this year. Ford is going down a similar path. It's expensive and takes a very long time to get in place for high-volume production & sales. Vague claims about "regulation" don't mean much. Bans are extremely difficult to implement... especially when "health & environmental" impact is involved, since Toyota hybrids already directly address those issues. In other words, what is the goal? Without that clarity, investment in the needed infrastructure to support whatever regulation is proposed won't happen. Change cannot happen in a vacuum.

6-09-2019 Behavior Repetition, Downplay. Becoming absolutely desperate at this point, I got this: *"That's just a HEV, a mild hybrid; that's old tech. Toyota has been remarkably resistant in pursuing plug-in EV tech, let alone BEV tech."* It's just like nonsense of the past. Repetition of the same old behavior with the hopes of impeding the progress Toyota continues to make is something I'm all too familiar with. Ugh. It's such a recognizable pattern. You'd think there would be something to make it different over time. That's not the case though. Over and over again, with nothing new, really surprises me. I'm in dismay at this point. There's no way they can get away with the deception. In this case, it's an attempt to downplay. With such impressive offerings now, how does anyone think it could work? I punched back with: That attempt to downplay a 219 HP system delivering 40 MPG plus AWD plus 1,750 pounds towing capacity for a base price of \$27,850 is quite telling... and ironically, fitting. Reality that the technology is designed for plug augmentation simply by adding a one-way clutch, just like what was done for Prius Prime, is clear evidence of Toyota planning ahead... forward thinking, not backward. They'll be able to advance their entire fleet with little to no disruption of business. It's a sensible plan... hybrid to plug-in hybrid to electric. That's the fastest way to get large-scale change for a extremely diverse audience accomplished.

6-09-2019 Behavior Repetition, Late. It's getting to the point of being unbelievable: "*The only way to make EVs price competitive is to actually start making and selling them in large numbers.*" Dealing with individuals that have no background related to business is difficult enough. But when they don't even bother to try to learn what's involved, it's like shooting fish in a barrel. They set themselves up for failure. It's impossible to actually win an argument when you don't know what the argument is about. Ugh. Now I'm in dismay. How can certain people be so blind to what actually makes a difference? I tried to point out the lack of understanding and provide some reasoning why. The behavior repetition doesn't provide any hope though. This same old nonsense will continue elsewhere with someone else. My old foes are long gone now. They death of Volt silenced them. Now, it's new misleading to deal with. Not even trying to understand... Here's how I replied:

That grossly over simplistic claim is why each time there's a "*Toyota is very, very late to the game*" post, it is validation of either being poorly informed or being disingenuous.

Of course, who here is gullible enough to believe that anyway? We know there's far more involved to making a vehicle price-competitive than to simply building more of them. Volume does not equate to being a better product.

Toyota is using their current electric deployments to make the future ones better. That 151 HP motor in Mirai would make the next plug-in Prius really nice. The carbon-fiber already in Prius Prime is proving extremely durable for the hatch. Using it elsewhere in the next-gen offering would be a nice improvement, since reduced weight means better efficiency by not needing as much battery to travel the same distance. The improved aero-dynamics from the dual-wave glass is another efficiency benefit. Then there's the heat-pump, an impressive use of electricity for keeping the cabin warm that other automakers have yet to use.

In short, Toyota is already working hard to get costs reduced. Each time they refine the motor, inverter, or software in their hybrids, that gain is transferred directly to EV efforts. The same goes for any improvement they come up with for lithium chemistry used for those battery-packs.

Put another way, the spin that Toyota is woefully behind just a lame effort to mislead.

6-10-2019 **Tundra Hybrid.** Someday, it will actually come. The whole world is waiting for that day, when a full-size pickup actually gets a full-hybrid offering. Toyota is a strong contender to fulfill that desire. The latest rumor comes about from some spy photos of what appears to be a mule. The photographer claimed acceleration that was silent until about 30 mph. It gave the impression of being a hybrid. Knowing that the Lexus LS 500h sedan already implemented a comparable propulsion size requirement (354 horsepower from a 3.5 liter six-cylinder hybrid system), that isn't too far fetched of a hope. That setup delivers a 33 MPG rating. Seeing the same thing in a pickup delivering around 30 MPG would be remarkable. It's fairly realistic for efficiency. We expect the next-gen Highlander coming late this year to deliver about 34 MPG. When you look back at Toyota's big picture plan, the entire fleet getting a hybrid choice was an expectation. After all is said and done, that is the outcome you'd want. Within the next year or so, that's reasonable. Despite all the problems other automakers have, it's not a problem for Toyota to invest heavily and relentlessly try until they get something competitive to offer. You may not hear much along the way, but results speak for themselves. The latest victory... RAV4 hybrid... make it clear that never giving up is their mantra. That slow & steady of the tortoise means crossing the finish-line at some point. Being able to pass others along the way is a nice reward for the effort.

6-11-2019 **Unsustainable.** How long can that terrible repetitive behavior be sustained? At some point, there's no audience left. The pattern of deception becomes noticeable. And even for those who are not bothered by such terrible practices, they don't want to waste their money on garbage. They will seek out a better deal. This is why virtually all the GM enthusiasts jumped ship. It is no surprise that so many of those who leased a Volt are now driving a Tesla Model 3. As much fight as there was about my claims of Volt only appealing to a small audience, there's no doubt anymore that I was correct. That asking of "Who?" was a sincere effort to raise concern about the terrible direction GM had turned. It was movement, but not advancement forward. Racing off on a tangent to serve a niche was a massive waste of opportunity. After the tax-credits are gone, there's nothing to show for them. The fleet remained unchanged. You go to a dealers lot and look around. What's different after all these years of Volt sales? With Toyota, you see a wide variety of hybrids. So what if only a single model currently offers a plug? The next step forward is easy, a simple move that customers will readily understand and dealers will need little effort to sell. It's a logical approach to traditional vehicle replacement. The chaos stirred by GM with Volt was just a smoke & light show. What did it really accomplish? The rhetoric amounted to a time & resources lost. Ugh.

6-12-2019 **Up to \$11,500 Off.** Today was a strange day. As the attacks on Toyota settled down, we got news of extreme discounts for Bolt. The advertisements said up to \$11,500 off MSRP from now to the end of September... which coincidentally is when the tax-credit phaseout reaches its final phase (only 25%). Naturally, there was a wild amount of spin. None of it made any sense though. We're seeing the same fallout we do every time from GM. On the third year, hope can no longer be saved. The market is saturated at that point. Any enthusiast interested in a purchase already purchased. And since GM does nothing but appeal to enthusiasts, there's nothing left. Notice that pattern? Two-Mode. Volt-1. Volt-2. Bolt. Each one suffered the same fate. In year 3, the mess became so unmanageable, drastic steps needed to be taken. At this point though, what is there to save? I found it amusing how someone interjected: "*GM is stockpiling ZEV credits (it has enough for meeting requirement now) in anticipation of the future.*" Reading the news, you'd discover it was actually preemptive damage-control or intentional misleading. Either way, GM announced a \$150 million investment to ramp up production for Chevrolet Silverado and GMC Sierra. It's like the current administration lifting restrictions to allow sales of E15, as a move to help out farmers struggling from the new tariffs. What you aren't told is that entities are being granted waivers so they will not be required to purchase more ethanol. It's a scam to make you feel better... much like GM's ruse by offering EV sales. There are really only token quantities, but most people never notice. They praise GM for doing more, when in reality, they are not. Just think of how pleased those new owners will be with such discounts. Their customer-satisfaction rating will be outstanding. Environmental impact though will be negligible, since those loud voices will actually be so few. Such discounts do nothing for a business being profitable either. Long-Term sustainability must be achieved through actual advancement forward, not markdowns to get rid of old inventory. Who knows, perhaps this is a move to clean house. A new offering that's far more realistic should eventually be taken seriously.

6-13-2019 **Dead Blog.** My first clue that the daily blog for Volt was destined to turn into a sight to feed antagonists (now more affectionately referred to as "*fake news*" websites) was the response to a Toyota presentation. None of the totally unrealistic expectations being set for GM could stake up to simply lying about what Toyota said. Volt becoming yet another "*over promise, under deliver*" example paled into comparison of outright misleading like that. Toyota had shared their intentions for the future, highlighting how expensive lithium battery-cells were still. It was all about being affordable. Those enthusiasts turned antagonists immediately spun that to an interpretation that Toyota feared the dangers of lithium chemistry. Word spread quickly about those claims of fear, even though people could look up the presentation itself to confirm nothing of the sort was actually stated. Sound familiar? That's exactly what this administration is doing now. They refer to a report and just make up information about what it is claimed to have said. Those are outright lies that enablers are all too happy to endorse. It's blatant greenwash. Attempts to undermine like that are dishonest and will ultimately come back to haunt those who spread such nonsense. I saw how that was a cover to conceal Volt shortcomings. Rather than endorse the technology, they attacked supposed competitors. That's why I constantly had to fight back whenever I shared information about the technology. They feared detail would reveal Prius could continue to stand up against misleading, that the design was an excellent balance of want & need. It was a fundamental mistake. Had they understood the "*Who?*" question, their beloved blog may not be dead now. We keep getting new articles, but almost no one posts anymore. Rather than the old routine of over one-hundred posts daily, there are only 2 or 3 now and sometimes none. What they held most dear was false promises and meritless hope. I'm glad to see it finally dead. They brushed aside the sincere "*too little, too slowly*" concern... which now the consequences of are undeniable.

6-14-2019 **Review Misleading.** It's starting up again. There are articles being published that pose as reviews by credible reviewers. In reality, this is "*fake news*" material being created to spread the narrative of shortcomings. The death of Volt appears to have emboldened some hoping to undermine progress. Seeing their blatant lies in print again sends a renewed message of desperation. This reminds me a lot of the diesel trouble. When the threat from Prius got intense, they'd fight back with efforts to mislead & misinform. That lack of integrity and at times outright dishonesty speaks volumes. I've learned how difficult it is to combat such activity; however, I am now armed with better online combat weapons. My videos continue to evolve, becoming even more informative while delivering even higher quality. That provides a means of reaching audiences those deceptive articles serve to confuse. Watching that level of detail will make those uncertain question what was claimed. All that sparring I did with Volt enthusiasts prepared me for this reach to mainstream consumers. I knew there would be an onslaught of attacks to come from those fighting to retain the status quo. I knew my audience. It was not a bunch of early-adopters taking advantage of a generous subsidy to purchase a niche. This is serious. Getting an ordinary shopper to take interest in a plug-in Prius means overcoming the endless stream of attempts to impede the reach beyond anything any of those GM defenders were willing to actually face. Change isn't easy. Reviews like the ones we are seeing now reveals some of the many barriers they continue to erect.

6-15-2019 Toyota Op-Ed. It was very nice to read a comprehensive op-ed submitted by a rather outspoken Prius Prime owner. The article was published on the big EV blog. Knowing how much potential Prius Prime has among that overwhelming jungle of EV choices, it was an especially big deal. The reason should be obvious at this point. The market for EV choices is saturated. Early-Adopters jumped on the tax-credit opportunity. Tesla emerged as the short-term winner, but there is no sense of certainty or direction now. We'd like to hope momentum will continue, but that's not how the mainstream market goes. Those buyers have very, very different priorities... which the op-ed pointed out, highlighting Toyota's recent presentation. I waited 2 full days before posting anything on that topic. It was important to find out what others had to say before chiming in. When I finally did, here's what I posted:

We all watched GM game the system for conquest while Toyota quietly used their hybrids to refine their technology. So what if those electrification refinements are used to benefit both EV and FC offerings? Driving needs variety dramatically and diversity is good business. Token efforts from other legacy automakers haven't many any impact to their own showroom shoppers.

Notice how Toyota is striving to reach a very wide audience now? They've captured some market with Prius, now they will capture more with RAV4 & Corolla hybrids. It's a sensible approach to set the stage for plug-in hybrid rollout. As this op-ed points out, the path to a profitable upgrade from hybrid to plug-in hybrid is only a matter of adding a one-way clutch and increasing battery capacity.

Toyota is a legacy automaker with a strong production, distribution, and sales. That means taking the time to ensure they truly meet their own customer needs is well worth it. No rush from early-adopter expectations will fulfill long-term goals. This is why Prius Prime was only rolled out in limited quantity to limited markets. Responding to feedback with a mid-cycle upgrade is a sensible approach to mainstream acceptance.

There's also the consideration of legacy fallout. Volt had such a heavy dependency on tax-credits, the opportunity for growth wasn't possible. Notice how their reveal immediately followed GM phaseout? Toyota patiently waited continuing with refinements to reach a very large audience every step of the way.

The potential is enormous. Traditional vehicles much quickly be replaced with cleaner choices right away. Toyota is leading that effort to transform their entire fleet.

6-16-2019 Prime Time. We got a video share last night featuring the first known 2020 Prius Prime available for sale. This is what I had to say about what I saw:

Takeaway from this first dealer video is the reveal that Toyota stayed true to their objective of reliable & affordable. Since they are now setting goals for the next-gen design, it only makes sense that they know far more than we do. We've seen this many times already. Toyota carefully studies the market as a whole and adjusts accordingly. That "plan way ahead, but remain flexible" approach makes some people crazy. I think it's great, especially when they take risks. Ironically, antagonists are the ones claiming Toyota doesn't take risks, yet they work extremely hard to hide the fact that it actually happens.

Trying a 4-seat configuration is the "Prime" example. It made sense back then to experiment with layout, knowing the "car" market was on a major decline. Prius needed to be redefined to retain an audience. That's normal next step after being a top-seller for several generations. In this case, we learned the middle seat remains an interest draw, despite the fact that several alternatives are available... Corolla hybrid, Camry hybrid, RAV4 hybrid. Toyota had originally targeted aged families for Prius Prime. Remember? They no longer need that middle; however, new uses... like Lyft & Uber... have emerged since then, raising the question of need again. Toyota adjusted accordingly.

Key is keeping design both reliable & affordable, while still remaining a draw. By adding back that extra seat, it makes phasing out the regular hybrid realistic without upsetting the balance of the overall fleet. It's now easy to see Prius being offered as just 3 variants... Limited, AWD, and Prime. That's what we hoped for all along... Prius turning into a choice that highlights the plug. In fact, that reinforces the "self-charging" promotion. Toyota is setting the stage well in advance. It's their forward-thinking that often takes a beating from "anti" rhetoric, but triumphs in the end.

Beside the seating decision was the battery-pack configuration. That was another big risk. Toyota had the choice between cargo capacity and kWh capacity. The decision for initial rollout was to bring back the raised floor. It's what we saw back with the prototype for Prius PHV that ultimately didn't make the cut. Knowing Prius Prime would be a limited rollout until mid-cycle, it was realistic to try the approach again. Why go from 2 to 4 stacks when you could squeeze in a 5th stack? They were designed to be extremely robust with a heavy emphasis on being affordable.

We now see that Toyota liked the results of their real-world testing. Data collected has so far proven those stacks are very reliable. And since reputation for reliability far outweighs cargo capacity, I back that as a wise choice. As much as I would have liked a better fit, the fallout related to Nissan's reliability decision reinforces taking this route by Toyota. After all, affordability is a difficult tradeoff and fitting cargo into Prius Prime hasn't actually been an issue. Remember, affordability also includes warranty coverage. Toyota's focus is on long-term and we know for a fact any increase in EV is a draw to the Prius audience.

With RAV4 hybrid selling exceptionally well and the fallout of GM continuing to get worse, we see Toyota's effort to position themselves to ready Prime for primetime could

really pay off. The market attention on legacy automakers to deliver something now is getting intense. Early-Adopters may praise "in the next few years" announcements, but that's not what ordinary showroom shoppers want. Seeing dealers embrace Prius Prime for 2020, because it fits well into their inventory and basically sells itself, is an expectation we can realistically see happening.

Very long story short, it's time!

6-16-2019 Public Charger. Asking for advice like this is great. A new Prime owner will be taking a highway trip and wanted to know what specific service for charging would be best. It doesn't actually work that way, as I explained: Signing up for just one service is like shooting yourself in the foot; however, that will be changing... not yet, though. The reason why quickly becomes obvious after you've tried a few. Even among a specific network, you'll find the experience varies dramatically. It comes down to each charger owner choosing how the equipment is used and how it will be paid for. I've seen quite a variety. Some are entirely free. Some are free for just the first hour. Some have a per/kWh fee. Some have a few based on time. Some have a flat fee. Some have an unlock fee, then add a per/Kwh fee. It's set at the discretion of the owner, not the service. I suggest using a cover-all-chargers type app, like PlugShare. You'll get reviews & photos from users. Those can be extra informative, especially since presence of particular services can be limited. You'll discover a more generic location finder will tell you more.

6-16-2019 **Understanding Dilemma.** It took me 2 days to finally answer this attempt to argue: "*I see you failed to provide examples. Just give us the top 5 from your writings.*" I wasn't about to give him the satisfaction. Having been through this countless times over the last decade with many others, there was no point doing it again. The repeat really wouldn't serve any purpose... though, I was intrigued by his "100%" claim. Here's what I ended up posting:

That reveals a failure to recognize the nature of the situation. This isn't a product priced at a only few hundred dollars that's expected to last only a few years. This is roughly 2 magnitudes more expensive (100 times) and should remain in service for over a decade.

In other words, this is a new category of problem. Comparing something with so little in common from either a business or consumer perspective makes no sense. Think about the logistics involved for automotive production, all the very large components requiring third-party suppliers. Heck, just the profit-margin alone makes the perspective profoundly different. The reality that automotive production gets so involved with politics adds a dimension of complexity too. There simply aren't issues on that scale with dilemmas of the past. This is breaking new ground, new territory... a new chapter involving innovation.

Your claim that "*Toyota's approach is 100% wrong*" doesn't have substance to support it. You certainly didn't provide any examples. In fact, even your "*old way of doing things*" reference falls short. We can clearly see that rollout of new tech in the past went just fine. We've seen fuel-injection & anti-lock brakes of the past and a slew recent safety features all change the fleet without issue. The transition to hybrid, plug-in hybrid, and electric won't be a big deal either. It's a natural step forward for Toyota dealers and Toyota shoppers.

Remember, the issue I brought up was GM's failure to recognize their own audience. Toyota isn't making that same mistake.

6-22-2019 **Video - Summer EV miles.** Warm weather is back. I haven't filmed anything since the extreme cold. Time to take advantage of better video hardware & software. Here's what I did, then shared:

It's very easy to exceed the 25-mile rating for EV miles during the summer months. Armed with a new tablet for better aftermarket data capture and 2 upgraded cameras since the original drive 2 years ago, the time was right for a new video to show that.

Watch for the commentary added to highlight specific points. Like before, you'll see me drive out to the coffeeshop twice. That route just happens to be the perfect distance, 15 miles total. So driving it twice to demonstrate the 30-mile EV range available under the ordinary circumstances I'd see on that drive, it's a good real-world example to share.

In this case, the temperature was mild but the wind rather strong. Being a round-trip, that influence of push or pull doesn't matter. You witness all the factors impacting efficiency in great detail. At the bottom, you see my dashboard. To the right, you see output from an OBD-II device presented on a phone app. Notice the wide range of information available while you drive.

In the end, the drive went just a little over 31 miles before plug-supplied electricity was used up. At that point, the gas-engine started and the system switched to HV mode (regular hybrid driving).

View the video at this link: [Prius Prime - Summer EV miles](#)

6-23-2019 New kWh Meter. A recent update to the aftermarket app for monitor extra vehicle data has me yearning to capture that drive again. Having a gauge now that displays a total kWh consumption/regeneration value is quite empowering... so much so, it will kill discussion threads from going on and on without certainty... just like the one where I posted this:

I'm at the coffeeshop now, the quarter-way mark, looking at the resulting captured data. It's 7 degrees cooler and I got hit by an extra stoplight, so battery capacity (actual) was at 70% rather than the 72% in the video. (That's an estimate of 79% rather than 80%.) It's all real-world data regardless. The more, the better. In this case, that's 23% of EV capacity available ($87\% - 13\% = 74$; $17/74 = 23\%$). The value shown for consumed/regened overall for the drive was 1.215 kWh. Now, this is where things got messy...

I consistently measure 5.75 kWh as a "full" charge from my JuiceBox Pro charger. That's a complete restoration of EV capacity, including losses from charging and whatever overhead there may be for cycling overhead during the charge and excluding sessions that pre-condition. Some would argue that's not the entire usable EV capacity based on the 8.79 kWh measure of the cells all added up. But my drive often doesn't end as fully depleted (13%), despite being in HV mode. That's due to the long regen I experience just prior to turning into my neighborhood. \Sometimes, it's enough to actually show a little bit of EV available. We know that low values (such as 0.8 mile) will often be suppressed from display. So, you must have an aftermarket gauge to really know what SOC the battery is actually at. But then again, a single percentage point that's truncated falls into margin-of-error territory. With all that being said, I could use a higher value as the measure of "full" for EV capacity. But including a from-the-plug value makes no sense when you are only measuring against consumption/regeneration results. So, I stick with 5.75 kWh.

So doing the calculation.... 23 of 5.75 is 1.322 which is not 1.215 kWh. However, it's close enough. We have a means of collecting & analyzing data that's more comprehensive than in the past. Combined with consistent capture approach, it's as accurate as you can get in real-world conditions.

6-23-2019 EREV is Dead, position. The fall of Volt has brought about a recognition of problems. Naturally, that means a round of shoot-the-messenger exchanges. It's different now though. Rather than rhetoric from enthusiasts, there's the actual death declared by GM itself and the obvious positioning of Toyota to take the market by storm. Nonetheless, dealing with stuff like this is a pain: "*How do you and John 'infer' what Toyota's position is... with the BEV trash talking video ads and all?*" I'm far from being alone now. These exchanges are taking place in new venues too. Those days of the daily blog are long gone. Here's what things have evolved into:

There's nothing being inferred. We look at the big picture. Those articles feed rhetoric by cherry-picking. Portraying the current Lexus position as the entire long-term plan for Toyota is just plain wrong. Yet, many choose to enable the antagonists spreading that spin.

You cannot deny that the "*self-charging*" promotion is an attempt to overcome the confusion related to "*hybrid*" labeling. It is a clear attempt for Toyota to set the stage for "*plug-in*" promotion. They are readying the market by trying to establish a new term to more accurately inform their audience. Again, this is why the KNOW YOUR AUDIENCE aspect of advertising is so vital. Toyota doesn't have any concern what a group of online enthusiasts think. That's not who they are targeting.

That's a fundamental mistake GM made with Volt. The essential question of "*Who is the market for Volt?*" was dismissed as unimportant. GM continued on with their own trash talking of BEV, but not in a limited scope as Lexus has done. Volt was a Chevy, intended for appeal to the masses, not a Cadillac. Those who doesn't recognize the difference between luxury & mainstream consumers hope to take us as fools, spreading nonsense about position.

It's really sad when that message is spread. But that's how spin works. Notice how vague the message actually is? That lack of detail is the message people pass along a message without any critical thought.

We study what Toyota has done over the decades and recognize the pattern. We also recognize the mistakes others have made and continue to repeat. That's how we get the big picture.

Think about how chaotic the market has become as a result of tax-credit phaseout. Those weak offerings heavily dependent upon subsidies are now showing their weakness. We saw that coming by looking beyond the cherry-picking. Others "*inferred*" that wouldn't be a problem. They were wrong, very wrong.

6-23-2019 EREV is Dead, looking back. In addition to the anti-Toyota position, there's the anti-everything-that-is-not-an-EV position. That can actually be even more of a problem. It's when an early-adopter loses touch with the market. They found a means of overcoming obstacles and doesn't recognize others as not having the same priorities or resources. That makes them a terrible source of feedback. Yet, they are the ones we hear most from. For example: *"You buy a hybrid if you really need or want to pay for two engines. They are more expensive to produce, the worst of both worlds, battery has to pull a stupid ICE around, ICE has to pull a heavy battery around. 20,000 miles in a Leaf never looked back will never go back."* That's the same old argument we've heard for a decade. Only, the technology has been significantly upgraded and the market much changed. Remember back when GM was first promoting Volt and the term EREV was coined? Pretty much no one does. That lack of background is how mistakes are made by repeating history. I pushed back with:

That's a blatant misrepresentation of what *"hybrid"* actually can deliver. It implies optimization isn't possible and neither is a plug. The example of Prius Prime demonstrates that Toyota can affordably deliver the BEST of both worlds. You get an extremely efficient HV system in addition to extremely efficient EV driving. With the addition of a plug, battery-capacity, and a one-way clutch any of their other hybrids can deliver the same thing.

Think about how popular a RAV4 plug-in hybrid would be for both dealer & consumer. It's a winning solution for Toyota's business. Everyone wins. Dealers get a product that's easy to transition to, with little to no interruption to process or profit. Consumers get an affordable plug-in that will deliver EV without any change to their driving habits. All they have to do is take advantage of the standard 120-volt outlet they already have in their garage.

Never looking back means not acknowledging the challenges still faced by most of the industry. Expecting everyone to just abruptly abandon old technology without any means of bridging to the desired long-term end-result is madness. It doesn't work.

6-23-2019 **EREV is Dead, cleaner.** Back when Volt was doing everything it could to retain attention, the idea of "*cleaner*" was pushed aside. Use of electricity didn't count. It was all about not using gas. That obviously fell apart once EV choices became the focus of being green. GM's gamble of that not happening, that EREV would dominate the market for generations to come, was a senseless risk. Now, the idea of EREV is becoming an associate with guzzling electricity in a costly manner. Volt was an expensive vehicle that inefficiently used electricity. EV propulsion focused on power, using an unnecessarily large battery-pack to compensate for losses. The decision to use a resistance-heater for electric cabin warming only made the problem of electricity guzzling even worse. So with it's death, we can now have constructive discussions about hybrids... well, kind of: *"If you were really looking at a more effective way to reduce emissions, at least in the US where average fleet mileage is 24-25 mpg, you would set a minimum vehicle mileage limit on all vehicles to 50 mpg. This cuts the emission they are counting in half."* I was a bit annoyed to see that. But you never know. This newer post-Volt audience may be receptive. So, I gave them a chance: Setting an arbitrary MPG minimum won't actually change the status quo. Powers resistant to change will simply fight it, as we now have countless examples of. What they'll struggle to counter though is upgrade mandates. Toyota is leading the way with across the fleet upgrades. Their upcoming next-gen Highlander hybrid is a great example. 34 MPG is quite remarkable for a SUV that large. With regards to pickup offerings, their hybrid system currently in a Lexus is the rumored to be what will end up in Tacoma. That would deliver an expected 30 MPG. So even before consideration of adding a plug, Toyota would have already achieved a significant reduction of emissions & consumption.

6-23-2019 EREV is Dead, math. A big part of the propaganda related to the "EREV" label was to avoid detail. The category was ambiguous. The definition kept changing. The accountability was missing. It was very much a marketing scheme conjured up to promote a product unable to actually compete. It's the name-recognition concept twisted into a plan to lead without merit. Fortunately, after 2 generations of deception, the effort fell apart. Substantial growth was needed. Dependency on subsidies made that far too unrealistic to continue. It was a terrible gamble, one that produced too many losses to be competitive. Remember, automakers are for-profit businesses. The show of a trophy vehicle would only take them so far. I continued my awareness raising by emphasizing origin, drawing attention to the recent sighting of hybrid impact:

btw, that assumption of "*This cuts the emission they are counting in half.*" is the outcome of successful greenwashing. You've been misled. Measurement of Miles-Per-Gallon has been exploited to conceal the reality that there's an aspect of diminishing returns. Even under the best circumstances, the approach is commonly misunderstood.

This is why the rest of the world has been using a quantity/distance measurement instead. In fact, that's why our own EPA now includes "*2.0 gal/100mi*" in their published materials. Notice how that now appears next to the "*50 MPG*" value on the window-sticker?

The reason for this is simple. An improvement of 5 MPG for a vehicle that was only getting 25 MPG represents far more gas than one that goes from 35 to 40 MPG. Just take a moment to do the math to see why.

For 15,000 miles of driving, the 25 MPG vehicle will consume 600 gallons. The jump to 30 MPG reduces consumption to 500 gallons. That's a 100 gallon improvement. For 35 MPG, the quantity is 429 gallons. That upgrade to 40 MPG changes it to 375 gallons... which represents only a 54 gallon improvement.

Adding a 25-mile rating EV capacity to that 40 MPG vehicle gets messy to standardize. But real-world data coming from Prius Prime reveals their driving to be around 75% electric. That makes the 15,000 miles of driving only 3,750 that depend upon gas. The result from a 40 MPG return in HV mode would come to 94 gallons. That's an improvement of 281 gallons.

See the problem? The temptation is to simply divide that overall distance of 15,000 miles by 94 gallons. What does that resulting 160 MPG actually tell you?

Now consider what the impact to gallons would be if EV range was either 20 miles or 30 miles. Not only does it get confusing, but there's also the reality of diminishing returns. None of which most people (even those here) take the time to consider.

To complicate matters even further, there's the fact that gallons only reflects the reduction of CARBON emissions. So, even if that better way of measuring consumption is used, it doesn't have any reflection upon SMOG related emissions... which means you have to ask what "*cleaner*" actually represents.

In other words, no crazy study necessary. Heck, no emissions target even needs to be

set. It all comes down to replacing the fleet with electrified choices. Putting emphasis on using more and more battery should be the goal, but not until much later. At such an early stage, just getting rid of vehicles without any battery-pack should be the concern.

After all, we have already seen how easy the transition is from hybrid to plug-in hybrid and how much that contributes to the desire for the next purchase to be an EV.

6-23-2019 EREV is Dead, personal. It was nice to see a complete lack of substance in the most recent reply. All he could do was go after me with attempts to discredit. That's the most telling clue of having nothing left. Death is confirmed in every regard. It's not damage-control at this point or even trying to feel better about making such a colossal mistake. It's plain old vengeance. I find that amusing... and quite ineffective, as my reply back should reveal:

Shooting the messenger, rather than even bother to address the issue of consumption & emissions... nice.

Toyota has a solid plan for advancing their entire fleet forward. From dealer to consumer, they address the impact change of among all beyond production who will be affected. This attempt to stir old rhetoric is just a final desperate act to distract from your preferred approach. It failed. Get over it. I remember those posts. In fact, that's how some of my videos came about. I used them to shot back.

Losing many battles puts you where on the "*dragging*" claim? It's easy to see how GM has no plan whatsoever to actually deliver something compelling anytime soon. Toyota on the other hand is pushing forward, showing undeniable progress in war as a whole to replace traditional vehicles. RAV4 hybrid and Corolla hybrid, the latest rollouts, show just how wide of an audience Toyota is striving to appeal too. Those are very much mainstream vehicles, both of which their hybrid systems could easily offer a plug model for later. We also see the push with larger vehicles. Highlander hybrid will have a next-gen rollout by year end. Rumors of Tacoma hybrid mule testing continue too.

What I find especially vindicating from all that is your irritation with "we" references. Knowing that there is power in numbers and that failed legacy automaker efforts are quickly becoming just a footnote in history, there's no reason to worry about shooting from that direction anymore. The industry simply isn't interested in that approach. Toyota is moving forward by offering a very wide range of hybrids, expanding to PHV offerings with Prius & Corolla, while also exploring EV models with C-HR.

Again, no amount of "*dragging*" nonsense will hide what everyone else sees.

6-22-2019 **Video - Summer EV miles.** Warm weather is back. I haven't filmed anything since the extreme cold. Time to take advantage of better video hardware & software. Here's what I did, then shared:

It's very easy to exceed the 25-mile rating for EV miles during the summer months. Armed with a new tablet for better aftermarket data capture and 2 upgraded cameras since the original drive 2 years ago, the time was right for a new video to show that.

Watch for the commentary added to highlight specific points. Like before, you'll see me drive out to the coffeeshop twice. That route just happens to be the perfect distance, 15 miles total. So driving it twice to demonstrate the 30-mile EV range available under the ordinary circumstances I'd see on that drive, it's a good real-world example to share.

In this case, the temperature was mild but the wind rather strong. Being a round-trip, that influence of push or pull doesn't matter. You witness all the factors impacting efficiency in great detail. At the bottom, you see my dashboard. To the right, you see output from an OBD-II device presented on a phone app. Notice the wide range of information available while you drive.

In the end, the drive went just a little over 31 miles before plug-supplied electricity was used up. At that point, the gas-engine started and the system switched to HV mode (regular hybrid driving).

View the video at this link: [Prius Prime - Summer EV miles](#)

6-23-2019 **New kWh Meter.** A recent update to the aftermarket app for monitor extra vehicle data has me yearning to capture that drive again. Having a gauge now that displays a total kWh consumption/regeneration value is quite empowering... so much so, it will kill discussion threads from going on and on without certainty... just like the one where I posted this:

I'm at the coffeeshop now, the quarter-way mark, looking at the resulting captured data. It's 7 degrees cooler and I got hit by an extra stoplight, so battery capacity (actual) was at 70% rather than the 72% in the video. (That's an estimate of 79% rather than 80%.) It's all real-world data regardless. The more, the better. In this case, that's 23% of EV capacity available ($87\% - 13\% = 74$; $17/74 = 23\%$). The value shown for consumed/regened overall for the drive was 1.215 kWh. Now, this is where things got messy...

I consistently measure 5.75 kWh as a "full" charge from my JuiceBox Pro charger. That's a complete restoration of EV capacity, including losses from charging and whatever overhead there may be for cycling overhead during the charge and excluding sessions that pre-condition. Some would argue that's not the entire usable EV capacity based on the 8.79 kWh measure of the cells all added up. But my drive often doesn't end as fully depleted (13%), despite being in HV mode. That's due to the long regen I experience just prior to turning into my neighborhood. \Sometimes, it's enough to actually show a little bit of EV available. We know that low values (such as 0.8 mile) will often be suppressed from display. So, you must have an aftermarket gauge to really know what SOC the battery is actually at. But then again, a single percentage point that's truncated falls into margin-of-error territory. With all that being said, I could use a higher value as the measure of "full" for EV capacity. But including a from-the-plug value makes no sense when you are only measuring against consumption/regeneration results. So, I stick with 5.75 kWh.

So doing the calculation.... 23 of 5.75 is 1.322 which is not 1.215 kWh. However, it's close enough. We have a means of collecting & analyzing data that's more comprehensive than in the past. Combined with consistent capture approach, it's as accurate as you can get in real-world conditions.

6-23-2019 EREV is Dead, position. The fall of Volt has brought about a recognition of problems. Naturally, that means a round of shoot-the-messenger exchanges. It's different now though. Rather than rhetoric from enthusiasts, there's the actual death declared by GM itself and the obvious positioning of Toyota to take the market by storm. The industry simply isn't interested in that approach. Toyota is moving forward by offering a very wide range of hybrids, expanding to PHV offerings with Prius & Corolla, while also exploring EV models with C-HR.

Again, no amount of "*dragging*" nonsense will hide what everyone else sees.

6-23-2019 EREV is Dead, ambiguity. More than anything, I find that most telling. When you push for detail and get that instead, you know they are bluffing... or in our case, intentionally attempting to mislead. There will be references to articles & videos, but no actual link or even a quote. So, the very idea of addressing context or audience is impossible. It what the antagonist does to evade getting confronted on detail. I saw that for an entire decade from Volt enthusiasts. Their hate for me grew to extremes. I kept out facts with lots of detail they simply couldn't deal with. Armed with a wealth of business research, their engineering arguments fell apart. They couldn't deal with those facts that reached beyond simply building a better vehicle. That's why I kept bringing up audience. Of all the challenges the technology faced, finding a way of appealing to ordinary showroom shoppers was well beyond what their technically-oriented minds were trained to do. They simply couldn't see that perspective. So providing detail made no difference in their willingness to try to understand. It was outright dismissal that what I was presenting had any relevance. That's why the ambiguity was enough. They didn't feel any need to provide more... which is why I kept pointing out the shortcoming of their "*good enough*" attitude. After so many years of dealing with that, it feels really good for not having given into the temptation to fight back on the same level. Instead, I kept on with my research and kept filming video to disprove claims. That detail is priceless.

6-23-2019 EREV is Dead, prevention. This kind of spin is how narratives are established: "*toyota made a bev decision recently, based on the china market alone. and they make a lot of decisions based on the japanese market alone. the rest of us get the crumbs, and we're grateful for them!*" That same old troublemaker just keeps repeating his own perspective over and over. Sadly, it's one of very limited scope and he clearly doesn't actually read some of the posts. It's the nonsense from years ago living on... just pass along a vague message and ignore real-world data. Their attack often includes audience, shooting the message with efforts to discredit. It especially angers them when you point out you are not alone. Fighting on a personal level is much easier, hence the limited scope. My fight with them goes on. The experience from dealing with the trouble Volt enthusiasts created provided lots of informative background... providing an great sense of how to prevent: Actually, we have been discussing the EV model of C-HR for over a year now. The perspective of "*recent*" is the antagonist narrative being passed along. As for that "*the rest of us part*", it is why the "*Who?*" question was asked so many times over the years. In fact, that's how "*know your audience*" came about. There was a genuine concern the EREV nonsense would mess up the market here. And sure enough, that "*vastly superior*" push soured reception here. I am not the slightest bit grateful for that unfortunate outcome, since it was preventable.... and I was one of those in the "*we*" that fought hard to try to prevent this.

6-24-2019 **EREV is Dead, failure.** Posts like this speak volumes: *"So the Volt wasn't cancelled. Its factory was shut down because the other model lines made there were cancelled. Now being a sedan-ish car, moving Volt production couldn't be justified. The drive train is in a couple of Chinese Buicks, so Voltec didn't fail."* That's ongoing damage-control you come to expect. The massive failure to achieve objectives is a very big deal. Every single time Prius was mentioned in the news, it was immediately followed by a message of superiority about Volt. Yet, that technology vanished. It was basically a fade. EREV was meaningless marketing. There was never a clear definition of what it meant. Every time that got called out, the definition would change. If you take the time to research that change, you see the pattern of evade & alter. It's not worth fighting the antagonists on any of that with an expectation of actually getting acknowledgement. You use those opportunities to provide exposition. It's a way of revealing history to newbies and those who hadn't paid close enough attention. To that post though, I just let him have it: That's called moving the goal posts. We all know the target numbers, dates, and locations... none of which that damage-control effort will forgive. This is yet another example of OVER PROMISE, UNDER DELIVER.

6-24-2019 EREV is Dead, trolling. Blatant trolling has become so common, the hope is that chaos will allow it to continue unchallenged. I'm fighting back:

Pretending this is new information screams unfulfilled objectives.

Reality is, the measure for success or failure was always based upon the ability for each automaker to deliver a system that could achieve sustainable & profitable sales prior to tax-credit phaseout. The reason for that is uneatable. It was the very purpose of such a generous subsidy. In fact, that is why each automaker was given the discretion of choosing their own timeline, to best utilize that limited opportunity.

GM squandered what they had, wasting it on conquest rather than finding a means of spreading the technology to other vehicles. That's why the lame excuse for Volt being discounted holds no merit. That system should have been implemented within a Trax or Equinox many years ago. Remember how all that EREV vastly superior nonsense? Volt sales plateaued at the 1,600 to 1,700 level. Each month, regardless of what GM attempted, growth was never achieved. That's so far below the business goal to keep the technology viable, there's nothing else to but try something quite different.

Toyota's approach is quite different, hence the absence of any constructive attempt to discuss the situation. Toyota still has time. They have an ample number of tax-credits available and they are already well into the diversification effort. Corolla PHV will be rolled out later this year, starting elsewhere. That gives them even more time to prepare the stage here for that necessary growth. In the meantime, RAV4 hybrid is pushing well into the mainstream, reaching a new audience GM could only dream of. It's a platform capable of offering a plug later too.

So all the spin about not failing won't cover up the reality of status quo remaining unchanged for GM. Their dealers are doing the same old push of giant guzzlers with no plan for the future. It's just a day-to-day survival situation... which is why there's reason not to consistently remind everyone of that past. You don't overcome mistakes in history by not acknowledging they ever happened.

This is why recognition of Toyota's effort genuinely change their fleet should be taken seriously. This antithesis thread revealed what about efforts to achieve efficiency & sustainability?

6-25-2019 **More Videos.** I'm compelled to continue filming, advancing my technique with each publish. The quality continues to improve... so much so, the videos now stand out. With the presentation so refined over the years and the for-dummies type commentary, it's becoming easy for the content to get dismissed. I have exactly what I need to convey the message that I need. The aspect of being a filmed-by-owner video is lost. There's no rough-around-the-edges element. All those years of refinement effort put me in a challenging position. Some moderated venues won't allow self-promotion. That content looks exactly like that now. Bummer. True, I can still stir interest in other ways. But the nature of many blogs & forums are to cater to newbies. Content that's well-polished and carefully thought out simply isn't a focus there... since that doesn't promote participation. In fact, that type of solid real-world data discourages it. Nonetheless, I'll keep filming. Know your audience teaches me that the content will be shared, just by a different means in the future. The audience is growing. That type of change... empowering others to share & conclude... is how growth takes place. So, more videos will come.

6-26-2019 **No Future.** There's a repeat of the "*vastly superior*" attitude emerging. Now that Volt has basically vanished from existence... which is strange, it's as if it never made any market impact whatsoever... we're seeing entirely new efforts to undermine. Rather than just attack Toyota specifically, the entire category has been targeted. For example: "*The push for electrification has put a number of OEMs in a weakened position as they lack true EV tech. To make up for it, they're trying to sell plug-in hybrids.*" The article with that opening line ended with: "*Numerous carmakers have huge EV plans starting in about a year for the 2021 and 2022 model years.*" It's history repeating, again. We get vague claims that hope is built up. Meritless hype feeds the excitement. Ugh. I responded to the link sighting that article with:

It's the same old nonsense we saw when hybrids were new. There was a constant onslaught of attacks all attempting to mislead about future by implying all worked the same way. It took quite a while to finally gather up enough convenient online material to easily disprove & discredit those source. Some were rather relentless, doing everything they possibly could to undermine progress. That's why I've been building up a collection of driving videos, each showing in depth detail to show their claims are a load of crap.

It's sad that PHEV are being attacked by EV supporters, but no surprise. Our owner's group here liked to mock me, but in a friendly manner... knowing my effort was to promote lithium-battery use for any type of automotive propulsion. For us, it's all about getting the most out of whatever plug you have available. We have honest exchanges about how each of our designs operate... which is a far cry from this article. Ugh.

The video I filmed yesterday captures detail about kWh consumption for a continuous drive using up the entire EV capacity. That trip of just a little over 30 miles using only electricity is great, but this article draws attention to the HV aspect. I'll have to do a fresh capture (now I add commentary) with a long drive using nothing but gas. That MPG is always impressive.

6-27-2019 **Wondering Why.** I liked this: *"I don't know the numbers, but based on the fact that I rarely see a Prime on the streets but often see the Gen4 Prius; I am assuming that Toyota is selling a lot more of them than Primes. I wonder why that is?"* It was someone trying to figure out the true situation, knowing that anecdotal observations can be misleading and sometimes just plain wrong. That's good to know some people are using critical thinking. This was my reply to that:

Neither our market, nor the entire industry, were ready for mainstream PHEV offerings.

The biggest problem was cost. That heralded PHEV leader for years was heavily dependent upon tax-credits for mere survival. Sales never grew to the level necessary to compete with other vehicles offered on dealer's showroom floors. It's production has been ceased as a result, without any successor model. The entire approach was abandoned. So, there wasn't any point rushing out the technology by other automakers. Toyota saw the benefit of refining & diversifying in the meantime.

That positions Prius Prime incredibly well for the necessity of appealing to both dealer & consumer. If the salesperson isn't able to get a worthwhile commission, what's the incentive to sell it? There's no point in pushing a vehicle facing profit challenges. Seeing Toyota invest heaving in the spread of the technology really helps. Diversification is the ultimate endorsement. Elsewhere this year, the Corolla PHV will be rolling out. Seeing the technology from Prius Prime emerge in another hybrid sends a strong message... especially for those wondering if RAV4 hybrid will someday also get a PHV model.

In other words, the stage is still being set. We'll witness the plug-in model of Prius become the dominant choice, leaving just the Limited and AWD as regular models. It's an essential paradigm-shift long in the making and very carefully thought one... hence no reason to rush.

6-27-2019 **Video - kWh Meter Data.** Understanding how the electricity is actually consumed to provide propulsion in addition to cabin heating/cooling is really important. I end up having to deal with posts from people who don't. That really confuses matters. Their claims are misleading because they didn't have all the information that was needed. So, I'm always on the quest to provide that missing detail. With this newest video, you lots of new data. I was excited to be able provide something previously unavailable. It looks like it will be really handy to have this footage readily available... which is what you now have. Here's the detail: The latest upgrade from that aftermarket app (called "*Hybrid Assistant*") I use to create Prius Prime drive videos with has added a very informative new meter. You can now see the electricity being consumed & regenerated. That display of kWh is real-world data we've never had access to on this level. It's a great learning tool to really understand what the plug-in hybrid technology is really delivering. Here's my first video using it, featuring a 30-mile drive of all EV with kWh data the entire way. I'm quite curious what others will have to say after observing that collection of content compiled into a single contiguous video. Feel free to posts comment on whatever information catches your interest. Here's the link to view it: [Prius Prime - kWh Meter Data](#)

6-27-2019 kWh Video Feedback. I did end up getting a few responses right away to the newest video. This was one long follow-up replies:

I'm working on a cheat-sheet. Posts like this are how I collect feedback about the content for it. In this instance, the topic is kWh.

kWh is the amount of actual electricity consumed by the vehicle. This is a big deal, since some plug-ins are more efficient than others. In fact, some are outright guzzlers of electricity. That's why drawing attention to how well Prius Prime uses its supply available will help endorse Toyota's well thought out design.

Think about kWh. That's the unit of electricity your provider bills you for. Requiring less to travel the same distance is a better return on your vehicle purchase. Your monthly statement will be lower. It also means you'll spend less time at the charger. So, knowing the actual efficiency rate is very important. Understanding of that starts with observation of how kWh is used.

Prius Prime has a 8.79 kWh capacity battery-pack. Part of that is reserved for longevity, never touched for the sake of avoiding stress on the cells. Extremes accelerate aging. There's also a portion of it reserved for HV travel. The portion allocated for EV travel is noted on the dashboard as the percent value from 100 to 0, when the numeric display option is selected. On that secondary display (to the right), it is the range from 87% to 12%. In other words, the dashboard shows "*usable*" capacity and the phone app for that aftermarket gauge connected to the OBD-II port shows "*actual*" charge level.

Watching the video, you'll see the Total kWh value go up & down. That's because it is showing the net result of using plug-supplied electricity and some of what it recovered when braking (known as "*regeneration*" of electricity). For that 30-mile drive, it states a 5.2 kWh as the transition point, where EV capacity is depleted entirely and HV mode engages. At that point, the gas-engine joins in to supply power for both propulsion & electricity.

The next step in understanding kWh is to look at what happens when you plug in. There are conversion losses going from household AC to the battery DC. There are efficiency differences from the charging speed as well.

6-28-2019 **Worth It.** Far too often... in fact, it is almost all the time... people don't place any worth on contributing to being green. Effort to endorse infrastructure and related components (like equipment & employment) get overlooked entirely, never given even a cent of value. It never gets talked about by those researching vehicle purchases and gets dismissed by antagonists. Undermining is the silent enemy. Progress is impeded by basically just ignoring what contributes to it. Ugh. So, I look for opportunities to draw attention. For example: *"A 240-volt Level-2 charge station is almost never worth the money. It provides much faster recharges, but that only matters if one can save enough gasoline which almost never happens or if one is serious about not burning gasoline."* That advice excluded factors not related to anything directly returned to the owner. I always hope some mention of green worth unrelated to "saving" is included. Sadly, that rarely happens. But at least I still get the opportunity to draw attention to the omission: Hope you don't mind me pointing out the trap you fell into... That's a sad sentiment passed along from rhetoric long ago, unaware of the message it truly conveys. Read that message again. Notice the complete absence of the other benefit? Most people don't. Focus is diverted entirely to gas consumption. That's the trap. There's no value whatsoever placed upon simply being greener. By installing a level-2 charger, you are doing your part to endorse infrastructure upgrades. It gives electricians & manufacturers both profit & experience to benefit the rest of the market. So, whether or not you ever take advantage of the reduced charging time (which undoubtedly, you will at some point), you've contributed to the movement forward... which we all appreciate. Sorry, it ends up almost sounding like a guilt-trip, but that is how to appeal to people when they focus on "worth it" equations which leave out some factors. Think about how easy that fact was to overlook.

6-28-2019

Who? Reset. It's easy to see history hitting the reset button. Know your audience. Almost the entire collection of antagonists are gone. These were the individuals who embraced group-think to push Volt. It's seemingly started innocent enough, with just a bunch of early-adopters sharing the same vision. But as their support systematically dismissed evidence of hurdles too big to overcome alone, they embraced "*vastly superior*" rather than seeking out alliances to help break down barriers. They became enthusiasts fueled by hope. It grew into a terrible hype. The ideas of substance & merit were abandoned. They'd eventually come to resist any type of constructive discussion. It's an awful pattern I have witnessed several times now over the 19 years of being actively involved in fighting the status quo in the automotive industry greening. They'd target me, rather than those fighting against change. Ugh. That was the origin of the "*Who?*" question but didn't become something to highlight as a problem until Volt came along... when I started asking "*Who is the market for Volt?*" They thought I was crazy. To those enthusiasts, the answer was obvious... them... hence, the group-think. My recognition of the same thing happening with ASSIST hybrids, then Two-Mode, then EREV is the result of meticulous study. Each made the pattern of incorrect audience a well defined match. They were all focusing on engineering and basically just brushed aside all other purchase priorities. They'd confuse want with need. That loss of perspective is what doomed them. It's like the EV problem now. I keep seeing "*affordable*" associated with the price of a vehicle in the low 30's. How is that supposed to be a realistic choice for someone looking to only spend something in the low 20's for their next vehicle? Corolla hybrid has a starting price of \$22,950. Remember the "*nicely under \$30,000*" goal? Those unwilling to acknowledge history don't. In fact, they pretend many of the other lessons learned from history simply don't apply to their situation. It's a push forward based on hope, rather than sound business. That's too much of a gamble. We've seen it failed several times on a huge level.

6-28-2019 **Who? Dealers.** I remember getting feedback about my attitude, claiming it wasn't the message, it was conveyance of it. That seemed sensible, until you recognize the pattern of dismissal. The information itself was never acted upon. Those not recognizing who just kept on with their pattern of defiance. They knew best and nothing provided would sway their belief. Their act of stubbornness contributed heavily to the death of volt. The reality of dealer-not-consumer never sunk in. That epiphany never happened, despite countless attempts to get them to see the problem. Ugh. It's come down to a lesson learned which some still refuse to accept:

Dealers have been the problem all along. Trouble is, early-adopters weren't interested in the bigger picture. Focus was entirely on conquest purchase, not actually changing mainstream buyers. GM crashed & burned because of this. Tesla gave a valiant effort to avoid the inevitable plateau resulting from tax-credit phaseout. Things will work out fine in the end, but that slow down wasn't an expectation properly set... despite countless warnings of it coming.

The only legacy automaker with a solid plan for getting dealers to embrace change is Toyota (though there is lots of potential for Hyundai). Across the board, we are seeing hybrid rollout... Corolla, Camry, Avalon, C-HR, Highlander. The latest has been an incredible success: RAV4. Think about how much easier selling the PHEV and EV models will be later with widespread acceptance of hybrids. That risk of change would have been mitigated, and in short time too. The expectation is currently set at 20 to 25% of RAV4 to be hybrids. What other automaker is seeing that level of penetration? Dealers who are on their game will establish a welcoming of new tech as a sales advantage.

Toyota also has the unique opportunity to also appeal to Prius owners, a massive base to draw interest from for their first PHEV offering. And with the Corolla PHEV rolling out elsewhere in the world later this year, there's an undeniable effort to stir attention from dealers. Corolla is a top-selling vehicle. Getting a plug-in version to market is a really big step forward. Income from routine maintenance will be lower, but being able to keep demand strong for sales will reduce dealer apprehension.

6-28-2019 **Who? Wait.** There's nothing wrong with delay... as long as you have a solid reason for it. Enthusiasts will wait for a miracle, hoping some announcement will result in a huge overnight success. They don't understand how much must actually take place for the sales they want to become a reality. It isn't a matter of build it and they will buy it. That was a painful lesson learned for the Volt enthusiasts. They truly believed a "*vastly superior*" product was all it would take. In fact, some still think the lack of advertising on GM's part is all it would have taken for it to achieve high-volume profitable sales. The realities of stocking inventory and the act of selling never get any attention. Focus is always entirely on the consumer... who doesn't pay attention. From their perspective, it really is just a matter of waiting. The problem is, for how long? That sentiment keeps getting passed along. We never actually arrive at that time. The wait becomes indefinite. I tried to convey that in this series of exchanges: That "*just give it a couple of years*" reply is getting really old. It's unacceptable to just give legacy automakers a free pass with an "*all segments will be covered by 2025*". The reason why is simple. Dealers will just wait. That's an entire vehicle generation, just waiting for introductory rollouts. Then how much longer after that do we have to wait until the high-volume sales actually begin? Annual sales worldwide are over 80 MILLION vehicles. Change needs to begin now.

6-28-2019 **Who? Excuses.** The exchanges continue. I could tell he was just searching for an excuse to dismiss me, rather than actually consider the information being shared. This summed up the situation well: "*And I believe you give people no credit for actually figuring out how to use new technology.*" That was a polite means of shooting the messenger. It was an attempt to get the consumer involved in the supply & demand discussion. I know how vital inventory is. With the initial rollout back in August 2000, through May 2002, you could only get a Prius by ordering one. All new purchases were sight unseen. The who back then was Toyota's diehard supporters, which is why they made getting one more than just pointing to one on the dealer's lot. That's why the mid-cycle rollout of the first plug-in Prius was also internet only, then switched to only select states. Toyota knew its audience and had a very clear objective (collecting real-world data from well-informed markets). So later when next generation came along, rollout come be to a wider who without any surprises. Unfortunately, the fallout with GM caused delay. But that's not an excuse, that's a wait with very good reason. This exchange was none of that. He just plain did not like what I was posting and I wasn't about to allow him to continued without a callout: That's a red herring, diverting attention away from the topic of dealers. People can't buy what isn't available. In other words, the true customer of legacy automakers are dealers, not the end consumer.

6-29-2019 **Who? Hate.** Lashing out is the next step, when an antagonist becomes so frustrated with the information shared, the effort turns into an expression of hate. For example: *"I have no love for any of the traditional majors and could care less if they go out of business. The ones that actually care about doing full EV's I care about. The rest? Hell with them."* He was letting emotion steer the discussion. Logic was abandoned. Points about having something quantitative to aim for... you know, a goal... was lost in the frustration of me not listening to the rhetoric. I wasn't taking the bait and he couldn't see why. That's because he didn't know who he was dealing with. Know your audience. I don't give in to hate. I don't let group-think make my decisions. I share observations and explain why my stance was taken:

Lack of substance invalidates that argument. It's so vague, there's nothing to actually discuss. We've been hearing the *"all electric"* mantra for an entire decade. The unfortunate legacy consequence of that was an exploitation of tax-credits.

The problem is forcing a specific approach, which history has repeatedly revealed to be a path to failure. Changing the mantra from *"all electric"* to *"full battery"* doesn't change anything either. It should always be about goals. Establish something meaningful for automakers to deliver. Without any real target, there's no competition, no incentive, no push. Business as usual simply continues.

In other words, you're giving them exactly what they need to retain the status quo. Notice how some automakers have announced the number of models they intend to deliver by 2025, rather than any actual vehicle quantity? All they need to do is rollout a token few to fulfill that horribly vague promise. They don't have to be affordable. They don't have to provide any specific range. Heck, they don't even have to use electricity efficiently.

So what if the industry expert in hybrids delivers a Prius Prime, Corolla Prime, Camry Prime, and RAV4 Prime? Each will provide exceptional electric & gas efficiency (as EV and HV ratings for Prius Prime already confirm) at an affordable price. And since they will be based upon high-volume platforms their customers already strongly demand, supplying an alternative propulsion system is a sensible approach.

I understand the desire to aim for the best, to not waste resources on transitional technology. But the reality of the situation is that legacy automakers are a for-profit business who serve dealers that require easy to sell vehicles who will favor profitable inventory. That idea of abruptly switching to a specific approach when it is *"ready"* doesn't fit within the realities of consumer need, salesperson need, dealer need, supplier need, or automaker need.

Who is the *"full battery"* label supposed to appeal? Someone commuting with a PHEV that's within the range of their employer or where they park provides chargers will experience *"full battery"* driving. So what if there's a gas engine available for long trips. The bulk of their driving will be *"all electric"* anyway. The bulk of their driving will be with only electricity.

6-30-2019 Who? Anger. Reading through the series of posts again, it became obvious that he had no idea how a plug-in hybrid actually operated and was quite frustrated with the lack of progress from legacy automakers. Back when there was Volt, that all too familiar delay attitude was expressed upon missed goals. Shortcomings would be resolved with the next generation, so act of waiting would be all that was necessary for targets to be reached. That was quite a gamble, very risky. Depending on too many things to happen for an objective to be reached is one thing. But now, there isn't even to shoot for. He just labeled the finish line as "full battery" without specifying anything else. There was no substance and I called him out on it. So, he deleted all his posts. Getting caught in the act and responding that was is intriguing. Since I have email notify enabled, I already had an offline record of all the posts. That meant I could constructively respond anyway. And I did, with a call out.. since the who became him:

The stance I have taken is the result watching you just brush aside history, dismissing those facts presented without any type of acknowledgement. No label necessary for that behavior. It's the outcome that matters. I got your attention. That was the point. Will you just go your own way and ignore those lessons learned or ask questions about how to prevent the repetition?

Again, lack of substance means not sighting anything quantitative. Just a vague "*full battery*" sets no targets whatsoever. Not having any type of time, price, volume objective is how that history happened. Being sick of labels & overplay is good reason to seek out strong personalities willing to step up. If that's you, sound off with some solid goals & realistic expectations.

As for spinning my belief to be that of hybrids only, you clearly need to read more posts . I'm all about EV, but don't at all agree with the polarizing approach many here endorse. They are the combative ones. I'm just trying to get attention within that chaos.

6-30-2019 Fallen Leader. Anyone remember all the relentless attacks on Toyota about how far behind they were, that following the industry leader would be a painfully difficult struggle? It's hard to believe that was less than 6 months ago. GM was the praised automaker who could do no wrong. Today, there was an article published where the comments posted said GM could do no right. Interestingly, there was much agreement. The reason why is obvious... sales of Volt & Bolt never amounted to any actual change. Status quo remains intact and early-adopters are upset. Despite so many warnings of tax-credit exploitation and niche pandering, they are dumbfounded about the outcome. It's quite extraordinary to witness. Timing is exactly as anticipated too. We are halfway through the 50% tax-credit phaseout and 2nd quarter sales results will soon be revealed. Everyone knows such bad news is on the way that there's nothing to fuel hype anymore. It's over. Right on cue to step through the ashes is Toyota. Their choice to not upgrade the battery-pack mid-cycle makes more sense than ever. It means they have a solid 2 years of real-world data to leverage. That scale of owner endorsement is how growth is achieved. Rollout to the remaining 35 states will be so much easier with that experience to refer to. This is why I put up with all the nonsense from those Volt enthusiasts. They were too shortsighted to understand who the effort should be targeted at. Appealing to enthusiasts was a momentous mistake. GM really blew it.

6-30-2019 **Innovation.** From that discussion focusing on GM's fall came this: "*The problem with legacy, run-by-committee, focus-group-driven companies is that they don't innovate. They try to give people what they think they want. Unlike visionaries like Jobs and Musk, they don't deliver what people don't even know they want.*" It was a thought-provoking comment about want, not even bothering to bring up need. I liked that. But rather get into the subjective aspect of advancement, I kept focus on the innovation effort itself with:

It's not a matter of getting legacy automakers to innovate. It's how to appeal to their true customers, their dealers. Remember, this is a for-profit business with a long history of resistance to change.

GM had a disastrous run with Volt. Design suffered from group-think fueled by exploitation of tax-credits. That's easy to see now, since feedback was from enthusiasts rather than ordinary consumers and cost-reduction efforts were far from target pricing. It's too expensive and doesn't appeal to their own showroom shoppers. But back then, leadership given despite that. It was a denial path to nowhere, which is confirmed now by that technology not being spread to make it profitable... the very purpose of those tax-credits. Lesson learned is innovation requires acute attention to audience.

Toyota is constantly ridiculed for focusing on hybrids, despite the overwhelming evidence they are setting the stage for high-volume rollout of plug-in models. We see Prius with that plug-in upgrade worldwide already. Corolla hybrid offered as a plug-in hybrid later this year in some markets. C-HR, which is a hybrid in Europe already, will be offered as an EV in China for 2020. What is compelling Toyota to push forward with their fleet transformation? It's their understanding of how to appeal to their own audience and not listening to early-adopter rhetoric.

We can see the obsession with SUVs here is making the RAV4 hybrid a strong seller. That's a terrible platform for efficiency; however, it does make for a compelling plug-in hybrid. Toyota has an affordable means of delivering that too. It's a next step forward dealers can easily embrace... which is a key component to making any innovation effort a success.

In short, look beyond just the technology itself.

6-30-2019

Mass-Market or Luxury? The question of "*Who?*" got asked more and more as GM's struggle for sales got worse and worse. The reason was simple; they were all about conquest but we couldn't figure out with who. Supposedly, the purpose of Bolt was to compete directly with Tesla. That seemed a bit odd, but made more sense than the split-personality of Volt going after both Leaf and Prius PHV. That was still a problem though. It made the assertion that Tesla was seeking a mass-market audience. With the price for Model S and Model X so high, it meant everything would be based upon Tesla somehow achieving that hyped \$35,000 price-point immediately upon rollout. Even then, market saturation was a very real issue. That's far above the mainstream expectation. All this depended upon sustainable sales being achieved quickly too. None of that happened. Both GM & Tesla are in challenging positions now. Fundamentals are now being analyzed too: *"It doesn't matter whether Tesla delivers 90,000 cars or 900,000 in the 2nd quarter - what's more important is whether Tesla goes mass-market or stays luxury."* That article opener really caught my attention. It emphasized what I had been raising concern about all along... audience... who? For GM, we know they have a heavy base of Pickup & SUV owners. That means the category of luxury is a bit skewed, since that category is typically sedan-centric. Coming from the Chevy brand, that makes no sense whatsoever. What about for Tesla? Those sedans which their current customers find absolutely stunning for looks are all early-adopters. They don't represent the mass-market. Is that a problem for Tesla? Disappointingly, the article didn't mention that at all. It's entire focus was on what volume was the correct level for the proper profit-margin? Balancing capacity with capability is a challenge. You really need to understand a large amount of influencing factors to get that right. With so much investor interest at stake, that's a very real problem. Remember what contributed to GM's bankruptcy? See those same elements at play now for the legacy automaker? That leaves Tesla in a difficult position of how to integrate as a new automaker into an aged & troubled system. To compete with ordinary consumer choices, price still needs to drop dramatically. Operational cost is wonderfully low for EV early-adopters, but that isn't something as easy to appeal with toward the shopper who focuses almost entirely on the out-the-door cost. Purchases don't often include fuel expense. In fact, that's why guzzlers remain so popular. Gas is cheap enough. So, consumers don't give it any priority. That's why the much lower cost for electricity is such a hard sell. Mass-Market appeal means far more potential. So, it's a really big deal to make intended audience clear. GM didn't and failed as a result. Tesla must now make the decision.

7-01-2019 **Down to 25%.** Big news today is that Tesla tax-credit phaseout drops down to 25%. That has renewed the rhetoric. But with the death of Volt, there's no real substance to those arguments anymore. As a legacy automaker, there was some leverage from GM on the topic. With Tesla though, it's basically find a different means of subsidizing progress. So, I was intrigued how the new discussion thread would progress. This is the quote I homed in on: *"No, the per manufacturer number is idiotic. A common pool makes sense. The pioneers don't get penalized and the laggards don't get rewarded. There was a lot of work to bring up the technologies, supply chains, and marketing to bring forth these products. The laggard companies did none of this work and still enjoy plenty of credits."* Knowing there's so much neglect & overlook related to the rest of what it takes to advance the technology forward, I had much to say:

The narrative of laggard fell apart when it was confirmed that GM exploited their tax-credits for conquest sales, rather than using them as intended to change what their own loyal customers would buy. There's simply no way to argue that either Volt or Bolt actually changed the status quo. We see those with old GM guzzlers simply replacing them with new GM guzzlers.

Each automaker being given an allocation of their own meant taking the time to do it right. GM's rush to market was wasted opportunity. Pioneer means you do something with whatever ground you break. GM didn't. We still doesn't see any model of SUV with any type of plug. That was the point of getting such a generous government subsidy.

Remember, the goal is to deliver something that can compete directly with traditional vehicles sharing the same showroom floor. That means each automaker must develop technology to appeal to their own shoppers. Retaining loyalty is a vital aspect of legacy sales. Those dealers depend upon repeat business, which requires an easy sales with a reasonable profit.

Of course, focus on *"bring forth"* is misguided. It implies we're stuck in the early-adopter phase still and nothing was accomplished. That's a load of garbage. Subsidies are not needed for the vehicles anymore. New tax-credit offerings should focus on the next stage: INFRASTRUCTURE.

Just imagine how well spent the money would be getting homes upgrades to offer L2 for each vehicle parked there. That would do far more to move mainstream consumers forward than just giving more to buyers already set on purchasing a plug-in vehicle anyway.

Just imagine how well spent the money would be getting employer... and businesses... and ramp owners.

It's all about moving forward. Pioneer efforts should be there now.

7-01-2019 **Well Timed.** Naturally, the attempt to draw attention to sad state of infrastructures and how those challenges are being ignored turned into an attack on Toyota: "*Toyota foolishly burned up nearly half their tax-credits on little PHEVs. By the time they go full BEV, they might not have much tax-credit left.*" There's so much of an obsession with delivering a BEV, they simply don't care about anything else related to mainstream acceptance. It's a fundamental mistake to evade balance, which is an essential to sustainable profit. It's what happens when group-think takes hold. They lose touch with the basics, choosing to lean on distractions as justification. That's sad. I point it out, but they really just plain don't care: Toyota won't need tax-credits for BEV offerings. That supposed "*foolish*" use for PHEV has already produced a remarkably efficiency system. Cost reduction is well underway. Battery refinements are pushing forward. There's even weight improvements coming from carbon-fiber. There's simply no merit to claims of having missed opportunity. Real-World data collecting from the plug-ins rolled out is serving its purpose well. Toyota is using that information to advance the entire fleet forward. So what if an EV doesn't come until the next stage when subsidies aren't available? At that point, the business of selling plug-ins would have been established anyway... which is the point of that money.

7-01-2019 **Do The Math.** He failed to consider the big picture, but it was a welcome change of pace. This was a discussion about charger setup at home... the very balance I had been arguing for in that other thread. It came to this: "*There should be some math to back up this analysis.*" That's usually how most of the posts progress. They get deep into the math, completely missing the point of contributing to green infrastructure. When reduced emissions is give a value of \$0 in those analysis, you are very likely to experience a pushback to anything related to doing-your-part consideration. So, mention of helping a local electricity co-op or a local electrician shop by provided some real-world hands-on opportunity for them is pointless. They simply don't understand the benefit that provides. It's really unfortunate. This is what pushes me to find new approaches and new responses. In this case, it was simple. Debating between sticking with the existing 120-volt connection or having a new line & outlet installed for 240-volt power overlooked something which should be obvious. What do you do for the second vehicle? Households tend to have at least 2 vehicles. Not looking forward enough to realize there's only 1 outlet available is quite shortsighted... especially when these discussions amortize cost over the span of many years. That level-2 charger simply becomes a requirement for the purchase of a second plug-in vehicle. It makes no sense running a lower gauge wire. If you have to go to the trouble of installation anyway... Since those arguments insist upon math being the primary means of justification, I simply showed my response as this equation: $2 \text{ cars} + 1 \text{ outlet} = \text{L2 needed}$.

- 7-01-2019** **Rush To Market.** In the past, arguments to disparage Toyota pretty much inevitably ended up with a turn to fuel-cell investment. It was an intriguing pattern of attempted undermining... since they were establishing a precedent I could turn on them later. For example: *"Toyota will go full FCEV before full electric. At least that is their plan."* I took that bait... but didn't respond with the hoped for rhetoric type response. I hit back with cold, hard facts. This is the type of information that makes them cringe, because there's no effective means to rebut what just go posted: The name of that vehicle is Mirai. It uses a 151 hp electric-motor, which isn't a coincidence. That's a size perfect for an EV model of Prius or Corolla in this market. Toyota is being clever by dual using tax-credits, taking advantage of the FCEV opportunity to help bring about a means of achieving economy-of-scale savings for upcoming EV offerings. It's a interesting win-win situation that many here overlook or don't understand. Why not gain experience for something with so much potential, refining the technology before ramping up? After all, we have already witnessed what rushing to market did for GM.
- 7-02-2019** **Too Bad.** Exactly as predicted, there was no effective mean to rebut. Instead, he just got really angry and lashed out with a personal attack: *"Toyota is anti-EV. Don't spin it, Toyota fan boy."* I was quite pleased about getting such a clear indicator of having nailed it. I found a weakness in their arguments I could indeed exploit. That was always the hope of letting them set precedent... since that often leads to them backing themselves into a corner. That pattern of antagonist behavior, which is often self-deprecating, is quite common. They provide there own material for defeat. That's why I push so hard, allowing them to fall into their own trap. It confirms their stance is not well balanced. Overlooking the bigger picture is most often their tactical error. With this exchange, that confirmation was provided: That evidence showing they are not clearly struck a nerve. Now, whenever you try to spread that narrative, you'll get a reminder of the facts. All along, it has only been timing. Ramp up doesn't need to happen yet. Toyota continues to refine its EV tech by using their PHEV and FCEV platforms. So what if my 80 mph electric-only ability comes from a small battery-pack currently. It's an EV in disguise. So what if the carbon-fiber hatch isn't seen by anyone. It's very effective why reduction. So what if most don't know about the vapor-injected heat-pump. It's an extremely efficient means of cabin warming. Toyota is a legacy automaker that will emerge with a strong showing, right there with Tesla, but serving a different audience. Too bad if you don't.

7-02-2019

No Substance. That discussion shifted from Toyota to GM, the expected outcome when cornered. In this case, it's to spin a rosy picture of the future. Trouble is, GM is terrible in regard to promises. They are vague & ambiguous. The more you dig to get detail, the more you get conflicted & misleading messages of intent. It's been that way since Two-Mode development began. You had no idea what GM actually planned to deliver. Enthusiasts don't care though. They spread meritless hype, like: *"Actually I think GM is starting to show so real commitment to the Bolt EV. Inventories have remained high and prices at dealerships have come way down but GM keeps shipping new Bolt EVs out of the factory."* That's a complete disregard for the market. It focuses entirely on a single vehicle without anything quantitative. The hope is to set an expectation based on assumptions the reader makes, rather than something that can actually be measured to definitively gauge progress. There's never any accountability either. When a promise isn't delivered, the response is always one of misunderstanding with the claim. What was said isn't what was actually meant is an effort to evade. Notice how *"real commitment"* and *"remained high"* aren't defined? Vague references like that are red flags. When pushed for detail, any type of ambiguous response is confirmation of no substance. I did exactly that, then posted this upon getting the confirm: Real commitment would mean putting it up against the true competition... other vehicles sharing the showroom floor. Remember, purpose is to actually change the status quo. No impact to that comes from conquest sales. Focus needs to be on GM influencing their own loyal customers, those looking to replace their old GM vehicle with a new one. Seeing the complete absence of any type of green SUV, the dominant GM product, is confirmation of no current commitment. Trax, Blazer, Equinox, Traverse, Tahoe... why aren't any of them offered as anything other than a guzzler? Two-Mode was rolled out over a decade ago. What happened to it? Why is there still nothing for the SUV line-up? Notice all the hype on GM's website now? There's a lot of electric & technology stories, but nothing of any actual substance.

7-03-2019 **Misleading Statistics.** That's what we called them ages ago. That has since become "*fake news*" fodder. Stuff like this is the source: "*Most people after driving a PHEV for 3 years will buy a BEV as their next car. So I don't see PHEVs ever gaining much market share...*" Often, the origin of such a claim is unknown & outdated. The method for drawing such a conclusion is questionable too, especially when it is so vague and without any references. Passing that claim along without question is the hope. Rhetoric builds upon beliefs that cannot be substantiated. Ugh. I punched back with:

A statistic based on an extremely limited sampling with a market skewed by limited availability and the scramble to take advantage of tax-credits before they expire tells us nothing constructive. In reality, mainstream consumers will flock to PHEV choices that are competitive with traditional vehicles. EV will come later simply because they are ready for a second vehicle with a plug, if they have capacity available. That PHEV will remain in their household.

Key selling point is that fact that many households have capacity challenges. Starting with a 120-volt connection is what will make things easy for both dealer & consumer. Making one dedicated high-amp outlet available is something that will come later, after the PHEV has been purchased. Getting a second line to a second vehicle is a topic "*most people*" avoid discussion about. Know your audience.

As for market share, that's also a limited scope issue. It will vary wildly from automaker to automaker. Toyota will thrive in that market because they have a very strong hybrid product-line already, showing increased growth and sustainable profit. Migrating to plug-in hybrid is an easy step salespeople will embrace. It's a simple upgrade option to sell, so why not? EV models take far more effort to sell to a showroom shopper.

7-03-2019 **June Sales.** When EV sales are posted, there's always a stir related to Toyota. The results of Prius Prime are an enigma. I provide background to draw interest in the thread, hoping to draw constructive discussion. Yes, I know, critical thought is a challenge when dealing with enthusiasts. But among early-adopters, a few helpful supporters will eventually emerge. This topic is great for filtering out hype. Hopefully, this helps that process along: 2019 Prius Prime inventory has been low, due to the 2020 model being that long awaited mid-cycle update which brings about that rear middle seat along with Apple CarPlay. The outgoing model was only available in selected markets as well, so sales expectations were never high with such limited access. When that new model begins delivery, the hope is there will be a ramp-up of production and nationwide distribution will become the norm. Knowing there will be market fallout from tax-credit phaseout anyway, it made sense waiting until the mid-cycle update was ready before going all out.

7-03-2019 **Decline.** It's quite common to focus on a single vehicle. Remember how the Volt enthusiasts would obsess with Prius, absolutely refusing to even acknowledge the existence of other Toyota hybrids. It was Camry hybrid that made them especially crazy. Having such similar size electric-motors was reason to be concerned about GM slipping behind. Of course, now with RAV4 hybrid so popular, it's over. The "*too little, too late*" has become a reality on several fronts. GM's supposed leadership didn't have any merit. There was no investment to spread technology to other vehicles, as Toyota has done. I make sure everyone understand that lesson learned too:

That perspective only works if you look at just Prius, disregarding what's happened with the rest of Toyota and the market here.

Toyota has used that window of time to rollout the new Camry hybrid, the new RAV4 hybrid, the upcoming new Highlander hybrid, and introduce Corolla hybrid. They also rolled out a new look for Prius, staging it for AWD and Limited models only while allowing the PHEV model to become the dominant offering.

Notice the when the mid-cycle upgrade of Prime was revealed? That's not a coincidence. It was part of a well thought out plan. Toyota was well aware of how GM was exploiting the tax-credits for conquest sales, rather than targeting their own customers. That meant Toyota would have to fight a pointless battle, wasting those limited subsidies with nothing to gain. So, Toyota avoided it by waiting... until the day after the first month of phaseout began for GM. It worked well too. Damage control efforts for Volt had come to a close at that point. The chapter in history it held had ended. Toyota got the spotlight and took full advantage of it, releasing a press announcement about the 2020 model.

Notice how well RAV4 hybrid is selling? That would make a great PHEV platform. All the work Toyota did with Prius Prime will transfer over nicely. You get the economy-of-scale benefit with a reputation for reliability established. It's a win for everyone along the Toyota production, distribution, sales, and ownership path across a widening array of choices... the full perspective. Growth is needed... many models... no dependency on tax-credits.

That's why an impression of decline doesn't matter. As stages change, there will be ups & downs. It's all about the overall advance.

- 7-03-2019** **Continue To Lag.** They don't give up. There's a never-ending push of the narrative about Toyota being behind. It's that mindset of making themselves feel better about GM's trouble by claiming someone else has it worse, even if there's no substance to the claim. Ugh. I hit back at today's slander attempt with: Toyota taking a different route to mainstream BEV doesn't mean they are behind. No legacy automaker has had any sale yet that wasn't subsidized. Others taking advantage of tax-credits is terrible gauge for how good ordinary demand will be. The race hasn't even started yet. That's why you question focus on Volt. It was an impediment for all those years. Always gloating about how far ahead it was, even though its reach never extended beyond niche. All that "leader" hype amounted to nothing. The technology never found a way to grow... which is why the approach Toyota is taking still has a great deal of potential. The smooth, quiet, efficient EV drive Prius Prime demonstrates is a taste of what's to come. There's a lot of other platform type work to take place before affordable, everyday type offerings are realistic. Notice how other legacy automakers really aren't doing much more than promoting what they are planning, rather than actually selling?
- 7-03-2019** **Approach.** The desperation is unbelievable now. Back in the, there's was the propaganda to leverage. But with real-world data so readily available, that doesn't work anymore. Attempts to misinform get debunked very quickly. Unfortunately, antagonists just switch to other tactics. In this case, they do whatever they can to change the topic. Diverting attention elsewhere doesn't work with someone so aware of their behavior. I just keep hitting back with facts: You're overlooking the platform those hybrids use & share. TNGA (Toyota New Global Architecture) enables that move forward, but time was needed to roll it out. That's worldwide. The discussion is about automakers & approach. GM bet the farm on Volt, choosing not to spread the technology until it was too late. Toyota is aggressively working to diversify, quite the opposite.
- 7-03-2019** **Better.** From time to time, there are attempts at constructive discussion. It usually breaks down when no substance for follow up is provided. For example: *"A common reason I hear from non-enthusiasts who want an SUV is being able to see 'better' because they sit higher and feel safer."* That sounds reasonable, but there's no context. When? Who? And now the question is what? What exactly is the "SUV" they are referring to? Is a crossover in their want list? With the acceptance of non-sedan variants becoming so popular, how small & short of a vehicle are they actually talking about? That element of better becomes a wash when everyone else is driving larger anyway. Notice how lack of detail makes you wonder what substance, if any, is credible to the aspect of better? Of course, there's me to inject some logic into those posts: Not following as close allows then to see better and it is safer. They really just use that as a justification... hence, know your audience. The takeaway from learning that is logic doesn't always sell. In fact, critical thinking is pretty low on the decision-making process for vehicle purchases. This is why Toyota had taken the time to create a hybrid design that's readily adaptable to support a plug.... RAV4. So when the time is right, they pull the trigger without consequence... the Osborne effect.

7-03-2019 **Profitable Stage.** I especially liked seeing this: "*Honda and Toyota continue to duke it out to see who can dominate with last decade's technology!*" It came from an antagonists who clearly didn't want to read anything drawing attention to PHEV progress. Watching others from a distance, rather than being dragged into the mess, is preferred. There is worry that Toyota & Honda could see success on a scale large enough to cause problems for GM, who has abandoned the PHEV market. Not having anything in that category to offer is a very real problem without a strong infrastructure to favor only EVs as the path away from traditional choices. Knowing Toyota & Honda, as well as others like Hyundai/Kia, will have a variety to plug types to offer makes the hype coming from supposed profitable rollouts coming in the next few years rather dicey. How much eggs-in-one-basket risk can be taken? GM's failure with Volt was costly. The closing of Lordstown production really hurt. This is why I stated over and over and over again the importance of diversifying prior to tax-credits running out. Imagine if GM had to retool to get Trax with Voltec offered in greater capacity? Switching over that location from Cruze to more Trax would have been a welcome improvement for everyone involved. It's a next step which should have taken place years ago. Instead, countless direct & indirect employment opportunity has been lost from inaction. That's really sad. I put the situation this way though, being sensitive to those impacted by such major executive decision mistakes: In other words, the effort is moving on from early-adopter to mainstream. That's the normal progression when a technology matures. It's the high-volume profitable stage all automakers hope to reach.

7-04-2019 **10 Year Ago.** It has been interesting to read through the discussion thread from exactly 10 years ago. This was back when Volt enthusiasts were under the belief that the design GM would be rolling out roughly 16 months from then would be a SERIES type hybrid. This was also when it was common knowledge that Toyota's newest generation Prius (rolled out just 2 months earlier) had a "*plug-in ready*" design, which meant a larger Li-Ion battery-pack could be swapped with the existing NiMH. Things went soar though and exchanges got ugly. By the time Spring came along (9 months later), those enthusiasts discovered Volt would actually be a PARALLEL hybrid instead and that new Prius had become far more popular than anticipated. Rhetoric had become more and more nasty as a result. In those decade old posts, I found lots of meritless claims about how superior the GM design would be over Toyota. It was evidence early on that they really didn't have much knowledge of how efficiency was achieved or the problems related to implementing the technology. They mocked Prius for having an "*evolutionary*" design, not understanding that's what would be needed. Revolutionary is not how you appeal to ordinary consumers, since those mainstream buyers are shopping for affordable & reliable choices that are well balanced... because that's what the dealer will sell. Anything related to good business was disparaged for the sake of endorsing what seemed then to be a "*vastly superior*" approach. It wasn't. 10 years later, that is overwhelmingly clear. Now, they are choosing to repeat those same mistakes, dismissing what they don't like and clinging to hope with substance. It's a mess, again!

7-05-2019 Promoting Change. The end of this year bring the end of tax-credits for Tesla. That's stirring lots of renewed discussion when sales results are a hot topic. July sales was an especially good example: *"If you can't charge it then it isn't included, no charge port then no inclusion. Hope that helps. BTW, that also excludes Toyota's "self-charging" cars."* There's lots of how-to-report monthly totals. Some EV supporters want nothing to do with PHEV. Others get irritated by the lack of clarity among hybrid offerings. This is the very reason Toyota is taking yet another risk that many refuse to acknowledge. The love to cherry-pick. I love to point out that's what they are doing. I try to do it objectively though, hoping to prevent confrontation by presenting lots of information to consider. This was today's attempt:

That is actually the point, when you come to realize *"self-charging"* is really just the first stage in marketing shift. Next will be to promote *"plug-in"* without deprecating the effort to draw attention to their work to phaseout traditional vehicles. This is a big problem for legacy automakers, a barrier to overcome that Tesla and their supporters often don't give credit for.

Consider how abused the term *"hybrid"* has become. 21 years after sales of Prius began, it represents anything that delivers more than just a continuously running engine. By changing to *"self-charging"*, it forces new discussion... which this group took and ran with, despite being such an EV-centric venue. They helped set the stage for that next stage. The term self-charging is now recognized as the type of no-plug hybrid Toyota/Lexus sells, not what other automakers sell with the *"hybrid"* label... a necessary distinction for phasing out traditional vehicles.

Think about how little showroom shoppers actually understand about the technologies available. There at the dealer, being presented with a *"self-charging"* and *"plug-in"* choice, there's no confusion. Both are obvious improvements over traditional offerings with obvious definitions of purpose.

EV supporters really struggle with how to get dealers to embrace change. Toyota doesn't. Toyota is setting the stage for a quick & easy transition. Consider how vital effective marketing much be to appeal to ordinary consumers. The *"self-charging"* and *"plug-in"* labels don't intimidate. They are a simple means of promoting change.

7-05-2019 BEV vs PHEV Sales. An article posted today on that topic left out a lot of things to consider. It was basically just a fluff piece to generate discussion, which is great. But that obvious exclusion of vital information was quite annoying. That's what happens when you focus entirely on numbers. Looking at influencing factors... the market itself... was disregarded entirely. That type of omission borders on fake news. Hopefully, the missing facts will be addressed. We'll see. In the meantime, this was what I had to say:

There are 3 major factors at play with regard to PHEV sales in the first half of 2019 that were not addressed.

First was the discontinuation of Volt. Knowing GM no longer had any definitive plans to rollout an type of PHEV tech to any of their traditional vehicles meant that production end represented an abandonment of that market. That means whether or not other automakers move in to fill that void must be taken into consideration. Remember, sales of Volt were almost entirely the conquest type. That meant there was interest from elsewhere, but few choices from elsewhere available.

Second was the limited availability of Prius Prime inventory. Toyota knew it had a 2020 mid-cycle update on the way for the second half of the year. That meant supply of 2019 models would be in small quantities to only the select markets it had been available. Nationwide rollout would not happen until after that update. So, sales results in the first half wouldn't be representative of actual demand... especially since the 2020 model would offer improvements based upon market feedback.

Third is the on-going influence of tax-credits. With them in place, we're still only looking at early-adopter buyers. These are people who cross-brand shop and take advantage of subsidy opportunities. Regular showroom shopper are an entirely different audience, not in any way represented by the sales results to date.

7-05-2019 Misrepresenting Sales. Stuff like this is very irritating to encounter: "*Hybrids flat since 2017.*" It's nothing new. People have been over-generalizing like that for 20 years. Anything with a battery-pack was called a "*hybrid*" vehicle. Nothing about its design, or even shape or size, made any difference. All the numbers were just lumped together and averaged. It's just like averaging price, instead of using median. That is deception tactic often used to misrepresent. The catch is, there are many who either don't care or don't bother to research what information they are actually passing along. The number simply validates their stance, so they use it. That's why I jump in with facts regularly to give a heads up to those who honestly didn't know and keep those who might be hoping to mislead something actually constructive to consider. In this case: Notice what's happening with the new RAV4 hybrid? It's a midsize SUV that delivers 40 MPG. There's a massive market for that particular audience, especially with a starting MSRP of \$27,850. Consequently, growth has been dramatic. Comparing the first half of 2018 to the first half of 2019, the growth rate is 142%. In terms of actual numbers here, June had 9,013 sales. For Toyota's design, that only requires the addition of a one-way clutch. Finding room for that extra battery-capacity is obviously with a larger interior like that too. So, there's a lot of potential. Flat is misleading.

7-05-2019 **Understanding MPGe.** Those trying to run reputable venue for sharing information about all vehicles with a plug are really struggling with those who are poorly informed... and those who just plain don't care to learn. They keep publishing articles from time to time about how efficiency is actually measured & represented. That makes a huge difference toward understanding the variety of technologies available. Not all electrics are the same. Not understanding that is a big problem, since it prevents advancement of discussions. If the knowledge sharing is remains stuck at a basic level and is routinely posted about with incorrect comment material, the integrity of the venue is at risk. For example: *"It should be just RANGE for an EV. For a PHEV it should be EV range then MPG when the sloppy OPEC gas awallower starts to spew it exhaust."* That seems innocent enough. But it is highly misleading. Any automaker can just add more cells to give the impression of efficiency. But in reality, its really a waste of resources. I tried to explain, yet again: Capacity of the battery-pack is a red herring, telling you nothing whatsoever about how efficiently electricity is actually consumed. 44 kWh/100 mi. 25 kWh/100 mi. Those numbers are from the article's illustration. They reveal that one vehicle uses far more electricity to travel the same distance. This is why even a short-range PHEV can be a much greener choice than an EV with a long-range capacity. More can actually be a disadvantage. After all, unused capacity doesn't accomplish anything. That's why the consumption rate is a necessary measure of true efficiency. In this case, the data reveals the one is an outright guzzler in comparison since it requires an additional 19 kWh of electricity to travel that same 100 miles. Think about the added expense to pay for those extra kWh and the wasted time waiting for longer recharge.

7-06-2019 **Timeline Downplay.** I see posts like this frequently: *"Don't worry about PHEVs. There is no long term future for them, they are a transition vehicle for people not ready to take the full step to BEVs."* Calling them out for lack of substance usually ends up a battle. Some feel insulted, since from their point of view nothing else needs to be said. Few recognize the absence of anything measurable. No quantity of any type... volume, pricing, duration, variants, markets, etc... is a dead giveaway they didn't actually put any thought into what they posted. It was just a gut reaction based on anecdotal observations. Constantly having to deal with such callous attitude about what some claim is annoying. But that serves as an indication of progress. Certain things are eventually overcome. Remember misconceptions from 20 years ago? It's a slow process. Even small steps are progress. Here's my small push forward for today: Just a transition vehicle? That downplay is telling. Toyota has sold over 13 MILLION hybrids and sales continue to grow. Prius Prime and Corolla PHV are now demonstrating just how easy it is to offer a variety of competitive-with-traditional choices offering a plug. Think about how long it will take for BEV to become a choice actually able to compete head-to-head with a traditional choice on the showroom floor. We all know that will eventually happen, but not anytime soon. Prices are still too high and profit still too low. That makes them very unappealing for dealers to even bother to stock them. How many 10's of MILLIONS of plug-in hybrids could be sold in the meantime? It's all about being realistic. You can't just blow off such a significant of a stage like that, especially when we all know that the first plug-in purchase will lead to serious consideration of a second with greater capacity. In other words, BEV depend upon PHEV to help deal with the pushback. Remember, the inherit nature of most people is to resist change.

7-07-2019 **New Battle Front.** Antagonists experienced an announced attack on a totally new front... a sucker punch. Out of the blue, Toyota revealed they are testing a new type of solar-cell for automotive use. It thinner than in the past, which makes it more flexible and more efficient. That efficiency rate jumps from the current 22.5% to +34%. It's quite an improvement. So much so, there's worry about this new arrow in Toyota's quiver. That equates to some sizeable levels of EV range being replenished while parked and while driving. That's a twist no one saw coming. Seeing Toyota on the offensive makes those antagonists crazy. They have no idea how to deal with that. Some of the old rhetoric isn't working well either. I was obviously amused to witness the struggle and was happy to join in the new battle: You're completely missing the point of getting more out of less. I have two 4K wi-fi cameras outside that never need to be plugged in. Each equipped with a small solar-panel makes them extremely convenient. It also means they don't require as large of a battery. Those same advantages translate over to a vehicle.

7-07-2019 **Desperate Already.** Downplay of the solar feature fell apart. This is what the discussion devolved into: "*Because Toyota is 5 years behind Tesla and they know it.*" That lack of substance is great. Repeating a mantra gets old, especially when something new like this comes out of nowhere. I was delighted to fire this back:

How are you coming up with such an estimate? Comparing a legacy automaker who sells roughly 10 million vehicles per year worldwide to a startup building infrastructure with lots of venture capital & subsidies and far fewer sales is pointless. They have little to nothing in common.

Choosing to ignore the current production Toyota is already delivering basically negates claims made anyway. The traction-motors used in Corolla hybrid, Camry hybrid, RAV4 hybrid, Highlander hybrid, Prius Prime, Mirai, etc. represent very solid EV experience, as does the production of all the cells used in their battery-packs. The heat-pump used by Prius Prime is industry leading for efficiency. The electric A/C is quite impressive for efficiency too.

Think about how much that is doing already to drive down production cost and build up a reputation for reliability. Seeing further R&D spent on exploring other aspects of electric benefit actually puts Toyota in the leadership circle. So claims of "*behind*" are just rhetoric passed along without substance.

You're overlooking the most important part too. For a legacy automaker, finding a means of getting dealers (their true customer) to embrace change is absolutely vital. Success in that realm is undeniable. RAV4 sales currently (first half of 2019) show 23% are the hybrid model. That shift away from guzzlers is momentum which will serve Toyota well as plug-in interest rises.

- 7-07-2019 On-Paper Scribbles.** A thread about solar is new territory... with the same old tactics. Some work. Some don't. In this case, it has come to everyone trying to calculate outcome. Antagonists are scrambling to show the effort is a waste. To do that, they often just make up numbers. I have real-world data to counter that with. So, I am: That estimate is way off. A full recharge of the EV portion of the battery-pack for me averages just 5.75 kWh. This morning, my JuiceBox Pro reported 5.58 kWh. Remember, I have to brake when approaching my driveway. So, there's no real concept of being totally empty or the same amount each time. Also, summer month deliver an average of 30 miles EV range. That supposed 4.3 kWh return would actually work out to about 22 miles... more than enough for the commute home... which doesn't consume the entire capacity anyway. In other words, on-paper scribbles don't translate well to real-world driving.
- 7-07-2019 Doses Of Reality.** It was really nice having someone chime in with one today: *"You realize that even on cloudy days the cells are still packing it into the batteries. The panels now days don't need direct sun or even sunny days to generate power. Just sayin'."* I had overlooked the fact that the antagonist was trying to steer the discussion to an ideal by implying solar would only work in bright conditions. Even with the small dedicated solar panels I have for each of my 4K Wi-Fi cameras, they fact is obvious. But I got hung up in his trap, not stopping to think about how effortlessly they keep the batteries charged. It works so well, that's easy to overlook. I never have to think about them. They just always work. A solar-array mounted on the surface of a vehicle won't be that efficient, but it certainly will be effective. Forced-Air cooling for the battery-pack, even when parked indirect sun without being plugged in, won't be a big deal. The system will simply take care of itself. Heck, that extra electricity while you're driving would come in handy too. Think about how expensive and inefficient Prius was when it rolled out over 21 years ago compared to what it is now. Toyota had to start somewhere... and they are already approaching a point with solar where some people will take notice. There's definite potential. Continued refinements of the tech will get it to that price-parity point. This is where patience & persistence really pay off. The catch is, you have to keep fighting antagonists with doses of reality in the meantime. Otherwise, there efforts to undermine will overwhelm the message of progress.
- 7-08-2019 New Chargers, Day 1.** The wait has been so long, I don't remember when it began. 2 of the chargers at the ramp I park on for work lost their network connection, but continued to work. You just couldn't interact with them online anymore. The ramp owner decided to replace all of the chargers there with new models. That was back during Winter, when the effort to do that was futile. When Spring arrived, the change over started. But progress didn't really amount to anything. Blocked off spots meant something would eventually happen. Finally, we got one new unit. It had a "not available" sign on it though for awhile. That quickly changed to having it turned on, but not programmed yet. We could use the 10 grace periods in the meantime though. Finally, it got setup. Complete! Phew! 3 more to come. All of a sudden, they did too. We then had to wait for programming. I had hoped it would be the next day. That didn't happen. 3 of us had to park there without plugging in. I was annoyed, since my drive to the ramp included an errand which ran the available range down to just 0.2 mile. It was barely enough to get there on just electricity. But sadly, I couldn't recharge. To my surprise, the 2 connected to the only working unit couldn't either. For some reason, it lost power after both started to draw from it. Eek! What was to come?

7-09-2019 **New Chargers, Day 2.** It was another strange day. The power on the 1 unit was still off. The other 3 had been programmed though; however, 1 side of 1 of them was displaying an error. Hmm? None of that was the big news though. To my delight, there appeared to be an unexpected change of policy. The charger was displaying "Free" when I checked online status. Could it really be that the fee for charging had been dropped? Since the ramp has an 80 kWh solar-array mounted along the many floors of its sunward side, that expense for electricity would pretty much be a wash. No daily cost to use the chargers certainly would be great!!! The chargers themselves are fantastic. No more messing with cords. The build in screen is incredibly informative. Chances of attracting more use are very encouraging. Sweet!

7-09-2019 **End of 2017.** Having read through the discussion thread a decade ago got me thinking about the end of 2017. Remember then, when things were really starting to look grim for gen-2 Volt? Enthusiasts new 2018 would be even worse. This particular quote is what I close my post at that time to provoke discussion on the old daily blog: *"We all know offering an affordably designed plug-in hybrid system in a small SUV, like Trax, is what GM desperately needs. We also know that the moment it is announced, demand for their traditional SUV offerings will see an immediate negative impact. That corner GM is trapped in has become quite obvious."* Advice about taking some thoughts with replies fell on deaf ears. It became a desperate effort to defend GM, doing everything possible to avoid addressing the "range anxiety" problem Volt was intended to solve but Bolt ended up doing instead. That digressed into Toyota attacks and a refusal to acknowledge the goal of replacing traditional vehicles... which is why I blog so much. It documents how long this problems persist. They learn nothing, which allows the problem to repeat. At this point, so many major battles have been lost (Two-Mode, Volt-1, Volt-2, Bolt) that the entire industry is looking at GM failure as a sign about how difficult it really will be to address change. BMW's step down of their highest executive overseeing their electrification efforts for the past 4 years was a major upset this week. It creates uncertainty among other giants (like VW & Ford) who make lots of announcements for the future but don't have anything laid out for deliver detail. It's all a *"here's what we're working on"* expression of hope. All of a sudden it will be the end of 2021 and we'll be wondering why not much actually happened yet from them. Thankfully, at least the push from Toyota is going well. We can see that quite a bit of effort is being expended to avoid getting cornered. With such an obvious trap, you'd think they'd at least try. Ugh.

7-10-2019 **Registration Fees.** Anyone else ever take the time to actually do the math? Try this, the new proposal for Ohio: *"For a driver who travels 13,500 miles per year in a vehicle getting 25 miles per gallon, the new tax would cost \$57 more, or about \$1.10 per week. The plan also establishes new registration fees of \$200 for electric plug-in vehicles and \$100 for hybrids."* That means if you are driving a 50 MPG hybrid, you'll have to the \$100 fee plus \$28.50 from the new gas tax. That \$128.50 total is more than double what the person driving the guzzler must pay... or is it? The impression of penalizing the person driving the hybrid to that extreme sends a terrible message. For the EV, that's a different calculation, since no gas tax whatsoever (original or the new addition) is paid. But if you do the math, stating a final gas tax of \$0.30 per gallon. Those 13,500 miles at 25 MPG would be 540 gallons. That works out to \$162 in the end. Sadly, it's easy to manipulate people's beliefs by choosing numbers that misrepresent... a common practice for those spinning a narrative. Be very careful. Always ask for detail. Always do the math. The actual of calculating a variety of scenarios can be quite revealing.

7-10-2019 **Not The Same.** Tactics used to deceive don't often change. Sadly, the majority of people have short attention-spans and don't bother to verify supposed facts. They just accept the information presented to them without question. It's a disturbing reality. We're seeing a lot of that now with the death of Volt. Even though it was a terrible example of what an automaker could deliver, it was the one every used. So, there was some type of baseline discussions could focus on. Now that it's gone, the obvious misunderstanding of how plug-in hybrid technology actually works and how much each design can vary is becoming a cold-hard reality to deal with. That means we see quite a number of posts which wildly misrepresent plug-in hybrids. Even worse, we continue to get evidence that some Volt enthusiasts who didn't know how their vehicle operated. It's quite remarkable to see how they assemble anecdotal observations into an incorrect interpretation like that. That spread of misinformation turns into rhetoric. I keep fighting back the never-ending problem of those not-the-same claims: Lumping all PHEV together is as reckless as lumping all EV together. PHEV that are affordable will continue on just fine. It fact, there's potential for growth now with the market thinning out. That's why MSRP has been so vital, despite the rhetoric here attempting to evade acknowledgement of certain models not having a dependence upon tax-credits. That's simply the next step taking place. Designs unable to compete directly with traditional choices (those sharing the same showroom floor) will see sales plummet when subsidies come to an end.

- 7-10-2019** **Premature.** It's the same old story. 20 years later, little about how people react to change has actually changed. We simply have new venues to spread the lack of objectivity. Collect a tiny bit of data, then draw a conclusion. Ugh. I dealt with more of that today, in the comments of an article stirring that very rhetoric... which is great for a publisher, since it attracts participation to their media source, but terrible for consumers trying to get constructive material: PHEV availability hasn't even rolled out beyond the reach of early-adopters; yet, some are calling them dead already. It's the same thing we saw in the past. Very limited sampling is used to draw a conclusion about an entire category. That's how narratives come about. Just pass along the same belief as group-think until no one questions it anymore. We saw that play out with GM. What got delivered for Volt was clearly not targeted at mainstream consumers, even though the claim was that vastly superior to Prius. None of that audience cared about the business fundamentals required to support such engineering. They just kept repeating a victory mantra. Sound familiar to now? There's just as much potential for some models of PHEV being embraced by the masses as some EV models. A conclusion about either is far too premature. Heck, we haven't even finished the initial subsidy stage yet.
- 7-10-2019** **Wider Scale.** Ironically, this attempt to look at the bigger picture failed to look at the bigger picture: *"On a wider scale, I think most people who buy a PHEV want to switch to electric but have range anxiety issues. But after driving a PHEV for 3 or 4 years and they decide to buy a new car, it will be a BEV as charge points become more ubiquitous and they realize lugging around a gas burning engine is not required. PHEVs are a stepping stone to BEVs, not a long term solution to pollution."* Through no fault of his own, this is basically just a lack of realizing there's more at play than what's been commented about. The difference between a peer attempting to be objective and an antagonists attempting to undermine is awareness. Do they realize their observations are incomplete? That's easy to determine. Just repeatedly present the information. If they go out of their way to dispute or evade, their intent is revealed as trying to impede. If they apply some type of critical thinking with the openness to feedback, they are successfully being objective. I already knew this individual wasn't trying to stir trouble and provided feedback accordingly: That perspective of "not a long term solution to pollution" requires turning a blind-eye to how many new vehicles are placed on the road every year. It's over 80 MILLION. That's a wider scale not to be overlooked. So what if there's an engine included for the next decade still? Being PHEV that only use the their engine from time to time represents a drastic reduction of both smog & carbon related emissions. Being realistic means seeing EV as the future, but accepting the reality that it will take over a decade of hard work to even get to a majority having changed. In other words, there are a BILLION vehicles that will be part of the transition period. Calling them a *"stepping stone"* is imply they are an insignificant stage on the path to EV. That implicit downplay contributes to rhetoric for those fighting to retain the status quo. Don't give them that opportunity

7-11-2019 **They Already Have.** This rhetoric was especially interesting to respond to: *"I still don't understand why PHEV manufacturers didn't follow the Volt model. That is a PHEV (strictly speaking it's a range-extended short-range BEV like the BMW i3 REX) that could be used purely in all-electric most of the time."* That second sentence was a confirm the person had no idea how Volt actually worked, that for possibly many years he has been spreading misleading information. Without additional context, that's difficult to assess. With a preceding sentence describing PHEV choices, you get a better idea of the mindset: *"But most models on sale now or being introduced have pitiful all-electric range and impotent performance."* Those colorful metaphors are a dead giveaway of a problem. They are insulting and extraordinarily vague. To belittle & mislead is exactly the type of response antagonists post. Hopefully, my reply to that had some type of positive impact: They have already. The common narrative would have you to believe otherwise though. It's a successful effort to undermine. Prius Prime works exactly as you describe. My EV drive ratio is 87% with 2,261 miles on the current tank. It will only get better over time too. As more chargers become available at retail & grocery locations, the opportunity to recharge while out & about will rise. That will push the EV miles even higher. Don't believe the rhetoric stating *"short"* range and *"anemic"* power. Those claiming that have an agenda to push a purist approach. That's really sad, knowing we have such a diverse market.

7-12-2019 **Your Impact.** Most people don't realize just how much of a difference their contribution can actually make. Some people do: *"I don't mind paying a little more to companies who are putting more charging stations in, after all how much more is it really and will that small amount make or break us?"* That made telling my story quite worthwhile:

Most people don't consider the true impact of that type of mindset... or haven't, until we share more experiences. Here's mine.

Back in 2012, the ramp downtown I park at installed 2 chargers (total of 2 level-2 connections). That worked out great with my Prius PHV. I could recharge for the commute home. That usage fee added up, drawing the owner's attention. A few years later, 2 more chargers were installed, bringing the level-2 connection count up to 6. That was great! They would actually fill on some occasions too. Last Fall, those newer chargers went offline (some network issue), though charging was still available. The choice was to replace all of them with the nicer models. Now, we have 8 connections available. It's really sweet!

That daily charging expense on our part was validation on the owner's part about that having been a wise investment. So, the investment grew. It's too bad that "pay forward" mentality isn't more common. There's no way of knowing if the owner actually made any money from the charging fees, but the benefit to others is undeniable. More chargers for people parking there is a win for everyone.

Think about what the visibility of more chargers does for those considering a plug-in purchase.

- 7-12-2019** **Neglect.** It makes you wonder how the big blogging website for plug-in vehicles continues to push a perspective like this: "...*but with just 1,100 Prime sold in H1, it's neglecting plug-ins.*" Seeing that on the subtitle of an article posted about Toyota European sales for the first half of 2019 was troublesome. Was that included to stir participation, knowing it would result in some rather passionate posts? I jumped in immediately, with this as the first comment: It made no sense stocking up on model about to become outdated. Those paying attention know that 2019 inventory was extremely low due to 2020 rollout on the way, which is a mid-cycle upgrade. That newer model will introduce center seating in the back (the real thing, not a mock spot like Volt had) along with a few refinements to interior features. The entertainment system gets Apple CarPlay and Amazon Alexa. There is no way to spin that as neglect.
- 7-12-2019** **Dead.** You can't help but to be amused by posts like this: "*Hybrids are dead, as they should be.*" That's a desperate attempt to spin a narrative of assurance. It doesn't work, since such a reality is fictitious. Nonetheless, you see them on a regular basis. This time, I punched back with cold-hard numbers: 110,267 purchases of Toyota/Lexus hybrids in the United States alone the first half of 2019 contradict that claim. 275,300 purchases of Toyota/Lexus hybrids in the first half of 2019 for Europe.
- 7-12-2019** **Already Delivered.** Things get really interesting why rhetoric turns to outright lies. It's so easy to disprove claims, you have to wonder if anyone falls for that nonsense. Based on my observations, that type of activity tends to soar interest. That's why moderators sometimes step in to deter the behavior. Bringing down the integrity of their forum will indeed make people lose interest. Anywho, you have to watch for them, then callout their post when found... which is exactly what I did upon seeing a post providing a suggestion of what should be done to make the idea appear untried: 88% is my EV drive ratio with 2,350 miles on the current tank. Your "*Most of the time Drive in electric mode, and use the ICE engine only on long routes.*" has already been delivered. Toyota's focus now is affordability. They are spreading their newest hybrid system, which is easily adaptable to support a plug, across their fleet. That will bring about not only economy-of-scale reduction of cost, that also provides a strong endorsement for the technology itself. Also, keep in mind that size of the battery-pack itself matters less and less as more businesses offer chargers for their patrons.

7-12-2019 True Change. The enthusiast trap is a simple one. You become fascinated with a new product, then lose sight of the bigger goal. That's so common of a problem, many fight to a bitter end without ever really figuring out why their dream fell apart. Oh well. All you can do to provide reminders of purpose. Today, it was with regard to how successful the progress forward has been for Europe: The point is to replace ICE choices with HV, PHEV, EV choices. That's exactly what Toyota is very successfully doing. They are transforming the showroom floor, appealing directly to loyal shoppers. This isn't about the subsidized conquest nonsense we saw with Volt from GM. This is about demonstrating to their customers (dealers who purchase inventory to sell) that embracing hybrids will feed a growing demand for more and more electrification. Automakers are a for-profit business. No matter how great a technology may appeal to enthusiasts, it makes no difference to the bottom-line. Far too many don't take challenges of having to achieve high-volume profitable sales from ordinary consumers seriously. Seeing Toyota/Lexus reach that tipping point in Europe, where more than 50% of the sales are now hybrid is a landmark achievement. That's what represents true change.

7-12-2019 Wrong Focus. There's an obsession with production capacity to such an extreme, many enthusiasts stuck. They have nothing to contribute... hence being an enthusiast, rather than a supporter. To provide support, something to help the process along must be done. Online arguing for the sake of defending a position doesn't accomplish anything... though, you'd never know it based on the number of chest-pounding posts lately. Capacity focus of the past was for range. So, the problems of being so single-minded are nothing new. From reading their posts, you'd think they were experts. That past will come back to haunt. Repeating the mistake of focus is common. It's about critical thinking. They don't. I try to provide constructive information, hoping some lurker will get it:

Production capacity doesn't matter when there is so much at play to retain the status quo. Setting up infrastructure (in this case, getting an atmosphere of change established at dealers) is far more important, especially when we know newer battery chemistry is forthcoming anyway. That's why Toyota is investing so much toward delivering affordable hybrids in the meantime. They make that next step to affordable plug-in hybrids a small one... which in turn makes the following step to an EV small too.

Remember, the dealer wants something that's easy to sell and the consumer wants something that's easy to buy. The decision to replace a RAV4 with a RAV4 hybrid is quickly becoming a simple one already. There's only a small price difference and the MPG improvement is obvious. It's an effortless step forward.

Think about Prius Prime. It will recharge entirely using nothing but the standard household outlet most people already have readily available in their garage. Plugging in takes no effort to understand. The act of plugging is simple. The benefit is obvious.

This is why having more battery-cells available isn't a priority. Focus currently needs to be on the market itself. Then when demand grows, that helps with the major decisions of where to actually setup that production and how much each location should deliver. Rushing that part can be a costly mistake. Think about how suppliers are already struggling with change.

- 7-12-2019** **Most Don't Bother.** A few of us on the thread discussing sales in Europe provided some numbers to consider. I was one of them: Avoiding detail is a common tactic from those unwilling to face the reality is actual sales. Pointing out how to best use the limited quantity of battery-cells currently available is an excellent means of stressing how a small number of EV sales achieves far less emission reduction than a massive number of HV sales. Put it this way. 1,152,108 Toyota/Lexus brand vehicles were purchased in the United States in the first half of 2019. Of that total, there were 110,267 hybrids. That's just under 10%, which is pretty much a solid 10% now due to the rapidly rising demand for RAV4 hybrid and the introduction of Corolla hybrid. Take that quantity and say each one uses an average of 1 kWh worth of battery-cells. 60 kWh capacity for EV would reduce supply ratio to just 0.16% of overall inventory. Why would a dealer bother when such a tiny quantity would be available? It makes no sense... which is why most don't bother.
- 7-13-2019** **Equinox Diesel.** Rather than spreading Volt technology to other vehicles, GM decided to focus on diesel instead. That's something even those wrong focus enthusiasts have a difficult time dealing with. That's evidence of just plain not caring. What a waste. The spin was quite amusing. They try to portray the situation as just one of disinterest. We tried. Customers weren't interested. End of story. It isn't though. Reading though one article on the situation sighted the hassle of "*needing to refill the Diesel Exhaust Fluid*". That's a major downplay, not journalism. Have they provided detail, you'd end up wanting even more. I remember estimates of needing roughly 7 gallons for every 15,000 miles. Think about where that fluid for cleaning emissions (it's urea squirted into the exhaust). You need a tank, a means of filling it, and the pump/squirt equipment for it to operate. That space, weight, and cost never mentioned by any diesel supporters. Curious, eh? By the way, if the system runs out, it is supposed to halt vehicle operation... like when you run out of gas. So, the effort on GM's part to roll that technology out for diesel models of Equinox & Cruze was a means of evading the obvious. Volt should have had a successor. Imagine what things would have been like if Equinox or Cruze would have been given that technology from Volt; instead, all that "*range anxiety*" work was just abandoned. Such wasted opportunity. Ugh.

7-14-2019 Tax-Credit Phaseout. There's a lot of mindless comments dominating discussions now. It's a passing along of the established sentiment without giving any thought to how things have changed recently. That makes you wonder how they'll react when recognition finally takes place. Not paying attention is putting it politely. I stated in this way:

Low-Hanging fruit can be beneficial. Tesla used their phaseout opportunity to ramp-up and sell as many vehicles as possible to establish a customer base and reach as far out into the market as possible. That's absolutely fantastic, exactly how those tax-credits were intended to be used. Kudos to Tesla.

Toyota still has tax-credits available and it certainly looks like they are doing the very same thing. Evidence of that is overwhelming. Rollout was limited to just select states. Within 500 miles over the past 2 years, Prime has basically been impossible to get here in the middle of the country and in some southeast states. A truckload would be special shipped from time to time, just enough to acquaint dealers with the technology. That holdback was an obvious wait for the mid-cycle update. Why waste tax-credits when you know that upgrade will be a more appealing vehicle?

Think about it. Phaseout period doesn't have a quantity limit. Toyota waiting until just before triggering that stage before significant ramp-up is exactly what Tesla did. That gives them valuable opportunity in the meantime to build up reputation from real-world data and experiences being shared by owners. Spreading endorsements like that is far more effective than any type of advertising. Again, that's what Tesla did. Their focus was the update too.

I find it quite telling how Volt was omitted from tax-credit discussion. Such a profound outcome from such a fundamental effort is a topic that should always be referenced. The lesson learned from that massive misuse of tax-credit sends powerful message of industry complacency. There's no denying anymore that GM exploited those tax-credits for conquest sales, using them for green praise rather than actually delivering something to appeal to their own customers. Enthusiasts loved the technology. Engineers did their job well. Kudos to them. GM management on the other hand, refused to spread that technology to vehicles GM shoppers would be interested in. No Equinox with a plug. No Trax. Nothing. They just let the phaseout period approach without even trying to reach beyond that niche audience.

Watch what happens in the second half of 2019. You'll see that preparation for ramp-up taking hold. Toyota knows their audience. They understand how to appeal to showroom shoppers, which is what their dealers depend up for stocking that inventory. Neither cares what rhetoric is spread online from antagonists. They simply want to sell lots of vehicles at a profit without a lot of effort... which is exactly how Prius Prime was configured.

It is interesting how those antagonists will spin that careful planning & patience as a narrative about "*dragging*". For that to be accepted, readers must dismiss facts to the contrary.

7-14-2019 **Kicking & Screaming.** Some just plain don't care. They like the narrative and are happy to contribute to rhetoric to keep it going. The usual "...with Toyota being dragged kicking and screaming." was interjected into what started out as a discussion about sales in Europe. As expected, a post without any supporting detail came along. It's just post an insult and wait for cheering. Ugh. I always have something to contribute when that nonsense attempts to derail constructive posting:

Confusing patience for resistance is a common problem, especially online.

That spin tactic is used by enthusiasts favoring other automakers to draw attention away from their silence. Notice how painfully quiet GM has been? Remember the narrative claiming Volt was dropped so GM could go all out with Bolt instead? Nothing happened though. Literally, the only message related to EV sales is that we can expect profitability in 2021. What kind of thing is that for the supposed leader of legacy automakers to say?

Of course, what evidence of kicking & screaming is there? A few point-in-time advertisements mean nothing compared to action taking place. In the first half of 2019, we have seen rollout of Corolla hybrid to new markets and introduction of Corolla PHV. That's a resounding step forward. It is overwhelming confirmation of change. You don't mess with the world's top-selling sedan unless you are serious.

To add a plug to a Toyota hybrid, it's only a matter of adding a one-way clutch. That allows the second motor (usually used as a generator) to contribute the extra power from the larger battery-pack to the wheels. It's a bump to performance with minimal cost... exactly what good design should deliver... which confirms Toyota had planned ahead... making claims of resistance an act of denial.

7-14-2019 **Move On.** Desperate attempts to change the topic are going nowhere. The reason why is simple, lost enthusiasts don't have any suggestions. They are just tired of having to deal with the fallout: *"It looks like it is time to move on. The same weak excuses keep getting repeated."* I had to listen to an endless stream of excuses as to why *"too little, too slowly"* really wasn't anything to be concerned about. They were wrong. Now, there's no reason to listen. I like that how hypocritical things worked out:

Ironically, you sight *"enthusiasts"* as vague, but then vaguely use *"people"* repeatedly in the very same post. That claim of *"Last year the argument was they would fall off a cliff and go bankrupt as soon as the 7500 credit was reduced."* has no source sighted. I ask, who you are referring to?

Low-Hanging Fruit was the message posted here on a regular basis. Remember that? It's a well fit analogy. It is specifically defined as: *"a thing or person that can be won, obtained, or persuaded with little effort"*. In other words, Tesla sales will continue, they just won't be as easy. Sales will simply plateau at some lower rate... nothing resembling a cliff or the implied death from that fall.

Seeing some type of demand reduction as a product innovator becomes a mature player is perfectly normal. In fact, that's what investors expect. Stability is far more important than being on the *"bleeding edge"*. Speaking of fitting analogies, think about what *"bleeding"* actually means.

In other words, your attempt to dismiss has fallen on deaf ears.

7-14-2019 **Crosstrek Review.** As other PHEV offerings enter the market, how will the online banter change? Mainstream consumers are so far removed from that isolated perspective, it's like we have 2 entirely different realities to deal with. One is obsessed with power & range, completely out of touch with the priorities not focused on electric propulsion. The other is just an ordinary consumer not really interested in doing anything special to reduce their emissions or consumptions. That disconnect is remarkable. Knowing that, reviews capture my attention. The one on Crosstrek today especially did. It was just a basic review, nicely done. I was first to comment, seeing if I could actually stir some type of constructive return: 118 HP (88 kW) is the output of its electric motor, something most people don't recognize the significance of. That particular specification is important, since it reveals Subaru used a component from Camry hybrid, not Prius. People often see the 8.8 kWh battery-capacity and just assume it is the Prius Prime system reused. It is not, as MG2 power output clearly confirms. That ups the count of PHEV offerings resulting from Toyota's hybrid design to 3... Prius, Corolla, and now Crosstrek. There's a 151 HP (113 kW) electric motor used in Mirai. Think about how nice that would be used in plug-in hybrid or even a electric-only vehicle. Toyota is quietly rolling out components for a wide variety offerings. That's refinement to efficiency & production which will have a significant payoff later. Think about what the upcoming EV model of C-HR will include.

- 7-14-2019** **Newbie Advice.** I'm really looking forward to the wave of 2020 Prime about to arrive. In the meantime, there are some still jumping on the opportunity to snap up a good deal on remaining 2019 models. One new owner today posting concern about heat resistance, wondering if he made a mistake purchasing something unfamiliar. That's quite typical. Everyone starts out as a newbie. Uncertainties vary though. So, you have to do your best to find out what the concerns are for that individual. That was pretty easy to address in this case. It was also quite informative. His purchase was an upgrade from an old second-generation Prius, the Iconic model. That was a testament to how well Toyota connected with owners of the past. Upgrades like that provide a strong endorsement. I help out by providing a little comforting advice: Park with the car aimed in the general direction of the sun and put up a sunshield for while it's parked. When you are ready to leave, use the all-windows down feature on the FOB to air out the car quickly. (I do that as I'm approach, so venting has pretty much finished by the time I unplug and get settled.) Then use the A/C generously on the drive home. No big deal. That's cool enough to keep the battery happy.
- 7-14-2019** **Late For What?** I wonder how much longer the "*late*" rhetoric will persist. There's not much of an audience anymore to care. National average gas price is only \$2.79, the SUV is more popular than ever, and battery cost has finally fallen to a reasonably competitive level. Seems like an affordable plug-in hybrid like Prius Prime is right on time. With tax-credits no longer skewing perception of demand, the reality of appealing to mainstream consumers should finally get acknowledgement. Refusing to recognize the terrible dependency placed upon subsidies was a terrible mistake. To think of all that effort wasted by Volt enthusiasts fighting pointless superiority battles based upon such a futile approach. Calling it risky is being polite. It was basically just plain stupid. Automakers are a for-profit business. Why in the world would they embrace any green technology that requires extra effort to sale and returns lower profit? Getting stuck with unsold inventory or wasting a ton of time on a lost sale makes no sense. Yet, that was the gamble enthusiasts had hyped as so realistic, it would crush the competition. Of course, they saw the competition as other automakers... not other vehicles sharing the same showroom floor. Some are still trying to keep that belief alive too. Ugh. If anything is late, it is them coming to the realization that hype doesn't appeal to ordinary shoppers.
- 7-15-2019** **Downplay & Enabling.** There's less and less of an excuse for this... at large, like when you randomly encounter someone and the topic of plug-in vehicles come up. But when online, those posters have no sound reasoning for this: "*Amen brother. Had the same experience test driving this car. Lacked any EV range. The whole Toyota (and Subaru) concept of paying a extra \$7K for occasional hybrid assist is lost on me. How about a real PHEV?*" What they are doing is passing along downplay, enabling one and other with rhetoric. It makes you wonder how seriously the casual reader takes those comments. I suspect many just filter through looking for something to agree with. That's unfortunate, but not a surprise. This is why it can be more effective at times to keep replies brief, like: \$27,600 MSRP for Prius Prime isn't that much more. Not sure what your definition of a PHEV is either. With my Prime, I have been averaging 27 miles of EV on the highway with A/C running. That no-gas-used driving experience is what?

- 7-15-2019** **\$3 to \$5 Thousand.** It is interesting to remind people about the target from so long ago. That's what Toyota had determined for pricing of their plug-in augmentation for Prius. That's exactly what got delivered too. Right now, the price is \$4,000 more. All that research seems to have paid off. Based on the direction the market is taking... now that tax-credit influence is fading... appears to reveal the pricing is how ordinary shoppers will be reached. Every person I talk to about plug-in vehicles has price at the top of their decision list. If it's too expensive, they just brush the discussion off as fascinating technology to wait for... rather than something to take advantage of. It's much like other tech. Phones are a great example. You know you'll eventually get something better, but there's no rush to upgrade. There isn't a guarantee of purchasing the best available either. In fact, most people tend to gravitate toward a balance of price. Having the absolute most of something isn't a compelling draw for non-enthusiasts. That's why my concerns expressed about Volt were so dead on so far in advance. Know your audience.
- 7-15-2019** **27-Mile Average.** We did the trip up to grandpa's today, staying there the entire day. So, there was ample time to recharge. 27.6 miles of EV on the drive there. 26.6 miles of EV on the drive back. We had the A/C on generously and it was highway driving most of those miles. The back of the Prius was stuff silly too. Since we're prepping the house for sale, there's lots of things to deal with. So, each trip home includes as much as we can squeeze in. It's amazing how much cargo that hatchback can swallow up too. The arrival home requires quite a bit of time to unload... which is really becoming a pain. But way, we can properly disperse the items. We try to donate & recycle as much as possible. Being able to avoid a dumpster by transporting all that is really nice... and being able to do it with electricity is even better.
- 7-16-2019** **EPA Rollbacks.** We can be said about this? The current administration is doing everything they possibly can to not only impede progress, but to also set back the goal posts as much as possible. Long ago, it was sad to see such activity. But back then, damage wasn't a serious concern. It was basically looked upon as a stall tactic. But over 15 years later, we are now facing very real consequences of inaction. Knowing you have technology to significantly reduce impact, yet choosing the selfish course of exploiting resources for personal waste. It's not like anyone is trying to get rid of heavy offenders... like the SUV... it's a matter of getting them to be much cleaner and use far less fuel. This is why there was always so much resentment for GM. It was never animosity for Volt claimed by enthusiasts. It was always the "*too little, too slowly*" concern. Rather than using the momentum Volt had established for pushing forward, it was reaching on laurels... ironically, the very perspective antagonists portrayed for Toyota. In reality, it was an example of reflection. They couldn't see it though. That helped divert attention away from the policymakers working hard to rollback EPA regulations. It's really sad to see so much resulting from not setting clear goals. I warned of the consequences. Bad things happen when you do nothing to prevent.

7-17-2019 Shipping Fleet. Ever notice how those dead set against more than battery-power being the source of portable energy storage carefully steer the discussion to only include personal transportation? They work really hard to prevent commercial applications from being addressed... like cargo transport. Sure, you'll hear about the possibility of large trucks someday. But that's just to get you to stop pushing. Don't! Keep at it. All you have to do is ask how shipping across the ocean will take place. Batteries are far too small for that to be feasible. It's just not going to happen. Hydrogen, on the other hand, is already well underway toward replacing oil. That's where fuel-cells will truly be game-changer. We need a cleaner & renewable supply of energy for trade. Commercial applications are realistic for that. They don't require infrastructure changes like our vehicles would. Service stations in every neighborhood is a non-issue. They only need that fuel at ports where they dock. That's far easier to support. It doesn't have to be absolutely clean either. Dramatic reduction of emissions is realistic even if there is some conversion overhead for now. Think about how long these ships will be in service. Getting that fleet to change to the new fuel will make a world of difference. In other words, like it or now, hydrogen will become a major fuel of the future. So, why not have some commercial vehicles using it too? Think about delivery & cab services. Their fleets could take advantage of that fuel being available.

7-17-2019 Media Misleading. It's very frustrating to read an article that includes opening statements like this: "*Many consumers appear to lack a basic understanding about how these various alternative propulsion vehicles differ (e.g., what's the difference between hybrids, plug-in hybrid electric vehicles, extended-range electric vehicles, and fuel-cell electric vehicles?).*" Nothing seems wrong with what was said, until you read more. This didn't come from a fake news sight either. It was supposedly a well-informed automotive publication simply conveying information about the variety of vehicles available. Sadly, that wasn't actually the case. Good intentions seemed to fall apart, somewhere along the way. It makes you wonder how much they've been spreading misleading information. This is what specifically got me: "*Offer extended-range versions of EVs. Stop developing and offering Hybrids and Plug-in Hybrids, which are only prolonging the use of the internal combustion engine.*" There is no actual definition of an "extended-range" vehicle. Volt tried that spin, but kept changing criteria as new offerings delivered better. It turned into a game of moving the goal-posts. Ultimately, that's how Volt died. The technology wasn't ever marketed with any clarity. Ordinary consumers had no idea how it worked, since the misleading continued to confuse. Media, enthusiasts, supporters, and the automaker itself all had different ideas of how the technology should be identified. It's really unfortunate "*plug-in hybrid*" wasn't acceptable. They wanted to be "*vastly superior*" instead. Ironically, that effort to stand out is what killed it. So now, even after production has ended, many still don't know what "*extended-range*" tells us.

7-18-2019 **Analogies.** This was interesting, since it came from an antagonist. You don't expect something constructive. But every now & then, something thoughtful does emerge. In this case, this is that entire post: *"Everyone loves to use the Kodak analogy. Google waited and copied Apple's expensive, high-end approach to touchscreen smartphones, but made it cheaper and more accessible. Android is now, by far, the most popular smartphone OS in the world. My point is that not all technology roadmaps indicate that the first-mover is the winner."* Since it wasn't intended as bait, I don't mind providing more context. It can be informative to paint a better picture of how change comes about when the position of an antagonist begins to change. Hopefully, pointing out shortcomings of an analogy help that process along:

That is an excellent point. People forget just how often being first in those initial stages of rollout ended up making no difference at all later. That's why the proper analogy for this situation is the TORTOISE AND THE HARE. Seeing the approach by legacy automakers during the early-adopter phase (subsidized sales) is solid reasoning why it doesn't matter.

Just look at how ineffective GM's exploit of the \$7,500 tax-credits were for Volt. Everyone was cheering the sales numbers. No one wanted to admit those numbers were really just conquest sales, not making any impact to the status quo. GM dealers just kept selling the same old ICE offerings to their loyal customers.

Then when you look at the narrative for Toyota, you get a struggle-to-catch-up message without any acknowledgement that their tax-credits have not been used up yet and their plug-in offering is targeted directly at showroom shoppers. Toyota is striving to refine their technology prior to their subsidy expiration... exactly what GM should have done... and exactly what Tesla did.

That *"cheaper and more accessible"* is absolutely vital and exactly when Toyota is doing.

7-18-2019 **No Meaningful Investment.** Claims that Toyota's effort isn't making a difference struggle to provide substance. For example: "*GM did refine their EV technology prior to subsidy expiration. They leapfrogged all their competitors - even Tesla - and released the first sub-\$45k EV with >200 miles of range, the Bolt. In contrast, Toyota has taken the same approach as Ford: no meaningful investment in BEV technology, relying on the subsidy to sell only enough PHEVs to meet regulatory mandates.*" That was the entire post. I found that truly desperate, knowing \$35k was actually the target for the "first" trophy. It was a blatant attempt to distract from the true goal anyway. I was happy to remind them of that too:

Using the word "*refine*" to describe the adding of capacity is confirmation of listening to the wrong audience. GM was catering to enthusiasts, the group sounding off about the supposed need for increased range. Toyota, on the other hand, continues their focus on affordability. They are not relying upon subsidies, which the \$27,600 starting MSRP for Prius Prime overwhelmingly proves. That's the "*nicely under \$30,000*" target the entire industry has been striving for.

Toyota listens carefully to the audience necessary for sustainable profitability, their own loyal customers shopping dealer's showroom floors. That's why their technology refinement takes place outside of BEV sales. The efficiency of their electric-motors, as well as the production cost reduction, used now for hybrids will directly benefit BEV in the future... when tax-credits are long gone. That's why the extremely efficient cabin heating & cooling for their plug-in hybrids is also a win for BEV later.

The spin about not making any meaningful investment requires turning a blind-eye to all of that, in addition to how much of a gain there is from their push to get their dealers to embrace change by shifting focus away from traditional vehicles with the wide array of hybrid choices. No amount of "*leapfrog*" claims can deny that. GM dealers are still doing the same old thing they did in the past. Neither Volt nor Bolt had any influence on their behavior.

In short, don't claim "*meaningful investment*" without the expectation of being called out to explain how the status quo has actually been addressed. Real change is often not easy to see, especially with "*200 mile*" or "*\$35,000*" market campaigns to convince you they are truly making a difference.

7-18-2019 **SiC (Silicon Carbide Transistor).** Remember hearing about this a few years ago? Toyota has been pursuing this improved thermal conductivity technology as a means of increasing efficiency. Since it reduces heat loss, which is an indication of energy waste, you achieve improvement. In this case, it equates to not only being more efficient, it is also faster. A future Prius would definitely benefit from this. Today, Toyota reminded us of their on-going effort by actually providing some detail. In whatever standard measure they were using to denote energy use by the inverter, it was stated that heat being lost was measured at 420 watts currently. Using SiC instead, the loss is reduced to 105 watts. That's a 75% efficiency increase. Without context, that's somewhat difficult to set a real-world expectation with. However, it does pave the way for pushing acceptance further into ordinary applications. Better use of energy is a win for everyone. In other words, it makes electric solutions even more competitive with traditional counterparts.

7-19-2019 **Change.** Flexibility has always been an impressive aspect of Toyota. Of course, having been a major force behind Agile, that should be no surprise. They expect change. It's part of the culture. You plan on adaptation. That's why the dynamic nature of their hybrid design has been such an impressive core to their approach. With that fundamental built in, it was a heck of an endorsement to continuous improvement. Change will happen. That's how I knew Volt was doomed even before rollout. So much was placed upon such a specific deliverable, there was simply no way to promote growth. It was trapped as a niche... hence asking "*Who is the market for Volt?*" hundreds of times. That technology didn't encourage change. Prius was quite the opposite, striving to adapt to a changing market. Toyota's choice to offer nicer rear-seating is evidence of that. They recognized & acknowledged how much their audience had changed. Who knew that just a few years later, even more change would come. Fortunately, Toyota addressed that too. I find it fascinating how some attempt to leave out detail, attempting to spin those changes as a mistake or backtrack. Think about where Uber & Lyft were over 3 years ago when Prime was revealed. A lot happened since then. Toyota brought back the middle-seat to accommodate that new requirement, one that never existed until recently. I have to keep reminding people of that, while also keeping the antagonists from spreading their rhetoric. Here's the latest: Toyota clearly stated years ago they were transforming the model, targeting their now older audience. With the family now grown up, no need for that middle seat. Knowing the sedan was rapidly losing favor to SUV choices, it made sense. Since then, that same audience has introduced a new market twist. They have become Uber & Lyft drivers. Both require a middle seat for the vehicle to be eligible. It's paradigm shifts like that which Toyota is good at being flexible with. RAV4 hybrid has captured part of that audience and the revised Prius Prime should capture another part. It's all about recognizing & understanding change.

7-19-2019 **Shame.** Toyota revealed the 2020 model Prius PHV for Europe. Not only does it include the updates we got for Prius Prime here in the United States, it also adds the choice of 17-inch wheels and the color black. That's frustrating to antagonists, as this sentiment expressed: "*Shame on Toyota.....this is coming up on third yr.....and no increase in range.....thank God we had GM volt.....they gave their customers.....*" That is the very reason I asked that "*Who?*" question for all those years. Enthusiasts didn't care who the customers were. All they cared about was short-term victory. That's why long-term defeat has been so hard to accept. Some never wanted to accept the knowledge of audience. Oh well. That's their loss, which I'm happy to keep providing memories of to prevent that history from repeating: GM's choice to cater to enthusiasts is why Volt died. Those range & power specs made production-cost far too high. As a result, it was a vehicle dealers simply had no interest in selling. With a price so high for a car smaller than Prius Prime, there was no appeal to GM shoppers. Toyota took a very different approach, striving to deliver an affordable balance... which is exactly what they achieved. \$27,600 for a 25-mile rating (enough to cover the average commute here) is something Toyota dealers will find competitive with other vehicles on their lot. Your reaction is the typical early-adopter perspective, continuously wanting more for less without consideration of what ordinary consumers have for purchase priorities or what a salesperson actually does. Toyota's strategy for post tax-credit sales to an audience shopping the showroom floor is something GM didn't bother to address. So, if you're dishing out shame...

7-20-2019 **2,669 Miles.** I wasn't expecting the most recent tank of gas to last 2.5 months. It just happened to work out that way. 10 weeks of getting to recharge at both work and grandpa's meant the HV driving was spread out nicely. That EV ratio ended up being 87% for the duration. 9.084 gallons is what it took for the refill. Calculating that to MPG, you get 294. Impressive, but unnecessary. My 2017, as well as the 2018 model, only displays a value up to 199.9 MPG. Beyond that, there's not much efficiency gain to report. It becomes a diminishing return with wild fluctuations... nothing really informative. Nonetheless, Toyota responded to customer feedback stating an owner preference of seeing higher values anyway. So, that changed with the 2019 model. I can simply look it up on the phone-app if I really need to find out what higher-than-200 values are being achieved. For example, the entire month of May worked out to an average of 428 MPG. Do I really find that valuable to know? Not really, but it is an effective means of reaching new customers. So... they find it valuable.

7-21-2019 Defeat & Surrender. The steady flow of Toyota advancement forward is beginning to make some so concerned, they are becoming absolutely desperate to impede discussion. You can tell too. For example: *"Is this a grid charging or self charging hybrid. What happened to toyotas fcev challenge. Are they going to accept defeat and sign a will of surrender to Tesla."* Talking about a scatter shot. You rarely see trolling with such a wide disbursement of bait. That serves as a comforting confirmation of having nothing left to fight with. He's clearly out of ammunition. Sweet! I advanced on that opportunity without hesitation:

Toyota is a legacy automaker with a continuous improvement approach, who has been extremely successful with that strategy choice. Tesla is a startup who has done exceptionally well during this initial stage (sales subsidized by tax-credits). What comes next is anyone's game. Think about that next step. Reaching beyond early-adopters is far more difficult. In fact, some of those challenges are entirely new. How much competition have you actually seen take place on the dealer's showroom floor?

Watching plug-in offerings stand head-to-head with traditional offerings requires a different means of appeal. It won't be a matter of stirring interest online. It will be an effort to draw favor from someone who hasn't done any study, an encounter with a person looking for a good deal on an easy purchase. How much of an effort will the salesperson make to entice interest? How many do you think dealers will stock?

With such a broad variety of plug-in design, do you really think a mainstream consumer will be able to make sense of it enough to make an informed decision within the timeframe they typically make the choice of what to purchase? That's rhetorical, of course. We already know the answer to that is no. They will favor the easier choice. Fortunately, that is a reality Toyota knows how to effectively deal with.

Most enthusiasts despise the continuous improvement approach. Well, too bad. That cold, hard reality of how sustainable business works is what they have to face the music on. Notice how everyone turns a blind-eye now to GM's failure with Volt? I got harassed for years from pointing out a *"too little, too slowly"* concern. GM wasn't doing anything to improve Volt technology reach. Improvement in that regard never happened. Appeal remained a niche.

Toyota is pushing their tech across the fleet. Going from hybrid to plug-in hybrid is an easy step with the HSD design. In fact, that tech has already spread from Prius to Corolla. And now with the strong growth of RAV4 hybrid, that next step of adding a choice of plug is an obvious one.

In other words, there is no *"defeat"* and *"surrender"* when you look at that bigger picture. Remember, Toyota sells over 10 MILLION vehicles worldwide every year. Having a variety of choices available for such a diverse audience is essential.

- 7-22-2019** **Apologies & Attacks.** This post made things rather interesting: "*I rented the Prius + 2 when on holidays. 2 adults, 2 teens, 2 kids..... It was, without doubt the worst, must under powered vehicle I had ever driven.*" Since I knew nothing about the poster, it was impossible to ascertain intent. I did find it strange though. Why was a comment about Prius being posted in a thread about plug-in hybrids? The absence of any detail or even context made figuring out how to respond even more difficult. I gave it a shot though, posting the following: "*That literally has nothing to do with the topic. Prius PHV has a much larger battery, resulting in much more low-end torque. Dropping the pedal for a quick lane-change delivers that nice EV punch you don't get without having a lot more electricity available.*" To my surprise, shortly after that came an apology. I certainly wasn't expecting what appeared to be an attack to result in that. He simply wasn't paying attention and thought we were discussing ordinary hybrids of the past. Finding out the topic involved power from plugging changed his stance. We were posting about something he favored and totally overlooked that. He was sorry for the error. Cool.
- 7-23-2019** **EV Panel.** A group of us were invited to host a discussion panel at one of the largest libraries in the metro area. I was intrigued, especially since I was selected as the coordinator. We'd start inside with a computer to display whatever information we wanted to share, then move out to the parking lot by their charger. I wondered how much of a challenge it would be to address the wide variety of topics attendees would have questions about, while also giving the owners participating an opportunity to share their experiences. Turns out, 2 were quite flexible, 1 had a well timed presentation, 1 had no concept of time. I ended up having to lead people outside while he kept going on and on. His stories were great for real-world examples, but the idea of exchanging the most valuable knowledge. You can't just dump that much information without consideration of goals. We were there to promote the variety of plug-in choices available. In the future, I'll allocate a specific amount of time to each participant to guarantee we don't lose sight of purpose. That move to the parking lot went extremely well. We had passers-by join in. Too bad I didn't think of getting some flags or a banner to help stir interest. Oh well, those who stopped to ask questions or to simply look thanked us. The owners didn't mind my push either. We all wanted to get to the show & tell part anyway. I would like to cover a more carefully planned out agenda at some future opportunity. Long story short, we're still getting a feel for the emerging market. This current stage isn't that far from the early-adopter stage. As tax-credits phase out, there is no clear message of next steps. The chance to find out what ordinary consumers want to learn more about helps guide us in the right direction.

7-24-2019 **Tesla Trouble?** Yesterday's event to show off the cars and answer questions for people made it all too clear that Tesla facing many challenges, in addition to what the industry as a whole has to deal with in regard to electrification. Tesla's offerings are perceived as "*too expensive*". I heard that message over and over again. So, topics like how to purchase & service one or even charging standards are never even discussed. The pricing barrier spells trouble. Will it remain that way? Who knows. The real trouble is seeing sales of both Model S and Model X flat line. Interest in Model 3 is souring their appeal. That lack of diversity creates a variety of business problems. Not having dealerships and not having tax-credits makes the situation even more difficult. This next stage in market growth is the very thing I expressed concern about for GM. They bet the farm on Volt. Remember all those "*one size fits all*" posts? That was all about expansion. It didn't matter how. It just needed to happen. That necessity of reaching out to a wider audience is absolutely essential for a niche product to become a standard technology. This is why antagonists fought so hard to keep attention on Prius. Acknowledging the success of other Toyota hybrids meant admitting GM really wasn't leading the way. Seeing Tesla fall into that same trap isn't encouraging. But then again, not being a legacy automaker does present some advantages. Whatever the case, this is a clear change of perspective. The idea of government-subsidy & investor-capital being the primary means of advancing forward is no more. The next step will be a challenge without that extra help. Perhaps the low-hanging fruit (early-adopters) will be able to promote the technology enough on their own to achieve that sustainable business need.

7-25-2019 **What Now?** News yesterday for Tesla was grim. Despite all those recent sales, quite a bit of money is still being lost. As a result, the CTO (Chief Technical Officer) announced today that he'd be stepping down. The expectation is a drop in stock prices... which means someone will provide a positive spin on the situation. Sure enough, it happened: "*Tesla Sold More Model 3s In Q2 2019 Than GM Sold Chevy Bolts Worldwide Since Its Birth*". Realistically, that doesn't actually say much. It's both vague and without context. We know that GM was all hype, never intending to make Bolt a major player. Seeing that should be easy. It was a compact wagon. Since when does GM have any interest in that type of vehicle? Without any desire to push that platform, their dealers couldn't care less. It's all about selling Pickups & SUVs, not a small car. That was rather blatant with Volt, but fake news sources (like that daily blog) maintained a narrative stating otherwise. As a result, GM had faded away. All those attacks claiming Toyota was hopelessly "*behind*" didn't alter GM's perception either. So, the expectation Tesla will somehow be propped up from comparisons to GM are futile. Unfortunately, online comments show the bait was taken. There was mostly just senseless bickering with no look forward. In other words, there is still no "*next step*" defined.

7-26-2019 **Kayaks.** I learned a lesson the hard way last time we went kayaking. While lifting the wet & slimy kayak onto the roof-rack, a gust of wind caught the mat (a piece of foam exercise padding) and the kayak itself. I ended up putting a fine set of scratches in the past on a small suddenly unprotected area above the door. Preventing that is easy, now that I see the outcome of not doing that. Just pinch a tiny bit of the mat in the door. Having transported kayaks on my Prius for 13 years now, that need hadn't ever come up. It was only a freak circumstance. But I won't be strong enough forever to ensure all goes well during those precious moments of potential contact. Today, I got to try that. We had an absolutely beautiful day to get out on the water. This lake was one was new for my wife, so having everything related to transport mastered is helpful. I wanted to make a good impression. After all, living in Minnesota means there is an enormous number of locations available to kayak. Long story short, today ranked among her top experiences. Our picnic out on the island was the highlight. 8 ducklings approached us. We had dried fruit to share. It was a good time for all. Being able to just pop the kayaks on top and drive out there for a day of fun like that is great.

7-27-2019 **Our Own.** It's really sad when photos are posted of plug-in vehicles parked in charging spots, but not actually using the charger. This is how one of those posts sharing a photo of one such situation ended his comments: "*You'd think our own would be more willing to do the right thing. Nope.*" My attitude toward not recognizing competition is well known. It's not other plug-ins or even other dealers. It is those who still favor traditional vehicles. I stated my observations with:

As time goes on, it becomes easier for others to see what I've been conveying for many years... know your audience.

Watching Volt enthusiast "*vastly superior*" attitude spread was a sign of not recognizing we were on a team all working toward the same win. They would fight and fight and fight, claiming victory against those who were trying to be players on their side. That effort to squash all other PHEV efforts was a clue about the trouble to come with EV efforts. Sure enough, we saw that same pattern coming from Tesla enthusiasts. They dominated plug-in events and didn't take tax-credit dependency seriously the same way, creating barriers for supporters (the rest of us) to overcome.

Fortunately, things are finally changing. Most enthusiasts have lost their voice due to tax-credit phaseout so significantly influencing market shift. There's still the reality of much needed agreement having been stalled... to the point of undermining efforts causing widespread disenchantment. Absence of a common approach for shared chargers is overwhelming evidence of that.

Notice there is still nothing in regard to a common message with regard to parking in those spots? Heck, we can't even agree upon what to do when one of our own parks next to a charger but doesn't use it. That basically invites non-plug-in vehicles to park there. If we don't care, why should they?

7-28-2019 **Back To Basics.** This step back is even further than just new owners asking about how their Prius operates. Someone brought up hypermiling and that stirred this: *"I think you have a much too narrow view of what hypermiling really is."* Which continued with a vague reference to choices & circumstances, then concluded with: *"But too many people focus on just a couple controversial items and use those an excuse to demonize the whole concept."* Remember my focus? I looked up one of my blog entries for an example and effortlessly found this: *"Among many things, he was the one that used to pump up his 44 max PSI tires to 50 PSI in his Corolla and drive only highway miles with it. That made his MPG abnormally high, in no way representative of what the typical person would actually get."* He later bumped the PSI all the way to 60... hence becoming so controversial. Other things, like throwing the vehicle into neutral and drafting was promoted. I wanted no part of that and made it quite clear of not wanting to be associated with any of that. My push was how the word originated. Being so anti-hybrid, he really didn't want that to be associated with Prius anyway. I posted the following in response to today's post: Remember, that term was coined from an argument with me. That very specific first ever mention in a post way back in history was when the fight was about how superior a Corolla was to Prius. He was dead set against hybrids. He later discovered how well thought out Toyota's approach actually was and changed his tune rather profoundly. In fact, he even very politely apologized years later when we met in Detroit. So, of course the view is far wider now. The original problem still remains though. Promoting a driving technique or approach to squeeze out greater efficiency sends a confusing & misleading message to ordinary consumers. Setting realistic expectations is how mainstream buyers are reached. Hypermiling does not. That is what enthusiasts do. So, it is very important for everyone to understand what actually takes place. By looking a wider view to recognize the concept, you make the situation worse. That fundamental flaw has never been overcome.

7-28-2019 **Too Simple.** Someone else joined into the discussion: *"His logic was simple, he stated not to lump all hypermiling techniques as deadly or puts other motorists lives in danger. Not all techniques are deadly or let alone even cause a wreck."* Even back then, I struggled with generalizations. Remember all those *"not the same"* posts? Intention omission of detail is unacceptable still. I replied back with: Not identifying what those techniques actually are is the problem. Being vague contributes was always the underlying issue. It should be crystal clear at this point. Remember, that all took place prior to gen-2 of Prius rollout. Not being concise confirms understanding is still a challenge. Keep in mind, the goal is to grow the market. That means reaching out to a new audience... which cannot require any assumptions. In other words, simple is not always a good thing. We must seek & promote a balance. Wisdom from owners is what sends the strongest message. I suggest only mentioning techniques we want to endorse and not even bother with labels. The term serves no benefit anymore. Think about how worthless the label of *"hybrid"* has become. It's too simple.

7-28-2019 **Fantastic Timing.** For years, I have been talking about how Toyota is refining their technology while waiting for GM fallout. That's exactly what we witnessed too. Played out right before our eyes, the supposed "*laggard*" achieved a great deal. Legacy strategy can't be a hope-for-the-best gamble. Yet, we watched it happen. Ugh. Now at the Volt is dead and Bolt is going nowhere... as confirmed by second-quarter sales results... the mid-cycle upgrade of Prius Prime has begun deliveries. Not having to deal with any of that GM rhetoric is fantastic timing. Every time plug-in Prius was mentioned, some Volt enthusiast would attempt to overrun the comments with a superiority claim. It was so annoying, since it wasn't going to accomplish anything... because GM wasn't investing in the technology. Volt just flopped around like a fish out of water, unable to achieve anything other than conquest sales. It was good reason for Toyota to steer clear. GM's terrible dependency on tax-credits made the fallout timeline easy to predict. No plug-in hybrid Trax. No plug-in hybrid Equinox. Nothing at all became of GM's huge investment in technology to blend engine & motor. What a colossal waste. Anywho, not getting pulled into that wake from that ship sinking is such a relief. Toyota can proceed unimpeded. Yeah! Looking online, I see 643 listed for the entire country. That inventory seems to be making its way here from the West Coast. There are some available in Colorado. I haven't found anything closer yet. Most everything else I see listed as "nearest" shows New York, New Jersey, and Maryland locations... which is 1,000 miles from here. Looking further, I see Arizona. Interestingly, there are some in Florida. That's a market formerly unwilling to carry any inventory of Prime. Perhaps they are ready to jump on board now... which adds to the fantastic timing. California obviously has a bunch, but that inventory is normal. What's expected to be new is stocking them in the Midwest. Only special-order shipments ever made it here. Hope is that will soon change.

7-29-2019 **Charging Infrastructure.** An article with a rather gloomy stance was published today. It pointed out waste from a lack of new thinking. There isn't much benefit to speak of still. Other than Tesla SuperChargers, most of the public chargers either get little use or get no attention at all. There's a variety of reasons why. Location & Pricing were among the most obvious. Very real challenges face business support still. Who? When? How? All those details need some type of common message, once the obvious challenges are addressed. It came down to not putting much reliance on public availability for market growth. Banks of charging stations will happen someday, but we shouldn't put emphasis on that. This is what I posted in response to reading the article: That's why I have stated tax-credits for vehicles should not get renewed. If there is to be a next batch, let it be for home upgrades. Keep in mind, most households can just barely support 1 vehicle. So, there's a very real limitation that will holdback market growth later.

7-30-2019 **Suffer? Lagging?** This popped up out of nowhere: "*Market forces are going to drive Toyota to release a BEV or suffer lagging sales.*" Well, not nowhere, it was actually a thread from 6 years ago someone bumped with a recent post. It was an intriguing place to stir old discussion with an audience of changed perception. Quite a bit has happened with regard to plug-in sales so far this year. I jumped in with:

0% sales are without subsidy here still. Of those sales dependent upon tax-credits, how many are actually profitable?

That criteria alone informs us the "*lagging*" is a long time coming still, even without consideration of the actual competition... traditional vehicles. With many provide high profits with very little effort to sell, the idea of a hard push for a vehicle requiring lots of information sharing to entice a purchase and razor-thin profit in return is futile.

Then when you consider the rest of the problem... home charging... the situation becomes almost pointless still. Much work needs to be done to stir those household infrastructure updates. How many people have nothing but a single 120-volt line available in their garage available for overnight charging? That's an ugly best-case scenario... and very much a reality, presently.

Toyota's push for PHEV penetration into the mainstream helps move that process along. The choice to get a Prius Prime is painless. It really is plug & play. It also stimulates the household consideration for upgrading. Being able to benefit from a 240-volt line becomes more and more obvious over time. Having it available paves the way for a BEV purchase later.

In the meantime, Toyota will be building up a solid reliability reputation for their plug-in offerings. Elimination of the engine later is not scary in any regard once that customer confidence takes hold. While that is taking place, there's also the gain which comes from refining production and preparing for ramp-up. These are all vital business steps the "*suffer*" forecasts don't ever directly address.

Put another way, evidence of Toyota positioning itself for the upcoming paradigm-shift is stronger than most other legacy automakers. They are doing something now, rather than just rolling out a token offering or releasing a lot of press info. Notice how TNGA is on-target to reach 80% of their fleet by 2023?

7-30-2019 **Forward Thinking.** It's a lot harder than most realize. I'm constantly having to explain why a perspective just provided is not that of an ordinary consumer. People participating online usually lose touch with what it's like to not be well informed. You just naturally learn about the market by getting a daily injection of new information. Catch is, that information isn't necessarily the bigger picture. In fact, most of the time it is about the immediate next step only. Fortunately, it is now getting easier to deal with that... so much so, I don't really even need to include the quote that provoked my post... since most is just the same old rhetoric, but completely absent of substance at this point. Speculation of the past now no longer applies. We have outcomes to refer to. Anywho, I kept the forward-thinking response rather generic today: This is why "*know your audience*" gets brought up over and over. As an early-adopter, you have little to nothing in common with a showroom shopper. Anyway, strategy is long-term. A purchase now isn't part of that. Remember the 2030 plan Toyota laid out? Think about how obsessive GM enthusiasts were about the first 200,000 sales, how no attention was being paid to WHO would be next to purchase. Look what happened as a result. Toyota isn't going to play that game and Tesla isn't a legacy automaker.

7-30-2019 **Future Influence.** This perspective is quite understandable: *"Early adopters, like me, you and others who bought gen 1&2 Prius models, influenced many future Prius buyers in the next decade the time came for them to consider a new car."* However, it isn't helpful. Hopefully, this is:

That's a red-herring. Prius Prime is setting the same stage. Again, know your audience. Ordinary consumers, those showroom shoppers that are looking to replace their aged Toyota with a new Toyota, will see the plug being presented as a new choice. Quite unlike you and I, they won't be well informed. They will simply trust the reputation of Toyota and measure it against the price they are willing to pay for a new vehicle. They won't cross shop. They won't get a tax-credit. They won't have a charger.

Think about what it takes to achieve mainstream popularity. It's not going to be a standout vehicle like Prius (though Prius will still very much be a player on the team). It will be vehicles that are basically just another vehicle on the street, only there will also be a small badge indicating it is somehow different. That will be Corolla and RAV4 as hybrids, then plug-in hybrids, recognized as "one of those" influencing others.

Toyota is targeting the masses by working their way up. It's the continuous-improvement approach they are well known for. It's entirely possible Prius only be available as a PHEV for the next generation. Whether or not an EV from Toyota is widely available yet won't make any difference on that front. Think about what an upgrade to battery chemistry & capacity would do for its draw for the Prius audience. Think about how much it would do to promote other plug-in choices.

Rushing to market is the monumental mistake GM made with Volt. They wasted tax-credits on conquest, only to lose those potential repeat customers later. Sales to the wider audience that are both sustainable & profitable is worth having to deal with the appearance of lagging. Notice how Volt enthusiasts claiming exactly that about Toyota have completely vanished? We faced their rhetoric on a regular basis. Now, they've grown silent... quietly watching what happens with the mid-cycle upgrade to Prius Prime.

Sorry about the push from time to time with reminders of scope & purpose, but you are the type of audience who takes the time to consider the bigger picture. So, the discussions are worthwhile for all of us. Think about how much has changed and how much we've learned since this particular thread was first started.

7-30-2019 **Not The Same.** It's amazing how much problems repeat. Today, it was: "*and yet, bolt and prime sales are similar*" That premature conclusion draw in terms so vague, it's difficult to readily identify intent. Of course, I know this person. He has just recently exceeded 80,000 posts on the big Prius forum. He just uses the venue for entertainment now. It's a big waste of everyone's time to have so many posts daily coming from someone who doesn't try. It's just a chatroom from his perspective. No time is taken to share posts of value. That contributes to enablers & misleading... which I find very frustrating. Anywho, this was my response to that today: Comparison of a vehicle with nationwide availability for years to one with limited inventory & market should not be taken seriously. Those sales have almost nothing in common. You know all too well Toyota held back 2019 offerings due to the mid-cycle upgrade for 2020. Remember those discussions back when 2018 inventory burn down was taking place? Even then, approach was difficult to deny... which is why similarity claims now don't hold any merit. Some still argued though, trying to convince us Toyota's patience was really disinterest. Watch what happens as 2020 models roll out.

7-30-2019 **Pointless?** Sometimes, drawing attention to puzzle piece doesn't actually help finish the puzzle. I noticed a potential clue about Toyota's entertainment system upgrade, but didn't know if raising discussion about it would be useful. I've learned at work, some people never really understand technical design no matter how much information you provide. It is sometimes a reality of them lacking the background to relate. They simply don't make the connection... like a puzzle piece. In this case, we never really had any detail explaining why Android Auto has been limited to just a few select vehicles. But to me, it seems obvious. A switch from phone-centric to automotive-centric is a really big deal, one that represents too fundamental of a change to taken lightly. In other words, it will be more of an introduction for a new native format rather than being an upgrade. It's similar to the shift from phone to tablet. Most people were blissfully unaware of how much actually changed. So, bringing up this shift could be rather pointless. Regardless, I did anyway: Being a software engineer, one who has worked very closely with many rollout challenges in large enterprise, that type of announcement raised red flags. Why the hold back? What weren't we being told? Today, that omitted vital bit of info became obvious. Toyota didn't want to commit to an outdated version. Android Auto hasn't been upgraded for 4 years. Pushing that out with the 2020 Prius Prime as an introductory offering would have been absurd. Toyota would have been lambasted for using such outdated software. Google just began rolling out the new version today. Think about how complex software upgrades to just phones are. Carriers routinely take a very long time to provide a new OS. Having to wait 6 to 9 months is quite common... and quite unrealistic for a vehicle model-year. See where I'm going with this?

7-31-2019 **Next Steps.** I am so looking forward to Prius Prime finally rolling out beyond the initial markets. Toyota's choice to hold back until after GM's inevitable fallout, then taking advantage of that timing to introduce a mid-cycle update, is fantastic. Areas which haven't ever had any Prius Prime on dealer's lots, like mine, will start from day-1 with a compelling configuration that doesn't have to compete with hype. The price makes it realistic. True, the decision to go with robust & affordable made cargo space limited. But that does a great job of setting the stage for whatever comes next. 2.5 years of real-world exposure (in my case, that means 35,000 miles of driving) is proof the design is sound. Time is the only means of achieving reputation. This certainly looks like it was time well spent. With only a single week of inventory listed online and much of it questionable (available already or en-route still?), the handful of deliveries mentioned in posts make July a month to exclude. No statistic from such a limited scope can indicate what's to come. August may not reach nationwide either. My expectation is to watch inventory in the established regions grow to available-for-immediate-purchase levels, prior to the usual next-year model rollout timeframe. That's usually in October or November. So, by 4th quarter things should be get rather interesting.

8-01-2019 **Squandered.** It's amazing how things can change: *"I really thought that GM was a market leader back in 2010 and 2011. Now? Not so much. Nissan? Dead in the water. So the early leaders have squandered their advantage."* That reflection of my concern is a sad validation of recognizing market factors correctly. Remember how often I got attacked for that very sentiment years ago? I kept posting *"too little, too slowly"* with evidence of opportunity being missed. Later, that turned to the use of *"squander"* to point out how tax-credits were being wasted. Rather than use their momentum to build a market by spreading that interest in their technology to other vehicles, all was lost. It wasn't even really a gamble. You cannot expect sustainable profit to come from a single vehicle. Voltec should have been diversified; instead, enthusiasts fought to retain the status quo. They became their own worst enemies. Battle after battle was to keep focus on just that one vehicle. Any mention to offer it in a vehicle like Malibu or Equinox was met with hostility. It's amazing to look back into the blog entries here documenting just how fierce the resistance to change really was. They allowed the squandering to persist, becoming enablers of a failed approach. Ugh. Of course, what's worse is not recognizing who. Those Volt enthusiasts blame GM, not themselves. Taking no responsibility for the obvious rhetoric they posted is terrible... and how history ends up repeating. Remember Two-Mode?

- 8-01-2019** **Extreme Denial.** Reading posts like this had become such a norm in the past, it was an expectation: *"Wait, as mature as the Prius is, and as big as Toyota is, they are still only 'limited to specific markets'? That screams like 'Compliance car' to me LMAO."* Reading it now though, you have to wonder. That smug attitude serves no purpose anymore. We are well past the stage when there was any type of required quota. Focus has turned to the entire fleet can be improved. That pushes attention to design. This is why range isn't considered as important anymore. Obsession Volt enthusiasts had with a minimum EV range collapsed when it failed to lure new interest. In other words, they came to the realization that *"compliance"* equated to *"enthusiast"*. As much as they fought my *"Who?"* question, they can no longer deny the association. Some extreme attempts still take place though, as the *"LMAO"* clearly confirms. I'm done with that nonsense. Dealing with it isn't necessary anymore. Their days of feeding fake news are over. I put it this way: Scream whatever you want. Who exactly will care? Reality is, the choice to wait to align national rollout with a mid-cycle update and avoid GM fallout looks to be an extremely wise decision. Getting some compliance credits along the way is just a bonus.
- 8-02-2019** **Trying?** I was a bit befuddled to read this: *"The truth is, neither manufacturer is really trying to sell very many of these cars."* I thought that particular individual, who routinely posts on multiple forums and seems rather well informed, would recognize the change taking place. It was in a discussion comparing Clarity to Prius Prime. Being an owner of a Prius Prime and an active participant there, I didn't expect such a statement. Apparently, he hasn't been paying attention. Oh well. There's a chance of getting something constructive in reply. This venue is a source of useful discussion... quite unlike some I've dealt with in the past. We'll see if this stirs anything useful: The reality is, inventory from Toyota for the 2020 model (which is a mid-cycle update, for those not paying attention) is growing nicely. Just 2 weeks ago, there weren't any. Now, the nationwide search shows 750 available. August should be interesting for Prius Prime.

8-03-2019 **Lame.** There is still some damage-control taking place for Volt. With failure on a such a monumental scale, there's hope GM's mistake will be absurd... since there's no way to forget it. That's exactly what happened with Two-Mode... which is why some of the same mistakes were repeated. Misrepresentation of what actually took place is how you enable that. I was always amazed how foolish of a choice that was. Now, they're doing it again! Ugh. Oh well. This post yesterday about July sales results started with: "*1875 PiP's is lame*" then went on to claim: "*The Leaf and the Volt have had much better years than this way back in the day. The Volt sold more than 24,000 in 2016 or 2,000+ per month on average. And the Volt did nearly as well in 2012 and 2013.*" I was not surprised in the least upon seeing that. That repetition of behavior is quite predictable. I wonder if he expected this in return:

That selective portrayal of Volt sales history paints a distorted history, since it doesn't take into account temporary surges caused by price-cuts when inventory piled up. The proper depiction of demand was the measure taken during steady periods. Those sales averaged between 1,600 and 1,700 per month for gen-1. It was a very consistent result, making the growth for gen-2 demand an easy measure to gauge. Volt failed to grow though. Sales remained at that same level... which is below what you label as "*lame*" for the plug-in Prius.

Reality is, supply of Prius Prime is still limited to the initial rollout markets (roughly a little under half the country). Delivery of the 2020 model (which is a mid-cycle update) didn't begin until the final week of July either. No mention of those supply factors is distorted history in the making. Omission of vital detail is not helpful in any regard. In fact, it provides material for anti-plug rhetoric.

Volt was doomed from the beginning anyway. Having such an extreme dependence on that \$7,500 tax-credit for sales and those sales coming only from conquest buyers sent a clear message GM would need to take serious steps to push the technology prior to reaching phaseout... very much like what Tesla did. That never happened though. GM never even tried to spread Voltec to a choice GM's own customers would find compelling, like Trax or Equinox.

Prius Prime is an example of taking a very different approach. The technology was designed from the start to be offered at a MSRP low enough to compete directly with other vehicles Toyota dealers, giving it far more potential to achieve marketshare those who once favored Volt could only dream of. The technology was also designed to easily be spread to other vehicles, as Corolla hybrid has already proven with rollout of a plug-in hybrid model.

Put in a completely different perspective, your effort to draw a parallel of the past to Tesla results now is what should be labeled as lame. As successful as Tesla has been (kudos!), it's still tiny in comparison to legacy automakers like GM and Toyota. Absence of a dealer network adds major challenges to growth too. Reaching mainstream consumers is far more difficult than early-adopters taking advantage of tax-credit opportunity.

Watch what happens as the effort to appeal to fickle-shoppers attempts to step forward. There are many difficult challenges to face still in the realm of plug-in

appeal. Change doesn't come easy and far too much focus has been on results of picking the low-hanging fruit.

8-03-2019 **Downplay.** Here's more from that damage-control effort: "*My Volt and your plug in Prius are both nobodies. They don't matter.*" There's an element of fear at play too. That's harder to detect, until you notice how many facts the person is willing to dismiss along the way. The desperate enthusiast ends up going way out of their way to avoid dealing with some important point you bring up. When you confirm that pattern of evading, it becomes an invitation to hit back fairly hard. They reach a level of uselessness like a troll who should no longer be ignored. It's especially good if you can constructively use their own words against them, especially in the form of a question: Attempting to portray Toyota's approach the same as GM is wasting everyone's time. Toyota created a far more flexible design and still has an ample number of tax-credits available. GM has nothing anymore to offer in the category of plug-in hybrid. Prius PHV gen-1 was only rolled out to 15 states, then production was halted when gen-2 design got far enough along to show that it should be the first nationwide offering instead... especially considering the plug-in market back then. When gen-2 was rolled out, restricting inventory to select regions meant tax-credits could be saved for mid-cycle rollout later. So, claiming it has already seen "*sales peak*" cannot be taken seriously. As for the muscle-flexing nonsense, that is incredibly weak... ironically. You know that the ability to augment any Toyota hybrid for plug-in operation is just a matter of adding a one-way clutch... which has already happened with Corolla. Just think of what that means. How many of those who "*most guys wouldn't want to be dead in*" won't be interested in a RAV4 hybrid with a plug?

8-03-2019 **LOL.** The smug is really getting bad. That's a clear sign of the next stage. Enthusiasts who took the gamble and lost are trying to make themselves feel better by laughing off the situation. In this case, it's those who bet everything on GM and now finally recognize that wasted opportunity I had pointed out countless times. Oh well. After years of getting attacked for expressing concern, seeing this outcome play out is great. It's confirmation of progress... clearing the path forward, as I expressed this way: Corolla has already become a PHV. Both RAV4 and C-HR are likely next candidates for the plug-in upgrade. Attempts to divert attention away from them by making the discussion about Prius is blatant desperation, a damage-control effort to make Volt look less of a failure. It's the same old rhetoric as whenever I asked when Voltec would finally get spread to another vehicle, like Malibu or Equinox. Face reality. Legacy automakers must design & distribute a green technology capable of competing with their own current traditional offerings. No amount of tit-for-tat will change that cold, hard fact of business necessity. Again, we see that RAV4 hybrid has the opportunity to become a plug-in hybrid by getting the same upgrade as Prius. With the addition of a one-way clutch, the existing system can utilize its generator motor for added propulsion power. That's an elegantly simple approach with lots of business potential.

- 8-04-2019** **Expired HOV Stickers.** Rhetoric that never caught on, but still gets attempted on a regular basis is the claim that plug-in hybrids never actually get plugged in. Their spin is that HOV stickers are so valuable, people are willing to spend a premium just for the sake of getting an improved commute. It's difficult to argue with someone who just outright lies like that. There's data to support such a stance. But even lacking merit, they still accomplish their goal of diluting & interrupting discussion. So, it has been a lose-lose situation... until having the thought about what happens to the vehicle once that valued special-lane access expires. Knowing the person exploited incentives, it only makes sense that they move on to something else. Such a move puts a used plug-in hybrid on the market... which is a fantastic means of achieving market growth. It's just like holding out until mid-cycle for highly wanted features. Some owners will upgrade because they have the means & desire. It's a brilliant approach... something I can't wait to point out the next time an antagonist attempts that deception again.
- 8-05-2019** **Unused Capacity.** I'm on a roll. There was an article published today titled: "*Electric Vehicle Efficiency Explained*". It covered all the basics. The same old content about EV benefits will get distributed over and over like this. That's unfortunate, since some will just lose interest. But then, it is nice having a readily available source of information like that. What differs are the comments. This specifically caught my eye today: "*You are always either carrying around the extra unused capacity of a battery, or the extra unused weight of a gas engine, or both.*" It hadn't crossed my mind to punch back with something rather terse. Shutting up EV enthusiasts who do anything they can to belittle PHEV is becoming more of a problem now though. Rather than looking upon them as a simple means of getting people plugging in with much greater numbers and much sooner, they don't want anyone to produce or purchase PHEV. The idea of plug-in hybrids is counter-productive in their minds. So, they spread whatever nonsense they can to impede. But now, with EV range so much longer and the spread of public chargers, it raises the question of necessity. Do you really need that much unused battery capacity? This situation is becoming the same "*needed to tow my boat*" argument. Does your daily-driver really require that ability? Why can't an infrequently used old vehicle serve that purpose instead? Remember decades ago when people had recreation vehicles, like the old pickup? That was capacity set aside for a specific purpose... a far lower cost option than driving around day after day with an ability you'll rarely actually utilize. In other words, park the aged guzzling SUV and start using a plug-in vehicle with a right-sized battery. Think about how much appropriate to be using close to its entire capacity each commute.

- 8-06-2019** **Clarity Pullback.** Seeing Honda take the step to pullback current inventory has invited narratives to be spun. Remember when that happened with Prius PHV when Toyota stopped production? Antagonists made up stories, claiming whatever they wanted. I suspected Toyota simply reached the stage of a next-gen design where they could confidently commit to it. They won't disclose that, to avoid the fallout related to new announcements. They'd simply burn down current inventory and wait. Sound familiar? That just happened again with Prius. The mid-cycle upgrade for Prime followed that same pattern. So when I saw this, I got rather annoyed: *"In a few years, PHEVs will just be overcomplicated EVs with woefully short range. These are Hondas. With careful maintenance they'll still be serviceable well into the 2030s. But they'll be obsolete well before then."* It's a narrative attempting to downplay the upcoming surge of PHEV sales, led by Toyota. I find it amazing how the patterns play out. You can see it coming. They respond in textbox style. Oh well, it's not like I don't point out my observations: The word *"obsolete"* does not carry any weight. It's just a buzz word used to make early-adopters feel better about the slow progress. We've seen that for 20 years now. Reality is, a PHEV like Prius Prime is less complex than a supposedly competitive traditional vehicle. Rather than all those gears to make the old-school guzzler more efficient, there's nothing but a power-split-device... which has overwhelmingly proven highly reliable. Addition of the one-way clutch to allow the system to disengage the engine entirely adds to engine longevity. That leaves you with a weak argument of *"woefully short range"* which falls apart as more and more destination-chargers become available. It becomes an even more difficult of an argument as the popularity of RAV4 hybrid grows. The idea of it later offering a PHEV model will drown out any last hope of *"obsolete"* having any impact. In other words, ordinary consumers simply won't care. Look at how indifferent they have been up to this point about what happens under the hood.
- 8-07-2019** **Attacked.** Sure enough, it happened. I saw this coming: *"You are just a Honda and Toyota shrill."* Just like our president, make it personal. Attack the messenger so the message itself gets lost. I suspect he'll be relentless too. That's when I get my best insight & confirmation. Sometimes, you'll even get a revelation out of it. The person will be so desperate to get you to stop providing data, they'll post something revealing. My experience with confrontations like this in the past has been fruitful. This is what happens when you feed the troll. So, sometimes I take the bait and run with it: Your reaction to the growing reach of Toyota has been interesting to observe. It's proof of the potential. So what if Honda pulls back to regroup in the meantime. We're still in the early-adopter stage (clearly defined by tax-credit subsidizing) anyway. When the true competition begins (direct sales against traditional vehicles), then it gets real... and none of your nonsense will matter.

- 8-07-2019** **Labels.** Exactly as anticipated, he turned to insults & name-calling. That's a textbox response and quite telling. It reveals he has nothing to actually argue with anymore. Every avenue of argument has been exploited already. I felt vindicated and posted: Doing everything possible to draw attention away from the topic, especially when that content is nothing but insulting the poster, confirms identification of a weakness or concern. In this case, you see the potential that mid-cycle update for Prius Prime has on the PHEV market and recognize how powerful of a message it will send for RAV4 hybrid. Seeing a plug added to an extremely popular vehicle is the dream for Voltec which GM was never able to fulfill. Labeling the current offering from Honda as "*compliance*" and labeling me as a "*shrill*" won't change any of that. The march forward for PHEV continues.
- 8-07-2019** **Still Clueless.** When a post this this goes unchallenged, there's reason for concern: "*In the i3 you just drive it any way you want and you're still 70% more efficient than a Prime.*" It's that group-think taking hold again. You end up with a bunch of enablers never questioning the merit of claims. They just go along with whatever is posted, reinforcing a rhetoric nature. The venue ends up becoming a source of fake news eventually. That's exactly what I witnessed with the daily blog for Volt. Grrr. Not bothering to check validity of supposed facts should be a red flag. I doubt my response will change anything. I tried anyway: Talking about not understanding how the consumption of electricity is measured and reported efficiency. Whoa! 32 kWh/100mi = BMW i3 ReX. 25 kWh/100mi = Prius Prime. It should be obvious how much more efficient Prime is in EV mode.
- 8-07-2019** **EV Misleading.** This attempt to mislead is getting old: "*As we know, many who buy the plug-in hybrids do so for the tax incentive and the ability to drive as a hybrid.....no need to ever plug it in.*" I wonder who actually believes that. Hmm? With online posts looking for enablers attempting to push a group-think, I suspect its an on-going effort spanning any venue offering the opportunity to submit comments. After all, most claims are never verified. That's why I refine my rebuttal to be short, to deliver some type of takeaway detail, and to ask a question. In this case, it was: Even with just 25 miles of range, annual EV miles would be 9,125. That is a lot of gas not consumed from just overnight charging using a standard household outlet. Why are you making the act of plugging in sound like a chore?

8-08-2019 **Propaganda.** When a supposed trusted source of information publishes this, you have to wonder: *"In a PHEV, the internal combustion engine remains the main energy source, with the battery and electric motor used to improve overall efficiency; the PHEV is propelled by the electric motor when the ICE is less efficient and otherwise runs on the ICE. Again, during braking, the electric motor works as a generator, recharging the battery. Since they rely less heavily on the electric motor, PHEVs can use smaller battery packs than BEVs."* This is when raising doubt is legitimate. How could any reputable source spread such misinformation? That is just plain wrong. Fortunately, several people sounded off about it right away. I joined in: It has already been pointed out that definition is incorrect, being the definition of a hybrid, not a plug-in hybrid. Everyone overlooked the final sentence though. Less heavily simply isn't true. A plug-in hybrid like Prius Prime propels itself entirely with electricity. Unless you force it out of the default EV mode, the engine won't start (electric heat-pump operates in temperatures down to 15°F). My entire commute is all-electric, just like an EV. Just because it has a combustion-engine available for when the smaller battery-pack becomes depleted does not mean the operation while using plug-supplied electricity is any different from an EV. It's really unfortunate we have to deal attempts to wash over detail like this. Not all designs are the same. Notice how few EV supporters ever bring up electric efficiency, treating all as if there was no difference? Notice how the "kWh/100mile" rating is absent from discussions?

8-08-2019 **What The Numbers Tell.** That revelation happened. Sweet! I got thinking about what his "*compliance*" push could equate to. Most arguments of this nature don't actually have any substance. There is usually just some narrative being fed, rather than some source of issue. Antagonists will just exploit a buzz word or manta. Watch for that absence of detail. Merit requires it. I wanted to know what a compliance vehicle would deliver for the automaker. What do they get from having to fulfill a regulatory requirement? Knowing that GM hasn't been able to meet California minimums, being forced to purchase clean-credits from Tesla is a bit of important information evaded. None of the enthusiasts want to acknowledge Volt & Bolt not being able to achieve the goal, that some type of compensation is needed instead. In my search, I found the actual equations. The resulting numbers tell a story. I bet this will stir even more emotion: In your haste to label the car as '*compliance*' and me as '*shrill*', you overlooked something very important. Like they always say, the devil is in the detail... Bolt delivers a 2.88 ZEV credit. $[(0.01 \times 238) + 0.50]$ Prius Prime delivers a 0.55 ZEV credit. $[(0.01 \times 25) + 0.30]$ That looks tiny in comparison, until you come to realize just how many Toyota stands to actually sell. The potential is enormous, knowing a profitable platform was used... quite unlike what GM did with Volt, which delivers a 0.83 ZEV credit. $[(0.01 \times 53) + 0.30]$ Think about how much that would drop trying to provide a Voltec version of Equinox, something GM costumers would actually be interested in. In other words, labels are meaningless. It's the numbers that really make a difference... and I'm watching the inventory of 2020 Prius Prime grow. It looks like Toyota is preparing to take a position of leadership in the affordable plug-in hybrid market... far more than just compliance.

8-09-2019 **First Real EV.** There are some who now feel comfortable speaking out against what had previously been unheard of. GM knew what it was doing and there was no possible way we could be better informed about the market... is the nonsense I continuously had to deal with. It was basically a exercise in insanity. They'd fight you in every conceivable way to discredit & dismiss. It was an amazing example of denial. Well, not anymore: *"If GM had any ability to forecast trends, their first real EV would have been a compact SUV similar in size to the Equinox. The Bolt is too small, and it looks and feels like a \$10,000 sub-compact econobox despite costing more than 3 times as much. The drive train is great, the packaging is not a good fit for the US market."* That is why I asked the "Who?" question over and over and over again. It was madness. Volt had no audience. Even enthusiasts were moving on. GM nothing viable to proceed with. The design was far too expensive and there was no strategy. So upon seeing a comment posted like that from the disenchanted, it's a bit difficult to reply with anything constructive. All the bridges were burnt so long ago, there's to path forward anymore. I don't have a suggestion to contribute, just observations: Introducing Trax with an EV would have brought about chaos. Worry about the Osborne effect has always haunted legacy automakers. That's why their is so much hate from GM enthusiasts about Toyota... who has figured out how to deal with the paradigm-shift. RAV4 hybrid sets the stage. Corolla hybrid adds to it. Both later becoming plug-in hybrids will help bring about a smooth transition to electric-only.

8-09-2019 **Incentivizing Charger Installs.** Many online fall into the trap of rhetoric. They'll follow a red-herring rather than do some critical thinking. It's quite counter-productive... and sadly, quite common. As a result, today's comments posted related to EV dominance timing completely overlooked what should be obvious. I tried to interject some logic: The fundamental flaw in tipping-point discussions is not looking at the entire equation. Even if a miracle happened overnight and battery density/cost reached that level, it still would represent market change. That potential for high-volume production & sales cannot be achieved until infrastructure is also upgraded. Tax-Credits for the automakers should be allowed to expire. In their place, we should all get behind federal subsidies going toward the encouragement of homeowners & landlords. Incentivizing the installation of level-2 chargers where people park overnight will make a massive difference. That's the key to drawing interest for plugging in. In the meantime, we will all see a massive growth in the PHEV market. A plug-in hybrid like Prius Prime is profitable and already has an audience to tap. Dealers know how to sell Prius and the ability to simply use an ordinary 120-volt outlet for overnight recharges makes that promoting that next step an easy one. During ownership, it makes the consideration of upgrading to 240-volt a far less stressful decision. There's no rush. There's no uncertainty It's a decision on their own terms. There's also a greater likelihood they'll upgrade with enough capacity for multiple vehicles. Despite seeing the meltdown of GM efforts and other automakers struggling to make something directly competitive with traditional guzzlers, no amount of in-vehicle technology will overcome the barrier faced still for overnight charging. Don't overlook that challenge of simply plugging in. With over 70 million new vehicles purchased every year, it makes a lot of sense to get a wide variety of PHEV choices to market as quickly as possible. EV will naturally follow.

8-10-2019 **Rise & Fall of Prius.** Media sources thrive on attention-getting material. That often meant targeting Prius, knowing it would generate lots of traffic to their content. Today provided a good example of that. It was a 9-minute presentation about how Prius is now dying. To believe that, you cannot look forward. Limiting scope like that is how most narratives work. Rather than just cherry-picking information, they formulate a seemingly comprehensive story to back their claim. That old technique of "lying by omission" has been used to mislead since long before Prius was around. But being such an online-centric formula for success, that exploitation of undermining opportunity has been popular... to the degree seemingly credible sources join in. Basically, it's the fake-news phenomenon growing to the point where people have no idea what constructive journalism is anymore. You'd think the evidence of not looking forward would be obvious. It is not. Needless to say, I'm quite curious what the posted comments related to it will be. Here are my initial impressions:

The report forces a strange perspective. You are led to believe the driving force behind any success is by pushing limits, rather than just simply selling a really good car at a really good price. In other words, they only see market change in the form of breaking new ground... which was never what Prius focused on. Not recognizing the purpose of Prius means not understanding what comes next.

Toyota's goal with Prius has always been to get mainstream buyers to change. For those who have been paying very close attention over the past few weeks, you've noticed what has been happening with the 2020 model of Prime. Inventory is quietly building. Toyota appears to be preparing to fill that void the others have left behind. The supposed "leaders" haven't been able to reach ordinary consumers. Prius Prime is designed to target that very audience. It's affordable, reliable, and easy to sell.

Put another way, the video closes history on Prius for those who knew it. A new chapter is about to begin, one that exceeds what happened many generations ago... reaching much further into the market of ordinary consumers than we've seen so far. The approach of "*elegantly simple*" that Prius was so well known for is about to become obvious for those who are just looking for a good car with a plug.

8-10-2019 **Mistakes.** This was the comment emerging from that rise & fall article that I chose to address: *"Given the mistakes made with the gen 4, I am hopeful (maybe unrealistically so) that the next gen can attract more buyers by a combination of going back to it's roots and advancing technology."* That's exactly the perspective I expect to routinely encounter in the near-term from casual observers. It's what we call anecdotal evidence. They take the information they have collected to draw a conclusion. Unfortunately, that means information is incomplete. You cannot learn everything necessary to be well-informed without study of the past. That knowledge comes from research, not anything you'd stumble across without digging. However, there are people like me who attempt to provide that missing background:

The narrative of "*mistakes*" is one that doesn't recognize Toyota's approach. Anyone who truly knows the automaker understands this. Most people are blissfully unaware. For those who have studied the process Toyota has taught us, the term "Kanban" is quite familiar. It's a totally different means of managing & improving. There's an inherent aspect to taking risk as a result. Failure is not looked upon as a mistake.

The reason why is simple. You try something. If it works, great. If it doesn't, you try something else. The key is to keep the scope of that change small. Notice the careful rollout to select markets and within limited timeframes? Toyota is always planning ahead, expecting one of many next steps to take place depending upon outcome of the previous. That flexibility is what most people completely overlook... seeing the changes made along the way as a mistake. It's adaptation.

Toyota saw the market for sedans & hatchbacks crumbling... hence the amazing RAV4 hybrid. This is why taking the risk of attempting to upscale Prius Prime a little by reusing the middle rear for comfort & convenience was worth taking. If it worked, great. If it didn't, the uproar would indicate demand for the old is still strong. At the same time, risk with the no-plug model had to be taken... knowing the plug-in model should become standard by gen-5.

Once you recognize the perspective Toyota has on the industry and how they have been applying it to their entire fleet as a whole, you'll see a very different picture than what the media has been painting... as well as antagonists, or anyone who wants to retain the status quo.

8-11-2019 **Watching Inventory.** Looking to the big Prius forum for feedback about that rise & fall video has been a problem. The website is down for weekend maintenance. So, there's no sharing of impressions amongst the group. That knowledge-sharing venue is silent. My own knowledge continues though. I have been closely monitoring Prius Prime inventory. It's easy, you setup the online app with saved search. A quick refresh gives a basic oversight of activity. Remember how I mentioned the available count climbed to 750 a week ago. Late last night, it exceeded 1,000. That number doesn't tell the entire story though. You have to watch for drops. Those represent sales. In other words, not only am I witnessing overall growth, I'm also getting a general impress of increased demand... which is exactly what has been hoped for. The careful planning to ramp-up both production & interest based around the timing of both a mid-cycle upgrade and tax-credit fallout is a very sensible business approach. Toyota doesn't care about hype. Toyota doesn't cater to enthusiasts. Toyota's interest is changing their own status quo. Seeing their fleet move beyond traditional vehicles is true progress forward. That's why I pushed those so hard who endorsed Volt, but fought against GM spreading that technology to one of their own mainstream vehicles. It was the move of an automaker simply not interested in actually making a difference. Dependency on those federal subsidies was obvious. There was no sincere attempt to configure a system with a competitively priced MSRP, something to challenge their own traditional inventory. Volt, then later Bolt, were token offerings which bared no resemblance to anything GM customers expressed interest in. Ironically, the result was a "*halo*" effect. That's when a vehicle creates a draw to the automaker, but the vehicle responsible for that credibility isn't what people end up purchasing. That's why the subtle approach Toyota is taking with Prime is so different. Sales are not just listed within the "Prius" category. There isn't a breakdown anymore. This will allow Toyota to shift away from the no-plug model without much disruption. Rhetoric for the supposed "*fall*" will be forgotten and the naysayers will deny the rise of Prius Prime was anything but inevitable. Ugh.

8-11-2019 **Seemingly Forever.** That's the sentiment we get from those who don't have much (or any) background in how long it actually takes for change to happen. In this case, it was from someone well informed, but annoyed at the timeline: "*Toyota always had the vision of making all their models optionally hybrids, amazing how long it took.*" He was painfully aware of the challenges faced when up against those fighting to retain the status quo. I jumped in to help out:

No surprise though. I always told people it would take an entire life-cycle to even get mainstream interest stirred. That meant a minimum of a decade. More realistically, the dealer-lot to sell-for-scrape duration is 12 years. In terms of generation, that equated to waiting for two of them to pass. Since the first-gen was really just a limited mid-cycle update, the start began in 2003. Bringing us to 2015 (that 12 years later) was right on schedule. At that point, the vision was falling into place... but still not complete.

The next-gen upgrades to Prius, Camry, and RAV4 have all been well worth it. The technology has proven robust & affordable, as well as very easy to sell. It's a winning formula.

What comes next is what this "*rise & fall*" curiously avoided any mention of. For those paying attention, it's not much of a stretch to see Toyota striving to make the PHV option standard for the next-gen of Prius. The design focuses heavily on being cost-effective. Dealers must have a choice that brings in easy profit... a goal none of the other automakers are in a position to address yet.

It's all about high-volume sales, not breaking new ground. That's why the perception of "*fall*" isn't actually a problem. Toyota's goal is to transform their fleet. Narratives of a necessary to push limits are just hype from enthusiasts. What happens for ordinary consumers is what matters. Remember, automakers are for-profit businesses with salespeople who aren't well informed and work on a commission.

For those of us who watched GM pursue glory through the exploit of tax-credits understand & appreciate Toyota taking a very different approach due to having a very different vision.

- 8-11-2019** **Awaiting Delivery.** It's nice to see posts that start with: "*So far 236,000 miles...*" He was telling us about his current Prius and the loooooong wait for deliver of his Prime. Since he's nearby (metro of Minnesota), I'm well aware of the lack of inventory. Only a handful have been sent to each dealer. That's the way it has been all through Toyota plug-in history. The center of the United States and Southeast Coast are not part of the initial rollout regions. The expectation is that will change upon 2020 ramp-up. Supply of that mid-cycle update is only now growing in the established markets. That limitation is somewhat bothersome, but quite understandable. So in the meantime, we share stories and ask questions: What will you be doing with it when your Prime arrives? btw, I have been watching the inventory. Lots of new arrivals and sale removals have had the availability count all over the place. There's about 10 listed within day-trip distance of us now. It's looking like Toyota is well prepped to go all out, with the choice of delay being a very wise one. Not having to deal with any of the past hype leaves you and I a clear playing field. I'm excited about starting up gatherings again. Not having any local inventory put quite the damper on things. But now, it should be a reboot of how Prius got started. That was really fun the first time around. Soon.
- 8-11-2019** **Internal Trolls.** When a popular forum poster gets out of hand, what do you do? I responded to this today on that very topic: "*Nobody guessed --- would hit 80,000 posts by 2020.*" I did. I pointed out his overwhelming of the discussions too: "*Seeing so many posts per hour everyday, it raised concern about drowning out participation of others.*" My lead up to that wasn't well received either. He got quite annoyed with me repeatedly posting know your audience comments... because it drew attention to his desperation for attention. It was an ironic means of making others aware of the resulting dilution of value... especially due to the laziness and lack of concern. His posts don't include quotes. It's always in third-person to avoid confrontation. All the words in his posts are lowercase too, making them further standout. The sheer volume is the biggest problem though. He literally posts over 100 times per day and has been for over 2 years now. So, most of the content is meaningless sound-offs or contradictions for the sake of keeping the dialog active. It's just him using the forum for entertainment. That's sad. Others who join to share their experiences or ask questions get pushed aside by his effort to retain the spotlight. Needless to say, I don't like him... and feel quite good about others finally noticing what's been going on. Trolls of that nature bring down the reputation of the venue.
- 8-12-2019** **RAV4 PHV.** There was a set of spy photos that began circulation on the internet today. Supposedly in Spain, there as a plug-in hybrid model of RAV4 being tested. That makes sense. It is a logical next-step with the spread of PHV technology. After all, the hybrid system was designed to readily adapt to using plug-supplied electricity. The simple addition of a clutch allows the larger battery-pack to supply greater power output to the wheels. It's an elegantly simple approach that supports the absolutely vital need to deliver a reasonable profit to dealers. They won't bother trying to sell something that isn't affordable. It must demonstrate sustainable interest. Toyota's approach is quite compelling. Proof of that is undeniable with RAV4 hybrid. It's next-gen upgrade has been showing strong demand already. That makes it easy to see the effort to refine an offering with a plug is a sensible move. That will most definitely help to bring the entire fleet forward, something all other automakers have been struggling with. The subsidized one-hit-wonder can't compare to a variety of profitable offerings. Needless to say, I was delighted to see those spy photos and the excitement they stirred.

8-13-2019 **Nonsense.** Reading this brought a feeling of vindication: "*The Volt died because the factory it was being assembled at was closing, and it was closing because the traditional cars made there weren't selling and were being cancelled.*" It was just more of that desperate nature to provide damage-control. Whether the act is to convince oneself or others of the outcome, it's a disconnect with reality I'm happy to point out: Circular logic is evidence of something gone awry. In this case, it was the fact that Volt sales were supposed to grow to the level of takeover. The goal was for Volt to become the replacement. Production of that traditional car was expected to end anyway. Volt failed to achieve that. For 12 years, we had to put up with claims of "*vastly superior*" technology from GM becoming the dominant force in efficiency sales. This followed the disastrous hybrid offering known as Two-Mode. We were besieged with the message of needing to patiently wait for this new plug-in hybrid technology to crush Toyota. I endured countless attacks stating my concern for GM's expensive & inefficient were unfounded, just an effort to save the reputation of Prius. Needless to say, any attempt to portray a false past will be called out. Volt died because GM didn't really want to sell it. Why would any automaker continue on with such expensive & inefficient technology... especially seeing how well Toyota is setting the stage for plug-in hybrids? Looking back at how hostile Volt defenders became just 6 months ago, absolutely desperate to provide damage-control for GM by pushing a narrative of Toyota "*falling behind*" so much, the automaker may never recover. We now see both Prius & Corolla have PHV models and its looking like one for RAV4 is one the way. 19 years of that nonsense from those hoping to undermine Toyota accomplished what?

8-13-2019 **The Key.** I was surprised to get backlash from posting this: "*You try something. If it works, great. If it doesn't, you try something else. The key is to keep the scope of that change small.*" It makes sense that the perspective of being cautious gets highlighted. But no effort to see beyond that is concerning. After all, that is the trap Volt enthusiasts fell into. So, getting this stirred memories: "*This is a great strategy to keep from making a major mistake. It also insures that you'll probably never find the next big thing. In math, this is known as getting stuck in a local minimum.*" That sounds sensible. But having proven false, it cannot be used in such a blanket way. The market is far more challenging to deal with than that overly simplistic perspective takes into account. I pointed that out with: Actually, that has been proven false. The act of being willing to refactor (take on all those small risks) will often lead to discovery. It's a constant state of looking for improvement opportunity. Eventually, you find one. In math, that's known as a complex equation. Think about what happens when you add, subtract, multiple, and divide in a variety of different ways. A small poke in the right direction can lead to enormous change. To put this in terms of the automotive market, you must recognize it is a moving target... one that doesn't follow any particular path or destination and will continue to alter as you travel. Knowing that, ask yourself what the "*next big thing*" could mean? If it is a battery technology, what penalty is there for Toyota working to establish a culture of change at their dealerships highlighting the benefits of electrification? Building momentum for moving away from traditional vehicles is perfectly fine taking small steps. Put another way, I'm approaching my 20th year of pursuing greener technologies. With such a strong background in that effort to engage ordinary consumers in the acceptance of true change, I see a lot of repetition... including some major mistakes. The strategy of staying true to goals is what wins every time, even if that includes very small steps along the way.

8-14-2019 **Notice.** I'm back to the "notice" posts again: *"I think Toyota had made a similar strategic mistake with its Prime availability. Kind of a self fulfilling prophecy by limiting these vehicles to specific areas of the country."* That begged for them. It's because most people don't. So, I end up sharing my observations. I collect lots of data spanning a wide array of influence and watch for patterns, which requires a lot more effort than simply agreeing with a trend. It means what I observe commonly goes unnoticed by others. In this case, it meant I had this to share: When looked upon in a vacuum, it may appear that way. But when looking at the bigger picture and longer duration, the prophecy to insulate themselves from market fallout appears to have been quite wise. Notice how both Ford & GM are preparing for difficult times? Notice how Ford & Honda are getting skittish on hybrids? Notice how GM & VW have given up entirely on all but EV offerings? Notice how Toyota is ramping up Prime availability?

8-14-2019 **Low Sulfur.** Remember the diesel insanity way back in 2006? That's when ULSD (Ultra Low Sulfur Diesel) was rolled out. It was to be the savior of diesel, a means of competing with hybrids as a clean solution. That obviously didn't actually work. True, it did indeed reduce emissions. But the reality was, that wasn't enough. Diesel was still dirty in comparison and no where near enough to be called "*clean diesel*" as the campaign to deceive tried to make you believe. Well now, that necessity to reduce emissions coming to the shipping industry. The new regulation coming for January 1, 2020 from the International Maritime Organization (IMO) will be requiring lower-sulfur fuel oil. That will help considerably; however, it's not a perfect solution. It will be expensive too. To be more clean, more refining is necessary... which increases cost for the fuel and cost to retrofit some existing equipment. This is why there is still on-going research into the feasibility of fuel-cell use for large container-ships. They must find a means of cleaner transport. Think about how much fuel each one of them consumes.

8-15-2019 **Oops!** I really like where this took the discussion: *"EV's may indeed become the dominant mode of ground transportation, but that evolution will not happen overnight either. It has to be competitive with the current technology and work within an evolving infrastructure..."*

In the automotive industry, that term *"overnight"* equates to a generation-cycle. Which means, being able to take the market by storm still takes 6 to 7 years. That's why Prius is still the only single vehicle in modern history to bring about a paradigm-shift. Tesla can't be included, because it started fresh, there was nothing for it to change from. Tesla was also very heavily subsidized by both tax-credits and investor-capital. Being a start-up means lots of low-hanging fruit, but major challenges after those picks are gone.

That brings us to the legacy automakers. Even if there was a will, there is not a way. We are now seeing the same desperation for profit as we did in the past. That pattern repetition can no longer be denied. In fact, it appears to be even worse this time. Anyone else remember how heavily Ford & GM relied upon SUV & Pickup sales for sustainable business?

This particular discussion is yet another component to the market taking a downturn. Notice how many announcements we get about a far better options than hybrids coming, but no detail whatsoever? Those incredibly vague promises of amazing future technology is exactly what we got in the past. Remember how GM attacked Toyota with all that *"stop gap"* propaganda? What about Two-Mode? What about ULSD vehicles?

It's about to get ugly for some automakers. All the belittling of Toyota for having prepared for such an *"unlikely"* turn of economic influence of the plug-in market is gone. Anyone else notice how the *"leader"* and *"behind"* insults have vanished from comments? For that matter, notice how antagonists themselves have disappeared? That's a sign of problem recognition... like, oops!

8-16-2019 **Setting Expectations.** Today's discussion was interesting. Out of the blue, someone just wildly threw out there what they believe EV range for the next Prius Prime should be. Of course, it didn't take audience into consideration. In fact, cost was entirely absent from those posts. There was nothing related to automaker or market either. That lack of any effort to recognize big-picture need is a red flag. Missing any reference to sales goals is a warning that scope & timeline weren't included in the calculation. That's even worse than being unrealistic. You can't exclude the fundamentals of business and expect to succeed. That's why I get eye rolls from my posts though. Few, if any, in online forums really want to discuss economics, marketing, or accounting. There's nothing exciting about those non-engineering aspects of the automotive world. So, many just pretend that stuff just magically works out if you have the right design. Ugh. I hoped to get the discussion back on track by providing a basis of analysis, giving them some actual numbers to consider back pointing out background: The unit-of-measure for a vehicle designed in Japan is metric. In this case, kilometers. For gen-1 Prius PHV, that target was 20 km. For gen-2 Prius PHV, that target was 40 km. For gen-3 Prius PHV... knowing that affordable & reliable has been higher priorities than range... would put it at 60 km. That's 37 miles.

- 8-16-2019** **Cost Reduction.** When Toyota designs something, there is always that quest to reduce cost. Achieving that through high-volume is an effective approach. The benefit is well proven. Think about the product-line as a whole. RAV4 PHV using a 13 kWh capacity battery-pack would be ideal to share with the next Prius PHV. That would fulfill an expectation of 60 km. It's in the realm of realistic options to pursue. That's why real-world research with mules takes place. They give the design a try, hoping to gain a confidence of it being a wise choice. If so, great. If not, you try something else. The key is to consider as many factors of influence as possible before committing. Reducing cost is challenging enough. Oversight can be costly. This is why we see Toyota rolling out to limited markets. They go to great lengths to validate decisions about stuff related to size & capacity.
- 8-16-2019** **Realistic.** It's nice to see hope growing for new PHV models to come from Toyota, but there's much people have yet to "*notice*" about the design. Some of it comes from outdated or incomplete information. Some of it comes from rhetoric. That means responses to new threads on the topic are all over the place. I saw that coming today and jumped in as quickly as possible to provide some background. Sadly, the antagonists are usually faster. And sure enough, that happened this time. But I still managed to provide an intercept: Keep in mind, purpose of that original plug-in Prius was to boost MPG and an affordable MSRP, not to provide any type of all-electric drive experience. So, there was never a sound reason to compare it to Volt. They were from entirely different categories. The initial rollout of Prius Prime was limited to select regions of the country, knowing the mid-cycle update (2020 model) would be the one to deploy nationwide. For those watching inventory recently, that ramp-up is now underway. Remember, the upgrade from regular Prius to plug-in Prius to create the "*Prime*" model (known as PHV in other markets) was to just add a one-way clutch. That enabled the second electric-motor (usually used for generating electricity) to contribute to propulsion power instead while also disengaging the gas-engine. Combined with a larger battery-pack, it pushed EV limits to provide an all-electric drive experience. Doing the same for RAV4 hybrid is quite realistic.
- 8-17-2019** **Sales Decline.** You gotta love seeing posts starting like this: "*PHEV sales are declining in nearly all markets...*" How long did that sentiment persist for hybrids? Needless to say, having over a decade of experience seeing such efforts to mislead & undermine has taught me to keep on pushing. That nonsense has very little impact. Understanding change is not something anecdotal observations can teach you. I fired back with: Generalizations tend to give misleading conclusions. Failing to recognize data is why. In this case, we see a major decline due to the exploit of GM coming to an end. Volt was clearly a niche, targeted at enthusiasts who took advantage of the tax-credit. That early-adopter audience has nothing whatsoever to do with the mainstream market. Demand for such fundamentally different groups cannot be compared. Prius Prime was only available in limited markets, waiting for this mid-cycle update (the 2020 model) before going nationwide. Corolla PHV isn't even available anywhere in the United States yet. Both are targeted squarely at ordinary showroom shoppers sharing nothing in common with early-adopters. The same will be true for a PHV model of RAV4. Keep in mind, appealing to those who would be content purchasing a traditional vehicle is far more difficult than winning favor by someone reading these comments. Their priorities have little to nothing in common with this group. Many couldn't care less about many of the arguments posted here. Know your audience.

8-17-2019 **Baby Steps.** Focus on Toyota has really become a hot topic: *"Toyota still making baby steps while others are racing forward."* It's a sign of impact. Antagonists see the potential... and don't like it. So, they attempt to belittle & insult any opportunity they get. It doesn't work though. I gladly point out why: Toyota's goal is to convert their fleet, replacing traditional offerings with hybrids. So what if it is looked upon as a baby step? It's a move on a monumental scale. Others are not racing forward in that regard. Focus on low-hanging fruit (subsidized token offerings) gives a false impression of change. The status quo isn't actually altered. GM's failure with Volt is the ideal example. Enthusiasts argued for years about how that *"leadership"* was winning the race. Those naysayers who absolutely refused to acknowledge it was a tortoise & hare situation have since grown silent. They were wrong, very very wrong. The culture at GM dealerships didn't shift to electrification. In fact, we have seen sales of guzzling SUV & Pickup choices grow. Don't be fooled into thinking what's in the spotlight at the moment represents progress forward. It's all about lifting the base. Appearance of being a leader doesn't take into account what it actually takes to get difficult customers to embrace change. Baby steps are almost always what's required to get them to accept a paradigm-shift. In other words, setting the stage for BEV by first getting the base to purchase PHEV offerings will likely be a much more effective means of achieving large-scale change quickly. Remember, Toyota sold 10.7 million vehicles worldwide last year.

8-17-2019 **Vague & Ambiguous.** Statements like this are a common problem: *"It's easy to implement hybrids. Implementing a true BEV is much harder and more expensive, as Tesla found out with the massive development costs of the Model S, Model X, Model 3 and soon Model Y."* They do nothing to look forward. They gloss over detail too. That *"soon"* is basically meaningless. If you are waiting to purchase one, how long does that actually mean the wait will be? Needless to say, I get annoyed by the lack of critical thinking. Many just post to make themselves feel better, rather than making an effort to help advance the masses forward. In reply, I posted: Since the topic is PLUG-IN hybrids, not regular hybrids, that claim is a red-herring. It's also quite ambiguous. What does *"implement"* actually mean? Getting dealers to train mechanics to support and salespeople to sell anything with a battery-pack is a major challenge. Also, Tesla's reach beyond the early-adopter market has yet to be observed. We have no idea how ordinary consumers will respond to a Model 3 without that generous tax-credit available. Heck, we don't even know how they will purchase a Tesla vehicle. So, that could be considered a red-herring too. It's what happens with legacy automakers who sell millions of vehicles per year that will shift the market. With worldwide sales well over 70 Million, turning a blind-eye to the established biggest players to instead focus entirely on a small-in-perspective startup isn't a balanced approach. Think about what next steps are required to reach beyond early-adopters.

- 8-17-2019** **Now, it's just a "Hybrid".** I find it quite amusing how intensely the Volt enthusiasts fought for "EREV" as the identifier of technology for Volt. Long before rollout began, they pushed to make it unique from any other offering other automakers would later rollout. And when that happened, the definition would be altered accordingly. Ugh. That happened twice, for both Ford Energi and BMW i3. It was so obvious that attempt to build demand for Volt while belittling all others was a desperate marketing move. Without any operational difference to actually distinguish it, that was just a meaningless label... as Prius Prime has overwhelmingly confirmed. Again, ugh. So now that the table has turned, I find the hypocritical nature of the claim quite fulfilling. To promote Bolt as the future of GM electrification efforts, Volt has been re-categorized as just a hybrid. No one refers to EREV anymore. In fact, antagonists get very frustrated when you bring up that past. They want to pretend that ugly chapter in their history never happened. Efforts to divert attention and downplay the situation are abundant. I particularly liked this one: *"There has only been one hybrid that did any good and that was the Prius. Even now sales on it have tanked. The hybrid was a compromise that just seldom worked out well."*
- 8-17-2019** **Effective Marketing.** It boggles my mind how the difference between want & need is so confusing. As a software engineer, that distinction has been absolutely vital for a successful career. You must carefully listen to the customer, correctly identifying the type of request. Are they specifying a requirement or a nice-to-have? Design with mistaken priority can be quite costly. You should balance what's delivered. Too much of either won't be a product the customer will enjoy using. Sadly though, marketing doesn't work that way. It heavily favors want, to the extend need isn't even addressed at times. The definition of each should be easy to understand. The reason why should be too. Sadly, I have to post that information from time to time, when an argument grows to an extreme due to a failure to distinguish the difference. Hopefully, today's attempt will provide some insight: Want = Feel, Opinion; Need = Fact, Necessity; Not seeing the difference is why the topic (snow tires) gets brought up so often. But then again, this is why Prius has been able to sustain for so many generations. Campaigns have come and gone, each trying to convince us of "need" based up what is actually a want. People have moved so far out of touch with recognizing or even questioning the difference, that lack of distinction is now normalized. Some would call that effective marketing.
- 8-18-2019** **For The Boat.** After all these years, that excuse still lives on. Someone who owns a giant boat justifies their purchase of a giant guzzler as necessary. They feel that logic validates their choice for daily commuting in that vehicle. It's what I heard today at the barbershop. You could tell he had absolutely no interest in any opinion from others. That was what he would continue to do, period. That's how Two-Mode came about, offering a solution for exactly such a situation. Only trouble was, the technology was far too expensive. It worked, but simply wasn't worth it. Ironically, the "gas saved" campaign went nowhere. In fact, that's why any attempt to try the same for Volt simply fizzled. It is what happens when emotion is the basis of a purchase.. the whole need verses want problem. They find ways of justifying the irrational. So, the fact that I encountered the very same "logic" all these years later is no surprise. People are compelled to follow their heart, rather than their mind. They may work out fine with other things, like relationships, but it's typically an expensive choice when it comes to lifestyle. Those are the facts of life...

8-19-2019 **Finally, It's Dead.** Today marks the final moment of that daily blog for Volt. 2 months ago, the very last topic was posted. You could submit comments, but nothing ever got approved. That pending status became impossible now too. A moderator removed the ability to do anything. It is marked as read-only. All activity has halted. That terrible source of misleading, a training ground for enablers & antagonists is now day. I had no idea such rhetoric could have transformed into a fake news outlet. So much hate emanated from there. I knew that would happen from long before Volt even first rolled out. The big clue was when the look of Volt changed from concept to production. Anyone who had submitted an interest form was not allowed to update their status. The count continued to grow, despite such a dramatic shift of expectations. That number became the first big source of spin. It had no association whatsoever with GM itself, yet was promoted as a commitment to purchase. There was no obligation of any sort. No deposit. No salesperson. No dealer. It was just a survey that grew way out of hand. Any familiar with such information knows only a small fraction of those who express interest actually follow through. Those numbers were treated as sales, long before any specifications of the vehicle was even revealed. That's how I knew this day would eventually come. You cannot run a business on hope. Enthusiasts gambled everything on meritless claims and group-think. It was doomed. Each ambiguous bit of information provided by GM fed them. I witnessed spin and damage-control on an incredible scale... or so I thought, until witnessing this president. He actions resemble the same behavior I had to deal with on that daily blog. That's why "*know your audience*" is so important. Fortunately, his ability to play a crowd will someday come to an end too. In the meantime though, just like GM did with Volt, there will be a lot of damage caused along the way.

8-20-2019 **Not Really News.** The dashcam footage from Tesla owners and all the hype about autonomous driving is starting to dilute plug-in news to the point of people losing interest. It's the quantity over quality issue. News organizations commissioned to deliver a quota of content every single day is counter-productive to the mission of cleaner transport. They push whatever content they can find to stir participation. Reads & Comments are more important than having a compelling story... which of course, dilutes the compelling story when it finally comes along. That loss of value is how many blogs fall. People simply become disenchanted with either the content or the vehicle itself. It's a very real problem for those trying to make a business out of the emerging plug-in market. What draws sustainable interest is a very real problem. If the vehicle simply works, like Prius, people naturally just participate for a short amount of time anyway. That's the sign of a good product. New owners check in for tips, share a few experiences, then move on. You don't actually want a product that endlessly requires some type of on-going effort. So, I'm watching the EV news struggle with lack of anything actually taking us forward. With so much ground broken now, focus needs to switch to building market, not pushing for faster & further. Recognize that problem from the past? You should... Give us real news!

8-21-2019 **Administration Rhetoric.** Just like we had to deal with when Prius was new, the current administration is dead set against promoting green technology: *"Trump said company founder Henry Ford would be 'very disappointed if he saw his modern-day descendants wanting to build a much more expensive car, that is far less safe and doesn't work as well, because execs don't want to fight California regulators.'*" That's really sad. It's the same old scare tactics. Say whatever it takes to prevent the move forward from being considered. Remember those claims of the past, where they said countless jobs would be lost if this new risk were considered? Not only was it meritless at the time, it was later to be proven false. Not adapting to a changing world is how so many careers were destroyed. They held onto the past as long as they possibly could. The same old fight to retain the status quo is taking place now. This is easy to see too. The desperation is manifesting itself the same way. Well being of the automaker is placed on the gamble that high-profit guzzlers will continue to sustain the business. That will inevitably fail. Change is essential to remain competitive. Our president knows they are safer, knows they work well, and knows they are overall less expensive. He'll ignore all that in favor of rolling back regulations and encouraging consumption. There won't be any way to hold him accountable for the extensive damage that will be caused for future generations to deal with. The rhetoric will obscure most of that effort to undermine anyway.

8-21-2019 **Declared Failure.** Whenever something about Lexus hits the news circuit, rumor mill, or just gets a random stir, there is always someone to push the resistance narrative. Wanting to portray Toyota as if it has the same audience as Lexus is what makes that effort standout. It comes from GM having normalized the multi-target approach with Volt & Bolt. We never really knew who the market was. Having a distinct market for mainstream and a distinct market for luxury seems beyond the grasp of some... hence the continuous mantra of one-size-fits-all. I replied to today's post that claimed *"kicking & screaming"* with my own message. Remember how the initial worry with Volt was that it would struggle to achieve mainstream sales, resulting in GM abandoning it with the claim of no interest? No one seems to anymore... now that the concern has come to fruition. That's exactly what happened. GM simply moved on to their token EV without any looking back. All that *"range anxiety"* campaigning was for what? I kept my reply brief, hoping the hypocrisy trap would keep any type of retaliation in check: It's interesting to watch the *"kicking & screaming"* rhetoric play out as the herald leader, GM, did a *"declared failure"* rollout without anyone complaining.

8-21-2019 **Waiting For Profit.** It didn't work. Focus was simply diverted to another antagonist topic: "*Kodak and Blockbuster waited until there were sustained profits to be made also...*" That is also a hypocritical trap. There's no possible way anymore to claim Toyota is behind without acknowledging the lack of progress from GM. Exactly as predicted, no effort to reach mainstream consumers would be made. GM built a vehicle with no appeal to dealers. What possible incentive is there to stock Bolt inventory? We have been told directly from GM that Bolt will not be profitable until next-gen rollout. That means the next few years will remain stagnant. Without a tax-credit available, such a high sticker-price, the pressure from other automakers, and the lack of dynamic-cruise, lane-keep-assist, or super-speed charging, what's the draw? GM is clearly resting on its laurels. Looking at the bigger picture, seeing an effort elsewhere in the fleet could justify the stall. But there's nothing, quite unlike Toyota's push of hybrids across the entire fleet. So, I responded with another short post: Turning a blind-eye to GM doing that is what? The rest of us see how Bolt's push has stalled until profit can be made.

8-21-2019 **Intent Reminder.** It was a decade ago when the hype of pre-release for Volt when expectations turned into rhetoric. The reason why was simple... there was nothing to back the claims. Statements claimed as fact were meritless. There was no data. There wasn't even specifications yet. They had nothing. I got attacked when pointing that out. So, I tried to keep discussion focused on the business aspect. How many Volt does GM intent to actually sell? To whom? When? It was a push without a plan. Knowing the tax-credit was limited, it should have been obvious some type of plan would be necessary... otherwise, opportunity would be wasted. You want to build up demand to a sustainable level prior to expiration. The reason why is simple. After the 200,000 sales, phaseout is triggered. That switches the tax-credit availability from quantity to time, allowing the automaker to flood the market. It's an opportunity Tesla capitalized on and GM wasted... exactly as predicted. All that "*too little, too slowly*" concern I got relentlessly attacked for has been confirmed as valid. I am vindicated for having been sincere about sales. I really was the looking out for the best interest of business & consumer. Sadly, none of that history is remembered. Looking back, you get a very different perception of what subsidy use should have been. That's understandable, considering how much has happened with the plug-in market over the past decade. However, not recognizing the "2020" perspective (what an interesting cliché twist) is a very real problem. Technology changes. Technology improves. It takes time though and you must best use resources available for that period. I provided all that history summarized into: Intent of the tax-credit was to establish a technology, allowing each automaker to build up production & reputation by their own choosing at their own pace. The catch was to complete that process prior to triggering phaseout. Tesla did a wonderful job of that. GM simply abandoned their entire effort to blend engine with motor. Voltec was never spread to any mainstream offering, like Trax or Equinox, as was expected. That was a colossal waste of opportunity. Remember all that "*range-anxiety*" campaigning against EV choices?

8-22-2019 History Disagreement. It is intriguing to find someone disagreeing with you when they have nothing to offer in support of their claim. I have this massive collection of blog entries, written back at the time of those events playing out. That provides an incredibly valuable perspective, one of not knowing what comes next. When you already know the outcome, any reflection upon that history is distorted & bias as a result of that uncertainty having been removed. You must take into consideration material from that time, documenting what people felt & believed would occur. That's why the "intent" discussion is somewhat pointless. It teaches you how to make decisions about the future, but does not in any way alter the past. Whatever happened, happened. That's the way it is. Wise or Stupid, it doesn't matter. The outcome is not for debate. In this case, the demand & reputation for traditional guzzlers remained untarnished. Legacy sales continue as they did back then. Ugh. Annoyed, I posted: You can disagree with intent, but that won't change it. A decade ago when the tax-credit first became available, the market was different... hence the relevance of pointing out the bigger picture. Again, that bigger picture is important. The tax-credit is only for 200,000 vehicles. Focus on the highly profitable with annual sales much higher wouldn't appeal to the true customers, the dealers. True change (actual impact to the status quo) means focusing on the more difficult challenge.

8-22-2019 Overcoming Assumptions. Setting realistic expectations is a means of preventing assumptions. Problem is, people continuously supply misleading information. It never ends... which is why trolls thrive in certain venues. It probably isn't intentional. It just happens. But then they become addicted to the resulting attention. That's the problem I have now with a certain Prius owner who has decided the big forum is there for his entertainment, rather than being a source for exchanging detail about ownership and the market. When it becomes that, you know there will be trouble... since overall value is lost. Newbies don't find it helpful and stop participating. Sadly, that's exactly what our current president is doing too. Making people become disenchanted results in less pushback when he does whatever he wants. Notice how many tweets we actually get daily now. Ugh. It's just like posting. Quantity rather than quality is a red flag. That's why when you encounter comments like this, it makes you wonder how much disinformation was spread to give such an impression: *"I don't understand why Toyota doesn't add a plug to these models and thus gaining eligibility for government incentives."* There are only 200,000 credits available per automaker. So, there is no gain. The finite quantity cannot be changed. For that matter, eligibility doesn't require more models. The only option available is to seriously ramp up production just prior to reaching phaseout. That's where the assumption part comes in, which I stated as: How do you know Toyota isn't planning to do exactly that? It certainly looks like they are setting the stage for high-volume availability to happen the same time as triggering phaseout... which would make it ideal, since that is when the tax-credits switch from quota to unlimited. After all, that is what Tesla did with great results. Just because GM blew it by not having anything in place doesn't mean Toyota will do the same thing.

8-22-2019 **Constructive Questions.** Sometimes, you get lucky. My assumption response resulted in: "*Curious then what is your prediction for when they hit the phaseout and what models will they have in place in the US at that time?*" I appreciate that type of post. It shows critical thinking. Rather than attacking the messenger or attempting to draw attention elsewhere, it's a worthwhile question. Yeah! That's so much more than the usual nonsense, especially when the rhetoric is so brainless. To that, I gladly answered with: I have no idea. Toyota has a reputation for carefully monitoring markets and responding in its best long-term interest. I have been watching inventory of 2020 Prime models grow in the established markets over the past 3 weeks. The impression based on counts appears that sales are already off to a good start there. It suggests the same will happen as new markets finally get decent delivery. While that's happening here, Corolla PHV owners elsewhere will be providing data to gauge rollout potential in other markets. I suspect we'll get a PHV model of RAV4 first.

8-23-2019 **Watching Inventory.** I have been watching the ups & downs of inventory for the 2020 Prius Prime. It took less than 2 weeks for another 500 to become available as ready-to-purchase stock. That doesn't account for those sold during that same time period. So, I'm actually witnessing the number rise, then fall. The point is to see an overall growth. That's how I know the market reach is taking place. Sales are very important, but so is being able to reach new customers. That requires supply to be on dealer listings. The phone-app shows that data. It's quite handy. I can already see August will be a good month for existing markets. New markets (like the 500-mile radius from me, here in Minnesota) hasn't seen any growth at all. We have a dozen vehicles listed, all special orders. Not being part of the initial rollout regions was a test of patience. Getting 2020 models as the first ready-to-purchase stock is fantastic. Customers (as well as sales staff) will only ever know this newest offering. Not having any type of legacy to deal with has benefits. That means a bit more waiting. I suspect new region rollout won't begin until close to the end of the year. Oh well. There should be a few announcements/reveals in the meantime. That gives Toyota ample opportunity to see the stage while we wait too. Stuff like training at the dealers is quite helpful. Hopefully, that's what some of those special-order deliveries are for. It takes a bit of real-world exposure before you get enough experience to feel comfortable promoting something so new. In fact, that's part of the reason why Toyota decided to rollout to individual market schedules, rather than to the entire country all at once. Experts for training are limited. So, while I wait, I watch inventory grow.

8-24-2019 **Today's Future.** It has been interesting to read some impressions of what the future is expected to bring. I hear comments that have no basis upon any market effort. People just see a need and expect it to somehow be fulfilled. Who will do that, when it will get done, and how it gets paid for doesn't get addressed. They just figure it will somehow be dealt with. That type of "magic" is pretty common. It's the basic non-enthusiast perspective. Stuff just happens. That's why there's such a fascination with Prius. It simply works. The future is "today" regardless of when you start paying attention. This is something mysterious & questionable by early-adopters. Some now, especially as Tesla phaseout is well underway, just expect an effortless growth to take place. Catch is, it's not like Prius Prime. The discovery process isn't as simple as coming across one while wandering around at the dealer. Pricing keeps in the "someday" category too. In other words, stuff like this coming up randomly in discussions is how you know a new chapter has begun. Rhetoric of the past is fading away... hence, the future arriving today... for some.

8-25-2019 True Change. This was an interesting observation posted about a rather odd new thread: *"He sees all the competition... He just doesn't want to spend the rest of his life waiting."* What made it odd was the critical thinking. This was starting out as a constructive discussion. Woohoo! I jumped in with:

You have been enlightened and now sit at the doorway of early-adopters. It is a *"grass is greener"* situation. You see better choices, but don't have enough exposure to really assess what that really equates to.

Think about where I started 20 years ago. I was watching electrification struggle to break out beyond a niche through the PNGV (Partnership for a Next Generation of Vehicles) program, a federally funded effort to help research & deliver 80 MPG vehicles. Prius came about as a counter-measure as a result of that. Toyota's technology revealed just how difficult it would truly be to provide via choices for the masses. That's why GM was doomed to fail with Volt from the very start. I made a lot of enemies by taking on the enthusiasts who pushed aside real-world data in favor of hope. Their desire to embrace the idea of a miracle break-thru clouded their judgment to an extreme, enabling a group-think which ended with disastrous results. What a waste of opportunity.

Looking for actual merit in the advancement forward is rather disheartening, if you want a solution for the masses right away. Status Quo has remained intact, despite the successful rollout of Model 3 from Tesla. It's an amazing vehicle without any real influence of change for our greatest barrier, legacy dealers. Understanding how they are the true customers of legacy automakers brings about the next-level of enlightenment for you. Think about who the *"competition"* actually is.

Knowing that is how you will begin to see Toyota's *"death by a thousand tweaks"* will overcome the barrier. It's not exciting to watch the seemingly glacial pace forward, but it sure is assuring to know that there is no turning back. Toyota's electrification push is across the entire fleet. With the newcomers of Corolla hybrid and the seriously impressive next-gen Camry hybrid and RAV4 hybrid, that should be easier to see.

Looking forward, we can set focus on Prius. For anyone who has closely studied the history, starting even before the dramatic reveal of Prius back in October 1997, will know how much Toyota plans ahead and builds flexibility into their approach. We can see how the stage is being set for Prius to become a PHV by default. Having the plug be standard, and the no-plug optional, is that paradigm-shift many have been dreaming about for a very, very long time... except, it will then be realistic. 25 years is a freakishly long time for a consumer, but not from the perspective of an automaker. This is why *"know your audience"* is so important.

Toyota's goal is to deliver an affordable & robust design. That's why this generation of plug-in Prius has that rather awkward sized battery-pack, but has a tradeoff of production-cost being low enough to compete directly with other vehicles on the showroom floor... an absolutely vital aspect of true change. We won't see status quo budge until without that profit reality... which informs us as to the design for the next-gen Prius... a better fitting pack, with a modest capacity increase and faster recharging, at a highly competitive price.

That may or may not be the greener grass you are looking for, but it is certainly what legacy automakers need to move forward.

8-25-2019 True Leadership. My contribution to the discussion included:

Also, don't lose track of what true leadership is either. Unlike what enthusiasts try to convince us of, it's not about bragging rights.

Toyota has been quietly introducing unique gains to give them an edge later, when legacy automakers suddenly discover HSD is an very effective means of delivering PHEV choices able to compete directly with traditional vehicles without any subsidies.

It's amazing how often the carbon-fiber hatch and the dual-wave glass get overlooked. Both require very high levels of quality, something that takes quite a bit of effort to achieve at both low-cost and high-volume. Combined that with the refinement needed to deliver both a highly efficient traction-motor and highly efficient heat-pump, you've got a winning set of technologies beneficial to plug-in vehicles.

So whenever you seem to get a little frustrated, seeing greener grasses for enthusiasts, remind yourself how Toyota is quietly striving to get an edge on the larger consumer market as a whole. Their pre-work to set the stage, prior to the masses taking an interesting in plugging in, to prepare their entire fleet. That readiness of design we see in Prius Prime and Corolla PHV clearly demonstrate the massive amount of potential. It's not far-fetched to consider a plug-in model of RAV4 hybrid becoming enticing enough for dealers to stock them as regular inventory.

Unfortunately, just like all the other successes of the past, a great deal of patience is needed in the meantime.

8-25-2019 **Playing Offense, again.** Having history unfold in such a familiar pattern is fascinating. The repetition now is just like I remember from years ago: *"Anytime there's an article pointing out Toyota's failings in the EV world, John's boilerplate, anti-GM, regurgitations appear. It's his defense mechanism."* When absolutely everything failed with Two-Mode and it was totally hopeless, the attacks dwindled to just claims that I was really just out to get GM. Doing everything possible to avoid address any aspect of what GM did to bring about such a monumental fail is confirmation of positions having switched. The same thing happened again, this time with Volt. So, I started playing offense again. There's so much real-world data in my favor, why not? There's nothing new to spin. Every exploit has been exhausted. It's over, as I witnessed firsthand today. The attack was so desperate, I couldn't help but take the time to really push back hard. So, I did:

You clearly didn't actually read the article. Instead, it was choosing to attack the one who not only expressed concern about GM's impending failure, but also quite accurately predicted how it would play out. I was dead on about GM's squandering tax-credits for the sake of conquest sales... sacrificing Volt technology along the way, rather than establishing something able to achieve sustainable profit prior to triggering phaseout. Production has ended and there is no vehicle using that technology anymore for GM's own home market.

That combined with the obvious move Toyota is making toward electrification is making you crazy. Your beloved Volt, which you abandoned for a Model 3, simply could not compete with what Prius Prime was evolving into. Toyota had already delivered a superior system, more efficient with both EV and HV drive, in addition to delivering a more efficient system for heating the cabin. And now that the model 2020 has delivered a mid-cycle upgrade, the inventory build-up in established markets and rollout to new markets is too much to accept. Adding to that, we now here of an EV concept on the way from Lexus.

All those years of having to deal with that nonsense about GM being the ultimate legacy leader and Toyota being hopelessly behind is about to pay off. Your lack of patience and refusal to acknowledge the bigger picture will be a hard lesson learned... and I'm happy to play offense on this one. Go ahead, dig dipper into that pit of denial. What do you claim Toyota has failed at?

Remember, we aren't even out of the early-adopter stage yet. That means mainstream acceptance hasn't started yet. That stage is defined by competing directly on the showroom floor, traditional against plug-in, without any subsidies. Watch what happens with Prius Prime. That starting MSRP of \$27,600 is the dream *"nicely under \$30,000"* goal GM was never able to deliver.

8-25-2019 **Lexus EV.** There is something on the horizon. An article today posted about a reveal coming in October stirred the rhetoric. Right away, there was trouble. It usually starts from cherry-picking, to portray some type of narrative. That avoidance of the bigger picture (what a legacy automaker with do with the technology as a whole) is a clear sign. With the tax-credit phaseout underway, anything new is looked upon with fear. Status quo disruption is on the way. I pointed out what was going on with: As this becomes a post tax-credit market, most of that GM damage-control effort no longer has an audience. GM's heavy dependency on subsidies became undeniable. It's over. The technology was too expensive to be spread to other vehicles in the fleet. Two-Mode made that mistake. Volt gen-1 made that mistake. Volt gen-2 made that mistake. Not being affordable is a very real problem. That's what brings us to Lexus. It is a luxury brand, serving consumers willing to spend more. So, expensive is ok. That makes a hybrid like the Lexus UX 250h, starting at \$34,150, a sensible choice. Increasing battery-capacity and adding a plug still keeps it within the pricing of competitive scope. People looking to get an upscale plug-in SUV will find this, which sets the stage nicely for an EV luxury offering to follow. It's all a realistic path follow. Looking to the mainstream market, we see Toyota offering Prius Prime at a MSRP starting at \$27,600. That is well within the reach of ordinary joe-average customers looking for something from Toyota with a plug. RAV4 hybrid starts at \$27,850. Increasing battery-capacity and adding a plug will work well for it too. With Corolla hybrid starting at just \$23,100, the effort to deliver affordability is easy to confirm. No amount of rhetoric can hide that cold, hard reality.

8-26-2019 **No Chargers.** A new type of grocery/convenience store was built just down the road from where I live. It was to be a much smaller version of the grocery store I could see from my house, but at the same time quite a bit larger than anything you'd ever buy gas from. And yes, it also sells gas. All that, combined with an attached coffeeshop spelled great opportunity for that chain which already took pride in offering chargers right from the start. Problem it, those chargers also had issues right from the start. One had never, ever been usable. The construction crew accidentally painted the spot with the disabled markings. So unless you have a handicap placard, parking there is impossible. That meant one charger went to waste. I contacted corporate and got a convoluted response that was just a lame excuse to cover their mistake. Nothing ever became of it. Still not fixed. So, I had little hope of this new facility built from scratch in a corn field would be done to actually support chargers. Sure enough, opportunity lost. My first stopped, I was greeted by a manager. My comment about the lack of chargers baffled him. In his mind, it made no sense to stop at that location for more than a few minutes. I silently just pointed to the coffeeshop, waiting for the view of the seating there to register. He finally responded with an, *"Oh! I send that suggestion forward for you."* I didn't say anything. It was far too late. No new work after just finishing up for a grand opening would obviously happen. That premiere new type of store had blown it already. Ugh. That would have been a great way to attract new business, especially in such a competitive area.

8-27-2019 **Unintended Outcome... Plug-In.** My own response to this brought about an unintended outcome: *"Yes, but that begs the question: Why is the Prius no longer considered cutting-edge eco-conscious technology?"* It was that type of "halo" spin of the past that fueled much of the debate. Purpose of Prius was constantly being misstated for the sake of undermining goals. Knowing this was a general audience and a fluff piece about Tesla, the attempt to portray Prius in a different light was to be expected. I responded several hours later (waiting for others to comment in the meantime) with:

No, that was never a question relevant to Prius. Anyone who has taken the time to study the history (or even better, witnessed it firsthand) knows that Toyota's purpose for Prius was to bring an affordable solution reducing emissions & consumption to the masses. That's why the other hybrids have been just as important. Corolla, Camry, and RAV4 hybrids are all part of the stage being set for the next chapter, that look forward the article fails to address.

Those next steps should be obvious. But those who by into the "*competitive*" narrative are choosing to disregard the current chapter in history coming to an end now. That low-hanging fruit (subsidized early-adopter sales) have little reflection of demand from the mainstream market. Those consumers are entirely different. That's why Toyota has responded accordingly.

Prius Limited, Prius AWD-e, and Prius Prime (mid-cycle update) are those changes... all new offerings within the last 8 months. It's all about targeting showroom shoppers, Toyota's own loyal customers, not appealing to those who seek cutting-edge technology. Know your audience.

Put another way, Toyota is moving toward that paradigm-shift, when Prius becomes a plug-in standard. To achieve it, the technology must be proven mature, not cutting edge. Being able to deliver an affordable plug-in (meaning it can compete directly on the showroom floor, no tax-credit help) is something none of the legacy automakers have been able to achieve yet. It's the type of leadership the "*innovation*" crowd is still unwilling to acknowledge.

Watch what happens with Prius Prime as it rolls out beyond initial markets. Large areas of the United States have been limited special orders. That lack of inventory was Toyota's choice to delay until the mid-cycle upgrade, which began the last week of July. So, it's going to take some time to get supply even to just the initial markets. But it is quite clear there's demand for an affordable plug-in hybrid and the Prius Prime sticker at \$27,600 is about to test those waters.

8-27-2019 **Superiority, part 1.** I saw this and immediately detected trouble brewing: *"people have no concept of how loud their gas engines are until they ride in an EV. When i first started driving my Volt, the silence was eerie."* Being a post on a thread about the electric-car coming to age, it would inevitably attract a wide variety of participants. So, I carefully thought out how to approach the obvious absolute perspective that message was attempting to push. It was a good idea to keep the response short and to the point: Best to rethink that claim. The 12 million Toyota hybrid owners know. They discovered city & suburb electric bliss long ago, no plug necessary.

- 8-27-2019 Superiority, part 2.** He was either totally clueless or a Toyota antagonist: "*as they chug dino juice every day?*" That's a dead giveaway objectivity wasn't going to be possible. His mind was already closed. This had already become an example of the "*vastly superior*" attitude I dealt with on a regular basis in the past, the heyday of Volt... when enthusiasts just plain didn't care about facts. That was the birth of fake news in the plug-in world. A website became an enabler. They would repeat rhetoric so routinely, it created a narrative telling the story of a false reality. I was blown away how they would outright lie. Those naive to their actions would get sucked in, helping to spread the misinformation. It starts with efforts just like this. Again, I carefully thought out how to reply: Doesn't matter that gas is used to generate that electricity. Once the engine shuts off to use it, the driving experience is just like an EV. That smoooooth & silent operation has been inspiring consumers for decades already.
- 8-28-2019 Superiority, part 3.** Yup. I got my confirmation: "*doesn't matter that gas is used to generate that electricity. it matters if you care about pollution. Prius burns gas and pollutes every day.*" He clearly just plain did not care. He wanted to portray Prius a particular way, intentionally misrepresenting it. With the death of Volt, there has been an expectation of spin emerging to make it seem more than it was. The start of that comes from lowering the bar. Claims of Prius not being able to deliver any EV drive experience whatsoever is an obvious path to that deception... since it was a common claim in the past. Only then, it was about Prius PHV. But now that even the regular Prius can deliver even faster EV speed on the highway, there's reason for concern about how Volt is perceived. GM had potential, but ended up squandering for praise instead. What a waste. I posted back with: That has nothing to do with the topic of experiencing EV drive. That also attempts to misrepresent Prius by omitting the fact that the Prime model is an EV for the first 25 miles... full electric-only driving up to 84 mph.
- 8-28-2019 Superiority, part 4.** He then got angry: "*Sure it does. You will be polluting most every day via the gas guzzling Prius, especially in winter. It is called a fact, ALL versions of the Prius guzzle gas and pollute the environment. Prius owners are virtue signalers.*" That attitude was easy to detect at that point. The insult to ALL owners of Prius made it undeniable. He wanted his superiority to remain untarnished. I was threatening his position. So, it was time to push back: Typical, changing the topic upon getting caught trying to mislead. Prius Prime (the plug-in model) dramatically reduces pollution to the environment. Entire commutes can be done using nothing but electricity, including winter. It delivers EV speed up to 84 mph and has a heat-pump that will electrically deliver warmth for the cabin in temperatures down to 14°F. Claims of virtue are an attempt to evade those facts by twisting it to an ALL absolute. Again, they discovered city & suburb electric bliss long ago, no plug necessary.

- 8-28-2019** **Superiority, part 5.** No surprise. It got quite a bit worse: "*typical, a Toyota propagandist deflecting the fact they have no EVs and all their cars and trucks are destroying the environment. Where are the fuel cells? ROFL!!!!*" The back & forth had become a great example of nonsense just like I had to deal with in the past. It was history repeating itself all over again, again. I always find that repetition fascinating. There's an aspect of the human existence which people tend to follow. It can be remarkably predictable. They refuse to acknowledge facts not in support of their beliefs and respond with insults as a defense. Efforts to change the topic are nothing new. That's been done for ages. Catch is, there is now a term for it. That label coined for such behavior is the "*What about?*" technique. Belief is sighting something else that is worse will forgive whatever issue is being discussed. That's classic evading, now with an means of drawing attention to the effort. I wrapped up the posting with: Thanks for providing the "*What about?*" example. That literally has nothing at all to do with the topic of experiencing EV drive.
- 8-29-2019** **Superiority, part 6.** Sure enough, there was no response. He gave up the fight. I called out his attempt to mislead. It served as a great reminder of how rhetoric persisted for so many years. There was always a hope of squashing early-adopter competition by false pretense. That was a bad sign, evidence early on that Volt would face serious challenges. Overcoming them never, hence its death. Spin will lead you to believe that wasn't way. But there's simply no way to justify such a massive investment in technology to blend engine & motor only to abruptly abandon it mid-cycle without any means of succession. No passing on to a preferred platform, like Trax or Equinox. GM just let it die when there was no longer any means of sustaining what had been given the impression of superiority. Having such heavy dependence on the \$7,500 tax-credit was overwhelmingly clear evidence of not being "*vastly superior*". Nonetheless, this owner felt the need to defend it. 12 years earlier, I sighted concern for the "*trophy mentality*" ...and that's exactly what kept it from making any progress. My ask of "*Who is the market for Volt?*" was on-going confirmation of a vehicle unable to reach the mainstream audience. To be superior, you don't have to do anything fancy. Prius introduced EV driving to a large population, period. It did. That's a fact. I enjoyed "*Stealth Mode*" a little over 19 years ago. No plug necessary.

8-29-2019 **That Attitude.** It lives on, despite Volt now being dead. Sadly, that makes it even easier to mislead about. Detail like how poorly it was loaded with safety features compared to Prius Prime is very difficult to show or even draw attention to. So, there will be a lot of assumptions in that regard. Fortunately, most enthusiasts never bothered with items on that level. They stuck to the basics. For example: "*You must have missed the 160k+ Volts sold over the years.*" Reading that today was annoying. It reminds me of the tax-credit for Prius, which was half that, was only for 60,000 vehicles, and remaining available at full value for only 9 months. That's a significant difference often evaded from discussion in the past. So now that this is in the past, I suspect it will too will be ignored. I'll keep providing the detail anyway: All heavily were subsidized. GM exploited the \$7,500 tax-credit opportunity for conquest sales... none of which impacted the status quo. Their dealers still push as many traditional SUV and Pickup guzzlers as possible. Notice how the technology was simply abandoned as the subsidy phaseout approached? It was a massive opportunity wasted. Just imagine if GM had actually rolled out that design to a Trax or Equinox. As for the narrative about a Prius coffin, you in for a big surprise. This year brings about a new look for the regular hybrid, a mid-cycle update for the plug-in, and an AWD model. Combine that with MSRP low enough to compete directly with other vehicles on the showroom floor, it reveals the game is far from over... quite unlike what happened with Volt. Think about how many sales each automaker has each year. Notice how insignificant 160,000 over 8 years really was? It's important to keep focus on the bigger picture, how much true change is actually taking place.

8-29-2019 **Electric Car Age.** An article with that title was published today. This was among the first comments posted: "*It amazes me how much the average person overthinks and complicates the whole EV purchase...*" That's ironic, since the typical guzzler purchase is basically with little to no consideration. How many people do you know of who didn't focus on other detail of there purchase decision? What any technical aspect of the propulsion system even considered at all? If so, did that decision of engine size take more than just a quick glance at the window-sticker? Heck, I've known countless people who didn't even take that much time when choosing not to get a hybrid. It was pretty much thoughtless. That means the plug choice must be with a simplistic approach if you want to appeal to ordinary consumers. The whole KISS philosophy is priceless advice. I responded to that comment accordingly: Actually, you are also overthinking it. Reality is, the average person will notice whether or not is has a plug. If interested, they'll ask if it is one of those with an engine back up. That's all. This is why I continuously state "*know your audience*" as a vital bit of information when discussing the post tax-credit stage, where major growth without subsidies is essential. Reaching mainstream consumers is dramatically different from enthusiasts, which means that growth us going to be far more difficult than simply appealing to early-adopters.

8-30-2019 True Growth. How many times you seen a variation of this: *"ICE sales are in the early stages of collapse, a situation that will not be helped by any upcoming recession. EV sales are booming with a growth rate..."* The understanding of statistics has been a fundamental problem with hybrids right from the very start. So, it goes without saying plug-in vehicles will face the same challenge... if not more so. Still to this day, 20 years later, many people have no idea the MPG measurement is fundamentally flawed. That's why most of the rest of the world doesn't use it to measure efficiency. In fact, that's why the *"kWh/100mi"* rating for electric-only operation was introduced here... to overcome that flaw. Sadly, many EV owners don't understand it still. Anywho, those are common examples of how numbers can be misinterpreted. Data alone isn't enough, as I attempted to point out: Don't allow percentages or subsidies distort expectations. It's more informative to look at actual quantities instead, especially those post tax-credits. The initial boom is low-hanging fruit, catering to enthusiasts. Shakeup of some sort as that stage comes to a close was anticipated. Tesla will likely plateau. GM and Nissan are already there with their EVs. GM's entire plug-in hybrid appears to be dead in all but the market for China. And we are in a holding pattern for VW. As for legacy automakers seeing a threat from EV, that doesn't make any sense. It's the need to end dependency on oil and the need to reduce environmental impact, not battery operation. In fact, the reverse is likely. Growth opportunity in the plug-in market will be their path to survival. How some legacy automakers travel that path will be interesting. Each will end up taking a different route. There's a massive potential for reaching deep into the mainstream to come from Toyota. Plug-In hybrid models of Corolla and RAV4 present strong potential, as Prius Prime is about to soon demonstrate with its mid-cycle update rolling out right now. It basically comes down dealer appeal. If you can draw showroom shoppers with very little effort, without sacrificing profit, you've got a winner.

8-30-2019 Ford Explorer Hybrid. The 2020 model will introduce hybrid tech to a platform which should have got it well over a decade ago, following Escape hybrid. After all, Highlander had a hybrid model, even as the platform continued to grow in size. In fact, next-gen about to rollout in February. Efficiency bump is anticipated to be in the mid-30's too. That makes today's reveal from Ford a bit of a head scratcher. 25 MPG is the combined rating for the AWD model. How is that competitive with anything? It's somewhat bizarre how the automaker thinks premium for a hybrid system is worth that. Of course, this is for the domestic market here in the United States. Over in Europe, a plug-in hybrid model is on the way. With a 99 horsepower electric motor, it won't be as EV centric as Prius Prime with a 91 horsepower, since Explorer is so much larger of a vehicle. Oh well, at least it's something.

- 8-30-2019** **1,000 Posts.** End of tomorrow will mark 3 weeks since he hit the 80,000 post count. This morning, it was already up to 80,966 total posts. That's an average of submitting 48 responses per day. He's posting so frequently, content is beyond lacking. It's just mindless clicks at this point. No one else comes even remotely close. I get really annoyed when quantity is valued over quality, especially at such an extreme. More is not better. All that activity on his part takes away opportunity for others. It's one of those lessons which should have been learned in kindergarten. You know, sharing. Ugh. I'm glad others notice how much he was altering the dynamic of participation. (That's a polite way of stating he has become a troll.) Overwhelming a forum with thoughtless banter brings down its value. Those looking for a venue to actually gain from the sharing of observations & experiences have a harder time finding it when so many posts contribute nothing to the thread. I know, my complaints do little. He clearly has no intention on posting with any type of critical thinking. However, there is an ignore feature. So those that do find so many unconstructive posts a pain to deal with can simply make them invisible.
- 8-30-2019** **Unrealistic Expectations, criteria.** Here we go again: "*If they can bring EVs with 200+ miles range, 125KW, and prices in the low \$30+K range...*" I know this is going to anger some Volt owner. It's inevitable. Goal setting was a fundamental problem for them. They'd measure success with arbitrary values. What are they basing those requirements on? 300 miles has been the distance to match for over 2 decades... since that was the basic minimum back in the 90's. I remember being satisfied with 300 back then and blown away when hitting 500 with my first Prius. Now, automakers include a massive tank to deliver similar range. (18 gallons at 30 MPG is 540 miles.) As for the charging speed, most consumers have no idea what that number means. Heck, even many EV owners really don't know what that equates to in terms of time needed for a full charge... or even partial. Price? Really? How are you going to convince someone looking for a sticker-price in the 20's that spending so much more up front is really worth it? That's incredibly difficult if the person simply scans the showroom floor to reveal there's only 1 plug-in choice offered. That's not a good endorsement. Think about what RAV4 hybrid is selling so well now. Everyone knows about Prius, but many would prefer the technology in a different body style... and such a popular SUV presents a golden opportunity. That's the ideal for attracting those who would not have otherwise been interested. Paying a little more up front delivers effortless efficiency gain, without requiring the exchange of any knowledge. The consumer already knows a plug isn't required. That's why adding a plug to Prius first sets the stage so well for a plug-in hybrid model of RAV4 later. It's the same pre-education effort... the very thing that was recommended to GM with Volt. Just think about how popular a plug-in hybrid Trax could have been. Oh well. That is what happens when you set unrealistic expectations.

- 8-30-2019 Unrealistic Expectations, familiar.** My response to the nonsense (lack of critical thinking) was as follows: That sounds painfully familiar. Remember 12.5 years ago? There were similar categories of criteria, setting expectations for a paradigm shift. If this could happen, this would result. Unfortunately, that placed the bar too high. There was no way it could realistically happen. And as we all witnessed, GM fell well short of that criteria. Seriously, how is the situation with VW any different? A small, expensive car doesn't stand a chance in this market, the land of giant guzzlers. Success in Europe means what for the VW business here in the United States. For that matter, how will success be measured? There's a profound difference between appealing to enthusiasts and actually changing what loyal customers purchase. Seeing a real effort being made with ID now is what was said about Volt prior to rollout. It was to be the start of real change; instead, it became a popular niche among early-adopters. The end result was production ceasing and no change at all to the status quo. Keep in mind how much effort there will be to fight plug-in progress. The technology achieving certain specifications is far from enough to get people to switch their purchase preference.
- 8-30-2019 Unrealistic Expectations, hype.** You want a great example of it? Go no further than GM's homepage. Oh my! It's all loaded with hype. There are several promotions for AV (Autonomous Vehicle) and EV (Electric Vehicle) technologies, making it appear as though that's the dominant product for the automaker. When you try to get actual vehicle information by clicking on the "Brand" link, a photo of Bolt covers your entire computer screen. (On a phone, you have to scroll down to see the rest of the image.) Then when you finally click on "Chevy", you see nothing but guzzlers... Silverado... Corvette... Blazer... without any trace of efficiency offerings. In other words, if you go directly to the Chevrolet homepage instead of GM, there's no trace of Bolt. I found that discovery fascinating. I tried the same for Hyundai. What a profoundly different experience. It was a variety on the homepage, a wide selection displayed up front. I tried the same and got the similar results with Honda, Toyota, Ford, VW, BMW, Nissan, and Chrysler. The hype we get from GM is very much a standout. That's why when I recognize the pattern repeating, I point out those red-flags right away. Enthusiasts of GM have been the enablers, allowing ambiguous releases to fuel hype, resulting in unrealistic expectations being set. This is why I pushed so hard for goals over the years. Enthusiasts would declare victory, sighting success on measures without any accountability. They simply claim that measure achieved had been goal all along. When it reality, it fell well short of what had been hoped for. That formula for disenchantment is what doomed Volt from the beginning. That's why there is concern now about the same emerging for EV merit. Rather than consider what mainstream buyers will actually buy, they fixate on values are somewhat arbitrary. Remember the "40 mile" expectation?

8-31-2019 **Android-Auto.** The process is beginning. 2020 Camry will get it, but detail hasn't been provided yet. There was only a vague mention, enough to stir discussion. I suspect that is in preparation for the upcoming Auto Show circuit. Those types of "*it's coming*" announcements are common practice to raise awareness that preparation is underway for reveals. I get frustrated at times with those online who pride themselves for being well informed, but don't actually bother to demonstrate critical thinking. They fall into the trap of assumptions. Ugh. Usually, it's the quest for detail that drives participation online. But sadly, fallout from propaganda of the past... like Volt hype... lowered the bar so much, there isn't much call for merit anymore. Vague is accepted as enough. That's why I get attacked when pointing out assumptions. People don't like when you draw attention to the fact that they made have made a mistake. In this case, it's an oversight related to what is actually included in the infotainment suite. The assumption continues to be that navigation will be the centerpiece of the system. No where has that ever actually been stated. That's a problem. I pointed out that missing detail asking how the HUD would be integrated: Navigation instruction not provided via the heads-up-display would then appear to be a rather major oversight. Those not understanding why Toyota didn't switch years ago now have an additional complication to consider. Loss of a feature, especially one that useful, isn't a good thing. We all know Toyota waits to do it right, rather than rushing to market like some other automakers. It's like any other type of upgrade. There are tradeoffs. Short-term gain can result in a long-term setback or an additional cost later.

8-31-2019 **Understanding Software.** More and more, it appears most people complaining about the lack of Android-Auto from Toyota didn't include any real thought about what that actually would require. That's based on the assumption I keep encountering with regard to navigation. People expect that to be the heart of the infotainment system... hence the seamless integration everyone desires. Doing that would mean customization to get the HUD (Heads Up Display) to present driving instruction. Those distance & arrow illustrations would be lost without some extra programming to work with the projection hardware. This is why first waiting for the software switch from phone-centric to car-centric was so important. Work could not even begin until that new platform was delivered. It simply made no sense trying to adapt deprecated coding. I kept my response less technical though, attempting to provide a simple analogy to help with the understanding of the software involved: Let's not forget how new large data plans are to most people. Being restricted to just a small amount or not even having data, was the norm prior to the last few years. In terms of vehicle ownership, that's extremely recent. So, there wasn't really as big of a market as those sounding off about falling behind actually made it out to be. People simply weren't in the mindset of bridging to their phone yet, which meant the benefits of doing so were still an unknown to them. Experience with Bluetooth should make that clear. Notice how many here complain about Toyota's software only to find out their phone is extremely old? Knowing that, it makes no sense rolling out any faster. You end up paying for it from having to deal with fallout from that older tech. My own experience is finding people at home having issues because they are still using a very old router. So even though their modem is providing great speed, the signal over Wi-Fi is severely impaired, resulting in a terrible user experience. As a software engineer for over 25 years, I'm well aware of how painfully long adoption of applications truly takes. You may get the user to upgrade, but that in no way means they will actually use the new features you provided. In fact, more often than not, they won't. Toyota is obviously also aware of that problem. Most customers embrace change very, very, very slowly.

9-01-2019 Horribly Inaccurate. Makes you wonder what the intent was upon reading an article so inaccurate. Was the misleading content intentional or did the writer research so poorly he was basically clueless? This was the title that caught my attention: *"Is the plug-in hybrid beginning a long goodbye?"* It posted July counts and arbitrarily compared them to 6 months ago. That's a bizarre metric. Seasonal cycles distort number naturally anyway. That's why everyone else uses annual comparisons. Anyway, this is what made me sigh: *"The plug-in hybrid came to Americans' attention in 2008 with the introduction of the Chevrolet Volt. Unlike prior hybrids like the Toyota Prius, which relied on a gas engine with a battery backup, the Volt reversed the formula and depended first on an electric motor that refilled by plugging in. That battery could power a trip of about 25 miles, after which a supporting gas engine would kick in."* It was a long-winded claim with false information. Ugh. The year was 2007 and the promoted distance expectation was 40 miles. It was the following sentence that clarified the writer's purpose: *"Fast-forward to this year, with all-electric models like the Tesla Model 3 and the Chevy Bolt gaining traction, and the outlook for plug-in hybrids is hazy."* That's not a fast-forward. If it had been, mention of the much anticipated mid-cycle update of Prius Prime would have been included. Also, Bolt sales have been terrible, dropping not gaining. Nothing about Leaf sales struggle is a dead giveaway either. This was clearly a propaganda article. Cherry-Picking like that makes it un-debateable. The clincher, though, was the close of the article: *"In July, Tesla Inc. sold more than 13,000 Model 3s, more than four times as many as the next most popular electric car, the plug-in hybrid Prius Prime."* Lack of regular 2019 inventory to make way for the updated 2020 model is good reason for sales to be lower. Though, some select dealers took advantage of the clearance opportunity, so there was actually a very short-term spike. It all comes down to sustainability in the end anyway. Volt was doomed due to its limited reach. There were only so many early-adopters interested in a conquest purchase. Tesla had a much larger audience, but there is uncertainty of what level sales will settle at. A single offering isn't enough to sustain the business as a competitive automaker either. Tesla could end up relegated to being a specialty vehicle without a diverse product-line. Toyota, on the other hand, is quite different. We already see Prius & Corolla as plug-in hybrids and expect RAV4 to eventually become one as well. Needless to say, I was quite annoyed with the propaganda stir. It's some of the same old nonsense emerging, yet again.

9-02-2019 Properly Selling It. That infotainment upgrade is stirring a new category of discussion. Most people have no idea how to market something. Enthusiasts of the past I battled with for over a decade learned that process the hard way, in a very painful manner. It's not like I did try countless times to share insight. They just plain didn't want to listen. So when I see that same behavior playing out again, I have to wonder what the outcome will be this time. Today, it was: "*Android auto is amazing. I use it on my phone which is mounted next to the useless 11-inch screen...*" It went on from there, but lacked substance. I provided this in response:

You see what makes Android-Auto better, but misrepresent the built-in screen to promote it. How is that actually constructive? The preferred means of conveying that better message is to point out why it was worth waiting for. What improvements does the interface switch from phone-centric to car-centric bring to make it a compelling choice to say goodbye to the existing interface? This is very important when it comes to upgrades, since some existing features people like will change. You want to make the tradeoff so appealing, the user welcomes it.

Fundamental shortcomings in the way people promote change is a very real problem faced in the automotive market. Look at how disastrous Volt was. The way GM handled that technology upgrade basically doomed it from the start. They had no clue how to draw interest. That "*230 MPG*" campaign collapsed almost immediately. The "*40-mile range*" campaign fell apart when real-world data was finally revealed. The "*1000-mile tank*" campaign lacked any type of cohesive message. And of course, the campaign to claim superiority to Prius depended upon outdated information.

See what was in common with each of those failed campaigns? None of them stated provided a clear ultimate goal. What exactly is the overlying purpose of that technology? Without understanding that big-picture intent, it just becomes a boondoggle to the consumer. Don't forget how powerful that "*good enough*" attitude can work against you. Why would they bother when it appears the existing system is working just fine?

9-03-2019 **Soon.** The wait is almost over. Sales results for August will be posted tomorrow. It will be the first month when the mid-cycle update to Prime was actually available. Though limited to those initial rollout markets still, it's the step forward everyone recognizes as an obvious improvement. Toyota's stance within the affordable-for-all category is becoming very difficult to deny. This comes at the same time as GM is about to face another 50% reduction of tax-credits due to the next stage of phaseout being reached. That puts them in a position where attracting loyal customers to Bolt is basically impossible. Their hope-for-the-best strategy is beyond excuses. It failed, miserably... which begs the question... will Toyota finally get recognized for perseverance of patience? Rather than give in to conquest like GM did, it was a matter of refining technology and holding back ramp-up until it could reach the right audience. There's no way to argue Prius doesn't target Toyota's own loyal customers. But now that enthusiasts see Corolla PHV doing the same thing and the potential RAV4 PHV could have, it's time to move on. The trophy fight is over. Only early-adopters cared about the supposed "*leadership*" within the stage of subsidized sales. Very soon is when the true race begins, the one to win the hearts of ordinary consumers in the form of actual change to the status quo... when we witness plug-in offerings replacing traditional offerings. When that inventory on the dealers lot begins to embrace change, clearly moving beyond just being a niche, we can call it a successful next step. The first big moment in that next stage is about to happen... very soon.

9-04-2019 **Real Impact.** This was interesting: "*Get ready for year-over-year monthly declines until something changes. The 2020 Bolt EV will help a bit, but both GM and Tesla are going to struggle to really make an impact unless their full Federal Tax Credits are restored. Outside of the Bolt EV and Model 3, the only really compelling EVs are either too expensive or too limited in availability to see high-volume sales.*" Notice how far we have come away from cannibalize comments? That concern of automaker choices competing amongst themselves was given up so long ago, most people have forgotten that was actually the point. It wasn't conquest. Group-Think has become so bad, they have completely lost touch with goals. This is why I was so hard on Volt enthusiasts, asking for that very think. Clearly state what the objective is. You wouldn't expect such a constructive request could erupt into a personal attack. I just wanted to know why the design was being promoted. What was it to achieve? Ugh. Having no clue anymore what it means to make a real impact, you don't stand a chance of moving forward. Which direction is that? In other words, where do you want the technology to take you? They obviously don't know. Efforts to scope a points has obscured what the race is all about. I keep trying to get them back on track with the reminders: To make a "*real*" impact, sales cannot be subsidized. It's all about changing the status quo, which means competing directly with vehicles people find on the showroom floor. We're stuck in the early-adopter stage until that happens. Realistically, if there are new tax-credits, they should instead be used for installs/upgrades to where people park overnight. Once a household/apartment gets a that 240-volt connection, purchasing something with a plug or something with more capacity is a no-brainer.

- 9-04-2019** **Purists Fighting.** The idea of absolutely no gas consumption is an interesting one. Those pushing it couldn't care less about how their electricity is generated or how efficient their electricity consumption actually is. They just try to demonize all vehicles that having anything more than just a battery for supplying power. Stuff like this is really starting to stand out: *"You still contribute to accelerating global warming. So you do make a difference for the worse. That is the inconvenient truth about hybrids. They are not zero emission and that is the problem."* It's becoming a real problem for those simply trying to end the reign of traditional guzzlers. The idea of transition is unacceptable. The discussion of electricity source is unwelcome. They only support EV purchases, period. I keep my responses to them brief & bitter: That short-sighted attitude is how efforts are lost.
- 9-05-2019** **Drawing Conclusions.** When the time is right, you'll know. Sales don't tell you that. They only inform you the technology itself is worthy. That's why the long enough claim is pointless: *"The point is that hybrids are *not* "reaching the masses" although they have been on the market far longer than attractive BEVs. I know more pure BEV drivers than hybrid drivers, and sales speak for themselves. You would be right if 20, 30, 50% of all cars were hybrids by now. They were around long enough."* Remember the difference between want & need when drawing conclusions: Prius Prime isn't even available nationwide yet. So that vague "reaching the masses" with a generalized "hybrids" claim is pointless. Reality is, the \$27,600 starting MSRP combined with the mid-cycle update rolling out now is that formula for reaching the masses. Toyota waited until the heavily-dependent-upon tax-credit Volt was no longer a market impediment before even bothering. It simply made no sense to, knowing GM was only just milking market for conquest sales. And with an end so predictable (phaseout trigger), it was easy to set the stage in the meantime with the introduction of Corolla hybrid & PHEV along with the upgrade to RAV4 hybrid. After all, what reason would there have been for rushing to market?

9-06-2019 **Falling Japan Sales.** Nissan Leaf is struggling. There are a variety of reasons why, especially here. But over in Japan, influencing factors are uncertain. So, we're having quite a discussion about that related to August results. Naturally, the topic grew to include Toyota... and the "falling behind" narrative: *"Toyota say BEVs are no good and that fuel cells are the future and unfortunately Japanese consumers buy into that absurdity. Japan's auto industry will be destroyed in the coming decade as they will be too late to the BEV transition to be able to catch up."* Even the term "BEV" reveals evidence of the push for a specific technology, rather than just embracing EV propulsion in general. The "B" is for Battery. And type of on-board generator is looked down upon by purists. It's really turning into a counter-productive issue. And since they refuse to even listen, I've given up on the hope for any type of objective response. So, replies are for the sake of conveying information to lurkers: Pushing that narrative becomes harder and harder as the rollout of Prius Prime continues. Even with inventory in the United States limited to just half the regions, growth of demand is undeniable. When the center and southeast of the country finally gets supply, the plug-in push will finally be underway. Of course, the announcement back in June about Toyota introducing 10 BEV models in the early 2020's should have put an end to the FUD effort anyway. That's 6 global models coming based on the e-TNGA platform. Those are all-electric vehicles spanning a variety of vehicle types & sizes. In other words, what you claim Toyota is saying simply isn't true. In fact, their plug-in aspect resembles the approach VW is taking. The fact that Toyota is also pursuing fuel-cell vehicles is called product diversity. They are an automaker not putting all their eggs into a single basket by spreading risk and offering choices. Lack of patience and the hope readers are not well informed is what some here hope to exploit.

9-07-2019 **Fighting Design.** Problems like this are quite common. What for key phrases, such as: "...it can be really helpful." Drawing a conclusion requires detail to support it. We didn't see that; instead, it was an inquiry that turned into a debate without substance. It's surprising how things like that get out of hand. Newbies fall into that trap. As well informed forum participants, we do our best to provide insight as to why the conclusion is incorrect. That happened this week with a question of whether or not owners put an additive in their coolant to reduce temperature. Having never even encountered such a product, I suspected that was something for people who race or use heavy-duty equipment. This was my post, with the hope of bring the posts to a close:

Fundamentally flawed assumptions are very much a part of Prius's rich history. The first of which was that more EV (engine off) driving, the better the efficiency. That may seem wrong now that there's a plug-in model and faster EV speeds, but back when there as only the regular hybrid, we would routinely see new owners attempting to squeeze out as much EV as possible. They didn't understand that the gas-engine provided electricity could return higher overall MPG when blended instead.

In this case, the assumption is that more heat is bad. Informed owners know that Toyota went to great lengths to provide a system that generates as much heat as possible as fast as possible. Heat is necessary for cleansing emissions. It is also used to warm driver & passengers. The higher temperature is an essential element of the hybrid system. Countering that by adding a chemical agent to reduce temperature will fight the very design Toyota strived to deliver.

You may have grown up and been taught that maximum cool is very important. In fact, that may still be true for older technology. It is not for the system in Toyota hybrids though. Acts to override intended configuration will result in a penalty. With this additive, the system will have to work harder to reach & maintain expected operating temperature, resulting in lower overall efficiency.

9-07-2019 **Familiar Attacks.** Looking through the long series of posted comments on the August sales article, I found this: "*PHEV with less than 20 miles of AER are pure horseshit.*" With such a wide audience on that general EV venue now, rather than the daily blog for Volt in the past, there's hope of trolling success with that same old bait. I'm curious what the results will be now that GM's supposed plan to abandon Volt in favor of Bolt is proving to be yet another "*over promise, under deliver*" situation. I combat those efforts with facts. Today, it was: Notice how the topic of "*kWh/Mi*" is rarely ever mentioned and an arbitrary cutoff value is brought up instead? Seriously. It is really unfortunate the guzzling of electricity gets a blind-eye but the topic of small capacity gets the spotlight. Enthusiasts of Volt hated the inconvenient truth of their prized vehicle delivering an EV rating of "*31 kWh/100mi*" compared to Prius Prime at the much more efficient rate of "*25 kWh/100mi*". They'd do everything possible to draw attention away from that to focus on range instead. Since when is using a lot of electricity less impactful to climate change than a system with EV drive which strives to deliver the most efficient means of electric travel? Wasting cleaner fuel is still waste. Most electricity does not come from carbon-free sources anyway. If an person buys a PHEV with a small-capacity battery but mostly drives within its EV range, how can you criticize that with a profane label?

9-07-2019 **Get With It!** That demand from a "*gotta laugh*" comment about the speed at which progress is taking place was yet another one of those individuals not considering the big picture. It was a continuation of understanding the difference between want & need. Enthusiasts don't ever really get it. That's why I had so much difficulty in the past trying to have constructive exchanges. Their priorities were focused on desire, not necessity. That interferes the understanding of change and recognizing challenges. That's why the rush to market can be futile. Not being properly prepared has consequences, as I try to point out:

How is that different from other legacy automaker schedules? Mainstream impact is many years away still for all of them. For that matter, why must progress be measured in any particular manner? Change of the status quo is still change. If a compliance offering leads to a for-the-masses offering, great.

Consider the approaches from the non-luxury choices. GM is well known for "*over promise, under deliver*". Volt didn't lead to any actual change, the plug-in hybrid technology was just abandoned. VW is a lot of talk now, seriously lacking sustainable substance. Their building of hope seems realistic though. Most enthusiasts can't stand Toyota's focus on moving their entire fleet forward, rather than focusing on extremes. But their opinion means little with regard to ordinary consumers. There's a good outlook from Hyundai/Kia, once they are finally able to increase production.

In other words, debunking myths is just a start. There is far more to address when it comes to being able to reach showroom shoppers. Remember, the point is to achieve sales able to compete directly with traditional choices without incentives or subsidies.

9-08-2019 **Advertising Campaign.** We are starting to see both television & online advertisements for the new Prius, specifically the AWD model. With a refreshed look and that ability to handle snowy conditions better than a typical sedan, there's new opportunity. The commercial I have seen repeatedly already features a drive on a snow-covered road where the available roof-rack is taken advantage of to transport skis to a mountain resort. It's a compelling ability most people probably wouldn't even consider. Thinking of a Prius as something for recreation like that isn't typical. Promoting that helps to draw attention to the new look too. For those who haven't been paying attention, they're a new audience. Hopefully, it will aid with the redefine of car choices. Seeing sedan options fade away is rather odd. But as the RAV4 hybrid continues to confuse messages by becoming a new crown holder for mainstream efficiency by delivering 40 MPG, despite being a big midsize SUV, there's a growing need to highlight what Prius still has to offer. This is especially important, since Prime is preparing to step into the spotlight.

- 9-09-2019** **Discontinued Support.** We get word every now and then about a charging-station having issues. It is usually because the parking-spot is often abused by people who just plain don't care. Some are traditional vehicle owners who feel plugging it isn't important. Some are plug-in owners who feel the same way. The latter is especially disturbing. When they park there but don't bother to actually use the charger, it sends a terrible message to everyone. In every case, we don't get squat for support. There simply isn't any input from whomever oversees the well-being of the chargers. Other reports related to support are about vandalism. I know of several chargers that the handles have been broken in a way that would never happen from actual use. It's quite obvious someone smashed the latch intentionally. Sadly, that sometimes ends up becoming news of it getting removed. The expense of repairing or replacing isn't ever part of the plan. That's why new of upgrades is on the level of miraculous. It almost never happens. Installing more is a rare event as well. Older charging-stations simply vanish. Hopefully, that will change... someday.
- 9-10-2019** **Upgrades.** There's a lot more to the upgrade of the infotainment system than people realize. Aspect ratio of the screen is yet another impact that had been overlooked. It's a reality that makes the hope of retro-active updates a problem. Some features simply won't fit. So, some of the new convenience improvements can't be taken advantage of. That hardware verses software difference is what being backward-compatible means "it will work, but not entirely". That isn't all bad though. Knowing new the design of Android Auto is auto-centric makes it a worthy upgrade. Phone advocates should take note. They don't though. This is why things get overlooked. Another example is wirelessly connecting. Did you realize most phones won't get. That upgrade is still to come. Having to plug in with a cord each time is easy to dismiss as an inconvenience while arguing online. But when you get in the car to drive, that's an entirely different matter.

9-11-2019 **Abandon Spin.** I liked coming across this: *"Toyota becoming the "standard" for PHEVs when pretty much every other auto maker is abandoning PHEVs in favor of putting all EV development money into BEVs?"* It's a statement ending with a question-mark. What is that supposed to actually mean? Having an outcome of misleading is the point. Antagonists make efforts to feed a narrative. You only notice it when stepping back to look for patterns. The consistent message of abandonment becomes obvious then. The easiest to see late last year was when GM announced the end of Volt production. The message conveyed by enthusiasts was solidified, GM would embrace Bolt as their one-and-only strategy forward. EV, the very antithesis of EREV, would become the new standard. It was easy to claim when nothing was actually happening. The entire world was watching Tesla, since it only had a few weeks remaining of full tax-credits. But now as GM is also in the phaseout stage of tax-credits, the situation looks much different. That heavy investment in Volt technology was for what? Nothing changed at dealers. In fact, the dependency on SUV and Pickup sales to sustain the business is becoming a critical liability. Union strikes are expected as a result when negotiations officially begin next week. Sound familiar? We saw the same disaster 12 years ago... only this time, the situation looks worse. Falling back on tradition isn't an option this time. It's about to get ugly. That means more spin is inevitable. What will its focus be? For now, it's on PHEV becoming the standard for Toyota. That's a classic diversion tactic. Pay no attention to GM... I posted this reality reminder: Refinement to EV operation is a benefit for both types of vehicle, PHEV and BEV. That electric technology is interchangeable. Claims of Toyota not investing is just rhetoric, efforts to divert attention from Toyota's hybrid success to rapidly move away from traditional offerings. It's that **how to appeal to existing customers** which others have not found a way to address. As for the other automakers abandoning PHEV itself, that's a cold, hard reality of design choice. Toyota found a means of delivering very high efficiency for both EV & HV operation at low cost. A simple look at Volt, you can see GM simply couldn't match. That technology was expensive and wasted both electricity & gas in comparison. So, it was abandoned.

9-12-2019 **Solid-State Recharge.** Ever think of the potential possible with better battery technology? The elimination of liquid or gel electrolyte from regular rechargeable batteries to create the solid-state type should allow dramatically faster charging. A solid electrolyte wouldn't be anywhere near the fire risk. There is the potential to store much higher energy densities as well. It changes the way we look at how much capacity is really needed for a plug-in vehicle, especially if the expectation of longer cycle life proves true. You could recharge more often for shorter durations. We're still a few years off before the experimental chemistries now show a practical means of becoming commercial products. Costs will be high even when those designs become worthy of using in vehicles. Our transportation outlook will change of when that finally happens. So, all the crazy now is really just a chapter in history... ramblings of enthusiasts and early-adopters.

- 9-13-2019 Good Grief.** Seeing a new perspective is difficult, in general. You tend to fall into the trap of not expecting big change. Ironically, that's what holds back the enthusiasts. They suffer from a group-think of believing change only comes in the form of "more" of something. That's why range & speed is so dominant of a discussion topic. In fact, that's basically all I ever heard from early-adopters. This is why their attention to the needs of business was basically non-existent. Good grief. You learn in Economics 101 that more is not necessarily better. Heck, that's true for introductory Engineering class as well. Ugh. That's why what is happening with Ford is so easily overlooked. I pointed out my observation: Ford pushing the EV model of Mustang as a SUV marks a fundamental shift in marketing. Here in Minnesota, niche cars like that gets stored away during the cold season. That would be a profound waste with an EV, especially since Tesla has proven capable on snow & ice. So, we see Ford attempting to rebrand. Why not? After all, you're going to see a lot of advertising for the AWD-e model of Prius. Able to handle adverse driving conditions is a selling point, something not to be ignored with the move to electrification. In fact, that is likely a big contributor to the strong appeal for RAV4 hybrid. It's an AWD platform edging closer and closer to offering a plug. That means redefining Mustang for it to survive in this newly emerging market.
- 9-13-2019 2021 VW Golf.** A pre-production next-generation Golf was spotted without camouflage. Since ID 3 is expected to replace the EV model, this will become the dominant plug-in hybrid platform for VW. There is supposedly a current generation with a slightly smaller battery-pack as Prius Prime (8.7 kWh verses 8.8 kWh), but it's not available in the United States. The expectation is a larger capacity for this market. Though, that would consume much of the cargo area, which is smaller than Prius to begin with. Thoughts are that the higher horsepower output of the engine make it terrible in regards to both efficiency & emissions. So, there's no telling what will ultimately happen. It may simply never rollout if all goes well for the ID family anyway. The 4 is expected for market, a taller body for those here who overwhelmingly prefer SUV over hatchback styling. That impacts cost, weight, and efficiency... In other words, it just more to add to the pile of speculation & hype. We really won't know until actual production starts. And even then, that doesn't guarantee high-volume sales.

9-14-2019 **Watching Inventory.** I'm still watching inventory Prius Prime. The counts goes up more than it goes down. That over change is a climb. They are all 2020 models all limited to the initial rollout area, with the exception of a very small number of special-order deliveries elsewhere. It's that long awaited ramp-up. Seeing market spread will be next. But as next year's model, that puts it ahead of the game. Early September is several months ahead of the schedule anyone should expect. Though, I can see antagonists already anxious to attack on the basis of it not being complete yet. There is always that spin. No matter what happens, they'll find a way of making it sound negative. That's how you know they have nothing of any merit to combat with. Getting the established markets in a position of being well stocked prior to moving into new territory is a sensible business move. After all, the measure of success comes through sales. Achieving change in mainstream purchases is the goal. So, seeing the coasts get all the initial delivery is a logical first step. Advertising is pointless until everything is in place. That means the secondary market, those of us in the central part of the country and that region in the south-eastern states will indicate when the time is right. When we (I'm in Minnesota) start seeing ready-to-buy inventory on dealer's lots, that day has arrived. I remember it happening in May 2002. That was a long time from me taking delivery in Early September 2000. Over 2.5 years of waiting. It was the same strategy then too, limited to special-order delivery until the market had reached an acceptance point. That's how reaching ordinary consumers is achieved. You push the technology to those who can help establish and work out details of how to combat antagonists. This well-proven approach is worth what seems an agonizing wait. Keep watching inventory. That's a key indicator of progress.

9-14-2019 **Electricity Storage.** The hope is this becomes more and more of a problem: "*But while it's not as efficient as direct electric powertrains, it is a clean and dense way to store power. Especially in countries like Germany, which currently has more power than it needs and nowhere to put it, there's a case for producing hydrogen with renewables when there's extra capacity in the grid.*" It simply isn't realistic to build massive bank of batteries for that excess. Keeping in in tanks though is a different matter. We already do that with gas anyway. Being able to deliver that to customers either as hydrogen itself or doing the convert on-the-fly to power chargers makes sense... especially when you consider the expense of a bank of chargers. Serving high-demand use that way could be more realistic than the expense of infrastructure for transmission. It's an interesting challenge to address. What is the best way to store electricity in the wide variety of situations we face? Sadly, that type of critical thinking doesn't happen often online. In fact, most commentary suffers from group-think.

- 9-15-2019 National Drive Electric Week.** This is what I shared on the big plug-in forum, as the first post in the topic: The big event in Minnesota yesterday that I participated in was great. It was a well represented ride & drive, offering wide variety of vehicles to learn about. I got to park nice to the flashy red Model 3 with my flashy blue Prime. On my other side was the Pacifica. Price was overwhelmingly the question most on attendees' minds. That meant I got quite a number of "*beautiful, but too expensive*" comments directed to the Tesla. Interestingly, the Chrysler minivan price was less of a concern due to it's very generous interior size. Starting with 120 volts for charging, then later upgrading to 240 volts, was the approach I heard the most often in conversations. It was clear many would be more than willing to try something with a plug, but unwilling to take the level-2 plunge right away. Range seemed a total non-issue. The "*switch over to gas*" aspect of PHEV operation seems to have become well understood at this point. Perhaps the inherent nature of Prius being a hybrid lends itself to the mastery of electricity & gas blending. So, adding a plug is just an obvious upgrade to the design. Overall, this year was an amazing experience. Market perception from just a year ago has changed rather significantly. The combination of climate change awareness with the attention tax-credit phaseout has stirred has been quite helpful toward move away from traditional offerings. It now seems a much less intimidating step for the ordinary consumer to take now.
- 9-15-2019 Solar Improvements.** Today we got a glimpse of Toyota's advancement for their next-gen solar design. These improved solar panels bump efficiency from the current commercial standard of 23% to a very impressive 34%. That is quite an upgrade, more than the typical generation refinement. It delivers the potential to add as many as 27 miles while parked during the day. In a bizarre sense of looking at the situation, that's an impossible perpetual machine actually built as a working prototype. You wouldn't ever need to plug it in if that's all the farther you wanted to drive... especially since charging can also take place while you drive. Realistically, cost & efficiency won't be that perfect. You get the idea though. It increases the green factor. Being able to contribute less to carbon emissions is helpful. That's a genuine reduction worthy of continued research & development.

9-15-2019 **Coming Disaster.** It should be no surprise that GM is at the center of our automotive mess. They are again putting the well-being of their business on high-profit guzzlers. That's was a big problem yesterday, when Drive Electric events combined with the auto-show launch in Frankfurt. But then news came this morning of drone attacks in Saudi Arabia, crippling half their oil production. That will cause oil prices to surge. Adding that to the pressure from both electrification and climate-change sure makes things interesting... knowing an old problem is about to return. Tomorrow, GM union workers will likely strike. That's 50,000 wanting fair wages, affordable healthcare, job security, and a few other issues resolved. How can months of negotiations failing be dealt with when so many other pressures are growing? This is why the push for consideration of the bigger picture is always so important. Laughing at Toyota for taking such a different approach certainly doesn't so bad in that perspective. Focus much be well balanced. Simply pushing a technology because it is "*better*" doesn't mean business will thrive as a result. This is why so many of the arguments online are meritless, not worth wasting time on. Advancements forward are complicated. Don't be fooled by enthusiast posts. Ask how the claimed superiority will actually help all the players involved. If something is omitted or overlooked, there may be problems to come. In this case, we expect the coming disaster to be morning headlines confirming a strike has begun.

9-16-2019 **Controversy.** After all these years, you wouldn't think issues like this continue to come up: *"I have also been confused about the charging to 80% vs 100% to reduce battery degradation controversy. Reading the forums most of the opinions seem to be..."* That word "*opinion*" is frightening. There should be no doubt whatsoever. It has been well established fact for many, many years now. Nothing remains to speculate about. Ugh. This shows the effectiveness of FUD. Efforts to confuse are on-going. Antagonists never let up. They feed discussions with subtle hints to make you question the wisdom of those who are well informed. It's quite frustrating. That's why I keep pushing for higher and higher quality video with lots of detail, as well as commentary embedded along the way. That is a means of communication to convey wisdom those hoping to undermine haven't figured out a way to attack. Video has proven a very useful weapon in the arsenal against their efforts. It's quick & comprehensive. It also means I don't have to go into great detail when posting. I can just provide a more-info link. That kept this response short & sweet: The pamper zone should have been common knowledge since day 1. For me, that first observation came way back in 2000, with my first Prius. That avoidance of full or empty was part of the design for battery longevity.

- 9-16-2019 Self-Charging Attack.** Looking for an excuse, an article was published to draw in participation. That's a bad sign. I remember in the past when a media source would publish something just for the sake of getting attention. It was rather obvious too. A simple search of their past showing they had no interest whatsoever in Prius, Toyota, or even green technology was a dead giveaway. Many of the performance magazines feel into that category. They were losing some of their audience and started to become desperate to restore interest. That ultimately failed. People move on just as quick as they appear. The enigma of Prius is unique to only certain venues. That's why the big Prius forum has not only retained massive audience, it as also remained true to the quest of clean & efficient transportation. Needless to say, I was annoyed by the blatant attack today focusing on "*self-charging*" as the means of stirring post activity. Ugh. Oh well, stuff like that is always an opportunity for exposition: Prius & Corolla both have PHEV models now. CH-R will be getting an EV model next year. There is an expectation of a Lexus EV reveal at the upcoming LA auto show. Claims of no interest from Toyota to deliver plug-in choices have no merit.
- 9-17-2019 Cylindrical.** News about Toyota using cylindrical battery-cells for their other plug-in hybrid was the big discussion today. I was curious where the topic would be taken. Most of it was related to Tesla, since they have the same supplier, Panasonic. No one touched upon what I thought would have been addressed, the difference that shape would make with regard to overall physical packaging. Focus was entirely on business, rather than engineering. That was a odd switch. After the day came to an end, I finally jumped in posting: No one has posted the most obvious still, after all this time to comment. Interesting. Look at the battery-pack for Prius Prime/PHV. The packing favored affordable & robust. The design of the stacks didn't fit well as a result, due to the size & shape of the prismatic cells. Giving cylindrical a try in Corolla PHV was the logical next step. Remember, Toyota likes spreading upgrades across markets & vehicles.
- 9-17-2019 GM Strike.** It is well underway now, unfortunately. Intriguingly, the highlight outside of the usual pay and healthcare coverage concerns is preparation for a mostly electric future. The union is well aware of how that will require fewer workers. That's a big deal when there are over 46,000 workers spread across 33 sites. How should that impact be handled? This is something that was never addressed. GM management avoided the topic, choosing to isolate efforts with Volt, rather than integrate them into the fleet. It was very much a niche. Never being part of a bigger plan is how Bolt was handled too. From the outside, the plug-in tech appeared to be the future. But from the perspective of production & sales, it was nothing beyond an experiment to test market acceptance. There wasn't ever a next step. This unknown is how negotiations fell apart. They saw the "*too little, too slowly*" concern as a very real problem. Executive action was to just stay the course and hope for the best. That trust enthusiasts put in them was sadly misplaced. Despite all the evidence showing how terrible of a choice that was, they did it anyway. Some people refuse to accept warnings. Now, the sadness is placed upon those workers now on strike, hoping their future includes electrification efforts... even if it means fewer doing that work.

- 9-17-2019** **Compliance.** Don't you just love encountering this: "*They're just compliance cars.*" It's meant as an insult, to belittle the technology. That's fairly effective too, since most people never question the assessment. They just accept that label without consideration of facts. Online posting helps with that type of propaganda. It's the type of rhetoric used with the hope of normalizing... you know, downplay to conceal importance. That is how detail gets overlooked. Vital aspects of design are simply never addressed as a result. That provides an easy means of dismissal. I do all I can to call out those attempts, like the one today: Compliance implies the vehicle is sold at a loss to compensate for a regulatory requirement. Proof that Prius Prime or Corolla PHV are not profitable simply hasn't ever emerged, since both designs leverage existing hybrids that are part of ordinary production. Adding a plug through a simple upgrade is a very meaningful way to deliver even cleaner emissions and even higher efficiency. In other words, it's yet another meritless claim.
- 9-18-2019** **2020 Honda CR-V Hybrid.** It's nice to hear about Honda's effort to move forward, but today's announcement really didn't tell us anything vital. It was the usual press release focusing on engine size & horsepower. What I found intriguing was the speculation that it would deliver higher efficiency since Accord hybrid has a combined rating of 48 MPG. Huh? The combined rating for Camry hybrid is 52 MPG. It simply made no sense; yet, no one called out that statement from the article. Comments posted just praised CR-V hybrid for the expectation of being more efficient than RAV4 hybrid based on that incorrect logic. I was annoyed that no one bothered to actually check the claim. It was a sad statement on how lazy we have become. Accepting what you read at face value, without ever questioning merit, is a terrible idea. Ugh.
- 9-18-2019** **California Waiver.** Our awful president, who has become hell-bent on the idea of undoing everything related to bringing us forward, has raised the stakes yet again. Now, it is an attack on California. He wishes to pull the emissions waiver they've had for decades. The claim is this is necessary "*in order to produce far less expensive cars for the consumer, while at the same time making the cars substantially safer.*" Then he went on to say "*there will be very little difference in emissions*" if emissions are managed on the federal level instead. And of course, none of that would be complete without adding "*you will be out of business*" fear if you don't accept the change. We have seen this very thing play out in the past, over a decade ago. The very opposite resulted. We got vehicles that were much more dangerous than ever imagine that guzzled gas... and sadly, jobs were lost from the struggle to sell enough of them. Ugh. It's the presence of evil. He just plain does not care about the logic. It's all about finding ways to make more money by eliminating regulation. That's such an embarrassment. I never imagined having to deal with such greed & stupidity. Destroy what you could have long-term for a short-term gain.

- 9-19-2019** **2020 Ford Escape Hybrid & PHEV.** Today's announcement was strange. The market for Europe will be getting a plug-in hybrid model of Escape. Why we won't here in the United States is a mystery... a bizarre decision without any reasoning. It's a big "Huh?" Of course, the strange expectation of an underpowered traction-motor is a mystery too. Will it really be as small as previous press releases have hinted? Though lacking in detail, there was a mention of having more than 30 miles of all-electric range from a 14.4 kWh capacity pack. That battery size could deliver that, potentially. But the question of how is unknown. But then again, the measure of efficiency from the European measure is different. Their testing results always result in more miles than what we get here. So, perhaps it all makes sense for there. After all, we already saw that very thing play out with Mitsubishi's Outlander PHEV rollout.
- 9-20-2019** **Lipstick.** Insult. Belittle. Offend. They do whatever it takes with online posts to undermine progress. It's really sad. Every now and then though, it backfires. I'll end up being inspired from a stir of information being accidentally revealed. Those subtle clues are what I'm always on the look out for. That provides a means of fighting back on their own terms. It's quite devastating, because there's no good way to respond. They get cornered and just have to give up. Today was such a situation. I saw this: "Lipstick on a pig." It wasn't a clue to any aspect of design they fear or something they have been working to conceal; instead, this was just a witty comeback. I was pleased to post what came to me in response too: Bacon comes from pigs. Pretty much everyone likes bacon. What are you saying?
- 9-22-2019** **Video: Mostly Highway Commute.** This is the back route to work for me. It's 26 miles. That's 7 miles longer than my usual route, but a great example of using more battery. Being mostly highway, that's more demanding of the electricity supply. So, I've been looking forward to capturing the drive. Despite being longer, it can be quite a bit nicer in the winter during extreme driving conditions. Traffic just flows along, rather than getting jammed up from the much more dense situation when closer to the cities on the bigger highway. At one point, I drop the pedal to the floor to demonstrate the EV power available even when you are already driving 65 mph. It gets up to 84 mph using only electricity without struggle. That's nice to know the gas-engine will remain off, despite the demand for a burst of speed. In the end, I make it to the ramp at work entirely with EV. There, I can plug in to recharge my Prius Prime. Watch it here... [Prius Prime - Mostly Highway Commute](#)

9-22-2019 **Endlessly Committed.** It's nice to see a request for help to understand the rhetoric: "*Can anyone point me to an article or serious discussion on why Toyota is so endlessly committed to hybrids (ie ICE engines basically), and still hasn't got a public push into pure electric vehicles?*" That impression of no EV interest is the narrative being pushed hard now. It's an effort to distract from problems other automakers are having. Keeping the focus off of them supposedly helps. Ugh. Refusing to acknowledge what Toyota is actually doing to promote a move to plugging it is how you confirm what they are up to. With that in mind, here's what I provided as material to ponder:

Simple. HV --> PHEV --> EV is the most effective means of changing the entire fleet rapidly without sacrificing business in the process. Look at how much of a disaster the EREV --> EV approach was for GM. They rolled out a horribly expensive design which dealers weren't interested in.

The reality-check in the situation is having appeal to existing customers at an affordable price. That's exactly why RAV4 hybrid is such a strong seller. Not only does it meet that criteria, it also sets the stage for a PHEV model. At the same time, that cleaner and more efficient HV is preventing more traditional vehicles from being purchased.

What other automaker has such a non-disruptive plan for dealers to embrace a large portion of their fleet with battery-pack offering so quickly? RAV4... Camry... Corolla... Avalon... Highlander... and of course, Prius. And that's just here. C-HR and a variety of other hybrids are offered elsewhere.

Corolla hybrid becoming a PHEV already (the next step beyond making Prius a PHEV) is evidence of Toyota pushing forward with electrification of their hybrids. That's quite contrary to claims of falling behind. The upcoming EV model of C-HR will help to further silence naysayers.

Again, look at the bigger picture, how dealers will embrace change. A one-hit-wonder dependent upon tax-credits doesn't actually change the status quo.

9-22-2019 **Sightings & Change.** There's a lot of patience required and a lot of rhetoric to deal with. Eventually though, you do get in a glimmer of hope... real progress you can measure: Here in Minnesota, where Prime is still special-order only, we spotted 2 yesterday. I can't wait until Toyota finally rolls out to the other regions. Delay until the mid-cycle update was a wise move. It avoided the now obvious fallout GM is having with their disastrous subsidy-dependent design. And of course, the regular model-year cycle for 2019 hasn't even come to a close yet. So, there's a few months of waiting still. But in the meantime, stir for PHEV interest emanating from strong RAV4 hybrid sales will be a nice attention boost for Prius. Patience is a virtue you must learn when it comes to Toyota. That's an automaker who doesn't give in to short-term gain. Their attentiveness to true long-term advancement can both be painful and distressing. At times, it feels like lost opportunity. But the ability to actually affect the status quo requires it. Think about what it takes to get a dealer to embrace change.

9-22-2019 Can You Explain? Shortly after posting the video, I got asked about extreme winter conditions. This was the standout comment: "*It seems it would be very harsh on an ice cold engine to kick on at 75 mph.*" I was happy to follow up with: There are videos of that already, except my garage isn't heated. I leave from it being in the 20's inside to temperatures much colder outside, getting onto a 70 mph highway just a few blocks away. No big deal. The system is designed to use the battery to protect the engine during the warm-up cycle. Watch RPM on those winter videos. You'll see how draw of the battery-pack is heavy while that process is taking place. Despite that, there's still ample power to merge onto the highway.... and that's the older generation of plug-in Prius. The newer generation of Prius takes on even more winter challenges. It includes a battery-warmer and a heat-pump. So, the electricity can be taken advantage of even more. Down to 14°F, you can enjoy EV driving without the engine ever starting. When the temperature is 0°F or lower, the engine will pre-warm anyway. Watch the aftermarket gauge data. You can see how the system was designed to produce heat very quickly. So, that "*ice cold engine*" situation won't actually happen. There are a lot of videos on my channel, with more data being supplied as my ability to capture it progressed. Here are 2 examples: [Prius Prime - Single-Digit Winter Commute](#) & [Prius Prime - Charge-Mode in Winter](#)

9-22-2019 Rationalizing Failure. Those years and years and years of Volt hyped I blogged about sure make for interesting reads now. So much hope was based upon meritless claims. All fell apart as a result. Lack of substance will do that. It has left some with the chore of trying to make sense of the mess remaining. For example: "*The rationale for an EREV is that it can go anywhere in a world without fast chargers but that world is gone... Another thing that must have factored in their decision is that a Bolt is worth 3X as many CARB credits...*" The market doesn't fit into such an expectation. Reality is harsh. Here's why:

First, that perception of a world with convenient DC charging is still very much a fantasy. Thankfully, the technology is proving realistic, but the practical nature of it becoming common is a long way off still. Think about how many vehicles are actually on the road and will be in need of a quick recharge. Think of the expense. Think of who & where.

Second, delivering something with dependence on CARB sales is short-term thinking. But the decision logic related to cost was sound. Bolt delivers a 2.88 ZEV credit $[(0.01 \times 238) + 0.50]$. Volt delivers a 0.83 ZEV credit $[(0.01 \times 53) + 0.30]$. With so little of a price difference, there wasn't good reason for Volt to continue.

Third, wider audience plug-in hybrid choices are coming. They'll nicely compliment & promote EV adoption in households. Think about how strong of a draw RAV4 as a PHEV will be. Compared to the seating & cargo for Volt, they're entirely different categories despite the potential for similar pricing.

When tax-credits have expired and the need for change reaches far beyond just CARB credits, the view of what should get offered looks different. Enthusiast delight with a niche offering doesn't necessarily translate well to high-volume, profitable production & sales.

9-22-2019 Harsh Reality. There are always a few who absolutely refuse to accept what happened: *"The Volt is (was) the greatest car that virtually nobody bought, because of laziness - not willing to adapt to plugging in regularly - and a generally wrong (hateful) perception of GM. Every second car on the road should be a Volt. Such a shame."* That type of spin is exactly why I documented as much as I could while it was actually playing out. I was quite obvious they would attempt to rewrite history later to conceal what really happened. I refuse to allow such an act. Not learning from history is how mistakes get repeated. This was my reply: It wasn't hate, it was misrepresentation. Volt was a great enthusiast car. That didn't mean the design or approach would be one for the masses though... which in the end, proved to be the case. The niche was well fulfilled. Both Model 3 (standard plus) and Prius Prime deliver 25 kWh/100 mi for EV efficiency. That puts the 31 kWh/100 mi rating for Volt into perspective. For HV efficiency, Prime Prime delivers 54 MPG and Volt 42 MPG. Then finally, comparing Prime's base price of \$27,600 to Volt's base of \$33,520 pretty much tells the story on fundamentals. Prime came better loaded with its base model too. Sorry, but that's the reality of the situation. Selling to the masses means recognizing different priorities. To be a high-volume profitable vehicle, range & power simply isn't as important. Think of what dealers consider for what they stock as inventory.

9-22-2019 The Industry? Gotta like this: *"...the industry can't wait for more EVs to be sold before increasing the number of charging stations, they need to increase the number of charging stations first."* That's yet another example of no critical thinking. Lack of detail should stir concern. Not having any actual "who" or "how" information doesn't though. The assumption is someone else will address the problem. It will just get resolved without any help from you. Ugh. That's why I ask questions: How would the automotive industry achieve that? A simple example is seeing the benefit of having chargers where people tend to spend at least an hour patronizing that business anyway... like a coffeeshop, restaurant, or theater. It seems sensible, until you try to figure out how. What benefit is there for any specific automaker to invest in any specific location or even a chain? Usage would have no correlation to vehicle purchases. In other words, there is no actual "industry" to direct initiatives. Heck, even trying to enforce minimum requirements or safety standards is a major undertaking. This is why Toyota is pushing their focus-on-the-masses approach. You start with a gain not requiring infrastructure change, but offering a gain if you choose to upgrade... something to entice as well as retain future value. With Prius Prime, nothing beyond an ordinary 120-volt outlet is needed. If you decide to install a 240-volt outlet later, charging time is reduced. Waiting for some landlord to install chargers for their business lessor simply isn't realistic.

9-27-2019 Fuel-Cell Distraction, FUD. Almost a full week of no real plug-in news about anything was somewhat bizarre. Seeing an out-of-the-blue attack on hydrogen from EV enthusiasts emerge as a result to break the silence was a predictable outcome. I was annoyed, especially when the focus was on spreading FUD (Fear, Uncertain, Doubt) rather than something actually constructive to stir decent discussion. So, I punched back: FUD about fuel-cell tech is a distraction from the bigger picture, an effort to misrepresent. The entire shipping industry via water (container ships) is being pushed to finally clean up its act. That necessity to stop guzzling oil is about to become a regulation reality. An obvious solution is to embrace hydrogen, the economics of which are profoundly different from that of passenger vehicles. That's true for commercial road (cargo & people) transport as well, which will follow. So, whatever nonsense is stirred here about fuel-cells being a dead-end equates to a futile effort to stop the inevitable. The tech will co-exist with plug-in vehicles.

9-27-2019 Fuel-Cell Distraction, Dead. It didn't take long before the discussion turned against PHEV. The desire is to throw all support in favor of EV and just letting everything else die by declaring it dead. Ugh. Needless to say, they certainly try. It's always a cobbling together of supposed facts to portray a narrative to support their claim. I found myself punching back again: Anecdotal observation would give that impression. But if you've been watching Prius Prime, the step forward should be obvious. 2020 model is a mid-cycle update, perfectly timed to take advantage of GM's fallout. In the established markets, the update is seeing both inventory & sales growth. That puts it right on schedule for rollout to the rest of the country within the ordinary model-year calendar. It's a move to help build plug-in reputation, both for reliability & affordability. Whether or not the current offering is an EV or a PHEV only matters to enthusiasts. Know your audience. Their customers will focus on the electric-only driving experience & price. Both of which set the stage well for a next offering, like a plug-in hybrid RAV4. Think about how well Prius Prime promotes EV purchases. The family starting with a PHEV will naturally consider an EV for their second plug-in vehicle in the household. It's basically a no-lose situation for dealers hoping to transition away from traditional offerings without having to take much of an inventory risk. Keep in mind, the gamble that VW is taking really doesn't really do anything to entice existing VW customers. An owner with a Tiguan now won't have an EV equivalent for many years still. Rollout will begin with smaller vehicles that have a much higher price tag.

9-27-2019 Fuel-Cell Distraction, Reluctance. That narrative to give the impression of defeat, helping to convince those of PHEV death, is to emphasize an impression of FUD with regard to the participant. It's a means of reinforcing the idea of technology failing to deliver. Antagonists worked really hard to fortify their false portraying of the true situation. It's really sad. Oh well. I just keep punching back: What some people label as "*reluctance*" others see as patience. Toyota packaged an extremely advanced heat-pump, an impressive carbon-fiber hatch, flawless dual-wave glass, and remarkable traction-motor efficiency together into a discreetly delivered as a next generation of Prius. Notice how all those naysayers about Prime focus only on power & range? Their avoidance of the technology employed speaks volumes. They refuse to acknowledge the advancements delivered, especially with regard to being both reliable & affordable. I do find it amusing how claims of being behind with the technology have no basis in actual market delivery. All those Prius Prime owners, and now Corolla PHEV owners, are now driving electric-only miles. They couldn't care less of Mirai contributed to that or not. EV driving experience is the same regardless of how the electricity is supplied. Each vehicle using those EV motors, power controllers, heat-pumps, etc. help to reduce production cost. Heck, even the hybrids and fuel-cell vehicles share battery-cells.

9-27-2019 Fuel-Cell Distraction, Victory. At some point, they simply declare victory: "*...that BEVs have won the race.*" It was bizarre the first time I witnessed that. The antagonist will just assemble some facts into a summary, something to seemingly support the narrative. It doesn't though. They just pretend their mess of disassociated claims all make sense when put together. Sometimes, it is to the point of absurdity. In this case, it wasn't. Instead, the person simply excluded what didn't fit the claim. Again, I was annoyed and punched back. Who knew the fuel-cell discussion would end up being about everything but fuel-cell tech. Ugh. Oh well, I kept at it: That's called cherry-picking. You know the commercial & shipping market will see fuel-cells as a common technology. They will co-exist. How much will vary depending upon market. But that absolute of a single solution isn't realistic.

9-27-2019 Fuel-Cell Distraction, Only. Another means of undermining is to state an advantage as being exclusive. The idea is to keep focus on that, as if you are being objective. In reality, what you are really doing is working to prevent any other advantage from ever getting attention. That single-mindedness is easy to maintain, since most online discussions have difficulty achieving any depth. It's a terrible means of conveying complex scenarios. The thought process is broken with the greatest of ease. Squirrel! Anywho, it was this today: *"HFCVs offer exactly one debatable advantage, faster fill up, and exact 0% chance of success in the passenger vehicle category."* I punched back with: No. There is another advantage many here desperately try to avoid mention of. It's the ability to store energy. Despite the fact that it is more efficient to hold electric in DC format using batteries, the idea of massive storage-banks simply isn't practical. In fact, the need for a lot of electricity quickly (think many 150 kW chargers all drawing at the same time) is a very real problem. That type of transmission is incredibly expensive. Getting supplemental electricity for those high-demand situations is an ideal application for a large fuel-cell stack located at the charger location. Get use to the idea of co-existence. To power our plug-in vehicles, we'll need power. Storage is a challenge to overcome. The ideal of solar & wind providing lots of electricity requires a means of putting it somewhere off-grid and being able to tap that supply rapidly. The oil industry won't just stop supplying energy. They'll be forced to switch to a cleaner & renewable fuel.

9-29-2019 Back to Offense. This was amusing: *"I'd argue that the more versatile and practical body type (a pickup truck or a "compact SUV" like the RAV4 or the Equinox) and faster charging speed at more locations are more important than the >250mi range."* It can hardly be an argument when that's what I have been saying for countless years. So, I just repeated the same sentiment, but pushing it, not in any regard a response to attacks anymore. That stage is over: Those are fighting words. I got attacked for years from that very suggestion. Volt enthusiasts absolutely hated me for pushing the idea of diversification. Equinox using Voltec (the tech in Volt) required a sacrifice of range, since it would be far less aerodynamic and much more heavy. Keeping it somewhat affordable made that situation even worse. But adding to the impractical reality of poor approach was CHAdeMO fast-charging already available for Prius PHV in Japan. It wrecked any hope of their mantra of more range being better. GM's dependency on tax-credits and the result of never being able to appeal to their own loyal customers is what stands out most now. Even the desperate excuse of abandoning EREV in favor of EV doesn't save them from the reality of not having anything beyond just conquest offerings. The goal is to change status quo, phasing out traditional choices in favor of something with a plug. While we witnessed Toyota improving upon RAV4 hybrid to set the stage for a PHV model able to compete directly with the traditional model, we watched GM rollout a diesel model of Equinox and create a new traditional Blazer made in Mexico. All that nonsense about Toyota being so *"behind"* has been revealed as meritless rhetoric. And to those who lashed out at me for expressing the *"too little, too slowly"* concern about not spreading the tech to a more versatile & practical body type, you now understand consequences of not critical thinking.

9-30-2019 **About Face.** More partnership info about Toyota working with Subaru regarding AWD delivery of electrification choices was released today. We quickly got this: *"It's fascinating to see the quick about face of Toyota... Toyota for years was saying that the best way to lower CO2 was to use Hydrogen, and Hybrid technologies."* I saw that as an invitation to jump into the fresh discussion with lots more info:

The *"behind"* narrative only worked on those not paying attention. There is no about face. Progress has been on-going, just not easy to see.

For those actually seeking detail, they discovered Toyota's electric-motors offered outstanding EV efficiency ratings. They also saw that Toyota's heat-pump was the industry's most efficient offering. Upon further digging, they'd undercover the use of carbon-fiber in a surprisingly complex vehicle part. All of which are technologies that carry forward to an EV. It's refinement of production to achieve lower cost while also proving reliability which have a significant payoff later.

At the same time, we see plug-in experience advancing forward with Prius Prime and Corolla PHV. Next year, the market in China will get an EV model of C-HR. For us here, it looks quite likely that the next plug-in would be RAV4 hybrid.

In other words, all that rhetoric earlier this year about GM's progress as legacy leader was just the usual meritless hype. It comes down to being able to actually get dealers on board. That means delivering choices directly competitive with traditional offerings. From the shopper perspective, that equates to an appealing price (no tax-credit) and an effortless means of recharging (existing 120-volt). Those are traits Toyota is already showing success with.

September sales for Prius Prime will confirm that appeal progress. Despite still only being available to roughly half of the United States, there is obvious growth emanating from rollout of the 2020 mid-cycle update.

Use some critical thinking. Having a large number of vehicles switched to plug-in hybrids quickly will have far more of an impact lowering overall CO2 than a small number of EV deliveries. It has the immediate benefit of preventing a new traditional vehicle purchase. That purchase of a PHEV will likely lead to the next purchase being an EV. At the same time, it encourages the upgrade to a level-2 charger at home. It's a win-win-win situation. Don't listen to the *"behind"* nonsense. It's not an about face, change of direction either.

9-30-2019 **From The Ashes.** There's nothing. To think, all that praise for GM's leadership... It was an incredible way to start a year of fallout. Enthusiasts continued to push the narrative of Toyota being hopelessly behind, on the verge of collapse. I saw that as reflection. Such heavy dependency on tax-credits and those sales only resulting in conquest was a sign of trouble to come. Adding to that the reality of profit coming only from the large guzzlers, it was a recipe for disaster. Sure enough. Strikers are voicing their upset. Volt is dead. And we don't hear anything whatsoever about Bolt. This last we was silence. Having no hype to blog about was strange. It was the reveal of hopelessness. There had been talk of pushing negotiations for Union workers to get production of EV pickups as their focus. The high-cost and low-volume expectations for that make it unrealistic though, especially with it not even starting for another year or two still. This is the result of "*too little, too slowly*" not being taken seriously. That concern to ensure the market was established prior to triggering tax-credit phaseout was genuine. They pushed me back instead of pushing GM forward. Those terrible enthusiasts were enablers of this disaster. So much opportunity missed. Ugh. Their final hope has been something rising from the ashes. That looks very, very unlikely.

9-30-2019 **Raise Awareness.** You can't make all the people happy all the time. It's just not realistic. When it comes to Prius, that means the more advanced users (owners with lots of experience) tend to desire additional information. The detail they desire simply isn't there though. This is why some seek out aftermarket devices. That's a means of getting more without having to ask anything of Toyota. Some do complain instead: "*It's a pretty stupid design.*" That was said about the question we see pop up on the screen upon shutting down when the system is hot and the temperature outside is hot too. The owner wanted the ability to specify that setting permanently. I pointed out: Know your audience. Toyota does, exceptionally well, as they have proven in the past. For this situation, it is an audience of those new to plugging in who mostly depend upon 120-volt charging. That makes asking the question quite sensible. It raises awareness, providing a subtle reminder of the importance of keeping the battery from getting hot on a regular basis. The last thing you want in an emerging market is a "*set & forget*" feature. No amount of arguing will change that. Far too many Prius owners of the past simply ignored the refuel message. Complaints about the battery not being fully charged because the \$@%^# cooling system ran in the meantime simply isn't worth it. You must make the choice each time for the non-scheduled charges. Sorry, but with over 25 years of dealing with users software doing wild things to their computers, I'm in full agreement with Toyota about using the "*raise awareness*" approach.

9-30-2019 **Balance & Disruption.** Discussions have taken on a quality of starting fresh. In a way, that is exactly what's happened. GM support has completely vanished and there isn't an expectation of anything from any of the other automakers until next year. We are in this strange dead zone, where a transition is taking place but people are not sure what will become of it. Legacy automakers are still lost. Tesla is in a place of uncertainty. The political outlook is grim. Who knows what will happen with the economy. And of course, people are still afraid of change. That just leaves us with traces of rhetoric to keep discussions from evaporating. End of quarter should bring interesting speculation, as well as a wake up call. That will be interesting. In the meantime, I repeated my summary but to a changing audience: It's the Tortoise and the Hare situation. While others were racing ahead and showing off for praise, Toyota remained steady and true. Pleasing enthusiasts and early-adopters simply hasn't ever been a priority for them. Their focus is on the masses, their own showroom shoppers. This is why dealers have been so willing to carry Camry and RAV4 hybrids as regular inventory. That variety is essential. It's about getting the right balance of tech & platform to result in genuine change without disrupting the business. It's ironic that many here actually want disruption. How is that type of inventory uncertainty a way to sustain profit to pay everyone involved in the production, distribution, and sales process? Problems like the Osborne effect are very real. So even without the political & environmental turbulence, there are major obstacles to overcome. Think about how many battery cells the hybrids are requiring. That's a ramp-up no one here has been paying attention to; yet, it is priceless experience necessary for mainstream EV offerings. Put another way, Toyota has been busy with requirements such as that for profitable high-volume sales to the masses. That is not where others have been.

9-30-2019 **Catch Up.** This is where the "*know your audience*" really comes into play. That old question of "*Who is the market for Volt?*" revealed those enthusiasts didn't have a clue. They were so obsessed with the engineering, they didn't bother to learn about the business. They figured a vehicle like that would appeal to everyone. They were wrong, very wrong. So as we emerge from the early-adopter stage (clearly defined by the availability of tax-credits), we must recognize that many priorities will be different. Willness to trade range for interior space simply is not acceptable. That's why VW isn't even bothering with ID3 here in the United States; instead, we will be getting the larger ID4. This is the reason seeing statements like this send a chilling reminder of mistake repetition: "*The only way for Toyota to catch the pack now...*" It's that group-think of online participants that are well informed and more than happy to make sacrifices believing everyone else shares their view. Ugh. I pointed out that's not the situation with: Enthusiasts here keep pushing the idea that faster & farther is the goal for all automakers. Toyota is not compelled by conquest. Toyota is taking a different path. So, there is nothing to catch up to. Focus is delivering vehicles able to compete directly on the showroom floor. That means MSRP is a much higher priority... hence starting prices of Corolla hybrid at \$23,100, Prius Prime at \$27,750, RAV4 hybrid at \$27,850, and Camry hybrid at \$28,250. Those are vehicles fighting for sales today. Each purchase means a traditional vehicle was displaced by something cleaner and more efficient. That's why new offerings, like the AWD Prius, are being explored too. It's all about actually changing the status quo at their own dealers, not chasing some pack after a distance trophy.

- 9-30-2019** **Huh?** The announcement that Toyota will have a partnership with Subaru has really stirred interesting posts... from those who clearly don't have any historical background. We've seen that approach at different levels of complexity for decades. Sharing technology is nothing new. It's simply a part of the automotive business most aren't aware of. Heck, even the most simple "*rebadge*" rollouts go unnoticed. So when it comes to something related to propulsion system, that big unknown is no surprise. It makes any discussion of the path forward challenging. If you mention diversity, their minds explode. Solutions that are not one-size-fits-all are pretty much impossible to constructively post about. Rhetoric thrives on simplicity, so you get bombarded by efforts to prevent critical thinking. Ugh. Despite that, I tried anyway: Someday, there will be an EV in that size offered here. The first elsewhere will be C-HR. Its hybrid model already shares the same platform as Prius. That is targeted for the European market though. The EV model will be the Chinese market. When we get something, who knows what body it will use. The likely next step for Prius here is to make the plug model standard. Keep in mind the flexibility Toyota puts into their design. This is why the real-world data Mirai provides for that 113 kW traction-motor is so valuable. It's getting an entire generation shakeout before even being offered to the wider audience. Remember, Prius was available in Japan for 2.5 years before rollout in the United States. And when that rollout finally took place, Toyota delivered it with an upgraded system. Gathering knowledge from a Subaru partnership fits right into that.
- 10-01-2019** **No Background.** The new month started with an analogy that just plain did not work... unless you weren't paying attention at all over the past two decades. Unfortunately, that no background problem is quite common. People make observations, then draw conclusions. Lack of any study leads them down a confusing path. I attempted to raise awareness of that missing information. Sadly, it probably won't help him. Luckily, we have lurkers who learn from posts. So, it's never a total loss: Out of context, that could be a convincing argument. But when you consider how the market has actually played out, that analogy doesn't work at all. BMW was the automaker without a plan, just an innovation which management could not agree upon how to proceed with. GM was the automaker with a plan, but it was an "*over promise, under deliver*" situation to the extreme. Toyota has a clear progress map they've been following. Each vehicle will get a hybrid option, one that will be upgraded successively to bring about a plug option. It shows solid commitment to their dealers, ongoing value of their product (used sales), and an easy to understand move forward across the entire fleet. As for partnerships and supplier choices, that type of activity is normal business. We've seen it for decades. That's how the major automakers became major. As for the claim about who the future belongs to, I suggest study of innovator's dilemma. Toyota is demonstrating a succinct means of avoiding that situation.

- 10-01-2019** **Sleuthing.** The thread started back in February of this year was my choice of revival for news related to Android Auto. It mentioned the need for us to do some digging ourselves, pointing out that information is usually available if you are willing to hunt for it. I seek that type of content all the time. It's what ends up in the logs for future reference. That builds background for setting realistic expectations. It also helps with the effort to be patient. Tiny bits of news are better than nothing at all. In this case, it was the next clue to upgrades related to the infotainment system: Today was the announcement that C-HR will be getting Android Auto. If you have been watching rollout of Prius Prime (2020 mid-cycle update), no news makes sense still. Sales in established markets are showing growth. Adding a highly anticipated feature would derail that effort to finally expand to the rest of the market. Imagine the demand spike! It's not Toyota's way. They prefer spreading upgrades throughout the years to keep interest fresh. In fact, that on-going improvement approach has been around since even before Prius and has proven very effective.
- 10-01-2019** **Understanding Sales.** Today, quarterly results will be shared. That means a lot of commentary will be posted from those who have little background or simply don't pay close attention. So, I jumped into the thread on that big EV blog to provide some information related to Toyota: Keep in mind that Prius Prime had an inventory burndown prior to the 2020 mid-cycle update and those models were only available in roughly half of the country. Near year-end, hope is the middle & southeast of the United States will finally get the opportunity to sell Prius Prime beyond just special-order. It made sense waiting until the update, especially with tax-credit phaseout having such a significant influence on original offerings. With a starting MSRP of \$27,750 and being immediately available at all Toyota dealers, it's easy to see the potential... that juggernaut we have all been waiting for from a legacy automaker.
- 10-01-2019** **EV Market.** September results were shared today. I obviously had something to say about the comments being posted, especially to one that was over the top optimistic: Careful. How many of those sales are to ordinary consumers? Reaching the mainstream audience is far more difficult than appealing to early-adopters. Tesla did a marvelous job of picking all the low-hanging fruit. Hope from doing that was to build up high-volume production while establishing a reputation to draw in the next stage of shoppers. It looks promising in that regard, but for how many? The higher price tag, lack of convenient trade-in, and lack of body choices means there are challenges to overcome still. Success of Model 3 is absolutely fantastic, but keep in mind how difficult that next step in market penetration will actually be. This market alone (United States) will see somewhere around 16M sales this year. That limits a perspective of "*utter domination*" to just the plug-in audience, not a measure with regard to the rest of what's offered nationwide. There's a lot of potential, but it won't be easy. Look no further than GM for a dose of reality. Enthusiasts celebrated sales of Volt while refusing to acknowledge they were really just conquests with no affect on the status quo. GM dealers just kept selling traditional GM choices to loyal customers looking to replace their aged GM vehicle. We need true change. Put another way, ask who the competition is.

10-01-2019 **Who?** I get annoyed when limited-scope observations become meritless generalizations. You can't take short-term results based upon a single configuration and expect them to translate well to mainstream demand. That's how many fall into the innovator's dilemma trap. Yet, no matter how much you try to point out the mistaken perspective, it becomes a problem anyway. Hope overrides logic. I keep trying to interject some critical thinking into discussions. It's difficult to tell how effective content like this is though: A plateau of sales at 15,000 would represent a great selling niche, something not unheard of in the automotive market. To get to the next stage, significant growth is required. The current stage is filled with those who cross-brand shop and take advantage of tax-credit opportunities. Legacy automakers appealing to those who shop the showroom floor is the next buyer to target. Call them whatever you want. I label that as the "*will my mom consider it*" stage. A major component to that is to diversify. It must be made available in different configurations. That's how the technology breaks away from niche and becomes mainstream. If mom doesn't even take time to explore the choice, we don't stand a chance of achieving the goal of ended traditional vehicle production. That audience beyond those who purchased a Model 3 are far more fickle than most here are willing to accept. We need to recognize how much more difficult growth really will be. That means careful observation of what actually compels shoppers to take a closer look... and to hell with specifications. Far too many here are well informed, with engineering backgrounds and no fear of embracing new technology. That isn't at all representative of an typical consumer.

10-01-2019 **Sales Down.** As expected, I was personally attacked. There are a handful of let down GM enthusiasts still looking for someone to blame. They see me as a good target to let out their frustration. Being disappointed about the utter abandonment of that technology they had endorsed for over a decade is one thing. But for nothing to replace it, that's too much to accept. Bolt should have simply taken over, as far as they were concerned. That was never realistic though... and they didn't want to accept my insight pointing out why. So, this is what they get now: It's just a stage. The natural progression of replacement technologies is for the candidates unable to sell well beyond early-adopters to cease production. Volt was too expensive, too small, and too inefficient. Being able to compete directly with traditional vehicles simply wasn't realistic. That doesn't mean other PHEV designs won't succeed where GM could not. In fact, GM itself may attempt to deliver another configuration capable of high-volume profitable sales. The next stage will begin, one that actually focuses on the masses rather than enthusiasts and without the benefit of tax-credits. Those choices will be quite different than Volt, despite also being PHEV.

10-02-2019 Really Sad. The start of this next quarter triggered the next tax-credit phaseout stage for GM. Most of the comments posted were pointless. It's far too late. The article highlighting the situation stated it this way: "*The task for GM, in a more mainstream segment of Chevrolet brand, is much more challenging.*" I had much to say. So, I waited a day, then posted the following:

Purpose of the tax-credit was to address that challenge prior to phaseout, so the automaker could take advantage of the switch to unlimited quantity upon reaching the 200,000 trigger.

Tesla did a phenomenal job of achieving exactly that. It was a genuine effort to strive for a high-volume production able to capitalize on that opportunity.

GM didn't bother. Right from the very beginning, the question of "*Who is the market for Volt?*" was asked. It was quite clear GM was using those tax-credits for conquest rather than make an effort to actually change their own offerings. Instead of evolving that tech into a form-factor their own loyal customers would actually purchase, it became just facade to garnish praise.

Meanwhile, GM released ambiguous information to feed enablers, those who supported the squandering of tax-credits by labeling automakers taking time to do it right as "*laggards*". It's a debacle on a monumental scale only now becoming apparent, despite all the warnings along the way pointing out the concern for that very situation. The deadline approached, yet GM did nothing to address it.

In other words, the technology in Volt should have been diversified years ago. Spreading it to a far more popular platform would have carried GM forward. Rather than introducing both Trax and Blazer as traditional guzzling SUVs, they could have featured a Voltec model. The extremely popular Equinox could have been an excellent choice as well. Instead, all GM customers have no plug-in hybrid whatsoever... despite most of the tax-credits having been used to advance that very technology.

So much opportunity was wasted. It's really sad.

10-02-2019 Sales Perspective. Among the final counts to be posted were those from GM. With the market down double-digits here for most automakers, the added pressure of striking workers made for a grim outlook. That's why I needed to post some realistic perspective on the celebratory remarks related to Bolt sales: That last-minute scramble to purchase just before tax-credit phaseout reduces from 50% to just 25% made the spike quite predictable. The real measure of progress will be sustainable sales at a profit once those subsidies are gone. This current stage is filled with early-adopters, people who take advantage of discount opportunities for new tech just like that. Each automaker must advance beyond sales of just 200,000 over multiple years anyway. Sales in the United States last year alone for GM were 2,036,023. For Ford, they were 2,381,635. For Toyota, they were 2,128,201. Both growth and diversification is vital; otherwise, what's the point? Plug-In sales will continue to be overwhelmed by traditional guzzlers. It turns into a situation where dealers don't even bother if a next step isn't taken. That's why the current tax-credits should be allowed to expire. If a new round of subsidies are introduced, they should be focused on infrastructure. Encouragement to get homeowners & landlords to install/upgrade charging capacity is what will help promote sales growth... on the scale that really makes a difference.

10-03-2019 PHEV Down, BEV Up. That was the summary of sales. It was a recounting of the worldwide market as of August... which really doesn't tell us much. We're in a state of change. The same is true for China and Europe. So, what can you truly learn from just that particular slice of time? Turns out, not much... except if it was to find out how EV enthusiasts are taking the actual detail. That "up" is really only a tiny amount. That "down" is a temporary shift due to GM and BMW struggles. This is the nonsense that emerged: *"PHEVs were a great idea - 20 years ago. Now, they are a joke and automakers cling to them in hopes that this "EV thing" will pass. How's that going for you Toyota? BEVs are the future."* I jumped on the opportunity to respond: That narrative is a joke. The well informed are keenly aware of how an affordable PHEV will contribute to the widespread acceptance of BEV later, but with a benefit immediately. Toyota's design is able to compete directly against traditional vehicles without tax-credit dependency. The starting price of \$27,750 for Prius Prime delivers 84 MPH top EV speed, electric A/C, and heat-pump to enjoy that EV future today without any range-anxiety concerns. It doesn't even require any upgrade at home either; an ordinary 120-volt outlet supplies all the electricity you need for recharging. It also encourages the upgrade to 240-volt charging without any pressure upon purchase. In other words, your attempt to downplay is being called out. I fill up my Prius Prime every 2 to 3 months. My commutes are entirely electric. I take advantage of the 55 MPG it delivers from time to time. To answer your question, it is going well for Toyota. The same design will work well as a RAV4, as it has already been proven with Corolla PHEV. The difference between hybrid and PHEV is basically just a matter of adding more battery, a one-way clutch, and a plug.

10-03-2019 **At least 50%.** I had to ask the question. What does "...at least 50% people which can charge EVs at home..." actually mean? It was on a new discussion thread about charging infrastructure. Most of the posts were beyond vague, lacking detail to such an extreme there wasn't really anything to take away. Those comments were nothing but echoes of the past. We are not seeing any progress. Lack of advancement is how you lose interest. Enthusiasts become disenchantment if you take to long. In fact, that's exactly why the GM followers of Volt were fewer and fewer. That "*too little, too slowly*" wasn't taken seriously. Point being, there must be a push. Mine is now in the form of directing focus away from public chargers. It's all about charging at home now. There's lots of opportunity. Let's do something about it. Here's my latest comment on that subject:

The basic rule of "*40-amp line will deliver 200 miles in 8 hours*" in itself is far from common knowledge still. So, the effort required to run conduit & wire from service-panel to new outlet location is a complete mystery for most people. How does one even get a ballpark cost estimate when every home has a completely different wiring situation? And that's just addressing the challenge to provide electricity for a single vehicle to recharge. Support for multiple vehicles adds complexity.

This is a topic many advocates dance around, avoiding it by focusing on just the low-hanging fruit... those already interested and willing to spend setup money in addition to just the vehicle purchase. Trying to get an ordinary suburb owner with a cluttered garage and electricity coming into the house on the opposite side isn't easy to setup. Those who have a detached garage in an alley and their service-panel on the house don't have it easy either. Yet, these are included in the 50% that technically could.

This is why starting with PHEV that encourage a post-purchase upgrade will help significantly with infrastructure investment. The homeowner will become comfortable with the need and be willing to spend the money to upgrade. That naturally leads to the next vehicle purchase consideration to be an EV. It's an effective means of getting a household to embrace plugging in.

Notice how none of that has anything to do with public rapid charging.

10-04-2019 Infrastructure. Forcing conversation beyond the immediate EV market is getting easier. In the past (when Volt dominated headlines), there was no vision beyond just enthusiasts. In fact, they absolutely refused to even acknowledge there was anything beyond plug-in offerings. It was a blatant effort to force a narrative. They simply didn't care about what the rest of the automotive industry sold. Those blinders were on so tight, any mention of "Who?" resulted in an onslaught of personal attacks. I sure am glad I took the time to document all that. It's almost hard to believe so much fight came from the "vastly superior" group. They exerted so much effort to undermine the very technology that was helping to promote plugging in, it's difficult to grasp. They truly didn't know their audience; however, some of us do. Here's my take on the situation as it stands right now:

Charging "*infrastructure*" is not well understood. Most people have no clue how a site with charging-stations is establish or maintained. Cost of tier-3 service (high capacity power during peak demand) alone is a major deterrent. So even without addressing how to pay for the equipment install, there's that very ownership real issue to address. Then of course, there is the sad fact that a charger could break or get vandalized, as well as dealing with the problem of ICE'd spots. All that sours appeal. Why would any legacy automaker to ever pursue, especially when you consider how many locations would actually be needed? Heck, even just installing some chargers at a dealership isn't likely to happen.

Starting with PHEV purchases is the ideal for rapid penetration into the mainstream. They stir interest for at-home upgrades, the most vital part of charging infrastructure. Getting households to install L2 chargers is the game-charger. Once we start seeing those 240-volt 40-amp lines appear as the norm for overnight charging (capacity for 200 miles in 8 hours), the purchase of an EV becomes a no-brainer. That reduces the need for public charging rather significantly.

Toyota is way ahead of the curve in this regard for legacy automaker push. Plans are underway to convert production in Kentucky to build more of the extremely popular RAV4 hybrid. Already delivering 40 MPG, it's an ideal platform to attract the masses. Adding a plug is only a matter of inserting more battery and a one-way clutch, as Prius Prime has already demonstrated. That's a cost-effective means of reaching the massive potential in our SUV-crazed market.

Preparation on that scale is absolutely vital for electrification to finally break out beyond subsidized sales to enthusiasts. Offerings of long-distance EV alone won't be enough. That's too slow and too few. Affordable choices starting with just enough EV capacity to cover a daily commute puts plug adoption in the fast lane. That will provide a major boost to ending traditional production for setting the stage to plug in... which is exactly what the RAV4 hybrid has addressing right now.

It's the change to "*infrastructure*" that we really need to focus on. Far too many here don't look beyond the immediate EV market.

- 10-05-2019 Cat Tree.** Having a hatchback is great. You can squeeze in a surprising amount of cargo. It will carry rather high & wide objects too. But when all 3 dimensions come into play, it can be a tight squeeze. For us, that meant trying to figure out how to also deal with it being deep too. Unlike the chairs, table, lawn mower, power washer, plants, coolers, lumber, and other objects I transported this summer, this one needed to fit without any ability to be wiggled in. One massive piece makes it harder. To my relief, the larger cat tree (4 levels with a tunnel in the middle) actually fit. The lift & twist maneuver presented doubts. But that worked. We have officially been able to carry everything needed inside just fine. The craziest cargo transport is still the queen size bed. It was the air type. All those pieces of the frame, the shell, the pump, as well as the pads and inflatable chambers needed to be carried in a single trip. 2 people on a 2-hour trip with all that inside ended up working worked fine. We even brought the coffeemaker and a few other things for the move. People are happy. Cats are happy. Meow.
- 10-06-2019 Personal Gain.** This was fascinating to read: *"He's so deep in the pocket of the fossil fuel industry, he's literally sacrificing the planet's future for personal political gain. He pulled out of the Paris climate agreement and froze fuel economy standards the Obama-Biden administration put in place for cars, and he's preventing California from implementing its own higher standards."* That op-ed from our former vice-president certainly summed up the situation well. What an incredible mess. It is what happens when people get lazy & complacent. They allow corruption to work its way in. Left unchecked... which is what happens when barriers are removed... it becomes a situation which causes damage. In this case, we see a president who just plain does not care and voters who really don't understand the impact that could have. This is why I so often asked the *"Who?"* question of the Volt enthusiasts. They claimed to be in support of mainstream consumers, but their actions clearly were not for that audience. It was a very clear conflict they absolutely refused to acknowledge. They'd just pretend all was ok and found enablers to provide validation. Look what became of that. GM has basically nothing to show for all that. Over a decade later, their dealers look even worse off. Not only is it nearly impossible to find a hybrid or plug-in, there are far more guzzlers than in the past. Cars are getting phased out in favor of lower efficiency vehicles. How is that resulting lack of choice not a sacrifice?
- 10-06-2019 Lost Everything.** GM didn't try. I raised alarms to the point where no one wanted to deal with me anymore. Opportunity was being wasted and they just plain did not care. Some still don't, hence this comment today: *"And while the Volt is a PHEV, it is definitely the best PHEV ever made."* It was more damage-control from an enthusiast. Knowing the EREV concept has been exposed as meaningless propaganda, the lack of any substance to work with means pretending nothing is wrong. Ugh. I punched back with: Best PHEV ever made, for enthusiasts, is the most concise manner of identifying Volt. That's pretty much a universal sentiment, which I agree with. It's easy to understand why GM didn't carry it forward to the SUV platform though, as they had intended back with the first generation design (that Saturn Vue plug-in Two-Mode). Plans carried forward still put too much emphasis on range & power, making it a very expensive approach. Nonetheless, it's easy to see how popular a Trax, Blazer, or Equinox with that tech could have been despite the challenge of price & efficiency. What did GM have to lose from trying? They pretty much lost everything from not.

- 10-07-2019** **2020 Update.** The category for PHEV is rather screwy right now, very much in a state of transition. Toyota has worked to steer clear of the tax-credit entanglement GM caused for itself. That meant waiting for Prius Prime's nationwide rollout to include the mid-cycle update. Fortunately, it ended up working out rather nice. The final stage of phaseout was triggered for GM last week and Volt is down to just 300 remaining unsold. That basically puts the 2020 right on schedule for 2020. In other words, marketshare growth is realistic. We can expect more over time too. Toyota's recent announcement to begin using their big Kentucky production plant for building RAV4 hybrid sets the stage nicely for a PHEV model of RAV4 to follow.
- 10-07-2019** **Moving the Needle.** This is that boil-the-frog situation again, but now with plugs: "*Gas is too cheap to move the needle for PHEVs IMHO. If you want to go clean then BEV is the only way to go. If you don't care about that, then the savings just aren't enough for people to care about switching. If gas was \$5 a gallon I think we'd see adoption increase rapidly.*" No matter what economic pressure there is, that's never quite enough for things to actually play out. So, enthusiasts make excuses by raising the bar. It's a big problem for the top-down approach. Fortunately, bottom-up doesn't have that issue. So, his IMHO is basically worthless. Opinions change. Facts do not, which I pointed out: History has already proven that seemingly realistic IMHO still unable to deliver. A decade ago when gas was over \$4 per gallon, the needle really didn't move for anything with a plug. Along the way, we have learned how much tax-credits helped established EV presence... but has yet to claim an audience beyond those who would purchase something green anyway. It's all about reaching beyond that audience. Hybrids taught use that formula for success. The ones that stir interest from those who couldn't care less about green have a price directly competitive traditional vehicles. The most obvious sensation is the RAV4 hybrid. That large of an AWD vehicle delivering 40 MPG for a price well within the price shoppers would be willing to pay anyway... \$27,850. Regardless of what the price of gas is, watching that hybrid become a plug-in hybrid will capture the imagination of ordinary consumers. They'll be able to purchase something with a plug that can deliver an all-electric commute. So what if they have to plug in for more EV range? It requires special effort. Just plug into a standard 120-volt outlet overnight. That's all. As much as we all desire BEV, it just plain is not realistic for the masses... yet. Only a single generation away is not a long time to wait anyway. Everyone can enjoy some EV driving in the meantime, while also moving that needle. Think about the contribution PHEV will do to help rapidly wind down traditional vehicle production, in addition to helping promote L2 upgrades at home. BEV will happen, just not yet for the masses. So, don't overlook the tech capable of providing a convenient bridge for accelerating mainstream acceptance.
- 10-08-2019** **Naive Comments.** Stuff like this is sad to read: "*I would like the 50 miles like the Volt.*" They simply have no idea what that actually means. It seems reasonable. The reality of the technology verses business is a harsh one though. There are very real tradeoffs to address. Most people are totally unaware of what they are. So, we get comments like that without any good outcome. They either just abandon hope or become disenchanted. Lack of information will do that. Enthusiasts spreading hype make it challenging to deal with. That means keeping replies to such comments brief: That large battery contributed to Volt being discontinued. It added too much to the cost, reduced both EV & HV efficiency, and prevented rear middle seating.

10-08-2019 **Awesome!** Every now and then, you encounter someone that's naive and the situation has a very positive outcome. That typically comes from simply not paying attention, where they really don't have any opinion because they weren't in the market. You really don't lose hope or become disenchanted when you aren't in the game anyway. If you're not shopping for a vehicle and have no plans to anytime soon, something a surprise like this happens: "*2020 Prius has a 3rd seat? Awesome!*" That came from a current Prius owner who is perfectly content with it. The impression I got was when the time comes years from now to shop for a replacement, he'll just compare what's available then. It's the go-with-the-flow approach. That's the same thing we see now with computers. When something new is always around the corner, you don't bother to get involved in the market until the time comes to make a purchase. Enthusiasts don't really understand that audience... which is why they have such difficult time recognizing why "*Who?*" matters... which is why I appreciate the sentiment of awesome. That was a great comment to read.

10-09-2019 **Process.** There are some who simply aren't aware of what it really takes to deliver something in high-volume, with sustainable & profitable sales. So, pretty much no matter what you post, they'll argue with it. Not fitting their expectations of process means they are woefully behind, to that. This provided interesting insight to that conundrum: "*They need to be a lot further along in the process than a concept car.*" Believing there is only one path to success is a very real problem. This is why I clash with enthusiasts. For that matter, it's why I end up arguing with those who believe new technology must always come from expensive vehicles. It's bizarre how they dismiss Prius, which has been amazingly successful and was always affordable... despite often being the vehicle which Toyota's technology debuted on. Anywho, that expectation of a specific step-by-step to be follow is madness. Talking about stifling innovation. You want inspiration & experimentation to come from any source in any manner. Creativity can not be forced in a specific manner. Ugh. Each refinement or replacement leads to a greater outcome, regardless of how it is achieved. It's one of those face-palm moments: There is no "process" to follow, only a set of components to develop & refine. For Toyota, they already have motor, controller, heat-pump, battery-chemistry, software, charging, etc. well refined. The only thing left is a variety of packages to put that tech into.

- 10-10-2019 RAV4 PHEV.** We got a tease from Toyota today. There will be a 2021 PHEV model of RAV4 coming next year. That's right on schedule, taking full advantage of the void GM is leaving behind and racing to get in front of Ford's PHEV debut. Of course, I'm most curious if it will be labeled as PHV or will carry the "*Prime*" naming... since my history intertwines with such a choice. But I digress. :) This new model will be the most powerful offered. That's intriguing. Highlights will be "*spirited acceleration, nimble handling and impeccable style*". It will also bring the Supersonic Red color to RAV4. Nothing else was shared. It really was just a tease. Fortunately, we got a specific date to focus on. It will during the Los Angeles Auto Show media days, on November 20, 2019. The expansion of choices is what will shake the industry. Having both a car & crossover offering incredible efficiency for an affordable price is what everyone has been waiting for, especially dealers. They'll be happy to carry Prius Prime when RAV4 with a plug becomes a draw. It's a very strong endorsement for the technology. That's the forward looking support they have wanted before taking the plunge. Investing resources in selling a niche is quite a risk, hence neither Volt nor Bolt actually changing anything at dealers. This coming from Toyota is quite different. You could easily see level-2 chargers getting installed for test-drive opportunities. When you have a top-selling vehicle stirring interest to plugging in, there's a lot of potential.
- 10-10-2019 New Warranty.** This announcement today is quite significant: "*Toyota is extending its hybrid battery warranty from 8 years/100,000 miles to 10 years/150,000 miles. The new warranty will apply to Toyota's entire 2020 hybrid, plug-in hybrid, and fuel-cell lineup.*" It's a profound step forward, directly addressing the biggest concern people have about anything with a battery-pack. Naturally, there was an immediate backlash to such an endorsement for their product. Spin is inevitable, but this time was remarkably quick and very easy to debunk. The claim was that Toyota has become so desperate to save rescue hybrid sales from their supposed downfall that they are extending warranties to retain customer confidence. I found it quite telling. That duration is the coverage all automakers were required to provide for ZEV ratings for many years now. It was a fundamental qualification often overlooked. With 20 years of history, what evidence is there that customer confidence was fading? We're just seeing ordinary market change, where there's a shift to a more preferred type of vehicle. In this case, it's the SUV... of which the hybrid market was pretty small in the first place. But now that it is growing, that means reaching out to an entirely new audience... one that simply has more concerns.

10-10-2019 **Smug.** More telling statements: "*Woo Hoo. Toyota has finally introduced the 2011 RAV 4 to compete with the Gen 1 Chevy Volt.*" That came from a new discussion topic about range expectations from the upcoming RAV4 plug-in hybrid. Some people never learn from mistakes. It's the same old nonsense. They obsess with a single trait and sacrifice all else for the glory it brings. That's the trophy mentality I pointed out potential serious barrier way back when Volt was first announced. Just a few months after the initial reveal, the bragging started. It made no sense. There was nothing of any merit to support such an attitude. Without any substance, the "*vastly superior*" mantra emerged. It was futile, of course. But that fate would take well over a decade to happen. Why would range alone be the determination of success or failure? I pointed out what should be obvious at this point. Clearly, it is not. A few still see the need to pound their chest in hollow victory, as I continued to deal with: Volt failed because it targeted enthusiasts, those who were more than willing to take advantage of the tax-credit opportunity for short-term enjoyment of range & power in a small vehicle that would never appeal to the masses. Seriously. It was doomed from the start. The technology itself was a different story. Born from the Two-Mode Plug-In we were promised a decade ago, it should evolved to the very thing Toyota is preparing to rollout. Think about how popular the affordable 40 MPG hybrid RAV4 already is. Think about how Toyota is planning to build it locally, using that large plant in Kentucky. Think about how easy it is to add a plug and larger battery to offer a PHV model. RAV4 PHV will be able to compete directly on the dealer's showroom floor without any subsidies, just good old fashion shopper appeal. Smug all you want about Volt, but that is something it never achieved.

10-10-2019 **Only Reason.** This is why most enthusiasts never break out beyond their niche: "*The only reason so many PHEV owners stick with 110v charging is because they almost all only have a 3.6 kW charger. And while an L2 charger cuts the charging time in half, they can usually still charge fully on 110 in under 6 hours.*" That's the look backward perspective, refusing to acknowledge early-adopter rollout is quite different from what finally makes it to mainstream audiences. In fact, that's exactly why Prius Prime is still only available in established markets. It makes no sense rushing, when you know change is coming anyway.,, for example, faster L2 charging. He further went on to claim: "*And by the time this (RAV4 PHEV) hits the streets, the VW ID.4 will be available with respectable EV range and likely not much more money than this, especially with the federal tax-credit (assuming it's still available a year from now).*" Again, that's not looking forward. Tax-Credits are limited to 200,000 per automaker. How many does VW have remaining and how many ID vehicles are they expected to sell annually? That rose-colored view of the upcoming world isn't realistic. I was happy to point out why: That outlook of the immediate future is far too optimistic, based on enthusiast perspective. Focus on what will actually work for the masses. It takes time to ramp up production and to get infrastructure in place. Toyota sees the right-time, right-place opportunity. That "*only reason*" is weak at best, and depends upon outdated & incorrect information. L2 chargers on a 40-amp line are quickly becoming the standard. That delivers a solid 7.2 kW charging rate, perfect for 8-hour overnight recharges... which deliver 200 miles of EV. So what if the first plug-in for the household doesn't exploit that full potential. It immediately an EV experience for the daily commute, representing a dramatic reduction of emissions & consumption, as well as encourages upgrades. With over 16 MILLION annual sales in the United States alone, it makes sense to target the masses... who are overwhelmingly in favor of a large vehicle like RAV4. Seeing a choice like that delivering 25-30 miles of EV represents a huge step forward. It will be a big rattle to the status quo without actually requiring much from either consumer or dealer. btw, how big of an impact do you really expect ID.4 to actually have? VW is less than 1/5th the size of big automakers here in the United States (GM, Ford, and Toyota).

10-10-2019 **Too Late.** Gotta like this attempt to outright dismiss: "*Nah, too little too late. By 2021 there will be so many BEVs available that PHEVs just won't be in demand that much.*" It was very easy to reply to that: Demand for an affordable large AWD plug-in won't be that much for a vehicle offering EV commutes and high MPG long-distance travel? You've lost your mind if you think there's an audience buying that load of garbage. Toyota is squarely targeting mainstream consumers with such an offering. Consider price. There are currently 4 models of hybrid RAV4 available, ranging from \$28,100 to \$36,630. Prius Prime starts at \$27,750, which is within the range for regular Prius at \$24,200 to \$29,250. That sets an expectation of PHEV model of RAV4 to be a very nice balance of price & ability, quite realistic for some showroom shoppers. As much as we would like BEV to be cheap & abundant soon, that just plain is not going to happen. While we wait, we'll get a few really sweet but expensive choices that favor those willing look beyond mass-appeal challenges. Learn some patience and help the rest of us encourage PHEV sales to stimulate household upgrades. What do you think the percentage of PHEV buyers that start with 120-volt charging will end up installing 240-volt charging within just a few years of ownership? Of course, now that tax-credits are coming to an end, the "*too late*" is basically meaningless anyway.

10-10-2019 **Too Early.** There are a few tending to damage control still: *"Too early to say the Volt failed... If you take the long view on Toyota plug ins it is too early to judge either. This article is not about the Volt though."* I find efforts like that telling. How can it be too early for a vehicle who's production has been cancelled without a successor to follow? What is there to hold onto at this point? I was happy to reply to that:

This article is about diversifying PHEV tech, exactly what Volt failed to do. After countless posts about how GM should have spread Voltec to a SUV platform, the reality that Toyota is well into their plans on doing that is vindication from all those *"behind"* and *"laggard"* claims. That rhetoric was really nothing but damage-control. Everyone knew the tax-credits were being exploit for conquest. So, none of the *"too early"* nonsense is going to take hold. It is meritless, just like those claims that Volt marketing was the problem. Trading range & power was a terrible decision, because it targeting the wrong audience.

Enthusiasts aren't what changes the status quo. It's the showroom shoppers, those loyal customers looking to replace their old Toyota with a new Toyota. GM didn't want to appeal to their SUV buyers with a plug, because that would have collapsed their dependency on high-profit guzzlers. It would have been an incredible example of the Osborne Effect. Toyota has avoided that by delivering a next-gen RAV4 hybrid and a mid-cycle updated plug-in Prius to satisfy the immediate demand... which it turn supports the transition away from traditional vehicles. It's a clever way of pulling the entire fleet forward. Even Corolla gets the hybrid option and already has a PHEV model elsewhere. btw, the next-gen Highlander hybrid is about to make its debut. And it too will be produced locally, here in the United States... which brings us back to Volt yet again. It was the successor to Two-Mode, the GM hybrid tech for SUVs. Remember the PHEV model of Saturn Vue?

10-11-2019 **Progress.** Having several years of agile experience and actual certification in the process, it's fascinating to see those without the background stumble to understand why such a different approach is being taken. They wonder how it could possible be considered an effective means of achieving progress. I take delight from having real-world experience from my career. The fact that is just happens to have such an overlook with my pursuit for greener tech is an amazing coincidence. Ironically, even the word *"synergy"* comes into play for both work & personal interests. Anywho, I encountered someone today who shared a background with continuous improvement also wise to the ways of agile. I posted: The point of a next-gen upgrade is to deliver something that achieves greater market penetration. And since Toyota quite literally changed the world with Kanban by providing an effective means of delivering continuous improvement, they have become the worldwide model of progress. Of course, that reality rubs some here the wrong way. Making adjustments along the way to adapt to an ever-changing market breaks their mantra. It's what happens when you set goals based on specifications rather than stating a business objective. The feedback from enthusiasts doesn't provide much with regard to mainstream consumer purchase priorities anyway. Just look for the absence of critical thinking by asking big-picture questions. For example, How will a plug-in hybrid RAV4 impact Toyota dealers?

10-11-2019 **Failed.** Quite upset about me being so blunt about Volt's failure to advance beyond just a niche, I got this: "*The Volt has sold as many as the Prius plug-in and Prius Prime. So I guess the Prius plug-ins failed too.*" Unable to deny anymore, acknowledgement with an inclusion is the next move from a disenchanted enthusiast. Unwilling to allow history to repeat again or to allow purpose to be forgotten, I'll keep posting reminders of what actually happened. It's interesting to see how intent was disingenious even way back then. So to see the outcome so accurately reflect those observations as that past was playing out, I'm intrigued to see what happens this time. This is how I put it: Purpose of the tax-credits was to establish a technology for the fleet prior to phaseout. That meant spreading it beyond the introductory vehicle to something mainstream. For GM, what was rolled out in Volt should have offered in a high-volume profitable vehicle, like Equinox. That didn't happen. Too late. Volt failed. For Toyota, there are nearly 90,000 tax-credits still available and the tech in Prius Prime will be rolled out to RAV4 prior to triggering phaseout. Purpose fulfilled.

10-12-2019 **Serious.** Much was said about the upcoming RAV4 plug-in hybrid. Ultimately though, there's always going to be a purist unhappy with anything but an absolute: "*Toyota does have a lot more credits left....but they are now selling multiple PHEVs that will use them up. I guess they just don't think BEVs will be a serious thing.*" Knowing this was just another troublemaker, the response was easy to provide:

Taking BEVs serious means working hard to change what their dealers offer. Pushing a variety of PHEV choices is a clear effort to move the entire fleet forward, supporting a very real impact for sales to their own loyal customers. Working bottom-up is an extremely effective means rapidly phasing out traditional vehicles. You appeal to those who are most resistant to change.

Watching GM pander to enthusiasts, wasting limited tax-credits in the process, achieved nothing in the end. A simple verify of that is to look at any GM dealer's lot. How many non-traditional vehicles are physically available on site for immediate purchase? They are all still guzzlers. Volt is dead. Bolt sales are lower Volt were. It was an incredible opportunity squandered. To suggest Toyota do the same is both irresponsible & irrational.

Know your audience. In this case, they are those looking to replace their old Toyota vehicle with a new Toyota vehicle. Attracting interest with the very popular RAV4 hybrid starting at \$28,100 is proving quite effective. Drawing attention to a model offering a plug doesn't require much at that point. In fact, focus won't even be on limited range. It will be a question of how fast can it be recharged. Potential buyers will envision their daily commute in EV and random errand running in EV. In other words, to insinuate Toyota isn't using tax-credits effectively is to turn a blind-eye to what is really needed for a paradigm shift to plugging in. Breaking the status quo takes far more than just appealing to early-adopters.

10-12-2019 **Juggernaut.** I'm on the offensive now. So this was thoroughly enjoyable to post: RAV4 hybrid is Toyota's juggernaut. Throughout the hype years of Volt, focus by enthusiasts was always directed to Prius. No matter how much I pushed to draw attention to how much more powerful of a hybrid system Camry had and the enormous potential RAV4 had, there was this underlying denial. When the need for diversification of Voltec was brought up, the response was to attack the messenger. Allowing the message of technology spreading meant acknowledgement of GM's failure to actually do anything to change their status quo. Their dealers wanted no part of anything requiring a move away from profitable guzzlers. Now, here comes that spread of technology from Prius to RAV4... from a hatchback to an AWD crossover. If anyone believes moving forward from a 28 MPG model (AWD LE) to a 40 MPG model (AWD LE Hybrid) for just \$850 isn't an easy decision, they've lost their mind. This sets the stage for a massive migration away from traditional offerings. Why wouldn't you get the hybrid model? At that point, stirring curiosity about the model with a plug becomes a simple matter for salespeople to promote. You just plug it into the existing outlet in your garage overnight for a full recharge. In other words, for those of you who attempted to undermine Toyota by using "*behind*" or "*laggard*" labels, it's time to face reality. The quiet giant is about to awake.

10-13-2019 Electric Pickup. UAW (United Automobile Workers) negotiations are not going well. Lack of agreement with GM management for nearly a month has avoided getting contentious, but that is expected to change. Something must happen. No one can afford work to be halted for so long. Word has emerged that a settling point could be for an upcoming electric pickup to be build in a Detroit assembly plant planned to be sold. This was a comment made in an article on the big EV forum about the situation: *"It's kind of a pity that GM wasn't able to make a more smooth transition from the Volt (retired in February) to a new plug-in electric model."* I wasn't about to let that opportunity for contributing my own insight:

Recall the facts. Way back in early 2009, the automotive task-force assigned to oversee GM's bankruptcy recovery efforts raised a *"too little, too slowly"* concern about Volt. They wanted GM to actually do something with the technology. Even back then, there was the impression Volt would become a showcase vehicle without any type of planned succession. And sure enough, that stumble to go nowhere is exactly how the situation played out. GM flaunted their conquest sales without ever making an effort to spread that *"EREV"* technology to any vehicle in their fleet. When Volt died, so did any chance of a plug-in hybrid becoming mainstream for GM.

Looking forward, how should an *"electric pickup"* be approached? That very same concern applies. Just building a small number of them for early-adopters to snatch up really doesn't accomplish anything. What type of pickup? Will it be a basic model which people rarely actually use the truck as a truck or will focus be on true heavy-duty abilities? Think about the audience differences. How many will be produced? There's the issue of profitability too. When should we expect high-volume production?

It's very easy to see GM messing up yet again. After all, they already went through this with hybrids. Remember what Two-Mode was supposedly designed for? GM never gave us any clear direction. Intent remained a mystery even after rollout began. That lack of any real plan carried over to Volt, hence the origin of that concern. Don't forget about the *"over promise, under deliver"* problem either. In other words, watch for the vague & ambiguous announcements. They were first raise red flags about something coming up short. Watch for the lack of accountability too. No concise goals is a dead giveaway.

In short, false hope is very easy to build. Don't give pity for what has been a series of pitiful outcomes. Look forward and insist upon detail.

- 10-14-2019** **At Home Upgrades.** Seeing the bigger picture often requires a nudge, especially with a comment like this: *"Sure beats buying an L2 charger and having an electrician come out to wire a higher voltage line to my garage."* I suspected the poster hadn't actually given it much thought. Providing detail is what I do. So, I did: L2 charger installs are currently the focus of electricity providers, with many scrambling to offer rebate programs. That charging infrastructure you establish in your house will become their profit focus in years to come. Having that means of selling you more electricity is a major win for them, hence finding a means of providing a subsidy for you. In our case, we got \$500 for each line (2 Primes = \$1,000). That's a big deal for any household planning to purchase more than just a single plug-in vehicle. Think about it. Most people only have capacity for just one 12-Amp draw overnight. This is why all the current sales during the tax-credit stage is really just low-hanging fruit. Those early-adopters look at the situation very differently from how mainstream consumers will consider plugging in. It's easy to get someone really excited about the technology to make due with L1 charging just one vehicle. But to truly change the status quo, it's getting the reluctant & second vehicles to embrace the idea.
- 10-15-2019** **Frustrating.** It is fascinating to watch a former foe, one who fought so hard to get me banned, now totally at the mercy of fate. His protective venue is gone. That daily blog for Volt died a slow death, where one by one the enthusiasts became disenchanted and left. 4 months ago, posting was shut off. There has been nothing since. Today, he tried to join a big EV blog discussion by venting frustration about GM having basically abandoned the EV market here. The mid-cycle updates for Bolt did not impress. I seized the chance to provide some exposition, along with some comment: Frustrated. Really? All those years of not sharing the *"too little, too slowly"* concern expressed about tax-credits being wasted on conquest sales weren't frustrating? Rather than spreading Volt tech to a popular vehicle, like one of the SUVs, it was shoot the messenger who pointed out the opportunity being missed. GM was well aware that they catering to a niche. Volt clearly wouldn't ever appeal to mainstream consumers. Enthusiasts refused to acknowledge that painful reality though. Instead, they endorsed that race in the wrong direction, hoping for some type of miraculous market change. It was a monumental mistake. The lesson learned is know your audience. Understanding priorities of ordinary shoppers by clearly stating goals directly targeting them is how to avoid repeating the same disastrous outcome. What does a person walking the showroom floor of a GM dealer truly consider important in the purchase decision?

10-18-2019 **Void.** There's nothing anymore. It's a strange sort of silence. Without any news or rumor or even hype, posting has dropped off dramatically. Loss of another 25% of tax-credit money for the final two quarters has killed what they had always leveraged as an expectation. It was foolish to expect subsidies to last, but that was the gamble they took. No miracle to save their flawed plan happened. I watched so many enthusiasts jump ship. Then when it finally sank, the few remaining kept the dream alive rather than face reality. At some point, no one will even know what I'm posting about anymore. There will be a discussion thread highlighting some recent plug-in news and I'll make reference back to that history... you know, stuff beyond the void, documented here so there's a record of just how stubborn & close-minded some people can be. They'll obsess with deliverable to a point where they become blinded to the original goal, unable to remember what they originally set out to do. That void can be helpful. You don't have some of the past to compete with anymore. Failed ideas are much easier to overcome the next time around when you have experience to better identify and better suggest what happens next.

10-20-2019 **Regret?** I know there was frustration, anger, disappointment, and dismay from this particular individual over the years. Not sure about regret though. That vehicle, for that matter a technology, he had defended so fiercely over the years was now dead. Much of his actions turned to shooting the messenger. He didn't like my pointing out of facts. Trying to get me banned didn't work. Trying to make me feel unwelcome didn't work. Heck, even trying to befriend me didn't work. I stuck to facts and he didn't like it. So, seeing this today got me curious: "*After the way they treated Volt...*" Speaking out about GM was not his forte. That change was clearly bitterness at work. Regret? Not sure. Perhaps I'll find out in response to what I posted:

Now it is understood why focus shouldn't have been on the engineering. All those "too little, too slowly" warnings, starting before Volt was rolled out, were genuine concern about the "*over promise, under deliver*" history repeating again. GM played that game already with Two-Mode. Those excited about the potential Volt offered turned a blind-eye to the realities of business, what had already become a disastrous effort to break away from the clutches of traditional guzzlers.

When gen-1 of Volt failed to attract interest beyond the realm of early-adopter sales, raised concern resulted in push-back from hope built upon ambiguous releases by GM. Sound familiar? That is what's happening again. Passionate enthusiasts will feed claims without merit. It's a wasteful cycle. So much opportunity ends up being missed.

As for the legacy dealership being a major stumbling block, that's a "*know your audience*" problem. Those wanting to promote the technology often don't recognize they are who has the greatest impact to automakers, not consumers. As much as supporters work to educate & excite people about what plug-in vehicles have to offer, it makes no difference when they cannot be easily purchased. True progress means getting inventory to change.

With so much history of delivery disappointment, we really need to focus on what actually changes the status quo. You want to make a difference with potential buyers, focus on getting their homes upgraded. That preparation for multiple vehicles in a household to all recharge overnight is what will sway dealers to stock more plug-in vehicles. Knowing their sales can be quick & easy makes all the difference. In other words, it's time to look beyond the petty arguments of power & range.

- 10-20-2019** **Nonsense.** It is always interesting to read stuff like this: "*GM is the biggest US auto company so they afford to do things their way. Low end cars are not going to be over-engineered like the Cadillac or Corvette. Their EVs are NOT cheap because they are NOT low end cars ok?! Your innovator's trap is utter nonsense.*" That's utter nonsense. GM is a big business with stockholders & dealers expecting them to deliver sustainable profit. The strike taking place right now should make it overwhelmingly obvious there is an expectation from their own production workers as well. For that matter, what about the obligation to suppliers? The very idea that not having to deliver upon expectations is absurd... hence the "*over promise, under deliver*" problem GM can never seem to shake. My interest comes from witnessing how deep the denial goes. Not wanting to face reality on such a scale is extraordinary. Yet, I see it all the time. In response, I keep pointing out the consequences of such denial: Volt is a great example of innovator's dilemma. It was intended to be a mainstream product... and your own response confirms it failed to achieve that. Not a Cadillac. Not a Corvette. It was expensive and only appealed to a niche... hence production ending. The nonsense is claiming that top-down approach was a better choice than bottom-up. We see a lot of potential with the latter, because there's still ample tax-credits remaining. GM's are used up. No plug-in hybrid SUV yet... and no effective means of delivering anymore... hence the dilemma.
- 10-20-2019** **Backward.** I added this to my reply after posting: "*btw, You have a backward.. Biggest means they have the most to lose.*" That really stirred some anger... of which, I'm not going to post. Quoting that doesn't serve any purpose. Point being, it was exactly what he didn't want others to know. Was he aware of that himself? I have no idea. But that word of such exposure is a painful reality he obviously didn't want to address. GM rambling on for years about how Two-Mode was going to revolutionize the industry. It was a constant impediment to Toyota that ended up being a colossal waste. Volt emerged out of those ashes, the non-truck implementation of the same technology. Despite going from prototype to production with a plug and being optimized for that platform, it was also a remarkable waste. Nothing became of the technology. Even the second-generation Volt (technically gen-3 Two-Mode) struggled to survive. GM still had no real interest in finally delivering a plug-in hybrid SUV, despite the prototype Saturn Vue SUV using Two-Mode with a plug having been promoted for availability an entire decade ago. No progress is what? Sounds to me like a massive loss of opportunity.

10-21-2019 **Very Angry.** Taking out their frustration on me is nothing new. This one was especially noteworthy though: "*SO WHAT?!?!..THEY CAN AFFORD IT!!!! YOU DONT GET IT NO MATTER WHAT...SO STFU ALREADY!!!!*" It was in defense of GM, who clearly lost a lot from so poorly managing Volt. Making excuses has become a momentous effort now. There's nothing left. All the damage-control reasons have been exhausted. It's over. So, they turn to Bolt for rescue. That isn't going well either though: "*The ONLY problem I see here with BOLT (VOLT too but its no more) is that its a COMPACT car size...*" It was the use of the word "only" that got my attention. I couldn't resist responding:

That rant above and this are history repeating. Clearly, that is not the ONLY problem. As the lesson from Two-Mode taught GM, the problem of pricing is far too big to ignore. That's why when Volt was first revealed, a target price of "*nicely under \$30,000*" was set. That was what Volt would need to be for sales to be both sustainable & profitable. With an aggressive timeline of 2010 for initial rollout and using up tax-credits prior to first generation completion, it was a reasonable goal.

Failing to see (or choosing not to), the trap of innovator's dilemma became the fate of Volt. Rather than capitalizing on the opportunity to adapt the technology, GM focused on feedback from their early-adopters. Trouble was, they were enthusiasts who didn't share the same priorities as ordinary consumers. That doomed Volt to fail. And it did. Production has ended without any successor. There is no plug-in hybrid available at the dealer for a loyal GM customer to purchase. That technology GM invested in has simply been abandoned. A green choice for the masses is still not delivered.

For a reality check, look at what Toyota has done. With roughly 90,000 tax-credits still available, the push to green the fleet is well underway. Camry, Corolla, Avalon, RAV4, Highlander are all common vehicles offered as hybrids able to compete directly with their traditional counterpart. Meanwhile, a mid-cycle update has been rolled out to Prius Prime, giving it the potential for nationwide sales no dependent upon tax-credits. Next month, the reveal of a plug-in model of RAV4 hybrid will take place. Combined with the revamp of the Kentucky plant to produce RAV4 hybrids, they are setting the stage for step forward with a potential for 500,000 per year. It is the very preparation GM never bothered to pursue. There was no effort to diversify.

Say what you want. That history is already written for GM. Whether the next chapter will have a better outcome depends upon those mistakes of the past being acknowledged and acted upon. If not, they could very well be repeated. Claiming the ONLY problem was being compact sized should raise concern. That is most definitely not the case.

10-21-2019 Agreement. Not everyone from that old argumentative time is angry now: *"I don't always agree with you, but I think the RAV4 PHEV is going to be a huge hit. GM has somehow managed to create a huge gap in their portfolio by not having..."* That use of the word "somehow" just buried within the comment was one of those ugh moments. How could that in any way have been unexpected? I pushed diversification for years. Oh well. It happened. Focus on what should come next is more important now more than ever. You think that will finally happen... asking sarcastically... Here's how I replied: It's more basic than that, a problem hiding in plain view. GM is obsessed with powerful vehicles. Worry about the *"trophy mentality"* came immediately following the reveal of Volt based upon how Two-Mode was falling apart. It was quite obvious power had been traded for actually being green. In other words, it was a matter of want winning out over need. Volt was doomed long before rollout even began. There was a glimmer of hope when gen-1 sales began to really struggle, when even the big price reduction did nothing to improve the situation. Hope of a second model, one configured for the masses, would actually come to fruition. Instead, enthusiasts chimed in and created a terrible enabler situation... encouraging GM to go even further down that range & power path. It not only sealed the fate of gen-2, it also created barriers for diversification. Meanwhile, the rhetoric grew to downplay Toyota's effort to do exactly that, diversify. Their plug-in upgrade was a simple matter of adding to their existing hybrid system. It was a profitable path to a wide variety of offerings. We see that happening too. Both Prius & Corolla hybrids now offer a plug. RAV4 hybrid is on the way to taking that next step too. In addition to that, we see a serious ramping up of RAV4 hybrid production, an undeniable setting of the stage for high-volume. I listening to all of those attempting to belittle Toyota with *"laggard"* and *"behind"* slander. They'd do everything they could to endorse the problem with a legacy automaker attempting to top-down rollout new technology to a market clearly not open to change. It has been confirmed a terrible decision. How could such a giant avoid the Osborne Effect with so much economic, political, and environmental problems stacked against it? Stepping back to look beyond the green factors, there's the simple matter of survival. GM followed profit when it was financially in trouble. We're seeing the same thing happen again.

10-21-2019 We Got Specs! Toyota just provided some specs on their upcoming e-TNGA platform. That's their EV program under development. Battery capacity will range from 50 to 100 kWh. That puts them in the just-under-200 to the somewhere-in-the-300s range for distance, spread across the variety of vehicles. Things are going to get interesting. Of course, I fully expect this reveal of information to be completely forgotten. Online posting about Toyota is mostly rhetoric. Getting actual news providing some specs for the upcoming EVs they are working on isn't exciting if you depend upon lack of detail. Having a poorly informed audience is how the antagonists thrive. Oh well. I now have a bit more to add to the arsenal. More weaponry is on the way too. A little bit more than a month from now the LA auto show will begin. That should be interesting.

- 10-21-2019** **Attacks.** Speaking of fighting antagonists, there's an endless supply of the rhetoric they spew. Fortunately, I recognize the patterns and now have refined what & how to reply. Some of their quotes aren't even worth repeating. It's the same old substantless nonsense. Avoiding facts is the dead giveaway they aren't even trying. That was what today turned into. He got tired of my posts, attempting to downplay them as rambling. That's the expectation when you post something business related. Economics, Advertising, and Market are all topics that don't hold the interest of those who thrive on range & power. My response this time to that was: If you don't want to hear "*ramblings*" about business approach for the transition from ICE to BEV, please use the ignore feature. Understanding impact to automaker, dealer, and consumer is important to some, so stopping the share of that information will not happen. As for that next 5 years statement, it leaves out some vital detail.
- 10-21-2019** **Troll!** No surprise, the attempt to call me out by exclaiming "*troll*" happened. That's inevitable. It's what happens when they simply want a venue for validating each other, rather than actually considering the situation and doing something about it collectively. I kept my acknowledgement of the desperate act to get me to stop focusing on business brief: The warning was that GM wouldn't spread Volt technology prior to tax-credit expiration, missing out on the opportunity as a result... and that's exactly what happened.
- 10-21-2019** **Uncompromising.** Some don't ever give up: "*The fact that my Volt can get me to work and back 112 km on EV only and makes your argument null and void. Sorry, but Prime will lose against my Volt with my foot only halfway down. Volt gives uncompromising performance in any circumstances.*" That typical chest-pounding to avoid recognition of problems is a very predictable outcome. It is one of those play-to-the-audience maneuvers. That gets you an applause, but doesn't actually accomplish anything. I really can't believe that childish behavior persisted for so long. So my work to remain ignorant is a bizarre waste. Though, that is the problem with change. Some people just plain don't want to. Pretending a niche vehicle will appeal to everyone is an act of denial easy to call out; yet, they do it anyway. Oh well. It was time for another brief reply: Attempting to dismiss cost by touting "*uncompromising performance*" is exactly the problem, a major factor that contributed to Volt's demise. That enthusiast perspective (putting the importance of range & power over everything else, especially price) is a disconnect with mainstream buyers.

- 10-22-2019 Worst.** I really get a kick out of reading these posts: "*Currently, Toyota makes the vast bulk of its income on ICEVs. PHEVs were a bridge technology that is long past its prime. It combines the worst of both technologies.*" The reason I like that is it provides evidence the antagonist really doesn't understand how the system is designed or operates. They literally just accept the rhetoric from others about it being a poor choice and never use any critical thinking to consider any detail. It's just the passing along of hearsay. I have learned to deal with it: Claims of "*behind*" require a forced engineering-only perspective. In other words, that intentional disregard for business is the basis upon which the "*laggard*" narrative is formed. Put another way, it's an effort to distract from the bigger picture. Reality is, Toyota has been focusing heavily on transforming their dealers... the true customers of the product they produce. If dealers are unwilling to let go of traditional inventory, no green technology will succeed. Seeing Toyota's push for RAV4 hybrid and the stage that sets for the RAV4 plug-in hybrid debunks any "*future*" argument. It is proving an extremely effective means of breaking the status quo. This is why bridge technologies are so important. Consumers cannot purchase what dealers don't carry. Being able to deliver a choice for quick & easy transition to both HV & EV is a best of both worlds situation.
- 10-22-2019 Digging.** Here's more of that same, tired rhetoric: "*PHEVs are OLD tech and arguing different doesn't serve you.*" It's interesting how some people will choose to fight plug-in vehicles that don't achieve their threshold of acceptance. Why? If it's affordable and does its part to promote, what's the problem? In other words, abandonment the "*No Plug, No Sale*" propaganda is underway. We're back to the mature perspective again. The obsess with new, disregarding tech that no longer stands out. It's the early-adopter perspective. They give the impression they'll do all they can to promote what they embrace, but in reality they move on as soon as it loses its edge. That disinterest for anything beyond initial rollout can be fatal to some products. The plug-in vehicle in particular needs the voice of experience. Sharing of stories producing real-world is priceless. Those researching a purchase will find results relevant to them compelling. The catch is, much of what an enthusiast shares isn't what a mainstream consumer would ever find familiar. That's why my videos attempt to point out what they would observe first-hand on their own, with some extra detail to help explain why they may find it interesting. In short, it is in no way OLD to them. As for the enthusiasts, here's how I told him what really matters: Prius PHEV, Corolla PHEV, and the upcoming RAV4 PHEV all use electric-motors, battery-packs, plug-in chargers, electric cooling & heating, and controllers/software to deliver an EV driving experience. Watching you dig deeper and deeper into your effort to mislead about how that tech plays a role in Toyota's future is serving me well. Keep digging!

10-22-2019 **Too Slow.** Rhetoric is never ending. Some simply won't give up. Their spin comes about by omitting detail and misrepresenting outdated information. That nonsense becomes "facts" they repeatedly post. Belief is that repetition will reinforce itself. Since most people don't bother to research, it works well to establish a narrative. At that point, the antagonist doesn't even have to explicitly mention the perceived shortcoming. It becomes a common belief. Catching it early is, hopefully, an effective means of preventing that from playing out. In the case today, it was pretending Toyota had only recently embraced change. I'm not going to stoop low enough to repeat what was said. Quoting a source who doesn't care about the truth gets old and serves to reinforce the narrative. So, I'm just going to share my response, an opportunity to provide some history & perspective: February 2012 is when I got my Li-Ion Toyota. That's over 7.5 years ago, no way "*recent*" in any respect. It was a Prius PHV. The 7-seat model of the regular Prius V followed shortly, also using a Li-Ion battery. Then in 2015, all Prius models except the ECO switched to using Li-Ion. The narrative of Toyota being too slow primarily comes from those doing damage-control for GM, which ended up resting on their laurels rather than spreading the tech to the rest of their fleet. Meanwhile, Toyota actually is spreading their tech.

10-22-2019 **Old Tech.** He kept going on and on, attempting to portray the technology Toyota utilizes as outdated. It's the same old "*mature*" spinning, where the antagonists tries to convince you that isn't the next natural step following early-adopter acceptance. You have to wonder if the person doesn't care about mainstream buyers or doesn't understand much (or anything) about the engineering. With so many component sharing opportunity, being able to leverage reusability on a massive scale should be obvious. In fact, achieving high-volume production is the most common means of lowering cost. It's a business fundamental completely absent from these discussions. I wanted to find out why, so I asked:

Are you really that poorly informed about how PHEVs actually operate?

- electric-motors
- battery-packs
- plug-in chargers
- electric cooling & heating
- controllers/software

Each of those elements vital to EV operation are part of the PHEV design. It's a win-win situation, offering an easy step forward while refining production of those shared components at the same time.

- 10-22-2019** **Avoiding Detail.** Even when you get some type of acknowledgement about a topic being avoided, there's the problem of detail. That recognition comes with an effort to prevent any type of in-depth discussion. If something is called out as important over and over again, they'll finally give in but don't allow any further attention. They just declare a conclusion has been reached and refuse to address it any further. That's a textbook antagonist move. I draw attention to that behavior: You're avoiding the details of how & when... which is why debates with you serve the purpose of helping to reveal weaknesses in the effort to penetrate mainstream markets. Your use of absolutes and careless disregard for cost & timeline are confirmation that BEV cannot reach that audience of ordinary consumers alone. Without the bridge PHEV can provide, BEV will just continue to only appeal to enthusiasts. That big picture is harsh. No generous \$7,500 subsidy makes growth far more difficult. Dealers aren't interested in a low-profit vehicle which requires a lot of effort to sell. No amount of debating with me will change that reality. It's a cold, hard fact. This is why an approach such as Toyota's, transforming the fleet from traditional to hybrid to plug-in hybrid is a promising step forward. It requires almost nothing on the part of dealer or salesperson or consumer. They simply purchase that technology stocked as regular inventory and get a quick how-to during the delivery process after papers have been signed. That's it.
- 10-22-2019** **Gotcha!** At some point, the avoiding detail by keeping things vague will fail. The next move for the antagonist is to just change the topic entirely, but remain within the category. It is the "*What about?*" strategy on a less obvious scale. Today, it was: "*You're avoiding the reality of climate change.*" He attempted to twist my callout of avoidance by claiming I was doing the same thing. I wasn't. It was really just a tolerance for accepting the discussion taking the long way. I knew it would eventually circle back around to my original point of shared components contributing to the advancement & growth of the fleet. I was delighted to point that out too: Gotcha! Climate Change is very much a priority. Reality is, deployment of PHEV will have far more of an impact. So what if their capacities are smaller. Daily commutes will become electric. That would be a massive benefit and it would be spread of far more of a popular much, much, much faster than BEV. No amount of cost-of-ownership debate will change the fact that most people simply don't care. RAV4 with a plug is something they'd be willing to consider though, even if there is a premium required to get it. This is why the effort with Prius Prime to prove out the technology prior to taking the next step was absolutely vital.. and the rhetoric of early-adopters meaningless. Lastly, I find it incredibly amusing how deep your denial goes with regard to the EV driving experience PHEV can deliver. The hope is you will eventually acknowledge that all-electric is all-electric.

10-24-2019 Compliance. Our president has exploited the reality that misrepresentation of a term or concept often enough will eventually distort its meaning to the point where people forget what it actually means. That's what we see with "*compliance*" from antagonists. They'll portray it as something slightly different, over time spinning it more and more. It is basically an effort to confuse. When that happens, there isn't much you can do. Their undermining has proven effective. Ask people what "*Global Warming*" actually means? Think about the original definition when the term was first coined. The use of the word "*Hybrid*" falls into the same category. It was intentionally misrepresented so often and in so many different ways, what it originally was intended to depict is lost. Anywho, knowing that, I kept my response brief: The term "compliance" is so wide of a term, it really doesn't have any meaning anymore. If you were to claim it is for CARB credits, then we'd point out how the factor & volume numbers actually equate... but you didn't. There's also the reality that pretty much every new green-tech starts out in the compliance stage before becoming a standard anyway.

10-24-2019 Home Setup. Online posting isn't just offense & defense of the new technologies. Sometimes, you actually get to address a constructive topic. Today, it was about home setup. There are those who genuinely want to advance a step or a few steps forward. They seek advice, asking questions with the hope of detail applicable to their situation. Others are individuals who will go out and teach what they have learned. That was the case today. We started with the basics. This is the message I try to convey to those not even aware of how to start: 40-amp line (240-volts) will deliver 200 miles in 8 hours. That rule-of-thumb is what we share at plug-in events for the basic knowledge people need as a basis for starting home setup discussions. Keep in mind, most households have more than one vehicle. That's why starting out with just a PHEV works out well, since it gets people plugging in right away (no intimidation making the decision at the dealer, knowing 120-volt works fine) and contributes heavily for the desire to upgrade to 240-volt later. The hope is that will stir interest in running multiple lines at the same time, getting the entire garage/driveway setup complete for all vehicles in a single effort. It's that entire household need many here fail to address.

10-24-2019 **How Much?** Placing value on something immaterial is a challenge. When it came to hybrids in the beginning, the value of smog & carbon emission reduction was zero... from antagonists. They absolutely refused to put any monetary attribute on a trait clearly defining the primary purpose of Prius. They always focused on saving gas. That was a contributing factor to why Volt had so much of a problem appealing to the green audience. It was neither an efficient electric-only vehicle nor an efficient hybrid vehicle nor a clean hybrid vehicle. When you looked at kWh/100 rating, MPG rating, and emission rating, they were all disappointing. The claim of "*vastly superior*" was easy to debunk, and without even taking cost into account. That's why the attitude we see today persists. It came from years of pushing misrepresentation & downplay agendas. Their own propaganda backfired. That's why I continue to ask questions. Today, it was all about asking for quantification of value rather than just accepting vague comments: Notice how many "*enough*" and "*get by*" and "*can live with*" comments come from discussions like this? They all make the same mistake of not knowing audience. As well of a job supporters try to do to make a compelling justification for avoiding the expense of a 240-volt upgrade, they fail to address security. Ordinary consumers tend to want a secure feeling of knowing no matter what the circumstances, they'll always be able to recover at home. With only a 120-volt connection, there is no message of strong confidence. Think about how much of a draw SUV sales were in the initial boom based upon safety alone. It made no sense paying so much more for so much less of an efficient vehicle, and there was no proof they were any safer. (Turns out, they were actually less safe.) But people were willing to pay that premium anyway. Knowing that even upon a late evening out (for pleasure or necessity) there will be no worry whatsoever about having enough charge available for the following day for whatever activities take place is worth how much?

10-25-2019 **Renewed Rhetoric.** Attacks on Toyota are really ramping up. That's a sign of increased awareness. They know change is coming. The death of Volt revealed serious problems for GM. Prior to production actually ending, belief was that Bolt would take over. That idea wasn't even challenged. Enthusiasts shifted over from EREV to EV without any reason of merit. There wasn't any substance to support their stance. Confirmation of that recently is why focus shifted over to Toyota. Being called out for not having any cards to play with or even any prospects on the horizon is a very uncomfortable position. Losing battles is one thing. Losing the entire fronts is another. Neither plug-in hybrid nor electric-only worked out. GM is screwed, especially when you step back beyond the technology to notice the chaotic nature of their business. Production is a disaster. There's no clear message anymore... hence getting irritated with Toyota. We see TNGA rollout has been so successful, there's no argument e-TNGA will follow the same process and result in similar returns. It's the plan GM never had, but should have. That's why I was constantly on Volt enthusiasts, to the point where they developed a hate for any type of business objective. Some still do, as I addressed today... witnessing the old rhetoric become renewed: Why are you spreading such misinformation? That is clearly incorrect. A quote from this website a few months ago stated the situation with the following: *"In the early 2020s, Toyota would like to introduce 10 BEV models worldwide, including six global models, based on e-TNGA platform."* Just because Toyota is diversifying their offerings by delivering a variety of choices doesn't mean they are ignoring BEV development. In fact, it's really quite the opposite. EV propulsion tech from PHEV offerings, like the upcoming RAV4 PHEV, will clearly make its way into other plug-in vehicles... including those without any gas engine. Toyota has stated their EV offerings will span many platforms: Compact car, Medium crossover, Medium sedan, Medium minivan, Medium SUV, Large SUV. In other words, they are much like other automakers, releasing small bits of info telling us about future rollouts.

10-25-2019 **Actions?** Level of desperation is easy to detect at this point. In fact, it's astonishing how bad things are getting. In the past, we had rhetoric. That was substanceless online babble. Very little was provided in terms of actual deliverables. Conquest sales were looked upon as representative of what would happen following the early-adopter stage. So, there wasn't any real outlook in terms of what actions were expected next. GM was given a free pass to exploit. Notice how different the situation is now with VW. We get dates & quantities on a regular basis. They may seem rather far-fetched and downright unrealistic (since no actual audience has been defined), but that's still way more than what we ever got for Volt. Much more is expected from ID and a lot faster. This is why actions taken by Toyota are so irritating for them. They see actual change. That's extremely difficult to argue. Impact to the status quo can be measured. Heck, it's so obvious, even ordinary consumers are starting to notice. I like that. Dealers do too. So, it is with great pleasure to post stuff like this now: You mean Toyota pushing their new TNGA platform across their entire fleet to replace traditional offerings with a wide array of hybrid choices, setting the stage for taking the next step with their e-TNGA platform specifically for EVs? That's going remarkably well, so much so, the big plant in Kentucky will be switching from Camry production to RAV4 hybrids. We know that there is a PHEV model of RAV4 on the way too. How does that not show a fast, profitable, and sustainable means of delivering EV later in high-volume? Notice how everyone pretends GM's anti-EV campaign with Volt never happened and that VW will magically transform a large portion of their business rapidly to EV choices even though nothing has been delivered yet? Ford making announcements now about several reveals on the way really don't tell us anything either. Ford simply stopped producing Energi vehicles and their EV was basically just a showcase vehicle. Changing the topic to fuel-cells to avoid acknowledgement of the actions taking place is telling. Toyota understands their audience. Toyota offers diversity for a variety of market needs. Toyota's actions clearly confirm that.

10-25-2019 **Volume.** It's the part of supporting plug-in vehicles rarely taken seriously. Everyone wants lots to be sold, but they really don't invest in the issues preventing growth. The best we tend to get is infrastructure build out... which does nothing whatsoever to entice dealer interest. Inventory expansion is a matter of diversification, not just pushing more of the same vehicle. The term "*volume*" should really be expressed as "*spread*" to more accurately express the desired outcome. Think about how different RAV4 is from Prius. The plug-in models, perhaps both could carry the "*Prime*" label, show an undeniable effort to step forward... well, 2 steps actually. Yet, some don't see it that way. In fact, some don't even notice how quickly change is happening. They stay fixated on the past. In a way, it is a game. Learn from the previous play, then take advantage of that right away. Realistically, most people don't have a good grasp of scale. Issues of quantity & time are often misunderstood... especially when there are so many intentionally trying to misrepresent. I try my best to share helpful facts to keep everyone aware of the bigger picture: That chart shows Toyota expects to have over half their sales non-traditional within the next decade. That's serious phaseout of guzzlers, a very high volume. What other automaker is striving to achieve change on that scale? Specifically with regard to the Ford topic, how much will a Mustang-Inspired Electric SUV transform the rest of their fleet? What kind of volume should we expect from them? GM's failure with Volt, an unprofitable niche without any successor of that technology, should have taught those here about setting realistic expectations. Appealing to showroom shoppers is far more difficult than pleasing early-adopters. Also, keep in mind there are only so many battery cells available. Even with serious production ramp-up, there's still the reality that 1 EV will consume roughly the quantity of cells needed for 5 PHEV. (60kWh distributed as five 12kWh capacity packs.) That makes a big difference when trying to reach a massive & diverse audience. Lastly, note that your source is nearly 2 years old now. Quite a bit has changed in the industry since then.

10-25-2019 **Keeping It Real.** Some people say it, but don't. What they deliver is tends to be overly simplistic. That's really easy to do when posting online. Those venues and the process don't promote detail or follow-up. A majority of posts are nothing but quick hits. It's a means of entertainment and self-gratification more than being a source of constructive efforts. That's just the way it is. You need dedicated private forums and in-person meetings to get true work done. In other words, some type of accountability is required. Hiding behind an avatar isn't real. Nonetheless, it is a good means of shaking out ideas and looking for weakness in arguments. Think of it as preparation for the "*real*" world. The topic of setting up chargers at home is still new enough to not have many problems with rhetoric, yet. This was part of today's discussion on that: The use of "*real*" implies the question focuses on difference beyond price. Considering an audience of ordinary showroom shoppers, not early-adopters, the biggest purchase decision influence is how the vehicle will be charged. For the masses, charging will take place at their residence overnight. Volt demonstrated the limits of 120-volt charging. 13 hours for 53 miles is a maximum. To leave for work at 7:00 AM, you'd have to start the charge during peak-load hours at 6:00 PM. That means a BEV requires a 240-volt charger for traditional-equivalent daily range. For a PHEV though, there's an engine available. So, getting by without any household upgrade is quite realistic. It's a good option for both buyer & seller. Expect PHEV sales to thrive throughout the next decade, side-by-side with EV offerings. They are both great starter & second vehicles for households embracing the idea of plugging in.

- 10-25-2019** **Untrue.** The effort to provide damage-control for Volt continues. There isn't much of that anymore. But when it emerges, the source is typically a past antagonist attempting to stir the pot. In this case, it was this comment: *"This sets it apart from most other PHEVs which blend battery with engine power under heavy demand at any speed."* I noticed his vague use of "most" with the hope to mislead. The expectation is no one will call him out on the ambiguous statement. No attention to detail allows assumption to take place... hence a successful effort to undermine. I called out today's attempt: Untrue. Prius Prime in EV mode will not start the engine either, even if you drop the pedal to the floor. That all-electric drive is unlike its hybrid counterpart, achieving a disconnect from any engine activity by literally disconnecting it via clutch. There are videos clearly showing that 68 kW draw of electricity, enough to merge onto a highway and drive in EV up to 84 mph. That can even be achieved while using the electric heat-pump at the same time.
- 10-25-2019** **Hold Mode.** If you can't misrepresent the market now, try misrepresenting the past. Ugh. He certainly tried. I'm not going to validate such attempts with quotes as much anymore either. That nonsense had its time. We learned from it and now move on. I will provide reminders of the history though: The older Prius PHV had it from day 1, way back in 2012. That "hold" mode was mocked & ridiculed, until 2 years later when Volt also got it. Another detail avoided is the fact that Prius Prime offers a charge-mode, which is surprisingly efficient. You can deliver a sustained 7.7 kW to the battery-pack and get 37 MPG all while cruising at highway speeds. It's a nice best-of-both-worlds feature, quite handy when you are on a road-trip with nowhere to plug in. We do that on our trips out west, storing up some EV capacity for use long after the engine has cooled. That electricity is handy for pre-conditioning too.
- 10-26-2019** **Losing Marketshare.** Obsessive focus on increasing EV range and the early-adopter market is a becoming a big problem for market growth. Many perceive the low-hanging fruit sales as a loss, one automaker taking sales from another. With a mature product, that could indeed be the issue to focus on. But when a non-legacy company is helping to break new ground, that's an entirely different situation. This is why Tesla shouldn't be treated the same as GM. There is nothing to phaseout. There are no old dealerships to convert. Heck, there isn't even existing staff to retrain. With GM, that has always been challenges enthusiasts simply dismissed. That lesson wasn't learned from Volt or Bolt though. The same blindness is a source of attacks on Toyota. They don't understand how the entire industry must work together to achieve mainstream change. Ugh. It's really unfortunate to have to address that still. You'd think real-world outcomes would help teach what should now be something recognized as the true problem. Sadly, that's not how rhetoric works. They spin what they want. I keep pointing out their oversight: That feel good story is really a narrative to avoid addressing the problem still faced by the industry. Battery technology (cost, density, and volume) are all still hampered. Research has always been pushing, striving to achieve those barriers to mainstream acceptance. Even now, as Tesla works to overcome saturation of the early-adopter market and loss of tax-credits, there is no guarantee the necessary growth will actually happen. However, Tesla's top-down approach compliments Toyota's bottom-up approach quite well. So, regardless of whatever online spin gets posted here, the effort continues. In other words, if you think marketshare is being lost, you really don't understand who the competition actually is.

- 10-26-2019** **Video: Test-Drive Suggestion (using Charge-Mode).** It was nice to finally have a chance to put together some detail to share on this topic. This is the kind of thing you cringe every time you hear about it. Sadly, being poorly informed or not making an effort is far too common. I've heard stories of people interested in Prius Prime, but ending up being disappointed at the dealer because no one bothered to charge the battery. Without that plug-supplied electricity, you don't get the full experience of EV (electric) driving. That's unfortunate. There is a handy solution though. Using Charge-Mode is a quick means of charging the battery. When you hold the EV/HV, rather than just pushing it, that feature will engage. It instructs the engine to operate beyond just HV (hybrid) mode. The result is electricity generate from gas instead of plugging in. That isn't the most efficient means of recharging the battery, but it is quite useful when you would like to go for a test-drive but the salesperson was unable to accommodate. Here's the video... [Prius Prime - Test-Drive Suggestion \(using Charge-Mode\)](#)
- 10-27-2019** **Not Ready.** Focus on Toyota from the Tokyo auto show was on the extra stuff the automaker does, side projects which are commonly not understood. That information is used to spin a "*not ready*" sentiment. It's annoying, but understandable. I pointed out: Trouble is, enthusiasts aren't actually paying close enough attention. Turning a blind-eye to Toyota's message of pricing is nothing new though. In fact, that was a major argument point against Volt even before rollout began. It was too expensive. That's still true an entire decade later. The cost-per-kilowatt problem remains a barrier for reaching the masses. So while waiting for battery technology to continue to advance, Toyota allows its engineers to indulge. Having that freedom to experiment, exploring the possibilities is priceless. It's unfortunate that opportunity is lost to so many. This builds a stronger development team as well as serving to help push the potential batteries have to offer. As for the disruption claim, it's interesting to see more posts from those thinking Tesla is the competition. It's not. Tesla is a major contributor to the effort to move away from traditional vehicles. Their top-down approach is complimented by Toyota's bottom-up approach. Both are working hard to appeal to very different audiences to achieve that same goal. In other words, the perspective of "*ready*" is audience dependent. The number of people unable conveniently recharge or to even afford a plug-in vehicle is enormous still. Not acknowledging that is doing a disservice to those who are struggling to overcome those challenges.

- 10-27-2019** **Lies & Hypocrisy.** There is quite a stir now, as audience changes. It's a look back at select history, giving a very distorted impression, at best. At worst, the new online participants will discover some narrative and follow it without question. The death of Volt was inevitable, since those enthusiasts pushing were terrible representatives of ordinary consumers. They certainly believed they were endorsing mainstream preferences though. Not seeing their effort was built upon lies & hypocrisy was a fatal mistake. How anyone could turn a blind-eye to so much conflicting data is remarkable. I would have never accepted the idea that such a large group could so easily disregard information like that. They did though. I replied back to the stir today with this reflection: We witnessed that quite a few times over the years. In fact, that's where the "*over promise, under deliver*" came from. It is odd that some still haven't figured out how that works. It's a matter of understanding audience. Who? When? Where? For example, advertisements are short-term. How many times have those here complained about "*self-charging*" with the implication that was the ultimate philosophy & approach for the across every division long-term? That's absurd. They are for at-the-moment sales; yet, they aren't treated that way. In other words, look for actual change. Do the actions taking place bring about a step forward? For an example of that, look at what happened with Volt. It never attracted GM's own customers. Sales of SUVs & Pickups continued to grow and sales of cars dropped significantly. Words of executives and promotions of the technology didn't result in any change to what the dealer's stocked as everyday inventory. It's quite remarkable how uptight some individuals get from announcements and how blind they are to recognizing true progress. Focus on outcome. What changed?
- 10-28-2019** **Moving Forward.** That stir continued on into the next day. Working with an entirely new audience on such an old topic is fascinating. They repeat the same mistakes, despite even more data disproving claims. It's denial on a scale you wouldn't ever believe. But then again, our history has a past plagued with believing what you want to hear, not accepting what you actually see. Ugh. To that, I say oh well and shared my observations: That's why "*know your audience*" came about. Toyota has never been interested in conquest sales. Looking at the disastrous outcome that had for GM with Volt, it has proven a wise choice. While the EV market matures, Toyota will push traditional vehicles out by phasing in hybrids, with RAV4 getting lots of attention... setting the nicely for the plug-in model to follow. What other automaker has such a simple process laid out for quickly moving their entire fleet forward?

10-28-2019 **Consequences.** Carrying rhetoric on, rather than learning from the past, seems to be this new audience's forte. Ugh. That's why history repeats. Oh well, again. I just keep sharing what I observe: Speaking of audience, it has been interesting to watch antagonists struggle with the steady progress Toyota is making. They have no clue how to effectively continue with their anti-EV rhetoric as the entire automaker product-line takes a step forward. And in this case with Lexus, it's several steps. The reason why is simple, they have no solid reasoning to explain how Toyota will fail. Descriptions like "*behind*" and "*laggard*" don't carry any weight when there's nothing of merit to support claims. That's quite a difference from the downfall we saw with GM. It was obvious how heavily dependent Volt was upon tax-credits. When expiration approached, cost was simply too high to offer affordable pricing and there were no other models to bear the burden. With Lexus being priced in a higher tier, that pressure isn't there anyway. Assisting matters, we'll see both hybrids & plug-in hybrids helping to push down cost through their volume from Toyota brand offerings. Launching an EV won't silence antagonists. In fact, they'll just find some other way of spinning the situation. Ironically, their efforts to undermine will end up helping to promote... since what gets posted will draw attention to the new offering... consequently, taking away attention from other discussion opportunities.

10-28-2019 **Group Think.** There's a mantra of old being bad that overweighs logic. Some just can't get over the idea that long-term outcome can come from long-term planning. It's bizarre how success is gauged upon trying something bold & new. The idea of steady & true (continuous improvement) is lost to this new audience. That makes sense though. A group of new participants may not have the background. No exposure to alternate approaches may give the impression alternatives are not possible. After all, the Volt enthusiasts were obsessed with a one-size-fits-all approach. They never ended up seeing the entire forest, fixation was always just the one tree. It's really bizarre when you see analogies & cliché playing out to such an extreme. It was like interacting a living caricature. Anywho, elements of that still persists... and I'm still dealing with it: That incredibly vague "*old tech and battery is the future*" reveals a lack of understanding how Toyota's hybrid system actually operates. Adding a clutch creates a vehicle capable of delivering all-electric commutes on a platform able to deliver profit in 2020. That's far from "*woefully inadequate*" in any regard. As for not understanding the tougher emission/efficiency standards, that comes from failing to look at the bigger picture.... which ties into your shared sentiment. It's a group-think problem. Focus is on just the newest offerings. As a result, ordinary choices are getting neglected. Toyota's mission is change across the board.... not to endorse token efforts.

10-29-2019 **Raising the Bottom.** California rules are a mixed blessing. CARB credits do indeed serve a valid purpose. They push automakers to innovate. That's change for the sake of change though. It doesn't actually encourage them to rollout any new tech across their fleet. In fact, what it really does is impose a minimum. There's no real incentive to advance beyond that artificial ceiling. It's an unfortunate reality many don't actually see. That's why the TOP-DOWN approach is favored so heavily. Focus on that paints a rosy picture. You get the impression of progress. Sadly, the benefit doesn't extend beyond the spotlight. That's why the BOTTOM-UP approach must somehow be included. Balance either within or from an industry perspective is vital. In that regard, we see Tesla and Toyota complimenting each other. It works well in early stages. Moving to the next step presents challenges. Seeing that isn't easy. Many online don't. That's where the rhetoric comes from. It can be difficult, if not impossible, to overcome. I keep trying: Good intentions on California's part have resulted in problems from some automakers. Rather than improve the emissions/consumption of their fleet, the outcome is gaming the system. Toyota sees no reason to endorse such behavior. It makes sense too. RAV4 hybrid is a large AWD vehicle delivering 40 MPG. It's profitable and sets the stage well for a plug-in model. The regulation from CARB doesn't push change across the board; instead, it encourages fleet offset. We end up seeing "*compliance*" vehicles for just those markets as a result. Often, they are low-volume and unprofitable. That creation of niche products is the reason for not wanting region-specific approach. A common standard raises the bottom. The other does not.

10-29-2019 **Distraction.** The rhetoric is endless: *"Because you don't need even a single EV to be compliant with CA's CAFE requirements. They are probably playing the distraction game so their competition would slow down investment."* The fight against it isn't hopeless. Change is slow & subtle, but it can be detected. It's a matter of pointing out the clues:

It is the distraction game. Ironically though, you've got it backward. GM rolled out an EV and had their enthusiasts spin stories to draw attention away from the reality that it did nothing at all to actually change their status quo. In other words, Bolt has been a token offering with no prospect of ever becoming mainstream. GM simply wasn't interested. Toyota on the other hand, wants their entire fleet moved forward... as evidence of their hybrid efforts overwhelmingly confirm.

Notice how Prius, Corolla, and RAV4 hybrids are all on the short path for their plug-in hybrid counterpart to becoming common? How does that in any manner reflect the claimed kicking & screaming attitude? When you look at the big picture, they are quietly pushing change within their own production. It's others who are spreading the lack of any current offering as somehow a massive resistance... like those in doing damage-control for GM.

Look at the other big legacy automakers. Do we actually see anything of substance from GM, FCA, VW, or Ford yet? None of them have rolled out high-volume profitable offerings either. In fact, Toyota is well ahead of them with regard to change at the dealer level. Inventory shifting away from traditional choices is undeniable. In fact, RAV4 hybrid is a runaway hit... so much so, the upcoming PHEV reveal should be quite a draw... enough to finally quiet those spinning stories.

That very real change on the showroom floor is what has the greatest impact... not the rhetoric we encounter online.

10-30-2019 **Knowing.** I heard arguments for years from early-adopters who thought they understood what mainstream buyers would prefer. It was madness. Failing to identify the mismatch, despite having it pointed out hundreds of times, turned into acts of obvious denial. This is why I keep pointing out the source of issue. Focus on the issue itself just encouraged the madness. Not wanting to accept a fundamental mistake in the market they claimed to be experts of kept me going, it provided a means of breaking through their rhetoric. In short, I saw they were wrong and wouldn't allow their misleading to continue. Here's how I describe it online, in the context of the on-going effort to provide damage-control for GM: That's why *"know your audience"* comes up so often. GM's customer is that who purchases vehicles from them, not who ends up with it in their driveway. Appealing to a regional manager submitting orders to stock inventory is far different from gaining thumbs-up from an enthusiast. Think about what they must consider for drawing interest to their dealer's lots. It certainly isn't the range-and-power nonsense we usually have to deal with here. It isn't anything related to emissions standards either. It's what they will easily be able to sell for a profit. This is why early-adopters have such a difficult time understanding why the next stage of sales is so much more difficult to achieve. It's a different audience requiring a different approach. RAV4 PHEV is most definitely different.

10-30-2019 **Intentions.** We seem to be reverting back to basic spin & downplay: *"Toyota on purpose chose to exploit the tax credits by making a low range PHEV that is the Prius Prime and have it slightly cheaper than the Prius. But the low electric range made it pretty useless."* Such a claim is easy to rebut. The enthusiast won't accept what you post, but it works out nice for conveying some history. After all, the online lurkers now don't have that background... especially with regard to intentions. So, I posted:

That's the standout statement on this thread. Toyota strived to deliver an affordable offering, one with a MSRP low enough to not have any dependency on tax-credits, and you spin it to look like they were gaming the system. That is just plain wrong. Toyota is well aware of how limited of a quantity the credits are and how vital it is to establish market pricing by setting a solid expectation long before using them up... which is exactly what they did. In fact, they did such a good job of that, there are credits still available for the upcoming RAV4 PHEV.

As for the "useless" claim, that's an act of pure desperation to post such blatant greenwash. Charging overnight 365 times (daily for a year), the resulting EV distance provided would be 9,125 miles. To say that amount of electric-only travel has no value is sad, a clear disservice to anyone promoting plug-in vehicles.

Again, Toyota's effort is to raise the bar for their entire fleet. Focusing on just a limited offering to fulfill a specific regulation isn't a complete solution. Certain offerings will get neglected as a result. Phasing out traditional vehicles with a rapid replacement of hybrids and plug-in hybrids ramps up the momentum for change. There's little resistance when you see the entire product-line adopting the use of batteries.

10-30-2019 ***I Don't Want Your Junk!*** I attended an event put on by the state of Minnesota. There's an effort to make it part of CARB (those states enforcing more strict emissions regulations than what the federal government requires). What level to commit to is what's being researched now... hence inviting a bunch of us to provide feedback. There was much to say from EV owners. The highlight though was when someone who was clearly struggling just to make an honest living finally got a chance to speak, then ended up screaming out that statement. She was really upset, hearing about the subsidies given for new purchases, then getting what she believed was no longer wanted as a used vehicle. Given the opportunity to address her directly (an unusual request) rather than taking the floor for general comment, I pointed out those used EV choices are not like ordinary used traditional vehicles. Even the state wasn't aware of this bit of info... *Toyota now provides a 10-year / 150,000-mile warranty.* A sense of awe overcame the audience, included that very frustrated person. With so little to ever need repair and such a guarantee from automakers, market perception can change. A used vehicle won't seem so used anymore.

10-30-2019 **Enhanced Hybrid Battery Warranty.** This is the official statement provided by Toyota about their warranty: *We're proud to announce a significant enhancement to our Hybrid Battery Warranty. Starting with the 2020 model year, every Toyota hybrid battery warranty is being increased from 8 years or 100,000 miles, to 10 years from date of first use, or 150,000 miles whichever comes first. This enhancement serves as an indication of our confidence in the quality, dependability, and reliability of our products.*

10-31-2019 **Used Market.** Armed with fresh feedback regarding audience, this was something I jumped at the opportunity to share.

A vital component almost universally overlooked when it comes to approach is the used market. If rollout begins with the highest priced new vehicles, there's basically no way someone who cannot even afford a new economy vehicle could ever afford something used from the top. It excludes that audience entirely. Focusing on customers who are looking for something new that's affordable means the used market will get supply... hence bottom. With all the publicity about how reliable and low-maintenance plug-in vehicles are, it makes sense ensuring that such a large group of shoppers are not overlooked.

GM actually gave that goal a lot of attention prior to the rollout of Volt, coining the phrase "*nicely under \$30,000*" to clearly identify the target they were shooting for. Unfortunately, GM did an absolutely horrible job of actually meeting their own goal... missing it by quite a bit. Ironically, their biggest competitor did deliver on that. The MSRP for Prius Prime, which is surprisingly well loaded for a base model, is just \$27,750.

Seeing how well Toyota hit the mark on affordability, it should be easy to recognize their next step... working to deploy that technology across the fleet. What other automaker has already demonstrated the potential to deliver a successor to traditional vehicles on such a massive scale without resistance from dealers? It's that bigger picture people online here continue to neglect. Remember, dealers don't just sell new vehicles. That used market impacts them financially too.

10-31-2019 **Cherry Picking.** When you get attack after attack, each attempting to spin a different topic without success, it's a good sign. Antagonists get and hope something will get the attention back on them. Each time though, shooting down their nonsense becomes easier. For example: "*Even an average BMW now pollutes less than an average Toyota.*" I was amused. He clearly just did a quick look at the chart published today and grabbed the next highest automaker, rather than considering the entire chart. Even more amusing was how old the chart was. That data was from 2 years ago. Think about how much has changed since then. That made the reply very easy for me and very difficult for him to argue: That's a great example of cherry-picking. Toyota's average is at 25.5 MPG. You went out of your way to avoid mention of Ford being at 22.9 and GM at 22.9 and FCA at 21.2 MPG. All three of those major legacy automakers are clearly trailing behind. Omission of important data is misrepresentation.

- 10-31-2019** **Poor Range.** This didn't work either: "*I have nothing against PHEVs, but their poor electric range is the reason their sales are slumping...*" It is ineffective, since it is so vague. Posting any actual quantity brings the discussion to a different place. So, I did: That's called anecdotal reasoning. You're making an observation, then drawing a conclusion unaware of other factors of influence. In this case, you seem to not realize Toyota burned down inventory, causing a sales reduction. That so-called "*slump*" was intentional. It made no sense whatsoever wasting tax-credits on the older model of Prius Prime to compete with the discontinued Volt. Waiting until the fall when GM was gone, then rolling out the updated model of Prius Prime while also revealing the upcoming plug-in model of RAV4 hybrid is why... vital information you did not include. And again, there is no way to spin 9,125 miles per year as poor. That's 76% of the annual average driving distance for most people. If they plug in at any other time besides overnight, their EV miles increase. That's a significant electricity benefit, period.
- 10-31-2019** **Supposed Studies.** His don't bother claim was made from a reference to some unknown studies. No source or even any data was provided. It just a horribly vague imply without any substance whatsoever. It went on to make this assertion: "*People installing a charger for such small electric range is a hassle.*" No detail at all is telling. But since I already knew his purpose was to undermine Prius Prime, there wasn't anything else to learn. So, I punched back: That reason you provided for why "*people don't bother to plug in PHEVs*" is the insight I needed to confirm you aren't actually trying. If you were, you would recant that claim and point out it was a spread of misinformation. The PHEV you have been repeatedly belittling only take 5.5 hours to recharge using a standard 120-volt outlet. Most households have several already in their garage. You just plug in the device that comes with the vehicle. There is no charger to install. Nothing about that is a hassle. As for the "*plenty of studies*" part of the claim, that's what I call useless. No reference whatsoever was provided as a source to support the statement, making it highly questionable when the study took place, who was studied, and what the scope of the study covered. Odds are, there was just some small sampling a number of years ago asking early-adopters what their opinion was of the technology back then. I eagerly await something constructive as a reply to this.
- 11-02-2019** **Scarcity.** The topic of availability is stirring discussion. Only those regions of the country which had offered Prius Prime prior to the mid-cycle update are getting deliveries. That makes sense. While ramp-up takes place, you really don't want demand to exceed capacity. So, focus on where there is interest already. Once flow of sales stabilize there, then move on to expanding territory. Growth is vital, but not if that requires sacrifice. Dealers are unwilling to accept that. They have plenty of other inventory to offer. Once Prius Prime becomes an easy vehicle to stock, then they'll actively engage. Unfortunately, the majority of those posting online don't recognize that aspect of the business... know your audience. So, I attempted to convey some of that information in manner others could comment upon: With regard to dealer inventory, it has been growing well in established markets. Watching online, I have seen the coming & going activity. Build up to have supply on-hand for attention the PHV model of RAV4 that will be stirred should work out to be really nice timing. Hopefully, shortly following that, the other areas of the country will start getting them. That's right on schedule for a 2020 model rollout. Everyone else getting them early is a plus. Waiting for other factors to first play out should really payoff. Some things show no benefit from being rushed.

11-03-2019 Dealer Misleading. Ugh! It's very frustrating... but by no means a surprise... to read this: "*On the Star Tribune opinion page, the president of the Minnesota Auto Dealers Association suggested that EVs don't work well in cold weather.*" That's blatant misleading. They work fine in the cold. True, range is cut quite a bit, but that has literally nothing to do with operation. In fact, the powerful electric-motors and battery-packs make them more reliable than traditional vehicles throughout Minnesota's cold season. Operation is not impacted. It's vague statements like that which supporters really resent. If he had been explicit, pointing out the reduction of sense of capacity (due to heater use) or the longer recharge time (increased for pre-warming), that's different. He didn't though. It was a blanket suggestion, void of any actual talking points. It's the situation where supporters don't get the opportunity to add comment about how EVs deal with the cold. For example, Prius Prime has a battery-warming system. Even in the dead of the Winter, my gauge shows the pack is maintained at temperature of 39°F while plugged in. That overcomes the impact of temperature on lithium battery chemistry when it drops below freezing. Keeping it above that threshold by staying plugged in is a simple means of addressing the cold. After all, how many people grew up having to plug in their vehicle overnight anyway? As for the driving itself, so much power from that low-end torque electric-motors provide is clearly superior to a combustion-engine turning the wheels. You get the benefit of regenerative-braking too. Having the electric-motor help slow the vehicle, rather than depending entirely on brakes which can lock the wheels, is also clearly superior. I find driving my Prius Prime here in Minnesota during the cold season a real treat. Think about how much gas I'm not wasting when stuck in heavy stop & slow traffic.

11-04-2019 Change. No longer reporting monthly sales is really hitting antagonists hard. They looked forward to attacking every month. In fact, I even saw a post last week anticipating the opportunity. It was a form of self-validation. They seek out a means for justifying support of a flawed approach. Each was easy to spot too. Just look for evidence of tax-credit dependency. When they quote purchase-price rather than MSRP, you know the scope of their view was limited to just early-adopters. A perspective which excludes mainstream consumers is doomed. Some are beginning to recognize the shortcomings of that approach. Assuming economies-of-scale and high-demand would have been well established by now was the mistake. They simply refused to be realistic. Pretending data which reveals an oversight doesn't help anyone... and they are now well aware of the consequences of not addressing that. I continue to point out that problem too. The change to quarterly results becoming the standard is painful for them. Everything related to their approach has been geared to micro. Having to shift to macro brings about a lot of uncertainty... and reveals they were clearly not prepared for this next stage. Oh well. It's not like I didn't say this was coming, as my reminder today pointed out: Limited scope of "*EV Market*" discussions made it a necessity. Participants weren't looking beyond what was happening in the here & now, making consideration of buyers beyond initial subsidized sales fodder for spin. Same nonsense every month is not what anyone in the industry should have to deal with. Switching to quarterly will better reflect what's really happening in the mainstream realm. That's what truly matters, not what enthusiasts say or do. Remember, the goal is get dealers to stock plug-in vehicles as regular inventory. That means volume well beyond the tiny monthly quantities we've been used to. Audience growth is difficult. It starts with a change of perspective. Think about those outside of the early-adopter groups really want to know about.

- 11-04-2019 Supply & Demand, lost.** That topic of scarcity opened up the opportunity for antagonists to launch a new attack campaign against growing interest in Prius Prime. It started with the usual: *"Toyota had the lead, lost it, but is not totally lost."* That's the simplistic measure of progress, based solely upon perceived efficiency... which translates nowadays to longest range. I find it quite telling when such a crude measure is depended upon. This is why Volt enthusiasts failed to understand the market. They never learned to look beyond just range & power. They brought about their own doom. I repeated that teaching moment for this new audience, who is quite unlikely to exhibit any more interest than the prior: Leadership is finding a means of reaching the masses. MSRP of Prius Prime overwhelmingly confirms Toyota has established a strong foothold in the upcoming market for affordable plug-in hybrids. You get both top-rated EV efficiency and top-rated HV efficiency as at price directly competitive with traditional vehicles, no tax-credit required. EV speed goes all the way up to 84 mph. Heat-Pump efficiency is the industry's best. What other automaker has delivered something capable of the same? You want more, plan to purchase the upcoming RAV4 plug-in hybrid. In other words, claims of Toyota having lost their lead are unfounded. As you say, it is not totally lost. They are an automaker who has strived to design a technology for mainstream consumer, something to bring about noticeable change at dealers. That is very much leadership, quickly unlike appealing to enthusiasts.
- 11-04-2019 Supply & Demand, behind.** That desperation to spin Toyota's position as behind continues on: *"Toyota get with the program, you will be left in the dust!"* I find it all quite vindicating. I did my studying and shared my findings with a wide variety of those willing to provide feedback. From friendly to outright hostile, they confirmed what played out and what is to come as a very effective means of change: It made sense for Toyota to remain only in the original markets (roughly half the United States) until the mid-cycle update was ready. That update (known as the 2020 model) is only now reaching decent supply levels in those markets. You can actually check inventory with just basic searches. The expectation is that 2020 model will be rollout out to the rest of the country sometime in the next few months, putting it right on schedule for 2020. Having waited means the introduction of Prius Prime in the center & southeast of country will be with seating for 3 in back. Combined that with some quick searches revealing the car itself is on it's 4th model-year, you've got evidence of Toyota leaving most others in the dust. Establishing reputation for a solid, affordable choice takes time.
- 11-04-2019 Supply & Demand, debate.** The typical media outlet will stir controversy to attract reading & participation on their website. This was a long since debunked claim from 2.5 years ago republished: *"And its gas engine might come on randomly and too often making its EV status debatable."* I was quite annoyed. That's the basic FUD from publishers, doing anything they can to keep strong stories from the past alive. From individuals, it is known as *"bait"* from a troll. I posted this to draw attention to the act: That statement in the opening of this article is not a subject of debate. It is evidence of having either inadvertently switched into *"EV Auto"* mode, a feature designed to ready the gas engine for brief bursts of power when called upon, or plug-supplied electricity was used up and the system was in *"HV"* mode. Because in *"EV"* mode, driving up to 84 mph and down to 15°F is all-electric. Even if you drop the pedal to the floor, the gas engine stays off.

- 11-04-2019 Supply & Demand, why.** This was a constructive comment that emerged out of the scarcity article stir: *"I don't understand why Toyota even offers the non-Prime Prius at this point, especially considering how many regular hybrids they have elsewhere in their lineup."* That's the kind of thing you get from someone new to the discussions, unfamiliar with any of the history and without any type of business background. They tend to come from an engineering interest, someone drawn to the technology with nothing resembling passion for sales. The aspect of economics tends to have little to no support in online discussions. That's why enthusiasts thrive and supporters battle with the mess they create. Knowing this audience, I kept my response to that inquiry brief: Those watching the rollout of TNGA know exactly why. It's all about raising the bottom first. The entire fleet gets that upgrade before taking the next big step... e-TNGA.
- 11-06-2019 Supply & Demand, reply.** I couldn't reply. Apparently, one of the growing sources for all-things-electric news will lock out posting after 48 hours. I started typing up a response to this, when I discovered the reply link wasn't available: *"Then it's weird they advertised against their own models."* It was a comment on the scarcity article from a person obviously not paying close enough attention to notice there is more than one type of message conveyed from an automaker. From big reveals, you tend to get mostly philosophy, direction, and strategy type information. From television commercials, you tend to get promotion of what's for immediate sale. Though, with all the misleading efforts at play, it is realistic to become confused. Also, there are certain automakers who are ambiguous by their very nature... to avoid accountability for having broken so many promises of the past. Anywho, I wasn't able to post this. In fact, I really didn't even finish my thought upon noticing it wouldn't be possible to actually reply. Ugh: The difference between advertising products and corporate plans is a concept lost to many commenting on articles like this. Of course, there are some who intentionally spin them to be thought of as the same. They most definitely are not. One is short-term. The other is long-term. In the case of the supposed "self charging" controversy, that's just marketing campaign for immediate sales. It has nothing whatsoever to do with expectations a few years from now. Remember, there are some who have much to lose from Toyota being successful with hybrid sales now and plug-in hybrid sales later. Think about how popular RAV4 hybrid has become. When the reveal of the PHEV model takes place in 2 weeks, there will be quite a number of enthusiasts upset by Toyota surge into the mainstream with such configuration that will undoubtedly be popular.

- 11-07-2019** **New Drive Videos.** I need to drive from St. Paul to a suburb on the opposite side of Minneapolis from time to time now. (We're preparing grandpa's house to sell.). It's a heavy traffic situation, cutting directly through a busy corridor during rush-hour. It's time to run the heater too, here in Minnesota. That makes for a very interesting commute. All that stop & slow driving, following by some highway travel provides the opportunity to add to the variety of video footage. My tires are only a few days old though, definitely not broken in yet. I'm also in desperate need of new wiper blades (which are on order now). The windshield was dirty and I had no easy means of cleaning it in the dark & cold. So, I just used this first drive as a chance to get sample captures. After all, this drive will be in the dark, something I have no experience with using the new camera setup. So, my attempt this evening was the complete effort. Sadly, I had an issue with the dashboard footage. It was underexposed. The rest came out well. Due to the timing & distance, I ran out of electricity just as I was exiting the highway. It provided a great example of how the hybrid system takes over after depletion. I can't wait to try the drive again. That next time, I will carefully check the settings on that dashboard camera. btw, seeing the approach of Minneapolis from the highway, then driving through the tunnel, looked great... especially in the dark.
- 11-09-2019** **Supply & Demand, deleted.** I have been checking that blog website to confirm the articles really do limit comment posting to just 48 hours. Turns out, they do. With so much new content provided on such a regular basis, it makes sense that they want to get readers to quickly move on to the next. I checked back on that scarcity article and was surprised to find one of the comments I had replied to was now deleted. It left my response out there, but the original source I was commenting about was gone. Fortunately, most of my posts include the original statement when it's buried within a long-winded comment. That ensures everyone knows what I was replying too. This is why I get so angered by that troll on the big Prius forum who never includes any quotes. You don't know what he's referring too... a common trait for dropping bait to stir discussion. In this case, it was nothing but a single sentence. It was also bait though, clearly an effort from an antagonist to provoke: "*Toyota get with the program, you will be left in the dust!*" The fact that it got deleted was intriguing. Did my reply actually get the message through? Not having a 2020 model widely available yet does make sense when we are still 2 months from 2020. Having next year's model debut just prior to next year makes sense... not several months earlier when dealers are still clearing out remaining inventory from the current year.

11-10-2019 **Local Supply.** A post first thing this morning on the big Prius forum was from someone local, commenting about the lack of inventory for the Minneapolis area. It's always nice to see local interest grow. I can't wait until supply actually becomes available. Then, I'll start up local gatherings. Those in-person encounters are priceless. They get to see the technology firsthand and get answers to the questions they needed to help solidify interest. There's very little point doing that until an immediate purchase is possible. So, I've been using the time while waiting for the mid-cycle update to finally reach local destinations to continue to collect data. I'll have lots to present by the time Winter here begins to fade. There's should be a ton of opportunity by then. In the meantime, I'll keep filming new video with narration. Preparing for a new User-Guide is already well underway. Things are falling into place. In the meantime, I posted this as a response: Minnesota isn't part of the original rollout market, so we have to tough out special-order only until the second wave. Fortunately, the inventory in those other markets is increasing and the sales swings are growing. That's a good sign. It's right on time for the upcoming PHEV expansion announcement too. With regard specifically to Minnesota, efforts are underway to become a ZEV state. That will result in a push for automakers to provide local supply. In also means new incentives. Work to provide public chargers is building. There's also an HOV access program starting next month. Stay tuned. 2020 will bring about change.

11-10-2019 **Late To Notice.** This couldn't have come any later: "*Something appears to have very gone awry in GM-land. The promised EVs aren't materializing...*" An entire decade ago, we saw the mess unfolding. From there, it got worse and worse. Enough not paying attention or blindly loyal will help keep real change from happening. History is allowed to repeat, to the point where mistakes become more and more consequential. Even the rhetoric sends mixed messages. There's no plan anymore. It's a big mess, as I was more than happy to point out:

For those watching GM way back when Two-Mode was first announced, the reputation for "*over promise, under deliver*" was already established. So when its failure resulted in the project to develop Volt, there was good reason to express doubt. When the bankruptcy task-force addressed expectations for Volt, they expressed a "*too little, too slowly*" concern. There was good reason to make sure GM didn't rest on its laurels following rollout. Unfortunately, gen-1 of Volt fell well short of expectations and hope was shifted to gen-2. The outcome of that was a heavy dependence on tax-credits and no interest other than from early-adopters. But rather than spreading the technology from Volt to a vehicle & configuration more appealing to GM customers, that got abandoned entirely in favor of its own antithesis. Bolt never made any sense either. It had no audience. Knowing GM heavily favored Trucks & SUVs, that compact wagon made no sense to shoppers at a GM dealership.

Think about it. GM introduced both Trax & Blazer. Creating new vehicles targeted directly at their own loyal customers that didn't include hybrid, plug-in hybrid, or electric-only technology was a terrible decision made many years ago. Going awry is not recent. Evidence of fundamental neglect has existed for quite some time. Nothing whatsoever to offer showroom shoppers shouldn't have to be promised anyway. The expectation has always been some type of advancement forward would take place. Instead, GM is still pushing only old-school guzzlers. Notice how the supposed "*laggard*" already has a strong selling SUV hybrid and in 2 weeks will be revealing a plug-in hybrid model? Another automaker is delivering instead. What is the plan for GM now?

11-10-2019 **Make It About Someone Else.** That's the typical response, rather than ever addressing the problem. This is what I got from the plan question: "*Actually Toyota holds the position of feet dragging on EVs.*" Do nothing to acknowledge GM troubles or even how they relate to the market as a whole. That bigger picture problem of dealer acceptance or consumer education means nothing to an antagonist. They only want to claim a win online. True change isn't a priority. It's all about appearance. Ugh. Oh well, their audience is getting smaller and smaller. I replied with: That narrative is for who? In 2 weeks, the reveal of a plug-in hybrid model of RAV4 will take place. The fact that it will be a PHEV will result in wide acceptance from mainstream consumers. You get EV commutes without any concern related to range. The fact that Toyota is working to get the hybrid built in Kentucky sweetens appeal. Customers will get a locally built vehicle with a plug. Spinning that to represent "*feet dragging*" is beyond laughable.

11-10-2019 **Journalist Truth.** Enthusiasts don't when they write statements like this: "*Unlike Europe and China, demand for EV's in the US has been methodically strangled. Except for the narrow demographic of affluent and progressive EV buyers, the general public knows little about EV's, except that they are too expensive.*" Efforts like that point out facts to support the truth of the situation. Fear of GM strangling the market was brought up way back when Volt was first unveiled. If done poorly, the entire market would be negatively impacted... just like what GM did with the diesel market. Their offering was so unappealing to the ordinary consumers, the entire market lost interest. They soured appeal for all automakers. That's what happened for plug-ins too. The promotion of EREV was so confusing and so poorly targeted, it only served to confuse and to work against the next step of EV. Now, there's a "*why bother*" attitude here. This is exactly why Toyota steered clear of GM fallout. Waiting until phaseout of GM tax-credits are just about complete is an ideal time for pushing PHEV offerings forward. Watch what happens as the next few months progress. EV interest will fade as plug-in hybrid interest grows. The reason why is simple. Consumers won't have to spend much or even learn much. They'll simply see the choice and seriously consider it. Seeing a RAV4 hybrid with a plug will be a very compelling vehicle to make a decision about. Think about how little either salesperson or buyer will need to do. It's a vehicle with basically no compromise, something they would have purchase anyway... but in a much more clean & efficient model. That's going to be a very difficult truth for some to accept... and they won't have to listen to me saying it. Journalists are already pointing out the coming change.

11-11-2019 **Making a Difference.** Some people desperately hold onto the past, rather than adjust accordingly to move forward: *"The fact that the 2020 Prius Prime has half the EV range of a 1st gen 2011 Chevy Volt is pathetic, especially considering battery prices have dropped substantially since 2011."* Appealing to the enthusiast market, who was willing to spend more and had a generous tax-credit, was never a realistic path to follow... and they still don't get it: *"The Prius Prime would get me to work on battery power, and then back using gasoline power. A 2nd gen Chevy Volt (2016 onward) can do the round trip on battery power, and would eliminate all of my gasoline driving other than out of town trips. That's a huge difference."* It didn't actually make a huge difference. There's much more to a vehicle than just range. I posted what really makes a difference:

Cries of *"pathetic"* ring with irony. Better loaded. Real 5th seat. More headroom. And a starting with a base price \$5,770 lower, there's no contest. Prius Prime was far more appealing to the audience Volt had intended to target. That's why we are now witnessing Volt fade away into history and Prius Prime inventory ramp-up.

Taking a closer look, we see that Toyota's offering was more efficient with both EV and HV efficiencies. The rating of 25 kWh/100mi from Prime was far superior to 31 kWh/100mi from Volt. That's also the case with Prime's 54 MPG rating compared to Volt's 42 MPG. Additionally, the heat-pump in Prime is the industry's top offering.

Want more impressive advantage? Take a look at the carbon-fiber hatch Toyota delivered with Prime. All those claims of GM being the heralded leader and Toyota being hopelessly behind make no sense when you consider how well that weight-reducing, strength-adding technology was implemented. In other words, I've been waiting a long time to get the opportunity to point out how the *"vastly superior"* mindset wouldn't measure up to the cold, hard reality of automotive business. Sustainable sales in high-volume for a profit don't come about from range bragging rights. That's the real difference... and it is quite huge.

11-12-2019 **Electric Announcements.** Lexus announced that at the upcoming Guangzhou Auto Show (on November 22) it will unveil its first battery-electric vehicle. This was the teaser provided: *"Specifically crafted to suit the needs of audiences in China and in Europe, this further advances the brand's desire to offer a portfolio of electrified powertrain choices for diverse audiences worldwide."* Expectations are that the EV model of C-HR will be highlighted too, providing specifications & pricing. It's the type of detail that should finally bring an end to the rhetoric. Much propaganda for other automakers was built upon the premise that Toyota would never deliver EV offerings, that they were exclusively interested in fuel-cells. That was always a load of nonsense, efforts to undermine based on a one-solution-for-all belief. The concept of diversity wrecks meritless hype... what enthusiasts thrive on. That's why so much antagonism emerged from Volt enthusiasts. Portrayal of a narrative depended upon single-dimension characterizations. Toyota offering a wide variety of choices didn't fit into their agenda... and now that reality is crashing down... coinciding perfectly with the phaseout of their tax-credits. This is why we are now witnessing a rather profound change from online posting. Evidence of having lost is obvious. Those old blogs and what I documented here will forever preserve their decision to turn a blind-eye to certain facts; instead, they chose to misrepresent & mislead. Ugh. I sure am glad to see that coming to an end.

- 11-12-2019 Dehumidify.** Ugh. It's troublesome to read comments like this: *"BTW - once you turn on the windshield defroster, it kicks on the ICE anyway, so it's almost not worth trying to do much in EV mode if you want to be safe."* It's very misleading. There's nothing you need to actually do. The ICE (gas engine) will cycle on & off as needed while in EV mode, automatically operating in HV while that extra heat is provided. You get the benefit of EV without compromising safety. Of course, there are a few who go to extremes while driving to squeeze out more electricity use. Some are unaware of the non-driving things you can do. That type of advice was perfect for this situation, to dodge the obvious growing of tension on this particular discussion. I posted: Dehumidify the vehicle before parking. Just open the doors or windows for a minute. The temperature difference will force moisture to escape. You don't need MAX defrost then (the button). Ordinary window blowing works fine then and it's all electric.
- 11-12-2019 Waste.** This was another Ugh today. It was based upon the precedent established, then heavily endorsed, to portray efficiency only in terms of MPG. I was annoyed by the Gallons exclusive, an obvious effort to conceal kWh consumption, to hide information about waste. That's because some EV designs are more efficient than others. Listing how much electricity was actually used reveals a different story from what was actually being portrayed. Anywho, that's what I was forced to accept. So, now being called out for doing exactly that, I can't help but to be amused. That hypocrisy is confirmation of what they did in the past to mislead. They would omit detail to undermine. Being called out on a double-standard is something they want to avoid. So, I felt free to draw attention to the situation: I remember the days of getting attacked for pointing out an EV could be considered a guzzler of electricity. Hopefully, those close-minded individuals have come to realize that extra electricity required to travel the same distance translates to extra time you have to wait for a charger to become available. Even if it is from a green source, waste is waste. Time & Electricity should be an important measure of EV worth. 58 kWh/100mi is in an entirely new league of waste. Whoa! Compared to the newest Model 3 rating at 24 kWh/100mi or Prius Prime at 25 kWh/100mi, that's an amazingly inefficient EV drive.
- 11-13-2019 Mainstream.** Fragments of past rhetoric still linger, a the definition of *"mainstream"* demonstrates. My guess of antagonists, now lost of purpose, feel the need to have some type of voice still. Having been proven incorrect, that's a difficult position to be in. They fought hard with twisted facts and lots of spin to support a failing effort. And now that has been exposed, what can they do? Most vanish. You never hear from them again. That was the beauty of hiding behind an avatar with a made up name. There was no sense of accountability. That's why most venues abandoned that type of commenting approach. If you were unwilling to associate your posts with your identity, you were probably trying to hide something. It simply makes no sense to conceal like that. Sadly, those days of being unable to trace source persisted for many, many years. It's over now; however, some still try to hold onto that past... which necessitates pointing that out: The widely accepted definition of mainstream here started over 15 years ago with hybrids was anything capable of sustaining non-subsidized profitable sales at a minimum rate of 60,000 annual. People like to move goal-posts though, especially with the entire EV market still leveraging tax-credits. Basically, it comes down to a breaking of the status quo. If you can get showroom shoppers to purchase the vehicle, you have effectively achieved change. If you are catering almost entirely to nothing but the early-adopter audience, it still isn't mainstream yet.

11-15-2019 **Video: Prius Prime - Cold Commute thru Minneapolis.** I enjoyed putting together this particular video. It provided an opportunity to show a type of commute I usually don't have to endure. But in this case, we had have to drive to that location fairly often. We are helping to get that home ready for selling. So, going there to do some clean-up after work meant jumping into the busy Twin Cities corridor while commuting traffic is at peak. That's something I normally wouldn't need to do. Capturing it on video was a nice benefit. Anywho, here's what I published: Electric heat and heavy traffic during rush-hour through Minneapolis represents a significant demonstration of the EV capabilities Prius Prime offers. Combined with some high-speed highway travel to follow with new tires not broken-in yet completes the commute from downtown St. Paul to a suburb home on the other end of the Twin Cities. Watch this video, paying close attention to the data provided on the right from an aftermarket interface. Compare that detail to what you see on the left, the dashboard of Prius Prime... [Prius Prime - Cold Commute thru Minneapolis](#)

11-15-2019 **Knee-Jerk Reactions.** It is interesting to watch comments like this gain traction: *"Meanwhile, a boycott against Toyota's support for Trump is coming on strong."* With so little merit to support them, you wonder how the intended audience will actually react. This is thought-provoking when it comes to automotive purchases. Are such financially large decisions really made with so little information? And does the shopper really care about politics? It's the type of rhetoric you have to wonder about. Does it make any difference? That's why I watch so carefully and document my observations. The market isn't all about engineering. In fact, there is little logic to it sometimes. But there is a strong element of practicality. Even the obsessively large & wasteful SUVs do provide some physical benefit. I hope at least a few of those who typically react without thought will try to consider the bigger picture this time and how seemingly good choices don't actually much, of anything. We'll see: Knee-Jerk reactions from those with limited focus (in this case EV enthusiasts) will give that impression. Many have demonstrated a genuine disinterest toward the needs of ordinary consumers, obsessing with range & power instead of actually addressing their purchases priorities. Appealing to the mainstream market means attention to the showroom experience is vital. Dealers must be on board, which means sales without any type of subsidy. A boycott will not achieve that.

11-15-2019 **Irresponsible & Behind.** That didn't go well. I got this in return: "*The fact is Toyota wants to squeeze every last dollar of investments out of ICE engines no matter how environmentally irresponsible and behind the times that notion really is. They're as greedy and stupid as VW thinking they could get away with faking compliance with emissions requirements... Seems like you and Toyota and Trump are circling the same drain.*" I was quite disappointed. My hope of some thought taking place before another reaction was crushed. Oh well. It gave me the opportunity to say more on the topic: Who? I was one of those fighting the fight to draw attention to what VW was up to. Things just didn't add up. I helped collect & present evidence to reveal why claims being made were not true. At the same time, I was also battling GM with its facade from supposed efforts to reach mainstream consumers with their plug-in efforts. Choosing to follow the narrative to support a boycott won't change the wisdom of the bottom-up approach. Toyota is pushing for change across a wide array of choices. That's something enthusiasts object to, since they believe only a top-down approach will succeed... despite the reality that it was a momentous failure GM has had attempting that. In other words, I have 20 years of history helping to confirm the perception unfolding now isn't really what's taking place. Toyota has carefully planned out a means of deploying green options their dealers will embrace and consumers will seek out. It's good business, something enthusiasts show no interest in... and I have hundreds of pages of blogs to prove it... very, very in depth market research. Take a look around. What have the other automakers actually delivered in terms of change not dependent upon tax-credits? Toyota is setting the stage by deploying PHEV models of Prius, Corolla, and RAV4, along with an EV model of C-HR. Each is targeted at ordinary consumers and is expected to be appealing to dealers. Remember, stocking them as regular inventory is vital. In other words, what merit is there for stating "*environmentally irresponsible*" and "*behind the times*" when we can see obvious work at play to disrupt the status quo?

11-16-2019 Other Automakers. Ugh, this narrative is well beyond annoying at this point: "*...the other auto makers shifted gears and started heavily investing in catching up, whereas Toyota pulled an Ostrich and buried it's head in the ground...*" It comes from the effort to convince people that electric-only vehicles are the only solution. If it's not EV, the automaker is supposedly now becoming desperate, falling so far behind they will have to scramble to catch up. Again, ugh. People are gullible though, especially when it comes to topics they know basically nothing about. You feed them some misleading information to let assumptions originate from. Don't allow owners to actually convey anything useful. That's why my videos have become such a powerful tool to counter that nonsense. This is how I replied:

You actually believe that narrative? It's the same old greenwash we've been hearing for years. Some have worked hard to convince us that Toyota is ignoring the market, despite the fact that evidence to the contrary is hidden in plain view. All you have to do is look around. The components for a great EV are being refined right before our eyes.

Start with what should be the most obvious. A vehicle's battery-pack is nothing but a series of cells assembled into a stack. The more stacks you include, the more capacity (range) the vehicle offers. It's not rocket-science. It's just packaging. The chemistry is being tested heavily in real-world conditions by Prius Prime. That data will go a long way toward making the next-generation something to truly contend with. No EV is necessary for that.

But if you want an EV already, look no further than Mirai. It utilizes a 151 horsepower (113 kW) electric motor. Again, Toyota is already real-world testing it. To give the technology intended for mainstream use such a heavy shake out in public with most people never noticing is genius. They are taking their refined design for electric motors and pushing it to continuous and heavy use. It's proof of worth without ever having to deal with audience challenges.

Then there's the heat-pump in Prius Prime, an industry leading approach... most definitely not catch up. Their vapor-injected approach sets it above the rest in terms of electricity consumption. It's the top for efficiency, something essential for being competitive. That is why we also see the use of carbon-fiber in Prius Prime. For added strength and weight-reduction, that's a nice advantage to have too.

In addition to all that, Toyota is working hard to change the culture at dealership. Their push for change with RAV4 is proving extremely effective. The hybrid version is selling exceptionally well... and that's before next week's reveal of the upcoming PHV model. Combine that with the build up of Prius Prime (mid-cycle update along with production ramp-up) and the introduction what should become paradigm-shift from the Corolla hybrid delivering 52 MPG and starting at just \$23,100. Put another way, what does "*catch up*" actually require? Think about everything that much change to achieve sustainable high-volume sales. Don't listen to those only paying attention to low-hanging fruit. They're in for quite a reality shock when the early-adopter market becomes saturated and subsidies expire.

11-16-2019 Witnessing History. It is quite fascinating to witness this history play out. It is like when I had collected a wealth of information to confirm gen-2 of Volt was doomed to fail. The evidence was obvious; yet, enthusiasts worked extremely hard to deny it. In that case, GM was studying feedback from gen-1 owners. That set them up for innovator's dilemma. And sure enough, the next generation made what started as a niche even more of a niche. I could see all along they were asking the wrong audience for suggestions. You want mainstream acceptance, you must carefully consider every bit of info that fickle audience is willing to share... not what early-adopters state praise for... then push for what they are unlikely to even be aware of. It's all quite important... and clues to success are very easily overlooked. Put another way, this reminds me of that scene in the movie "*Raiders of the Lost Ark*" when they came to realize the Nazis were digging in the wrong place. It was just a matter of time, waiting for them to figure it out their mistake. Then, things would get ugly. That's exactly what I witnessed too. I watched history as a participant... which is quite a different perspective from those telling tales now. Looking back, you get a very different impression than while it is playing out.

11-16-2019 This Latest Kerfuffle. I had much to say about it: Toyota knows their audience well. Being able to offer a variety of PHV models provides a strong endorsement for moving their dealerships forward. The choice of a few plug-in options complimented by a wide selection of hybrids sets the stage for EV sales later, while also taking advantage of limited battery supply now. It's simple math. There's far greater of an emission reduction by spreading 60 kWh of battery cells across 5 plug-in hybrids (assuming the next capacity increase is to 12 kWh) than to just 1 electric-only vehicle... since the other 4 would still be traditional guzzlers. Think about the likelihood of the next purchase from a PHV owner being an EV. This is why conquest isn't a concern. After all, you want the entire industry to move forward. Having some Prius owners help Tesla become established isn't a bad thing, as many attempt to lead you to believe. In the meantime, battery production is being refined and its chemistry improved. While in the same period, people are upgrading infrastructure in their garages, driveways, and parking lots. Put another way, the spin about Toyota not caring or being hopelessly behind don't match up with the reality of what's actually happening behind the scenes. That's why the term "*narrative*" has become the modern identifier for trolling. Antagonists hoping to undermine hope you only pay attention to what they claim is important, preventing the bigger picture from being seen. Having fought the green war for 20 years now (I still vividly remember my discovery of Prius & Insight way back in 1999), I see this latest kerfuffle as just a new chapter in that on-going history.

- 11-16-2019** **Getting Caught.** I didn't expect my response to this to get a forgot-to-mention so quickly: *"a lot of people who like toyota quality say they want a toyota bev. but if toyota actually made one, i doubt it would sell much better than bolt or leaf"* Knowing my audience, I was well aware what actually happened is he got caught attempting to downplay. Simple realities, like cost, are often dismissed by this particular individual. That's why the spin of his claimed intent of that comment, after I posted mine, took place. He said he meant *"today"*, but the absence of *"had"* and *"have"* in the post don't support that. Both the tense & context being wrong confirms I was right for having posted what I did. Also, he's been warned about being so incredibly vague, hence: There's no sound basis for drawing that conclusion. Leaf's audience has moved on due to the constraints of not having any type of active cooling system. Bolt's audience was nothing but conquest sales, never appealing to GM shoppers and heavily dependent upon tax-credits. In other words, both were rush-to-market approaches... the complete opposite of Toyota. Toyota will have the benefit of extensive real-world experience prior to rollout here. The variety of PHEV offerings and 2 likely EV models (CH-R and a Lexus) will provide a means of accurately targeting the masses... a goal well worth taking time to achieve. We have infrastructure upgrades happening in the meantime. Heck, just being able to accept a 100 kW charge-rate would be enough completely negate any type of comparison. This is what the big picture consideration is all about. Claims of *"catch up"* simply make no sense when others are not there either. For that matter, boycotts are often pointless for the same reason. Think about all the broken promises of the past and how many rollouts fell well short of their goals.
- 11-17-2019** **Irony.** Sadly, EV advocates don't advocate as much as they could. Time & Resources are wasted on anti-hydrogen efforts. This particular group-think pile-on really brought that point home: *"The irony is 4 Teslas in ~20 minutes would be a similar throughput of 4 hydrogen cars fueled over ~20 minutes."* It was nice seeing something sensible posted. I jumped into the crazy with: Adding to that is the irony of megawatt EV charging stations may very well end up with hydrogen sourced fuel-cells to supplement electricity during times of high demand. Of course, it doesn't matter. The shipping industry is looking into hydrogen to replace diesel. So whether or not passenger vehicles use it is a moot point. Realistically, it doesn't matter anyway. Starting with cars is far less expensive than commercial vehicles, which is really the primary target. EV enthusiasts simply feel threatened by the multi-fuel solutions. Ugh. It's somewhat amusing to foresee hydrogen being used for green storage later too, since the grid can't hold all of it.
- 11-17-2019** **New Tech.** A new technology isn't new forever. Some forget that reality: *"Those people who buy based on trust aren't going to 'risk' buying some new-fangled technology. They will buy a gas-powered Corolla or Camry."* Think about how little the typical showroom shopper knows about how any of those vehicles they are looking at actually operate anyway. For that matter, the better informed usually don't either. At best, they have a general understanding. That's easy to deduce too. Just consider what those seeking information ask about. I encounter that on a regular basis. It's a good reminder of how much work still needs to be done to educate. Much wisdom needs to be shared from those experiencing a plug-in everyday. Put short, I responded with: RAV4 hybrid is proving that claim outdated. A few years from now, it will be reasonable for the model with a plug too. That's the point of bringing the entire fleet forward... the tech won't be thought of as "new" forever.

- 11-17-2019** **Constructive Questions.** It's really nice to see them from time to time. I suspect they will increase fairly soon with this new audience about to come in as a result of the PHEV model of RAV4 reveal. That will definitely stir inquisitive minds. Until then, we get stuff like: *"I still don't understand why auto journalists keep quoting the electric-only range. In real world driving, isn't it very unlikely you would ever be driving in electric-only mode, since you'd have about half the total combined engine power available to you? What am I missing here?"* Knowing audience, I suspect the RAV4 will provide quite a bit more power. After all, 3 years have passed since rollout of Prius Prime became a reality. A lot has been invested in the technology since then. Anywho, this is what I posted as a constructive answer: That's because the reality of the situation is you don't need that much power. Sure, a writer catering to enthusiasts will try to convince you otherwise, but not a true journalist. My PHEV provides 68 kW of electric draw from its battery-pack. That's 91 hp, which gives the impression on paper of being inadequate. But when actually in real-world driving, that's enough. In fact, it's plenty for driving around in the suburbs. Even highway merging doesn't require more power. It's there if I need it, but I find that I don't. Driving without starting the engine isn't a big deal.
- 11-17-2019** **Preheat What?** That question absolutely had to be asked after reading this: *"I remember reading that you can't plug in a Prime for charging and then use that power to preheat the gas engine once the battery is full."* I following through with: Since EV driving can far outlast engine coolant, that would be a pointless feature. Engine block heating comes from a separate plug anyway. In other words, check your source. Something clearly isn't right with that claim. You can preheat the cabin (aka: *"pre-conditioning"*) any time you want, regardless of battery level. Without being plugged in, it will draw directly from the battery. And yes, it will dip into HV capacity if called upon. While plugged into 240-volt, it will do a combination of rapid pull from the wall, a little bit of battery, then pull from the wall again. That basically warms up everything using the heat-pump. There is also the battery-warmer. I'm not actually sure if that operates without being plugged in. But it certainly does work when you are. With temperatures below 0°F parked outside without any protection, mine was kept at a comfortable 39°F last year. That's what the lithium chemistry needs to operate more efficiently. Below freezing, electrical resistance increases quite a bit.

11-17-2019 **UDDS.** That stands for "*Urban Dynamometer Driving Schedule*". No one is even noticing that qualifier, which is a pretty solid confirmation of not understanding the significance. In plain english, that's the "city" test. In other words, panic about Prius Prime not qualifying for the new California rebate program starting next month is inevitable. People see the "35 mile" criteria and just assume that means the overall EPA estimate. The purpose of such a requirement is to help mitigate emissions related to stop & slow traffic... city driving, not anything to do with the results you get while cruising at high speeds. Ugh. This means, we must explicitly point out that Prius Prime does indeed achieve that expected EV distance in driving conditions related to those the rebate is designed to specifically address. It's yet another one of those poorly-informed-consumer situations there really isn't a good way to teach about ahead of time. Many haven't ever even noticed there are several measurement categories for efficiency... as hybrids clearly provided evidence for. Heck, there are many who really don't know much about the impact of seasonal changes. So, the influence of speed not being observed is no surprise. Needless to say, it's reasonable to expect a surge of last-minute purchases as month-end approaches. That will certainly add to the confusion of sales results, especially with this next reporting to come at year-end.

11-17-2019 SUV Obsession. The upcoming reveal from Toyota has brought about an extremely uncomfortable situation for antagonists. There quite literally have nothing left. Every single argument has been exhausted. Toyota is now about to do what I complained for years about that GM should do. Anticipation for very high demand confirms I was correct. Even before getting any detail, they know GM failed to follow through. Two-Mode, to gen-1 Volt, to gen-2 Volt never resulted in a plug-in SUV, exactly what the obsessed audience here craves. It's such a monumental mistake on GM's part, there's not a word to say about it. This is much like VW's diesel failure. The outcome was inevitable. They were pursuing a course that simply made no sense. Anywho, this is what I posted, with the expectation of now backlash:

Who is the market for Volt? That question asked hundreds of times to Volt enthusiasts in the past was for the very reason brought up here... rising demand for SUVs. It simply made no sense watching GM waste tax-credits on conquest sales, leaving nothing for their own loyal customers. Showroom shoppers were getting hosed and no one seemed to care. Equinox got diesel instead of Volt technology. It was absurd. Then came the new Trax SUV. It didn't get technology from Volt either. Following that was the new Blazer. Same disinterest toward diversification. So when Volt died, all that effort to blend motor & engine did too. GM just abandoned what they had supposedly strived to deliver. It's really unfortunate GM didn't throw their support behind electrification of their primary product, finally. After all, Two-Mode (the predecessor to Volt technology) had a prototype plug-in an entire decade ago. Saturn Vue was supposed to be the premiere vehicle. It was a SUV.

The real problem isn't the technology, it's the money. New technology delivers razor-thin profit, if any. And once GM opens that can of worms, it's going to be a self-inflicted disaster. By avoiding change so much, basically supporting their own dealers' resistance, the automaker has set itself up for the Osborne Effect. Making it worse, GM no longer has cars to help leverage sales or efficiency quotas. All bets have been placed on the SUV as the offering for ordinary showroom shoppers... none of which are green.

In just 3 days, we will see how that could have been avoided. Toyota's RAV4 AWD hybrid starts at a MSRP of \$28,100 and delivers 40 MPG. That in itself directly addresses the topic of this article. 40 MPG is a rather substantial efficiency gain over GM's Equinox AWD (1.5 L, 4 cyl) delivering just 27 MPG. Heck, even the smaller GM Trax FWD delivers only 28 MPG. So when the reveal comes this Wednesday, providing detail about the upcoming plug-in hybrid model of RAV4, it's not like Toyota will fall into the same trap as GM.

To think, all those posts about how desperately behind Toyota supposedly is. Then as if overnight, there will be excitement among ordinary consumers upon discovering they won't have to give up driving an SUV. They'll just have to upgrade to a hybrid or plug-in hybrid.

11-17-2019 **Outright Lies.** I saw this attack unfolding: "A 25 mile range (*in real life 15-20 at best*) is a joke. Just who are they trying to fool? It's a hybrid 99% of the time. That's why the Volt was a great PHEV (60 mile EV range)." There were so many things wrong with that claim, I had to think about what to comment. Posting any sort of detail with someone how just plain does not care really isn't helpful. They'll just spin facts and make anything that follows about you. That evade & distract is so annoying... and still quite common. Keeping replies brief and with a callout to raise awareness is my suggestion. For example: Blatant efforts to greenwash like that are fascinating. They are so easy to disprove; yet, attempts are made anyway. Why? Look no further than Prius Prime. With its 25-mile rating, seeing low 30's in the summer is quite common. And that's all-electric until battery depletion, even if you drop the pedal to the floor.

11-18-2019 **UDDS Detail.** The characteristics of the UDDS rating are:

- Distance traveled: 11.04 miles
- Duration: 31.233 minutes
- Average speed: 21.2 mph

It's the "city" driving cycle, which we know Prius handles exceptionally well. That's what is important when addressing emissions from heavily congested traffic... which is a priority for California... hence the focus.

11-19-2019 **Gaming the System.** Toyota's perspective is regulations have unintended consequences. We have witnessed automakers gaming the system rather than actually changing. They exploit opportunity for short-term gain. It's that simple. Legacy automakers have much to lose. It takes a monumental amount of effort to bring about anything that could cut into profit. Fear is a major deterrent. So, they look for a means of delivering something seemingly worthy instead. That's why Volt was problematic right from the start. In fact, that's how the "vaporware" claims came about. Even if all of those overly ambitious criteria could be achieved in that short amount of time, there was no next step. Things would simply fall apart following that without any clear plan of succession. Think of it from a "diet" analogy. Sure, you could meet your weight goal, but could that be maintained afterward? And was whatever you did to achieve it healthy? Affordable? Repeatable? When stuff like that is not considered upon setting the goal, you know you're doomed. GM was destined to fail. The plan wasn't comprehensive. They were given the chance to game the system... again. Toyota doesn't want to allow such history to repeat, even if it means some bad public-relations spin as a result. Overall, it simply isn't worth it.

- 11-20-2019 RAV4 Prime.** What more needs to be said? The name speaks for itself. That long-awaited reveal didn't disappoint. There will indeed be a plug-in hybrid model of RAV4. It will be rolled out this coming Summer, just 7 or 8 months from now most likely. It's the fastest and most powerful configuration anyone could realistically imagine. Toyota clearly did its homework. The configuration looks impressive. Loaded with safety features and AWD standard, the expectation of high demand is an easy prediction. The detail specification shared that really stand out is 302-horsepower and 0-60 in 5.8 seconds. along with 39 miles of battery range. From an efficiency perspective, the listed 90 MPGe is one to ponder. People still have no clue what that equivalency-rating really means. But then again, this audience won't really care anyway. The fact that it will deliver daily commutes that are all-electric for most people is all the more that needs to be conveyed about the technology. Detail isn't a priority for this audience. If it was, all those cost-per-mile and cost-of-ownership reports would have prevented them from purchasing any type of SUV. This is a hybrid with a plug from an automaker with strong reputation for quality. Enough said.
- 11-20-2019 First Impressions.** Quite curious what others had to say, I kept the post about my first impressions short: Both cost & efficiency are often dismissed as unimportant. We learned all too well that the focus on power & range blinded most online participants into a group-think that was ultimately tragic for Volt and its associated technology. Toyota's strategy is proving a wise approach for fleet deployment (product diversity, not commercial sales) and dealer acceptance... both of vital importance for reaching beyond the early-adopter market. It's how profitable, mainstream volume is achieved.
- 11-20-2019 Phaseout.** Discussion of tax-credits immediately dominated the posts: *"That's the thing with the tax credit advantage, pretty much as soon as an automaker who has been participating at all starts selling big numbers, it'll be going away quickly."* It was interesting to see what is supposedly a well-informed group reveal they really don't have a clue. Several made comments that were just plain wrong. None even attempted to touch GM either. That topic has obviously become taboo. The mess with Volt has become such a monumental failure example, everyone is pretending it didn't happen. They don't want any association with it, in any manner. So, I didn't even bother with a reference. Those who had once whole-heartedly endorsed GM's approach will remain silent from now on anyway. So, this is how I replied: That isn't how it works. Once the automaker hits the 200,000 mark, phaseout begins. That phaseout stage switches from a fixed quantity to unlimited. Tesla took advantage of that with Model 3, which has worked out remarkably well. Notice the timing of the volume increase. Toyota will do the same.
- 11-21-2019 Asking People.** This was great: *"Go ask 10 random people."* That's not who. Ugh. Know your audience! Think about it. If the person isn't even in the market for a vehicle, how much shopping would they have done recently? Odds are, they don't have a clue what the market has to offer. Why bother researching if there's no chance of purchase? Financial situations change over time anyway. Driving situations do too. So even if you have heart set on something, it simply may not work out. I was annoyed by how carelessly that comment was made. This is how I expressed my feeling about it: That's not the audience. Focus is on showroom shoppers, not random on-the-street people. Ask 10 of them in the summer of 2020 whether they would like the regular, hybrid, or "Prime" model. How many do you think will recognize (at least on a high level) the difference and be curious to find out more?

- 11-21-2019 Choose Wisely.** That same resident troll is continuing his ways on the big Prius forum... not quoting the post he's replying to, overwhelming conversations by posting so frequently, and never bothering to use uppercase letters. Recently, he has added to his lack of constructive material... not reading carefully. I've seen posts that simply don't make any sense. All that is annoying, but not as unfortunate as his latest: "*you have to flex your muscles when you can. i'd like to see them ban toyota*" It really becomes a problem when there's encouragement to resist or fight without actually providing any reason why. His posts are always so vague, it's hard to even spin them as ambiguous. There's just nothing to support claims. How do you counter someone who's just using the venue for entertainment & attention? He clearly doesn't care about doing anything meaningful. Dealing with troublemakers of the past, there was always some type of vendetta. They were trying to achieve something. He just passes time, convincing himself that limiting posts to a quantity per day similar to others is unnecessary. Being the top by a very wide margin isn't a concern. Ugh. That example from today was a substanceless protest against Toyota's take on varying requirements throughout the United States. Naturally, that's been spun as siding with the current administration in favor of freezing regulations. It's not. But really can't argue with people who thrive on group-think. There are many enthusiasts who need to make themselves feel better by exclusively focusing on others, rather than including some self-evaluation for balance. Anywho, the best response is to be brief when replying to individuals like that: Choose wisely. There are unintended consequences. In this case, we have witnessed automakers gaming the system rather than actually changing.
- 11-22-2019 Owner Encounters.** An unspoken benefit of having a public charger near the entrance to the grocery stores is the opportunity to get to chat with new owners. I have done that a number of times now. They're easy to spot. You see them struggling to either get in the spot itself or struggling to figure out how to use the charger. Each has been quite relieved when seeing my gesture to help. I take the time to talk them through the process, demonstrating how the system works with some detail about setup. Those have been great experiences. The one this evening was too, but it wasn't with a new owner. I just stopped to chat with a gen-2 Leaf owner at a ChargePoint station. He was having trouble with his card, so I used mine to unlock the charger. It was a great opportunity to collect real-world data. With the Leaf this evening, it was steady 6.1 kW. The result was 11.24 kWh of electricity delivered in 1 hour 50 minutes. His timing was interesting. That is precisely how long it takes to recharge my Prime. I get a steady 3.5 kW rate to deliver 5.8 kWh. He got all charged up and I got some interesting data.
- 11-22-2019 Lexus EV.** It was revealed today, for China, Japan, and Europe. The name will be UX300e, like its traditional counterpart but with an "e" suffix. Range estimate on the NEDC cycle was 400 km (249 miles). Motor output will be 150 kW (201 horsepower). Battery-Pack capacity will be 54.3 kWh. Fast-Charging (DC type) will be 50 kW, which works out to roughly 50 minutes for a full charge. Using 6.6 kW at home (AC type) takes about 7 hours for a full charge. Vehicle weight is 1,900 kilograms (4,188 pounds). This will be the first EV offering from Toyota, but more are on the way. Lexus will also be getting its first PHEV offering too. Availability of UX300e is expected by 2020 year-end for China and sometime in 2021 for the UK.

11-22-2019 Pack Cooling. The topic is a "hot" one (pun intended) among EV enthusiasts. Support for what type is far from universal. Some absolutely insist liquid is required, but material to support the claim remains elusive. Reasoning for keeping the pack as cool as possible is for the sake of longevity. This is especially important when it comes to super-charging. Transfer of electricity involves some loss of energy, which comes about in the form of heat... resulting in the acceleration of chemical aging. What none will tell you though is that heat is required for super-charging. The catch is not overheating... but no one ever provides those numbers. Lack of detail is a red-flag. I have read comments that Tesla warms their pack to 121°F for enabling high-speed DC charge-rates. That's hotter than I have ever seen the battery-pack get in my Prius Prime. In other words, there's much we don't know about various systems & chemistries. That's good reason to not insist upon something without supporting evidence, especially as the technology advances. Outdated information can be a problem too... which brings us to the upcoming Lexus EV. This observation was posted: *"Examining the battery pictures reveals an air cooled battery using a blower motor up front by the HVAC system. Probably uses cooled air from the ac system you can see the air passage ducts."* I posted the following as a reply to that: Forced active-cooling works just fine with Prius Prime, which has a smaller pack... resulting in it getting pushed to full draw for EV acceleration. Longer operation from a heavier vehicle, but with a much larger pack and cooling supplemented by direct HVAC, seems an effective means of temperature control... especially with on-going chemistry advancements.

11-23-2019 **Tipping Point.** That term is being brought up a lot recently, but it doesn't actually tell us anything. I used a new topic featuring the expression to once again point out how it means different things to different audiences. After stating exactly that, I wrote:

For example, we hit "*Peak Oil*" an entire decade ago based on the simple fact that the audience changed. The instability initially caused by \$4 per gallon gas was dealt with by introducing a flood of new investment. Now looking back, we see that those big players never actually recovered. The stability was restored by a number of smaller players filling in the gaps... but with newer technology... which permanently altered the dynamics of the playing field. So as someone directly involved in that market, you have new players.

That parallel works its way into the automotive industry as well, but with climate change and emission concern adding to the problems related to that change in the oil industry. Like gas stations, the true buyers of the product aren't the consumers. They require their big tanks to be filled so they will have something to sell. Sound familiar? People still need transport. People will still go to a seller for their purchase... their local dealership. Newer technology comes into play here too. The new players are suppliers.

Most drivers looking to purchase a new vehicle couldn't care less. That audience doesn't matter. They do though, to dealers attempting to make sense of where their business is heading. That's what makes this topic so complex, no brief online discussion thread can address it properly. In fact, some won't even really notice what's playing out until years later. Just look at the failure of GM to do anything with their once highly praised technology for Volt. All that effort only to abandon the effort.

Notice how GM's CEO just made this statement: "*We've announced we'll have 20 EVs globally by 2023.*" Think about who that was directed at. It was a group of investors, not future GM customers. That diversity of a product-line addresses exactly what Volt failed to achieve. It doesn't address volume though. Having a wide-variety of choices doesn't mean there will actually be enough produced to meet demand. Supply isn't being talked about yet. That audience will have to wait until this audience is first satisfied. In short, focus on actions, not words.

11-24-2019 **Pack Warming.** We are getting more questions about that now. Unfortunately, I'm not having much luck collection data for that. Detail remains elusive when there's a delay of Winter. Here's what I had to contribute today: Sorry, it hasn't been cold enough lately to give you a firm answer yet, with respect to the battery. It will though in a few weeks. Two years ago, my Prime spent Christmas week outside in -9°F high temperatures (Wyoming) without any trouble whatsoever, despite not having a place to plug in. Here (Minnesota) at work when I plug in, I have checked the battery temperature. It's kept at 39°F in those same conditions. When the outside temperature is near freezing, I have seen the battery temperature at 59°F. The question now is if there is warming activity when not plugged in. Stay tuned. The warm spell will soon be gone here. With respect to the engine, it will just stay ice cold until called upon. Then when that moment happens, the battery-pack will supplement power to keep the engine from getting stressed. Basically, it just idles for the first 1/2 mile or so to get everything going before taking on any load.

11-24-2019 Troll Types. Most anyone who has participated online for any amount of time has encountered the troublemaker type. They are just there to serve as an antagonists from an outside interest, stirring upset for the ultimate purpose of undermining whatever the goals are of that venue. This is why the enthusiasts on the daily blog for Volt hated me so much. I was polite & constructive, quite the opposite of a troll. I would carefully analyze all the information they'd share to counter me, then respond with something to debunk their assertion. Point after point, I would show them how they were incorrect with real-world data to support my claim. It was an effort in madness. They would desperately try to shut me up, but could not... and the moderator saw I was bringing in more participation and wasn't ever doing anything to hurt or offend. My work to prove technology worth (or lack of, in that case) was vindicated in the end too. You can read my old posts as shockingly accurate predictions now... because I based them on quite a bit of study, which I opened shared. My findings were never a secret. My position was always clear. They just didn't like it... which brings us to the other type of troll. That type is very friendly and is often looked upon as an ally. They are always there to respond, but rarely provide anything of substance. That's the rub. They basically just serve as a means of emotional support. There's no real harm... unless you actually need help. When post after post after post isn't constructive, you have a difficult time finding content of value. Their posts end up cluttering up what would otherwise be useful information. Anywho, after saying that, I have something new. This is the first time I have ever witnessed the 2 types of trolls take over a discussion topic. Watching them battle it out for attention was intriguing. Both lost their audience. It became nothing but a 1-on-1 posting exchange. Both ended up without an audience. That's what we call a lose-lose situation. I was quite amused.

11-24-2019 **Approach.** I'm really enjoying this abrupt shift in discussion: "*Is the Prius Prime being de-emphasized by Toyota?*" It's the result of antagonist rhetoric having vanished. There's nothing left for them to work with. Every single exploit they tried has finally been debunked. Phew! That was a painfully long endeavor. Now, we can answer questions like that. I was happy to, too:

First, keep in mind that Prius rarely gets advertised anyway. In fact, Toyota has even stated the power has been passed to us, where owner endorsements are far more effective. So, we end up promoting it via word-of-mouth instead.

Second, Toyota has a long history of being a quiet player. They simply don't promote until they are ready. That means regardless of how intense the rhetoric gets, it really doesn't matter to them. Their cards aren't played until it's time to call.

Third, the strategy of diversification is absolutely vital at this stage. To be able to both reach deep into their own customer base and to take advantage of the tax-credit phaseout opportunity, they will wait until supply is built up before jumping.

Watching the inventory rise in the established states, it's rather obvious Toyota focusing on them prior to the RAV4 Prime reveal. Quietly wait for old inventory to be cleared out while delivering the mid-cycle update (2020 model introduces a middle-rear seat) in the meantime. That sets the stage for an onslaught of purchases from those wishing to take advantage next month to file a credit claim on their 2019 taxes rather than having to wait an entire year for 2020 taxes. Then in mid-January when the Detroit auto show stirs attention for RAV4 Prime, Toyota can then respond accordingly. If deliveries to the established states keep up with demand, rollout to the rest of the United States can begin. If not, supply will continue to focus there. At some point, national rollout will begin. It's not like you can't order a Prius Prime elsewhere. You just have to wait.

The point is Toyota offers a variety of choices and they are working hard to discontinue traditional vehicle offerings. The increase of warranty across the board to 10yr/150k is solid evidence of that. Drawing attention to new choices is key. So, we are likely to see emphasis on the AWD Prius in the meantime. The new look and that obvious new feature is very well timed to coincide with the dramatic changes unfolding in the industry, related to both dropping demand for cars and the desperation of others to distract from the success Toyota is having with hybrid upgrades. In other words, 2020 is going to be a year to remember. Think about where the market will be by Earth Day. Neither GM nor Tesla will have tax-credits available anymore, while Toyota will be very well positioned to take advantage of them.

11-24-2019 **Unable.** That recent statement from GM marked the end. It was a clear abandonment of the past. This is what declared their war over: "*We've announced we'll have 20 EVs globally by 2023.*" We witnessed Two-Mode, then Volt (which was really the next-gen design), then gen-2 Volt fight major battles and each lose in spectacular fashion. To put things in perspective, that was 15 years of claiming to be vastly superior, but failing to actually deliver. The propaganda effort was amazing. Their minions were ruthless. I was attacked on a regular basis for pointing out how a hybrid could be properly done. They simply didn't believe in incremental upgrade. It's amazing how continuous improvement is disregarded as an effective means of change, despite overwhelming evidence to the contrary. Much of the resistance to that approach is a cultural issue. Management of some corporations don't operate that way. Focus on the biggest financial return, rather than long-term viability, is a self-destructive problem. Yet, we watch it play out several times from several sources. GM is by far the best example of that. They screwed up, repeating the same mistakes over and over again. It's amazing how enthusiasts absolutely refused to acknowledge the pattern. Just like with the political efforts now, they did everything possible to avoid addressing the issue itself. It was an endless stream of excuses, blame, and distraction. The outcome is a reveal of being unable. GM never found a way to deliver an affordable & profitable solution which could actually compete with itself. Their hybrids weren't good enough to compel their own loyal customers to switch. Toyota's reveal on Wednesday is why GM's statement on Friday happened. RAV4 Prime offers such an enticing draw to showroom shoppers considering a RAV4 purchase, there isn't anything to argue. The reasoning for that choice is sound.

11-24-2019 **Organic Process.** It has been fascinating to watch the political disaster turn into a mess with so much confusion, people lose track of priorities & purpose. They end up fighting just for the sake of not losing. They learn to live with the truth, working hard to convince themselves the outcome justified their actions. The final "*win*" is whatever they can figure out how to accept. It's an organic process. Changes of position over time are claimed to be the expected result they were working toward. That is a load of crap, of course. This is why I document history as it is unfolding. When I follow the daily posts and comment about them that very day, including quotes of what was said, there's nothing to argue. It can't even be claimed that statements were taken out of context when such comprehensive documentation takes place. There's lots of detail and follow up. I refer back to the past with great accuracy as a result. Pointing out what they believed then, versus what they are saying now, is how I confirm wins & losses. It is proof of intention & change. This is why I always push so hard for goals. I can see the discomfort of being proven incorrect. They struggle to adapt and ultimately find a way to accept that undesired outcome. Assumptions about how to achieve reduced emissions & consumption can lead to a lot of conflict... as anyone who took the time to read that history related to automakers is well aware. When it comes to the parallels in politics, the same applies. If you are poorly informed or just don't make an effort to understand, you'll have to come to terms the same way. Too bad that cannot be avoided. It's inevitable. Our society needs to rebalance from time to time.

- 11-25-2019 Repeating History.** We heard from the same executive today, the president of GM, that we did a decade ago. He said the same thing too. It was quite remarkable to be reading the same reasoning for EV not going mainstream, again. He set the "*not ready yet*" narrative by highlighting Range, Charging Infrastructure, and Cost... which all sound legitimate, until you notice the information is cherry-picked. The situation was portrayed as if there were no other choices available. All of those reason had been the justification for Volt. It was to deliver an affordable solution to directly address range-anxiety. Now, he's pretending none of that technology ever existed and there's no other choice available. It's a clear effort to move away from the EREV disaster. I was astonished, since it left enthusiasts with nothing whatsoever to work with. Not only was that tech allowed to die, we now see damage-control working hard to bury it all as deep as possible. Make it go away by focusing on the future a few years away instead. It was the same evade & delay. GM over promised and under delivered to such an extreme, they don't want anyone to ever remember it happened. This is literally just like Two-Mode. All those years of propaganda followed by massive market failure. The sales speak for themselves. What a mess... and that history is repeating, yet again.
- 11-26-2019 GM Trailblazer.** OMG! The morning today started with the reading of a press-release that left me in awe. GM is introducing yet another SUV. It's another old nameplate revived, but now smaller. For size, this one will fit in between Trax and Equinox. No where in any of the hype was mention of electrification. The reveal did mention "*technology*" though, but there was no clue what that actually referred to. If you follow the link, there was online info about Automatic Braking, Collision Alert, Pedestrian Braking, Lane Keep with Departure Warning, Distance Indicator, Teen Driver, and Seat Reminder. The topic of efficiency was completely absent. I quite literally could not find any reference in any article. There's a choice of FWD 1.2 (137 hp) or AWD 1.3 turbo liter (155 hp) system. Nothing else of a technical nature was available. I suspect the MPG rating is so bad, that information will continue to be difficult to find. You certainly won't see it advertised. Comparing to a 40 MPG hybrid, there's no contest. So, the fact that GM is offering nothing whatsoever to compete with is no surprise. I can't image what happens when the RAV4 Prime hits the market this summer. Talking about not even trying. All the crapola that was thrown my way, only to have nothing to show for afterward is truly remarkable. I feel so vindicated for having documented all that in such extreme detail, seeing this outcome if the situation wasn't ever taking seriously. Ugh.

- 11-27-2019 Cybertruck Backlash.** It has been interesting to watch the backlash. Tesla's reveal of an electric pickup that can best be described as "*overkill*" has many EV supporters left wondering. How is such an extreme going to transform our fleet of guzzlers to being clean & efficient users of electricity? Rather than just deliver a truck to be a true workhorse for those genuinely using a pickup as a pickup, this is already looked upon as being an expensive gimmick. It's similar to the problem Tesla has had with "*autonomous*" driving. That has nothing whatsoever to do with being an EV. Yet, it is associated with what is at the core of Tesla vehicles. It makes you wonder about purpose. Who will these appeal to? The post-credit audience is uncertain. With Model S and Model X falling out of favor to Model 3 and the upcoming Model Y, what is the expectation for sales & market? Seeing backlash with this reminds me of when Volt changed from concept to production. That caused quite a stir, resulting in the first of several exodus events. This is why I was constantly asking the "*Who?*" question. Audience was uncertain and each supposed move forward caused it to shrink. If this will diversify choice, great. But such a design doesn't give the impression of being what a pickup should be. Remember how the SUV became a commuter vehicle?
- 11-28-2019 Some Things Never Change.** Renewed attacks with the same old claims were inevitable: "*I NEED the Real Deal, Liquid based heating AND cooling.*" Despite the reasoning becoming weaker and evidence building up to the contrary, they try what seemed to work in the past. Trouble is, the new audience isn't an gullible. Rather than blindly accept the statement, some will ask questions. The thing that has changed is they now have enough anecdotal observations to wonder why. That little bit of curiosity makes quite a difference. The troublemaker thinks they have an opportunity to undermine some more, so they push their luck... until they finally trip over a contradictory fact. Though in this case, it didn't even take that much. We've been through this too many times already. So, my reply was: Rather than better technology that doesn't need the added cost & complexity, you insist upon a work-around. That's interesting.

11-29-2019 Measuring Success. I insist upon goals, long before the product gets too involved in development. What is it attempting to accomplish? What is the scope? What is the timeline? Those are sensible criteria to measure progress. Some like to muddy the waters by injecting: "...*not exactly a fair benchmark.*" That was a conclusion drawn by an antagonist, one obviously annoyed by things not going his way. I was amused. He didn't like the bigger-picture account of why such actions have been taking place by Toyota. That comes from refusing to recognize dealers as the true customer of an automaker. It's the fatal mistake Volt enthusiasts made with GM, assuming that broker in the middle would somehow just magically embrace such a profound product change. That never made any sense. Why would a seller SUV & Pickup choices suddenly begin catering to the compact car audience? Remember a bulk of their sedan business was to fleet buyers, not showroom shoppers. Anywho, this is why I knew from the start diversification of the technology was essential prior to tax-credit phaseout... which is why seeing Corolla & RAV4 hybrids become plug-in hybrids like Prius is right on schedule. This is why "*fair*" doesn't even come into play. It is a necessity. It must happen. Antagonists don't like that, and I knew this one would be especially frustrated by this: There's no benchmark. It's a cold, hard reality of business. Profit is required, period. This is why the early-adopter stage stirred little interest from dealers. They wanted nothing to do with subsidized sales. This is also why raising doubt with arbitrary measures and injecting uncertainty by pretending prior discussions never took place remains an exercise in distraction. Watch what happens. Toyota's slow & wide approach doesn't appeal to some, so those upset spin stories to make it seem there's only a single path to success, one contrary to Toyota's success model... hence a meaningless benchmark.

12-01-2019 Getting It Wrong. Coming across articles with facts or purpose or expectations mixed up is... sadly... quite common. Today, it was: "*The legacy automakers are trapped in the famous Innovator's Dilemma. They want to embrace electrification, but they're afraid of driving customers away from their profitable existing products...*" I don't know if the writer heard that term and didn't bother to confirm it was defined the way he thought or he simply needed something to submit for publish. Needless to say, the content didn't make much sense if you were well informed prior to reading that mess. This is the garbage we have to deal with the damage from for years to come. Some such mistakes get passed along so often, they become a perceived truth eventually. It's an unintentional narrative. That happens a lot when some aspect of the vehicle's operation is taken out of context. To see the entire "*electrification*" topic be portrayed in such a misleading manner, it's difficult to know what will come about as a result. There are hints of a paradigm-shift. That's the potential of getting caught unprepared... a really bad outcome of getting it wrong. Think about what could happen when at some point plugging in gets a nod of acceptance from some unusually influential source. What will consumers demand then? What will dealers be able to supply? The key is being prepared, having a variety of responses prepped and at the ready. This is how I jumped into the discussion with all the comments being posted for the article: That is actually avoidance of the Osborne Effect. The trap of innovation is what we witnessed with GM from Volt. Instead of the next generation becoming more mainstream, it appealed even more to a niche... hence dilemma. Drawing a wider audience is difficult, but absolutely essential and best prior to subsidies expiring. Tesla did a fantastic job with that for Model 3, taking advantage of the unlimited quantity during phaseout. Toyota is now setting up to do the same with the Prime models.

- 12-01-2019** **Blizzard, No Plug.** The long & late Thanksgiving holiday weekend provided a great opportunity to observe behavior when being parked outside for 3 days without being plugged in. We had a blizzard pass through, at my in-laws in Wyoming. When I booted the system, it fired up without running the engine, all electric. Outside temperature was 18°F. Battery-Pack temperature was 17°F. Battery warming clearly doesn't go that long (I believe the longest duration is 48 hours) and only does a high setting when you are plugged in. Nonetheless, it was still using only electricity. Sweet! With so much Winter to come still, I'll have plenty of opportunities to observe, noting more detail. I started the engine by pressing the HV/EV button. After 5 minutes, snow was already melting off the windshield. I turned on MAX defrost. The rest was gone quickly. At the 10-minute mark, I switched to Charge-Mode. It worked fine, despite the battery-pack still being cold. After charging up a few percent, with the cabin toasty warmed and all the windows cleared, I shut everything off. That worked great!
- 12-02-2019** **No Demand.** That article sure stirred up a lot of rhetoric. That was expected though. Enthusiasts were forcing the "*EV Market*" perspective, which was clearly defined by early-adopters taking advantage of the tax-credits. So naturally, their point-of-view was one of high-demand with great potential. The very idea of addressing possible setbacks as a result of that generous subsidy disappearing was "*anti*" talk and nothing more an effort to show favor for inferior designs. Ugh. They clearly didn't understand how low-hanging fruit works. That initial surge of interest rarely persists. Some type of resistance always comes about. If upgrades are planned accordingly, the reach out to a new & wider audience can be just fine. However, it could also result in no demand. The catch is understanding & recognizing the entire market as a whole. There's always some form of barrier. You just need to properly identify it. What will the other automakers be doing? A saturation of supply could really mess up pricing. Heck, even the messaging can become confused with too many choices. As much as I try to point that out, it usually gets dismissed: Know your audience. Dealers are who Toyota interacts directly with. How many of them are requesting EV inventory? The answer is very few, hence taking another means to reach the same end. Several choices of Prime (Prius, RAV4, Corolla) will bring about their interest. That's the reality of the sales market... much to the chagrin of early-adopters.
- 12-03-2019** **Taking Bait.** There's that subtle hit the reset, while at the same time attempt to discredit the messenger: "*Perhaps you should share that wisdom instead of playing cryptic sensei, and less people would brush off what you are trying to say.*" We've come full circle. The spin has caught up to itself. That repetition is how you know there's nothing more to extract. I do take the troll bait from time to time as a confirmation, just in case: I have already, several times. People have a way of conveniently forgetting when each new thread is started. The nature of these exchanges is for the RESET button to be pressed, preventing conclusions from being drawn. That's how they keep their favorite discussion topics alive. Ironically, some of the same individuals complain when I repeat myself. In other words, I don't take the bait. My suggestion to you is to ask a specific question instead.

- 12-05-2019 Retrofit.** Lots of questions are now being asked about the possibility of existing newer models being able to get Android Auto. Software upgrades of that nature are new territory. It's opportunity for automakers to explore. Toyota is very much part of that now. That's why exploration of a \$199 retrofit program is taking place. Will it cover expenses? Is the process easy enough? And how many takers could there be? So many questions. Very few answers. It has been done before. That's how I got cruise-control in my 2001. It was a feature intentionally withheld, a means of filtering out all but the most dedicated. Toyota wanted die-hard supporters to purchase that very first offering. After getting it, they ended up providing a kit to add the feature afterward for a reasonable cost. That could happen again with this.
- 12-06-2019 Demand Spin.** Finally, something more than just hearsay: "*Toyota's Biggest Problem Is Keeping Hybrid Car Models in Stock*". That article pointed out the overall growth at dealers, despite the change-overs with Prius. There really is a transformation taking place with mainstream appeal. When the country's top-selling SUV is available as a hybrid and history's top-selling car of all time is also available as a hybrid, that shift in interest is a simple one to understand. It's pretty much impossible to counter too. This isn't an argument against hatchback. It's an obvious new appeal for ordinary strong sellers, RAV4 and Corolla... both long-standing profit-providers with names so common, they truly represent mainstream purchases. We knew someday this would come. It's that balance of cost/payback. The equation is sensitive and varies. But the line kept drew near, since the technology continued to evolve.
- 12-06-2019 Marketing.** There are some who participate online that still don't understand: "*make a product that people want, instead of what you think they need.*" I don't expect my response to make any difference in that regard: That logic is exactly what contributes to the problem of Innovator's Dilemma... which is the very problem Volt died from. The spin online about that not being the case is good reading too... so much damage-control effort for such an obvious mistake. GM chose to focus on enthusiasts, asking them what they wanted... rather than finding out what mainstream consumers actually needed. That created a highly specialized gen-1 Volt. They repeated the same mistake for gen-2 Volt. It became such a much praised niche, but actual sales were terrible. Thinking a want is what they "*need*" is a very real issue. There was so much justification in the past for Volt, based on marketing, not the actual recognition of necessity. True requirements are a solid measure. People turn a blind-eye to that data.

12-06-2019 **Strategy.** Sometimes, it just goes on and on: "*Toyota vs. electric cars: Smart strategy, or Innovator's Dilemma?*" That article has been republished and referred to several times. It's how the rewrite of history takes place. You just keep pushing an idea, leaving out detail. The narrative eventually takes hold, but never really gets a strong following due to the lack of substance. Oddly, it can still be advantageous. I jumped on that opportunity to raise awareness: That's smart strategy. It's easy to recognize the difference. Just look at tax-credit dependency and the diversity of product. GM exploited conquest sales, wasting the subsidy opportunity for that rather than establishing a profitable & sustainable base. In other words, they innovated for enthusiasts instead of focusing on their own base. That is exactly what Innovator's Dilemma refers to. Toyota did the opposite, directly targeting showroom shoppers. We see Corolla & RAV4 hybrids being sold so fast, keeping them in supply has become a challenge. This is why Toyota is switching over their Camry production in Kentucky to RAV4, which has capacity to deliver 500,000 annually. That will become a vital part of meeting RAV4 Prime demand. It will be high-volume sales Toyota's core buyers. No part of that is a trap of innovation. Notice how GM never spread their technology?

12-06-2019 **Damage Control.** I'm seeing a rise in antagonist posts: "*...but the damage-control phrase is too vague understand what it may apply to. Sorry.*" When that comes from someone you know you have already had this discussion with many times, it's pretty clear their motive isn't sincere. They tend to be polite trolls, those who are respectful of others but absolutely refuse to be constructive. This just spin & evade to keep the posts coming. When it comes to Volt specifically, that is literally all they have left. There simply isn't anything else remaining. All other excuses have been exhausted. Production ended and GM has no intent to do anything more with their investment. They are writing off the effort to blend engine & motor & battery as a massive loss. They'll take what they learned with regard to the motor & battery part and abandon engine entirely. That's an incredible gamble. Expecting existing customers to make the jump directly from traditional guzzler to EV is a massive risk. How will they get dealers to even just start with a modest inventory? Who among their salespeople will want to try to sell such a dramatic platform change? That's far more than the usual paradigm-shift more enormous industry players can handle. With so much profit at stake and so many customers (their dealership network), reaching their consumers with a clear & concise message seems nearly impossible. GM has done a horrible job with that in the past. People still don't really know what Volt was intended to address... hence the damage-control. Spin like that wouldn't come about if the goal had been obvious. Duh! How many times in the past did I try to point that out. Ugh. Oh well. They are dealing with it from the point of failure now: Detail has been posted countless times. Volt needed to achieve sustainable sales prior to tax-credit phaseout; otherwise, production would be cancelled. Since that's exactly what happened, any excuses now are damage control. Even worse is the technology itself became too much of a niche... hence Innovator's Dilemma. That most definitely isn't the case for Toyota. We're seeing the Prime tech in Prius being deployed in both Corolla and RAV4.

12-07-2019 This Next Stage. Following a very argumentative discussion, a topic that drew it the usual trolls, I tried to wrap up days of efforts to prevent closure using this: *"The big take away from that chart is that the Tesla Model 3 is crushing everyone. AND sales are increasing even as incentives are decreasing. Talking about everything else is like discussing the deck chair positioning on the Titanic. No?"* His post was intended to bring a constructive nature back to the forum, so we could actually draw some type of conclusion. I took full advantage of the invite:

Ironically, using an analogy to Titanic is quite fitting, but not the message you were trying to convey. Tesla could be compared to Titanic surviving the iceberg hit, not sinking and actually making it to port. It's just a single ship arriving to the destination at great expense. That's why my push to get acknowledgement of the bigger picture continues to get the positioning of chairs response.

KNOW YOUR AUDIENCE requires looking at the entire fleet and all of the use that will actually occur, not just a single trip. In this case, that's what GM failure with Volt was all about. They gambled everything on a single vehicle. It was pretty obvious how desperate enthusiasts were to force narratives to the contrary too. When the potential for Camry hybrid with a plug was brought up, they'd attack the messenger. Then when RAV4 hybrid came along and the second generation of Volt fail to grow sales, the hostility was raised more distractions raised.

Tesla was the easiest distraction to focus on. It relied upon lots of venture capital, money from green credits, and heavy utilization of subsidies... none of which could be sustainable. Fortunately, excitement about the potential remained strong. But now with less than 4 week left of federal monetary encouragement (the sales boom resulting from the unlimited phaseout stage), the question of sustainability becomes all too real. Innovator's Dilemma already played out with dire consequences for GM. The outlook for Tesla depends upon breaking out beyond the single-product reliance, especially since that AUDIENCE could just be low-hanging fruit... the EV market... not mainstream consumers.

That brings us to the main topic, addressing that bigger picture. How will GM building a battery factory change the situation with potential for market saturation? In other words, who is being targeted for selling those resulting battery-packs?

We keep hearing the narrative of Toyota focusing intensely on hybrids but ignoring the reality of dropping sales for Prius. That's a cherry-picked perspective. It hopes you won't notice both the regular Prius and the Prime model were undergoing mid-cycle updates, consequently there being little inventory made available. Waiting until 2020 for that new production to ramp-up, timing it to coincide with the availability of the introduction of Corolla hybrid, rollout of the next-gen RAV4 & Highlander hybrids, and the reveal of RAV4 Prime.

That is what's called a well thought out coordination of fleet change... because it so nicely matches up with both the ending of tax-credits for both Tesla & GM. Think about the position Toyota will be in for Earth Day 2020.

With all that change carefully orchestrated to directly target their own showroom

shoppers, it sets the stage nicely for a turn to dedicated EV designs. The technology itself will already be deployed in the 3 plug-in hybrid models (Prius, RAV4, Corolla) while the EV models of CH-R and UX300 make their debut. It represents a moving forward of a wide variety of choices. You won't be forced to decide upon that single offering designed specifically to appeal to enthusiasts of the past.

Read through all that history of spin and now damage-control if you want good background. It isn't necessary to understand what this next stage involves though. All you have to do for a clear look forward is to consider what the sellers will actually sell.

12-07-2019 **Downplay.** This came from an antagonist: *"Every manufacturer has been cutting models, even if just because there are fewer buyers now."* He's basically a troll who has been accepted as a regular forum member, despite very frequent posts of an argumentative nature. I suspect he thinks of himself as a devil's advocate. His endless upset doesn't fit the profile though. He continues to be vague too, which is a sign of not being objective. I was intrigued if a vague reply in return would stir anything constructive: Add "downplay" to the types of responses. You continue to treat GM's failure to use the tax-credits as intended as if it was no big deal. They were squandered on conquest, rather than establishing a new technology for their fleet. It was a big waste. Not only isn't Toyota doing the same thing, they haven't used up their tax-credits yet. In fact, they are positioning to take advantage of the phaseout stage just like Tesla did. That's a very, very big deal. Again, it's about each manufacturer targeting their own loyal customers to advance their entire fleet to greener choices, not to earn trophies and gain praise.

12-07-2019 Stage Confirmation. That article got so much attention buried within an somewhat related discussion thread, it was freshly posted in the news section of the forum. That should attract new participants, hopefully more than just the trolls who were exploiting it. This is what I posted as the first comment in that new topic venue:

Misconceptions tend to emerge when a new market stage begins. That's easy to identify. A new audience is drawn to the technology, which is exactly what we are witnessing now.

In the past, we saw that with "*hybrid*" technology. There were countless incorrect assumptions, some fed by intentional efforts to mislead. People didn't understand and would often fall victim to simple answers to there questions, accepting the information at face value rather than questioning it. Lack of detail makes the situation worse. You end up fighting for years to debunk preventable problems.

We are seeing the same thing happen with "*Innovator's Dilemma*" claims. Most don't actually know the full definition. They just hear about the challenges related to adopting new technologies and don't dig any deeper. Assumptions abound from there. You end up with scores of misunderstanding to address. Ugh.

In this case, the dilemma is more involved than just what the technology itself seems to present. Success from innovation comes about from catering to a desire. You ask enthusiasts what they want, then build to satisfy that criteria. When the next generation design opportunity comes about, the manufacturer is supposed to reach out to other audiences.

The reason for this is simple. The manufacturer must switch from proving the technology to making it appeal to a much wider market. This is where GM failed with Volt. The gen-2 design became even more specialized, targeting only niche buyers. GM's own loyal customers were not interested. The technology became a dilemma.

That most definitely isn't the case with Toyota. We already see the hybrids taking the next natural step, to offer full EV driving. The addition of a plug and much increased battery-capacity (with resulting power increase) is already taking place with Prius, Corolla, and RAV4. That's a clear demonstration of the technology not being limited to a particular audience.

That "*Prime*" technology can also be used in the next step to follow, going from plug-in hybrid to electric-only, since many of the components are shared. The motors, controllers, battery-cells, and even the heater & cooling are all on their way to becoming high-volume & profitably produced... which is the goal, not a dead-end as the "*dilemma*" is believed & portrayed to be.

It's really unfortunate we have to deal with such misconceptions, but not at all a surprise. They are what comes about when a technology advances forward. In fact, that's how you know a new stage has begun.

12-08-2019 Winter Questions. It's nice having a collection of video to share that provides detailed answers for those wanting to learn more about cold-season operation. This is what I provided in that regard to today's questions: That battery-heater alone is reason to stay plugged in during "extreme" cold. For those who experience intense winters (for me, that's Minnesota), it means the plugged-supplied electricity can be used far more than you'd expect. Notice on the following video how, despite the outside temperature of -1°F (-18°C), the battery-pack is kept at 55°F (12°C). That means it can be taken advantage of still. Watch the % for the charge-level in the detail provided by the following video: [Prius Prime - Extreme Cold \(commute home\)](#) The coldest extended duration I have experienced without plugging in was Christmas 2017. We were out in Wyoming celebrating with family. Sitting there for over 8 hours in -9°F (-22°C) unassisted meant only minimal electricity from the battery-pack would be available. (Lithium chemistry experience a increase in resistance when its temperature drops below freezing, hence heating it for better draw & charge efficiency). The system started just fine. I obviously let it warm about for a few minutes before driving, but there was nothing else special needed... only some patience. For those who experience ordinary winter, the battery-heater means you'll be able to squeeze out as much electricity efficiency as possible. You still driving in full EV mode until the entire EV capacity is depleted, as this video shows in detail: [Prius Prime - Cold Commute thru Minneapolis](#)

12-08-2019 Posting Battles. Scope is changing. That really throws those who haven't moved on. They argue a perspective without anything to gain. The just like to win online. I suspect some simply aren't aware of that pointlessness. For example: *"That argument about subsidies is old. Maybe you could have claimed that in 2018. But as the subsidies have dropped in half twice Tesla is still production constrained..."* Evidence of outdated audiences & objectives is abundant. So, these posts are to just summarize the history:

Age of an argument doesn't make it any less relevant. In fact, that constraint doesn't even address the bigger problem. Being able to more easily supply 150,000 to 200,000 vehicles per year still very much means Tesla is trapped in the *"EV Market"* rather than moving to the next stage of sales... which is what this discussion is supposed to be about.

That next stage is being able to supply several vehicles annually at that capacity. In other words, the goal moving forward is to achieve greater penetration into the mainstream. That's why the tax-credit was such a feared barrier, no one wanted to discuss it. In fact, that's why so many *"EV Market"* arguments took place. People put on the blinders and didn't want to admit 200,000 per automaker over the course of 10 years was so tiny of a volume, it only served the purpose of proving the technology.

Tesla has very, very successfully proven the technology. Kudos to them for that. It's exactly what Toyota needed for them to take the next step. Because the business reality was, Toyota needed an endorsement from another major player for the entire industry to move forward. But now, it gets difficult for everyone. Each automaker must figure out how to reach out to a much wider audience, maintaining reasonable supply while also delivering a reasonable profit.

In other words, stating *"old"* means acknowledgement of what *"new"* represents. The big automakers sell several 150,000 to 200,000 vehicles per year. For perspective, there were 2,129,385 Toyota brand vehicles (which doesn't include Lexus brand) purchased in the United States last year. Think about how difficult selling plug-in models on any type of meaningful scale (representing noticeable change at dealerships) will actually be. Put another way, upping the game is going to be far more challenging than just winning some online posting battle.

- 12-08-2019 Better Chargers.** I see quite a bit of effort being expended to justify sticking with the standard 120-volt charger that comes with Prius Prime, rather than considering an upgrade at some point. There are things that make a 240-volt charger better. That rarely gets attention though... mainly because those leading the discussions don't have one. Lacking that experience, it is somewhat of a bias claim. And of course, there's the shortcoming of not being able to support a second vehicle. One standard outlet is fine, but you'd have to be lucky enough for it to be one with an higher capacity (20-amp wiring) and be willing to tolerate slower recharges for both vehicles. In other words, upgrading at some point is inevitable. That's why I keep pointing out that any type of future subsidy should focus on infrastructure, not the vehicles. Anywho, this is what I posted to at least keep the discussion somewhat flowing: People overlook the basics. Sure, the standard charger can handle the load, but only under controlled circumstances. That's why there is no recommendation for extension cords. Even if you use a gauge large enough to support maximum draw, it doesn't mean the outlet it is plugged into is actually properly wired for that. It also doesn't mean the charger will be safe from whatever it will get exposed to while being used and not used. That's why the point of some of this is moot. Who will accept liability if something goes wrong? 240-Volt certified chargers provide heavier & longer cords with weather-resistant cases and mounting brackets.
- 12-08-2019 Keep Digging.** A handle of antagonists have hung around, preying on those unaware of their efforts to undermine. But when it comes to me, it's an effort to misrepresent: "*Oh Myyyy, how does one put a positive spin on the above toyota fact?*" It's the same old nonsense we've seen for decades with green transportation and now gets daily attention in the political scene. They sight debunked claims as being uncertain, confuse the topic by introducing red-herrings, and attack the messenger. I find it all quite amusing at this point. For a Volt enthusiast to still be fighting, it's rather senseless. There are no more battles to stage. That war has been lost. So, I watch posts like this with curiosity of how much deeper he will continue to dig himself. It is already hopeless. Production has ended. GM has no intent to spread the technology. Lack of a successor means it's over. EREV is dead. Of course, that was a meaningless term anyway. The definition changed every time the rest of the industry moved forward. This is how I dealt with his obvious provoke: Efforts to avoid addressing specific issues directly related to this topic are very, very telling. LIQUID COOLING is one such issue. You absolutely insist it is a necessity. I point out that is really just a work-around until more robust & affordable battery-chemistry becomes available. It makes no sense to endorse added cost & complexity long-term. You also shoot yourself in the foot by making that assertion of need. With such a requirement, it forces a large & inflexible pack design. Being able to distribute stacks of cells for better weight distribution, better physical fit, and better accessibility isn't possible. You become stuck by limitations of your unsubstantiated claim. Keep digging. Each negative spin response for more rebuttal material to help reveal shortcomings & motive.

12-08-2019 **More Digging.** Continued attacks tend to result in some type of revelation or summary. He just kept trying to spin any way he could to somehow bring down my credibility. That's a common response. Basically, they just try to confuse the matter to the point of you struggling to convey any type of concise message. Quite the opposite happened with my. It solidified my argument points. It's an involuntary debate, where their engagement strengthens my stance while weakening their own. That pretty much happens every time, since most arguments lack substance. They end up with nothing to fight with and reinforcing my stance. In this case, I got a nice list to use later for just such encounters... since they will inevitably repeat:

Nope, that's your spin to evade addressing what I actually stated. My comments were about long-term approach...

- reduced cost
- reduced complexity
- better weight distribution
- better physical fit
- better accessibility

Keep digging.

12-10-2019 **Purpose?** Posts like this are interesting: *"If I'm really only getting 25 miles of EV for my electricity \$\$, I'm better off just running the car in HV mode all the time."* It's the same old generic math we've seen for 20 years, with no awareness of what actually happens as you drive. From a pure financial perspective, you're never better off purchasing a new vehicle anyway. There are tradeoffs, of course. But those don't get addressed. I try to point out the basics. Many people posting comments like that have already made up their mind, so there isn't much sway opportunity. You can enlighten others in the process though. That's why I try to formulate a short & sweet response with the hope to provide some type of thought-provoking info: Didn't you purchase your Prime to also make other people better off? There's a very real benefit from using less gas and emitting fewer emissions, even if you can't equate it to a monetary value. You'd be amazed how much your small contribution to a larger cause really adds up.

12-10-2019 Green Halo. I always got a kick of that term. What it meant was an automaker achieved the image of being green and that helped them sell their fleet of non-green vehicles. The fact that Toyota actually sold hybrids negated the claim. There were indeed green. Change on the dealer's lot was genuinely happening. Camry hybrid and Highlander hybrid purchases were happening regardless of what happened with Prius. It was real, not a halo. Some try to interject Tesla into the legacy automaker equation as if that somehow also applied. That makes no sense. Tesla was 100% green right from the start. It helped pave the way, not create barriers as this twist claims: *"They allowed a newcomer to the industry to steal that away from them. This stumble will cost them. They could have sold a Prius EV in half or less than the quantity Tesla has sold Model 3s in the last year and maintained their green halo."* Confused? It's a jumble of messages requiring a forced perspective. You must believe there are only winners & losers, nothing in between... that all EV buyers are the same and have the same wants & needs. Ugh. I fired back with:

The situation isn't zero-sum. The market doesn't work on a micro level either. This is a macro-economic change, requiring multiple players. None of the big ones wanted to play along though. GM, Ford, Chrysler, and VW all chose to resist in some manner and did so for 2 decades. Tesla filling in that void provides exactly the type of ally that has been needed. This is why *"know your audience"* is such a vital part of the equation.

Many will argue until the cows come home that top-down & bottom-up approaches cannot co-exist. Reality is, they are complimentary. That's why so many online battles are pointless. That's why claims of *"behind"* are words of rhetoric without substance. What cost is there to taking the time to ensure they are delivering change their dealers will embrace? Rushing to market without a robust, profitable, adaptive set of technology advances is not how attract mainstream buyers. In other words, following a belief that not capturing the early-adopter market represents a huge loss in the realm of appealing to ordinary consumers is futile. The *"halo"* remark confirms a mismatch. Who does RAV4 Prime target?

12-10-2019 Media Misrepresentation. Pushing a narrative to draw interest to your website is common. Using online articles to stir activity is nothing new. Ages ago, we'd see articles about Prius from enthusiasts magazines having no interest whatsoever in that type of vehicle. They knew it was a new audience with potential for a lot of growth, so they tried to capitalize on it. Nowadays, it's no where near as obvious of a membership mismatch. For example: "*As the article on Innovators Dilemma says, Toyota is marketing the RAV4 hybrid as a upgrade and not stressing the MPG. So if it is perceived that way, their strategy is a success.*" I was drawn to a green website posting that without any reference to what green represents now. They should be well past MPG at this point, focusing on kW, kWh/mi, and emissions. Oh well. Supposed "*journalists*" are usually just writers getting paid by the word. True in-depth investigation requires comprehensive reporting, not just a fluff piece with buzz words. This was my reply:

The catch is, there is not an innovator's dilemma. It's a perception being portrayed by not looking at the bigger picture. The example of "*not stressing the MPG*" provides evidence supporting that. People already know what HYBRID FROM TOYOTA means. There isn't anything to stress. There isn't even anything to advertise. The technology has become so ubiquitous, nothing needs to be said.

It's as elementary as knowing "*there's an app for that*". Nothing else needs to be said. The technology involved and the anticipated benefit has become knowledge so common, you're just wasting time putting any focus on it. Remember, advertising a complex product means focusing on what the potential customer doesn't already know, not sighting the obvious.

As for success, you must know what the goal is. Toyota currently has their desired take-rate set in the 20% to 25% range for RAV4 hybrid.

12-10-2019 **Seems.** My response to that interjection of Tesla from that effort to force a look at the here & now, rather than consider the bigger picture and impact to the market along the way, wasn't taken well. He just blew it off with: "*And yet, it seems that none of them have taken advantage of it.*" I liked his lack of commitment. Unwillingness to take a stance based on a concise goal or a wide perspective is nothing new. That's how I end up butting heads with even some supporters sometimes. They end up feeding a narrative by not taking the time to really consider what's being portrayed by their stance. What message are you trying to convey versus what people are actually hearing? I provided some perspective to that with:

Like I said several times, not recognizing the bigger picture... Your use of "*seems*" is encouraging.

Toyota is very much taking advantage of the situation, it just isn't obvious to those still viewing sales from the "*EV Market*" perspective. That's a tough habit to break. Dealing with mainstream consumers is far more difficult than early-adopters, so the tendency to not realize you've walked into that trap is understandable. It's why so many have misidentified the stage as Innovator's Dilemma. Toyota is simply waiting for the cycle to end. After all, it was very predictable.

Tesla did a wonderful job of using the opportunity to their advantage. Once passing the 200,000 threshold and triggering phaseout, they worked hard to deliver as much supply as possible during the unlimited period. It clearly worked to their benefit too. But that is just about over and what comes next won't be easy.

GM simply just gave up. Almost all of their tax-credits were squandered on conquest. It was a terrible waste of opportunity. Rather than using the subsidy to actually change what happens at their dealerships, Volt was just used for attracting one-time buyers who have demonstrated no loyalty. Sales fell apart. There was no audience to focus on when their phaseout was triggered.

Toyota still has quite a few tax-credits available. They are setting the stage for dealer's wanting lots of Prime models to sell. RAV4 will lead the way with a very nice Prius following. It will be a chance for leadership which other automakers will feel sucker-punched for not preparing to join in for... except Ford, who sees strong potential plug-in hybrid SUV offerings.

The market is being primed (yes, I know) for a paradigm-shift and infrastructure just plain is not there yet for EV support. We see it everyday with shortcomings from existing charge-stations. Fortunately, that will change. It is quite realistic to get what's needed in place. The catch is, that will take a lot more time & money than the "*EV Market*" wants to recognize.

Practical. There are always a few who try to be the voice of reason, keeping topics constructive & civil: *"If you can't say something nice, don't say nothing at all. GM fails are legendary."* But to actually move on, achieving closure and sharing a message of what was learned, you have to sometimes tell it like it is. Ironically, not doing that can bring about a next stage anyway. That's how the mistakes of Two-Mode were passed along to Volt. Rather than understanding that history, working to prevent it from repeating, a group of enthusiasts unwilling to open their minds set the stage for failure again. Ugh. Telling them doesn't do any good either. Some are just don't want prior experience to tarnish unrealistic hope. Again, ugh. This is what I said to that:

That's how rhetoric with Volt began. I pointed out the pattern emerging, how its approach resembled that of Two-Mode failure. Supporters became upset, turning a blind-eye to such information... becoming enthusiasts, enablers for history to repeat.

This is exactly why Toyota's schedule is the way it is. They went out of their way to avoid GM fallout. Every time the topic of adding a plug to Prius came up, there would be a hype reference to Volt. Despite lacking substance, it simply wasn't worth competing with propaganda.

Toyota simply refined the technology while waiting for that to play out and for the market to finally recognize that to keep their large & powerful vehicles, they must also embrace a practical means of making them far cleaner and much more efficient.

12-11-2019 Restart. This sound familiar...? GM just stated they will be putting heavily emphasis on SUV sales to create enough profit to fund their EV program. That's exactly the story we got over a decade ago for Volt. Literally, nothing has changed. It's the same old excuses, again! The stupidity of not evolving the technology in Volt for use in Equinox goes so far beyond sensible logic, it's crazy. The next-generation of Two-Mode was actually supposed to be that. But instead of rolling out that prototype Saturn Vue with a plug as some type of production configuration to enter the EV market, the path of pursuing Volt was chosen instead. That provided a buffer of time. Using that time to build that Equinox with a plug would have justified the delay & expense; instead, the entire program was abandoned entirely. We are now seeing what essentially appears to be a restart. Rather than take the next step, move backward to make the next few years appear to be productive. Remember all the rhetoric about GM being the industry leader and Toyota being an entire decade behind? That's all nonsense. Toyota will be delivering a RAV4 with a plug this Summer, roughly 6 months from now. GM is still many years away from offering even just an Equinox hybrid. They had Tahoe hybrid over a decade ago, then killed it. They had Volt, then killed it. Now they have Bolt, but do nothing to promote it. Using the excuse of generating profit for EV development by pushing traditional SUV guzzlers is pathetic. Look at how well the RAV4 hybrid is selling.

- 12-12-2019** **Outright Lies.** We are seeing false facts being pushed around in the political world so much, it is becoming normalized. We have embraced corruption. Rather than actually consider the detail, we choose rhetoric. For example: "*The Prius used to be the best most efficient car on the market, now it's no where close.*" The hope from that is the reader will be too lazy to consider what "*efficient*" really means. Rather than being a measure of energy consumption, it is portrayed as just raw MPG numbers. That's the same type of deception we got from diesel antagonists. They'd misrepresent overall efficiency for only the value that came from only highway driving and only with a manual transmission. So even without taking into account emissions, the narrative came out to be the diesel was a better long-term strategy to pursue. That gas overwhelmingly been proven false. The latest hybrid tech achieves much higher MPG than diesel. Anywho, the measure of EV efficiency uses "*kWh/mi*" measures instead. The same type of deception can be used to mislead to. Omitting certain routes & temperatures will portray a false narrative. You have to start somewhere though. And in this case, it's as simple as calling out outright lies. That one number provides a basis of stirring constructive discussion. In this case, the person posting the comment abandoned the thread. He got caught attempting to mislead. This is all it took to point that out: 25kWh/100mi is among the highest efficiency ratings for EV propulsion. Your "*no where close*" claim is just plain not true, as that value clearly confirms.
- 12-13-2019** **2020 Highlander Hybrid.** Toyota's push for hybrid technology unmatched by others is obvious with this newest reveal. It will be built in Texas, making it more American than so many other supposed domestic products, it's rather remarkable. Anywho, the efficiency rating jumps from 28 MPG with the previous generation to an amazing 34 MPG. This upcoming new generation uses the TNGA platform Toyota has been working hard to deploy across a wide variety of vehicles. In fact, the upcoming goal of 80% will soon be reached, right on schedule. Anywho, this rather large SUV hybrid with a 3,500-pound towing capacity will have a starting price of \$34,600. How will the other automakers compete with that? GM certainly won't come even close. Ford may have some worthy technology, but will it be a true contender in a market Toyota dominates? Being able to simply trade in your old Highlander for a new hybrid model is an easy approach Toyota dealers will likely embrace with little hesitation... especially with the success RAV4 hybrid has already solidified. We're beyond the establishment stage. Hybrids are the new norm with plug-in variants leading the next stage. That's exactly what has been needed to reach the audience desiring a large family-mover. It's a bit of a surreal moment to consider in automotive history. This hybrid will deliver quite a bit higher efficiency than family-movers of the past. Remember last year's model of minivan?

12-14-2019 **No Consistent Message.** The damage-control continues: "*GM Was Right to Stop Making the Chevrolet Volt*" Turns out, there are quite a few more hidden enthusiasts than expected. They keep feeding editorial opportunities with articles of that nature. Following that title, was this opening statement: "*As a Chevy Volt owner for over seven years, I completely understand why many Volt owners are upset at the news that GM was cancelling the Volt and not pursuing any other Voltec-based vehicle platforms.*" It's a never-ending effort to spin the past, in this case, portraying a stance they didn't actually take until the end was obvious. I got attacked relentlessly for saying the very same thing. They felt it was really a clever scheme to dilute Volt. Putting the same system in a vehicle like Equinox was a terrible idea as far as they were concerned and that sentiment went on for years and years. Needless to say, I want to know more about what brought about their change and how far they will go to conceal how they were once against that very idea. This is what I posted on a discussion thread about the article:

That got me really curious. With so many excuses exhausted and those doing damage-control in such deep denial about how poorly their defense strategy is working, what could he possibly say in a positive manner?

It started out fairly well, sighting "*Chevy Volt Cost Too Much To Build*" as a primary reason. But that was an internal perspective, nothing with regard to the rest of the industry. Then, I got to this: "*Undaunted, Voltec proponents also point to Toyota's plug-in hybrids as evidence that GM could apply the Voltec platform to larger vehicles.*" Then it went on to claim: "*The problem is, Toyota's HSD is fundamentally different than the Voltec system.*" That got me yearning for detail, which didn't follow. Instead, it was: "*Toyota's plug-in hybrid system is designed to run off the gas engine under all circumstances but off the electrical propulsion system only under limited circumstances. That's the exact opposite of the way the Voltec system works in the Chevy Volt.*"

In short, the turn to misleading and outright lies has taken the spotlight. That's the same desperation I saw years ago. GM couldn't compete legitimately, so their minions was spread false information instead. Ugh. The conclusion got even better: "*In other words, in order to achieve what Toyota is doing with their HSD, GM would need to fundamentally change the Voltec architecture. It would lose its essence as an electric vehicle powertrain with a gas generator backup, and it would become just another hybrid.*"

That was great. It showed that even a long-term owner really didn't understand how his own vehicle's system was actually designed. Volt's engine was never just a "*gas generator backup*" as BMW's i3 overwhelmingly confirms. Of course, Prius Prime does too. It delivers up to 84 mph using just electricity. How can that not be "*essence as an electric*" operation? The engine doesn't start until battery depletion. Reading the comments, I saw perspectives all over the place... which revealed what was really at the heart of GM's decision to stop. There was no consistent message. Even after an entire decade, people still had no idea what GM was hoping to achieve.

12-16-2019 Business Perspectives. These two statements made today were fascinating. GM CEO Mary Barra: *"GM believes in the science of global warming. We believe in an all-electric future. It's not a question of if, but when."* Toyota EVP Bob Carter: *"Somebody's got to buy these things. I've been saying we're going to see electrified armageddon. Because of the cost premium, supply is going to get ahead of true customer demand."* Notice the difference? GM's perspective continues to be a vague statement of green intent without any substance. It's the same ambiguous garbage we have been getting since way back when Two-Mode was still in development. There's an apparent commitment, but no sense of being in touch with the actual market. It's a belief of the *"if we built it, they will buy it"* mentality being realistic. Remember how well that worked with Two-Mode, Volt gen-1, Volt gen-2, and Bolt? Each has been an incredible example of what not to do. Business mistakes have been plentiful. So to earn trust of this next effort being different, we actually need to be told something. That complete absence of substance is reason for concern. Toyota sees this... and has been getting a lot of flack for adapting accordingly. 17.8 kWh is the expected capacity for the battery-pack in the upcoming RAV4 Prime. Why is not being an EV portrayed as a shortcoming? It is far enough to cover my entire commute, both directions in Winter driving. So what if that all-electric driving experience is limited to 39 miles for the sake of being competitively affordable? Ugh. Think about what sales will become if VW really does saturate the worldwide market with 1 million EVs per year starting in 2023. Combined with whatever GM will supposedly produce along with Tesla, it becomes a real paradigm-shift without any means of stimulating change. What will be the incentive? Reading online sentiment with regard to cheap gas and climate-change conspiracy, where will demand come from? Remember, each of these EVs will require a dedicated 240-volt charger (a 40-amp line will deliver 200 miles in 8 hours) for realistic overnight charging. That alone is a major barrier for mass acceptance to overcome. RAV4 Prime won't necessitate that. With an ordinary household 120-volt outlet, you'd be pushing limits of available time with a 12-hour recharge, but it would work for initial ownership. The upgrade to 240-volt charging could come later. It would not be a sales impediment. In other words, pressure won't be on Toyota dealers the way it would be for GM dealers. It is recognition of the fragile balance of supply & demand. That's vital for good business.

12-17-2019 Upgrades At Home. Every time the victim-card is played, claiming Tesla & GM are victims, I feel it necessary to point out a great purpose. Money to fund change should be focused on the more meaningful efforts. Doesn't it make sense to help a homeowner upgrade their home to support every plug-in vehicle they will own over the next few decades rather than just use that money for a single vehicle purchase? I don't understand why more people don't see the value of having a 240-volt connection available for charging. Benefit from investing in infrastructure should be obvious. What you setup now will be used for many, many, many, many years to come. So when I see articles with a title like this, you know what it makes me rather crazy: "*In blow to Tesla and GM, federal electric car tax-credit not extended.*" That's so short-sighted of a view, it's almost self-defeating. Think about the audience that is intended to reach. What message does it send? There's no invest-in-a-better-future-for-everyone sentiment. It comes off as an automaker complaint or whining, rather than a conveying support for being green. Think about how important it is to make people feel the effort is to benefit everyone. Focus on homeowners (as well as landlords, whatever "home" is for you) to promote plugging in regardless of brand is the type of message to send. Ugh. This is what I posted as a comment in reply to the flurry of victim posts: Tesla used the credit well, as intended... building a base of customers for a new automaker. GM squandered their credits, using them for conquest sales rather than intended... changing established customers for a legacy automaker. Credits shouldn't be extended anyway. A better use would be helping build infrastructure instead... upgrades at home.

12-18-2019 Surprise Victory! Turns out, my suggestion is exactly what happened. The federal bill to include funding for renewed tax-credits toward plug-in vehicle purchases got changed at the last minute. That money was dropped; however, the section for infrastructure upgrades survived. Sweet! Just like I said, new money as an incentive to choose a plug-in vehicle should now be used toward upgrades at home. Where you park overnight should get those funds. That is a permanent investment which will deliver benefit for decades to come, well beyond just the purchase of single vehicle. Not only will that be available for all of 2020, it will also be retroactively available for 2018 and 2019. That's fantastic for both existing and future owners. 30% rebate (up to \$1,000) on costs associated with the installation of an EV charging station can be applied to your taxes as a credit. Amending a prior filing for that is fairly simple too. This should reach quite a number of people, regardless of what they purchase to plug in. Having that faster recharging readily available is nice, especially if you combine it with discounted rates associated with overnight programs provided by many local power providers. If all goes well with the upcoming presidential election, perhaps would could see an extension of this more meaningful means of promoting the use of electricity for travel. Celebrate one victory at a time. This is a great win. Hooray!

12-19-2019 MPG Lies. Seeing it happen again is rather surprising: "*The other part of Toyota's DNA was born into the RAV4 Hybrid, which, at 39 mpg combined, was the most fuel-efficient crossover without a plug behind the 40-mpg 2020 Ford Escape Hybrid in AWD.*" You'd think with the incorrect reporting in the past and the resulting fines anyone looking at numbers would do so with care. This was clearly a spin article favoring Ford's AWD hybrid dishonestly. Grrr! Both hybrids deliver combined ratings of 40 MPG. For the RAV4, it specifically gets 41 MPG city and 38 MPG highway. No where is there a 39 MPG value. Sadly, no one called out the issue in the comments either. It makes you wonder what will happen when both plug-in models become available.

- 12-20-2019 State Purchase Incentives.** Minnesota Department of Transportation is now testing a 3-year pilot program that gives a MnPASS credit of \$250 to eligible electric-vehicle drivers and \$125 to eligible plug-in hybrid drivers. This is used to pay tolls associated with the use of HOV lanes. Purchases or leases between November 1, 2019 and October 31, 2022 will qualify. In the press release, the purpose was stated as: "*The MnPASS incentive is geared toward people who do not already own an electric vehicle, or who are perhaps on the fence about purchasing.*" An unexpected perk is the MnPass program will be expanding in 2021 to become interoperable with E-ZPass toll systems. That means a large section of the Midwest and upper East-Coast will be able to accept that credit money. Cool. Additionally, the credit can be used now to pay fees in the Minneapolis Airport parking ramps with combined with a ZipPass account. It seems a well thought out means of promoting a better future here. Sweet.
- 12-21-2019 Escape PHEV.** Some new detail was provided today, including price. \$34,235 for the base offering will be looked upon with interest, for some. That's \$3,200 less than Outlander and will have roughly 10 miles more EV range (14.4 kWh capacity). Actual range delivered in real-world will be subject of great debate. I can't imagine how that will play out, especially when RAV4 will deliver further range and quite a bit more horsepower. The Ford is thought to only be FWD, which will give it a clear disadvantage comparing to Toyota's AWD. This is another one of those situations where audience is key. Who will Escape be marketed to? Will they care? For that matter, will dealers even show support for stocking it? The becomes especially odd when you consider tax-credit price brings it down below the regular hybrid. That's not quite what Toyota saw with Prius, since the Prime model looked very different and had less interior space. Toyota likely won't face that situation with RAV4 either, since the plug-in model will be the fastest and most powerful. I suspect it to be closer to a wash... especially considering how high the demand is for the hybrid model. Availability is what really matters. Will Ford push supply and encourage dealers to stir demand? There are many unknowns still.
- 12-23-2019 Dropping Sales.** Reports of struggle in China with EV demand are becoming common. The reason why is simple, subsidies have changed. No incentive money is offered for any New Energy Vehicle with a NEDC range rating below 250 km (155 miles) anymore. For those meeting that criteria, subsidies have been cut in half to 24,750 yuan (about \$3,500). This could be a foreshadow of what is to come here. There are only so many potential buyers for expensive-but-discounted vehicles... hence the low-hanging-fruit situation. Those in that group with disposable income available and a strong desire to drive something green will take the plunge; the rest will sit on the fence. We certainly saw that with Prius over the years. There were many who believed in the technology and the cause, but just couldn't pull the trigger on a purchase. Hesitation really hurts. The market is quite fragile, even with a government pushing for clean. Here, it's a disaster. We have heavy oil subsidies still and that industry working hard to undermine electrification efforts. They provide an abundance of excuses not to bother... which you can read in comments of those article. Whoa! The denial is amazing. There are far too many who seek validation to stick with a traditional vehicle. It's really sad. So, hearing about the struggle in China should not be any surprise. There is much stacked against progress... even in the face of obvious air-quality issues and climate-change problems. Ugh.

- 12-24-2019** **Rising Sales.** The situation in Europe is quite different than China. Sales are rising. The catch is EV rise has slowed. Faster growth is coming from PHEV sales. Reasoning for why is unclear. An interesting twist is the best-seller is by far Model 3. Tesla is leading by a very wide margin. That could simply be an initial surge of buyers and year-end incentives. We'll find out as the months proceed and VW rollout nears. The closer that gets, the more hype will likely drown out the voice of reason though. That being a domestic market, there may be nothing to learn from. Too many factors are at play. It is nice to see the push, regardless of why. That could help pull our market here out of its complacency. It's sad to have been regarded as the leader, then disregarded as important after making some idiotic political choices... which were just plain stupid... so short-sighted. Anywho, the technology progresses, even when there are slow downs and new barriers encountered along the way.
- 12-26-2019** **New Narratives.** When the audience changes, as we are seeing play out right now, you get entirely new perspectives... which consequently feed new narratives. Many of which come from those providing no data to support their claim, based on limited anecdotal observations. Today, it was this: *"American auto buyers are rather belatedly waking up to the fact that hatchbacks are a lot more useful and convenient than sedans... American auto makers have responded with lifted hatchbacks which are marketed as "CUVs" or even "SUVs"... So I submit the recent sudden decline of the American sedan is mostly due to a shift to hatchbacks."* Absence of any substance to explain why is always troubling. Far too often, we see people drawing conclusions emanating from basically just hearsay. This was yet another example. A solid fact is there has been an ever-growing shift to larger and larger vehicles. One reason is as our population ages, easier in & out becomes a greater priority. Like it or not, that compels drivers to abandon aerodynamic benefit of a car in favor of a less efficient SUV, since it offers higher seating. It really is that simple. No other reasons are necessary to mention. That would take us away from the basis of the faulty assertion and newbies often fall into that trap. They lose focus of their own argument, posting for the sake of winning an argument rather than exchanging info to learn. I explained the situation: Omission of vital detail would give that impression. Reality is, the explosive response to the second-generation Prius back in 2003 was in part due to it being the only midsize hatchback available in the American market. Impacting change in another regard long ago was the much higher profit from SUV models. The impression of *"belated"* or *"sudden"* comes from no longer trying to hide the disinterest in sedans. They are a difficult sell in several regards... with the look forward being the most pressing. It's a heck of a lot easier squeezing battery into any platform other than a sedan.

- 12-28-2019** **Former Foes.** I check up on the old GM forum from time to time. Remember their meritless praise for Two-Mode and blind hope for Volt? It was a terrible venue for any type of progress... which made it a great source of rhetoric research. They provided a wealth of undermining insight. I was always fascinated by how they would unknowingly volunteer very helpful information. Anywho, there were a few there who hated Toyota so much, they would relentlessly attack anyone who showed favor. I did, so I was always having to deal with surprisingly hostile posts. It was quite remarkable. I look back in dismay just how bad it actually got. Having documented their actions sure is nice. It's hard to believe just how bad things really got at times. Needless to say, times have changed. GM failed miserably, several times. Many there have simply given up. One particular individual who never showed me any mercy posted this today in response to the recent details revealed about the upcoming Highlander hybrid: *"This is going to cement Toyota as the go to for a 7 passenger. The MPG without any real penalty is huge."* That 36 MPG rating is so much better than anything GM every delivered in that category, it's no surprise to finally see a change of heart. This quote that followed cemented the sentiment: *"You have to be an idiot to not applaud Toyota on this."* To finally see even the much staunch express positive attitude toward a former competitor is a very good sign. Of course, he still may be a little combatant toward me, but who cares. Highlander hybrid will deliver incredible efficiency and will be built in Texas. That's something he could never say about a large SUV from GM, even on a big GM forum.
- 12-30-2019** **Provoke.** This attempt was quite telling. Comments about an article highlighting expectations in the coming year from Kia was: *"All electric range for the plugin? <=25 miles, color me unimpressed. I'm not looking for much over 25; Toyota has become the inadequate standard."* There was nothing mentioned of EV range or Toyota. It was just a former Volt troublemaker absolutely desperate for some type of interaction. The death of all hope from GM has left him without any type of daily fix. That old blog provided an on-going source of rhetoric to stir excitement. With that now long dead and nothing at all to anticipate anymore, not to mention Toyota becoming an even greater threat to whatever he wanted in the past. I was absurd. Several people took a bit at his trolling trap, but none stuck with the theme. He's basically getting the cold-shoulder from everyone. That's what happens when your goals become insincere. What had been once anticipation of great change turned into an effort of spite. Seeing the provoke fall flat was a nice reminder of why it is so important to stay focused on the big picture. He dug himself so deep into a false promise, he lost touch with what really mattered. What would winning a discussion really accomplish?
- 12-31-2019** **Until 2020.** This caught my attention: *"Good thing Tesla that Toyota is on a limited run of Prime..."* It was a great opportunity to provide some exposition for all those now paying attention: Toyota knew 2020 would bring a mid-cycle upgrade for Prius Prime. Toyota knew 2020 would bring about the rollout of RAV4 Prime. Toyota knew 2020 would bring an end to tax-credits for Tesla. Let's not forget the perceived competition for Prius Prime either. Every time it got a mention, someone would always squeeze in something about Volt, despite its obvious mismatch to customers. Toyota knew 2020 would bring an end to tax-credits for GM. In other words, it simply made no sense to go beyond a limited run until 2020.

- 12-31-2019** **Tax Liability.** I wonder how common this is: *"I've been trying to search online but couldn't find an answer. Is there an income limit to claim the federal tax-credit?"* It's an interesting question, especially if you really given it any thought. Without any experience, it would be difficult to even know what to look for. I suspect most people probably haven't ever been in such a situation. So, I'm hoping my short & sweet answer does the trick: No limit, you just need enough tax liability to cover it... which most households commonly do. Remember, it reduces what you pay to the government, rather than being a monetary gift.
- 12-31-2019** **More Confusion.** Sometimes, you have to wonder if some people are so poorly informed, they just make wild guesses. I didn't get the impression this writer had any idea what he was really dealing with: *"In today's market, several automakers like Volkswagen and GM have completely abandoned plug-in hybrids, while only a handful of PHEV models are actually able to handle the average American round-trip commute of about 32 miles without tailpipe emissions."* Since when is that the average? VW just upgraded Passat from 9.9 to 13 kWh. And Ford is about to introduce its new Escape plug-in hybrid. More importantly though, what does he believe the purpose of PHEV is supposed to be? We are about to start a new year where many of the apparent industry experts really don't have a clue. That's going to cause quite a bit of confusion. Ugh.
- 1-01-2020** **Happy New Year.** It started with: *"Without access to the full \$7,500 federal tax-credit (or even part of it), Tesla is now at a competitive disadvantage to other manufacturers that offer an EV model in Tesla's market segment."* Coming from a blog website for all plug-in vehicles whose posted content at times is almost entirely Tesla topics lately, that was no surprise. There's a lot of Tesla content available, but the imbalance makes it appear to have a bias.. which is a formula for attracting enablers. They lose credibility as a result. It's a difficult problem to overcome when you want to attract participation daily. Anywho, I obviously had something to say on the topic: Those key words... IN TESLA'S MARKET SEGMENT ...reveal the narrow scope we cannot afford to be trapped within for 2020. For Model 3, there was an audience with very limited choices and tight deadlines. Over 16 million is the expected outcome from new vehicle sales for the United States for 2019 means it achieved the amazing feat of capturing 1% for the year. Kudos! That is a temporary low-hanging-fruit situation though. The challenge will be to maintain it. With a variety of new choices becoming available and the reality of just how small of a quantity that actually is for a mainstream automaker to sustain their business, their *"market segment"* far from certain. For perspective, there were 2,129,385 Toyota brand vehicles (which doesn't include Lexus brand) purchased in the United States in 2018. The outcome for 2019 is expected to be similar. Any regard to *"competitive disadvantage"* is short-sighted and narrow-scoped. Sales must grow significantly, without any dependency on subsidies.

1-01-2020 **Renewed Rhetoric, reason.** That troublemaker from the past failed to attract any enablers; instead, there was a fairly objective post which I decided to respond to. This was the quote I specifically highlighted: "*There's no reason why smaller PHEV's can't be very quick, handle very well, and go at least 50 miles on electric power alone.*" Hopefully, this ends up stirring more construction discussion:

There's no reason? That belief comes from years of rhetoric, which the death of Voltec has overwhelmingly confirmed a terrible idea. GM started with an understanding of the market, stating a primary goal of "*nicely under \$30,000*" to set a clear expectation of affordability & profitability. That was to be their small PHEV offering. They abandoned their own goal in favor of range & power.

Toyota's delivery of RAV4 Prime shows what the PHEV market could have become for GM, an automaker whose audience is would have wholeheartedly embraced a SUV with a plug just like that. Keeping Prius Prime on the balance for range & power makes sense for this generation of battery chemistry & packaging, since it meant an affordable price without dependency on tax-credits. It still got the suspension upgrade for handling well, in addition to the industry's most efficient electric heating system.

Focus on what priorities will draw in the largest audience. This is vital for sustainable high-volume sales. It way the article of Kia's future offerings address a variety of electrification approaches. Heavy emphasis on range & power proved a fatal choice for GM.

1-03-2020 **Past Sales.** There was silence yesterday, nothing to report until today. All the reporting would take an odd twist too. Rather than the usual rhetoric stirred from monthly statistics, everyone is shifting to quarterly outcomes. That should help to reduce the usual entertainment posts, those with no constructive value. Hoping for such discussion is a bit of a stretch though. And of course, it is way too easy to slip into the trap of looking backward... which is exactly what happened. That perspective long after-the-fact results in a tainted view, since most of the time some vital aspect of that situation is forgotten or overlooked... as was today: "*BEV sales today are similar to HEV sales in 2005. If you look at 2000-2005, you see exponential growth.*" That seemed innocent. I pointed out why it didn't portray sales of the time accurately: The overlooked reality is there were no tax-credits back then, only a tiny deduction... between \$300 to \$400 for most people. It wasn't until 2006 when the first tax-credit became available and its purpose wasn't to establish technology, as is with EV purchases. Purpose was to push hybrids into the mainstream. Now, PHEV is what ordinary consumers will embrace to fulfill plug-in interest. It's a best-of-both-worlds approach at a time when cost makes it directly competitive with the well-established choices. As much as people hope for strong growth among EV choices, its just not realistic for the masses. They have bigger fish to fry. Upgrading their home for recharging and trying get the most from electricity simply isn't a priority for them. They aren't the customers anyway. Automakers make money from dealers... who have other priorities too. We'll see a shift in 2020. Change is slow though and there are many forces working against electrification of any type.

- 1-04-2020** **New Year Spin.** I found this quite annoying: "*It sure seems like Toyota's other hybrids are eating the Prius' lunch.*" That article title wreaked of click-bait. Reading a little into it, I found: "*It might be the subject for more prognostication later, but as we discussed Prius sales in the office, many of us wondered if it is the beginning of the end for the hybrid and PHEV Prius.*" Why would Toyota discontinue offering a hatchback, especially with the introduction of rear-view camera mirrors? It's the ideal replacement for the loss of market with sedans. Looking at comments posted, I didn't see anything related to plugging in. The existence of Prius Prime was totally overlooked. It's how narratives are established... they just portray a view as if it represents a comprehensive look. That reality of pushing a perspective is nothing new, but this is still good reason to call out the publication attempting to get away with it.
- 1-04-2020** **Reviving The Past.** I wasn't expecting new life to emerge on the forum part of the dead Volt blog. It happened though. Ugh. A familiar troublemaker was attempting to stir some of the same old rhetoric, but as new lies focusing on RAV4 instead of Prius. I really don't even want to post those quotes, since they used blatantly incorrect information to show favor for the claimed superior design from GM. Their propaganda for EREV is attempting re-ignition. What possible benefit could come from trying to undermine Toyota's progress? None of their arguments were compelling enough to kept the technology from ending production. Rather than the Two-Mode evolution to Volt ever coming back to an SUV form, it died. Why would anyone attempt to push the same narrative again? You'd think any type of effort to get GM's attention would try a different approach. Making the same meritless claims again doesn't make an sense. Renewing failed arguments is bizarre. That's a degree beyond desperate. This isn't even a repeat a history at this point. It has turned into some type of anti-green movement, where they are so upset about having lost they can only achieve fulfillment by trying to bring back what happened years ago. Trying to revive the past is a new twist.
- 1-05-2020** **Calling Out Publications.** I finally had it. Tired of bumping into references to that misleading article, I commented on Facebook post linking to it. That would stir feedback. And it did right away, before I could even finish my blog entry. Turns out, some reading it hadn't actually realized there was such a blaring omission. This was my comment: Notice how the article makes no mention of Prius Prime, only pointing out the most vague "*PHEV Prius*" reference possible near its conclusion? Focus was placed exclusively on the hybrid model, creating a narrative is used to draw interest to a publication. Real journalism doesn't leave out vital information like that. To be objective, the article should have pointed out the sales of Prius Prime have been showing signs of increase due to the mid-cycle upgrade halfway through 2019 but that would have confused the "*If Toyota could re-envision the Prius...*" message at the end of the article BECAUSE THAT IS EXACTLY WHEN TOYOTA JUST DID WITH PRIUS PRIME. Omissions like that are troublesome. Ugh.

1-06-2020 Over Promise, Under Deliver. It is rather bizarre to witness mistakes being repeated. You'd think the online forums as a whole would become better educated over time, learning from the past to prevent tripping up over the same problems & oversights again. Nope. Newbies keep joining, poorly informed and easily influenced makes them quite vulnerable to falling into the same trap. They do too, taking most of the group with. Watching that can be somewhat surreal, like knowing an accident is about to take place, then watching it play out. Even when you try to prevent the repetition, they go out of their way to stop you from interfering. True, some actually want & encourage the mess. Others just don't understand. Anywho, it continues to happen:

Think about how wanting some have become, blinded by logic. They gobble up every word, as if it was guarantee. Those who question for detail get drown out by a sea of enablers. GM worked that angle for years, providing ambiguous statements that would feed hype. Enthusiasts thrived on meritless claims. Substance wasn't important. All that mattered was a commitment without any accountability. Now, we are seeing VW follow in those same footsteps.

Meanwhile, those automakers actually trying to make a difference, but in a much more subtle way get the "*laggard*" label. We see Toyota about to deliver a 39-mile PHEV system, offering 302 horsepower, 0-60 acceleration in 5.8 seconds, and AWD. That will come as an option in a very, very popular choice of vehicle. So what if it includes a gas-engine for driving after depletion? Most people's commutes will be entirely with electricity, providing exactly the same experience as driving an EV.

This is why the advice of "*Know your audience*" has become so vital. Automakers sell their product to dealers, not directly to consumers. Those impressive specifications are what will appeal to dealers purchasing inventory, not some grand plan to electrify. Those promises are meaningless to them. They want something that can be easily sold with little effort for a decent profit.

1-07-2020 Video: Battery Temperature. We have had an ongoing discussion on the topic of battery temperature. The exchanges have been rather well thought out too, quite productive. I enjoy those rare opportunity to share like that. Today's addition to the stream of observations & conjecture was: "*If the garage is 39 and the battery is at 59, it's pretty unlikely that the battery heater ran. It only runs enough to get the battery to a few degrees over 32 (maybe up to 37 at most).*" That was an excellent point, which got me thinking. So, I took the time to collect some real-world data: I was able to confirm behavior. The battery temp was 69°F at midnight when charging completed. I unplugged, then checked 3.5 hours later; the temp had dropped to 62°F. Another 3.5 hours later, I plugged back in; at that point it had dropped to 57°F. An hour later, the temp was now at 55°F and the charger did not report and electricity draw during that time. btw, I have witnessed 41°F from that battery-heater with the garage at 14°F and charging not having taken place for 3 days. Here's video showing exactly that... [Prius Prime - Extreme Cold \(commute to work\)](#)

1-10-2020 Hummer Returns. We haven't heard anything for GM for quite awhile. Today, there was suddenly a buzz about Hummer coming back as an electric variant. There's no detail of any sort. It's the same old ambiguous nonsense... only this time, there's a blatant effort to completely ignore middle-market. In the past, we had Volt promoted as a vehicle for the common person, but it was obvious by the price that wasn't the slightest bit realistic. Yet, that was the way it was presented for many years. In fact, it wasn't until the end that their was admission of it really just being a niche. That expensive and for a limited audience is what stirred so much trouble. GM clearly had not delivered what they promised; yet, enthusiasts continued claiming they did. I never expected such outright dishonesty. Fortunately, the end of tax-credits for GM brought an end to Volt, which heavily depended upon that subsidy for survival. So, the idea of Hummer returning is a head-scratcher. Who exactly is that intended for?

1-11-2020 Refusal. Some just don't want to accept what's happening:

It has been interesting to watch the same failed lines of reasoning used again. Much of this we've seen in the past with GM from Volt enthusiasts. They didn't understand the larger market either. It's easy to appeal to early-adopters, especially with subsidies. They refused to acknowledge that limited audience though. They refused to recognize the dependency on tax-credits too. But most importantly, they absolutely refused address the need for growth.

To achieve growth, the technology must diversify. Tesla managed to avoid the innovator trap by sacrificing Model S for Model 3. That better targeted their premiere product to the wider audience, bringing price down in the process. They still don't have a true second offering yet, something quite different from the first.

That's where Toyota shines. So what if Prius Prime is supposedly small and under-powered. In contrast to it is the upcoming RAV4 Prime. That's large, fast, powerful, and offers more range. True, the next-gen Prius Prime will deliver similar improvements, but one is a hatchback and the other a AWD SUV. That's true diversity. They appeal to entirely different audiences.

RAV4 Prime, along with the upcoming EV models of C-HR and UX300e, all demonstrate taking a step forward to reach out to entirely new consumers. Each will offer its own appeal. Each set the stage for higher volume to come. Many here refuse to acknowledge that.

1-11-2020 Worst? When someone insinuates doom, why not call them out on it? Far too often, we get an antagonist attempting to stir emotion. It always depends upon being vague. If you actually confront them asking for detail, there's the potential for their argument too fall apart. Most of the time, they'll just change the topic as an escape to avoiding admitting to the deception. Sometimes though, you get lucky. In this case, it was a rather simple catch. What do they actually mean by "worst" with regard to plug-in ownership? I asked: Worst case scenario is what? Replacement of the battery-pack after 150,000 miles (or 10 years, whichever comes first) would result in an entirely renewed EV capacity connected to a hybrid system without many miles on it. Isn't that an ideal for an old vehicle? Think of how much potential age problems a traditional vehicle faces at that point.

1-11-2020 **Expensive.** This was the answer I got to the "Worst?" question: *"Worst case scenario it reduces every year and 7/10 years later the battery tech or design is outdated and too expensive to replace as that design is no longer in production."* Turns out, he had nothing of value to argue with. Merit is usually lacking. But without any substance at all, it was just a move along situation: 7 years after production ends, the automaker must stock replacement parts. That's a federal regulation, part of what allows them to continue selling new vehicles. As for *"too expensive"*, that's an evade. There's no contest that it will cost far less to breath EV life into the car with a small-capacity battery replacement. Keep in mind, a PHEV will retain far more resell value than an early-generation EV, due to having a gas engine. Even with reduced range, the PHEV continues daily-drives and long-time just fine.

1-12-2020 **Trolling.** There are a few who work hard to stir discussion. They bring up the same topic over and over, as if it had never been addressed. They ignore evidence already presented in previous posts. They use ambiguous references to cause incorrect assumptions. The list goes on and on. Their purpose is to keep posts active. So, drawing a conclusion, is unwelcome. They work hard to undermine any advancement in that regard. The goal to prevent a change of mindset is all too familiar. Ugh. The only good thing I can say about this type of *"troll"* is that they are polite. Others are rude & hostile, so I do at least appreciate that aspect of their posting. Today, it was: *"Not sure what exactly you were counting as an "early-generation EV", but the fast depreciation on many of them was due to incentives on new."* It was about resale value. I was annoyed. That topic simply doesn't make any sense in such an early stage still. He pretended to have no idea what I was talking about, despite beating this issue to death with him already. I humored him anyway, this time, since it was a nice opportunity to provide some exposition:

You know. It's the entire "EV Market" up until December 31, 2019. Not a single vehicle with a plug competed directly with traditional choices yet, because the qualification had not been met. Its price must not be subsidized. To deliver sustainable profit, it must be able to stand on its own. Looking at how that is achieved, we see 2 obvious examples:

Tesla is striving to achieve high-volume sales without the generous \$7,500 tax-credit and an early-adopter audience now faced with many choices. The gigafactory efforts combined with migration to Model 3 are big steps toward the goal, but it has only been 11 days since phaseout of the federal subsidy. Delivery of enough profit to everything necessary to sustain the business remains a challenge, without any clear path or timeline. Mainstream buyers are far more difficult to appeal to than early-adopters.

Toyota is demonstrating they are already well on their way to high-volume profitable sales with a plug, looking well past their phaseout of tax-credits. Evidence of that is undeniable. Their largest production plant in the world (over 9 million square-feet, with 8,000 full-time employees) has added RAV4 hybrid to what they produce. It's in Georgetown, Kentucky, making it an ideal location to capitalize on PHEV opportunity. Adding a plug to the hybrid is an option showroom-shoppers will naturally be drawn to.

Both examples look beyond the *"early"* activity in the market still playing out, one that doesn't even adhere to a standard approach for charging yet.

1-12-2020 **Up North.** A new thread started on the big Prius forum came from a new member identifying himself from: "*in the deep north of Winnipeg, Manitoba, Canada*". He shared interesting data. It matched mine remarkably well. So, I took the time to shared some detail in addition to providing some data points:

Here in Minnesota, we have been experiencing Winter warmer than usual. The outcome is just like what you have observed.

Lows have only been below -10°C (14°F) a few times so far. That means much of EV range has been shared with heat-pump operation. Resulting EV range has been around 35 km (21 miles) for my usual mix of driving. With mostly highway, I have seen it drop another 5 km (3 miles). None of that is a surprise. It's routine for me driving a PHEV since 2012.

When the warm weather returns, so does the EV range improvement. My results in Summer are very close to yours too. My longest EV range also ends up being 55 km (34 miles). Seeing even higher, like those who live much further south, is something I can only imagine.

As for calculating operation costs, I don't bother. My recharging at home is done off-peak (late night hours), to get a discount from my electricity provider. When taking trips to visit my sister-in-law's family in Wyoming, the consumption at 80 mph (129 km/h) is an indulgence I can afford... and MPG is still more efficient than everything else I encounter along the way. Those kids are growing up fast and there aren't really that many opportunities to visit.

1-12-2020 **Claiming Denial.** There are some who have become so entrenched in the effort to portray Toyota as a "*laggard*" they are now posting claims of denial that are blatantly incorrect and very easy to disprove. It's bizarre when you witness such desperation. For example: "*If they were just biding their time then it would be wise to show that the know that and prepare factories, make battery deals, make sure they have a steady future supply of necessary materials, start educating their engineers and factory workers. So far every sign points to that they are in denial and will have an extremely rough time to keep up in the transition when it accelerates.*" That absolute is just plain wrong; yet, it was posted with great confidence. Dismay for such bold moves to undermine is something that never cease to amaze me. Some simply don't care. Ugh. This was my response to that nonsense:

Narratives to claim "denial" are abundant, because Toyota doesn't hype. That's not part of their culture and they have no interest to engage in rhetoric. So, they remain quiet. If you actually take the time to research, you'll see the very claims you presented are false.

Toyota is preparing factories, making battery/supply deals, and educating their workers. In fact, they have a \$7,000,000,000 (yes, Billion) investment underway in that regard for just a single location. Their largest production plant (the one in Georgetown, Kentucky) has just begun production of RAV4 hybrid. That's a major step forward in their effort to deliver a PHEV model of RAV4 later this year.

Note that RAV4 Prime will be Toyota's third PHEV model, joining the Prius & Corolla hybrids with a plug. In addition, there is the upcoming EV models of C-HR and UX300e being rolled out.

How you can state "*every sign*" with any type of sincerity is a mystery. Toyota is clearly preparing for the transition.

1-12-2020 **Continued Attacks.** They never end; however, some with knowledgeable information to share do stand up from time to time to deal with it. Today, this came from someone who worked for Toyota for 32 years: *"Toyota does not care about rushing something to the market in 2020. They advanced the 2030 plan to 2025. The BEV push will come in 2022. They have 157 billion in cash and financial reserves and no significant debt, they own all 40 assembly plants."* His long comment ending with that statement was great. I jumped in (after liking the post, of course) with:

Well said.

I have been closely watching Toyota's technology advancement for the past 20 years. Each next-gen Prius has delivered an obvious effort to improve the entire platform along the way. The extremely successful rollout of TNGA very much sets the stage for eTNGA, confirmation of a massive invest in the future.

It's unfortunate that most daily contributors post comments with no regard to that type of fundamental investment. They focus on elementary aspects of design, mostly range & power, completely neglecting the importance of what it takes to rollout a diverse & profitable technology.

To be able to deliver on a massive scale, avoiding as many challenges along the way, takes a lot of work that will never get proper acknowledgement. Evidence of that is the obvious overlook of what it takes to get a PHEV to flawlessly deliver a full EV driving experience. All of the hardware & software necessary for a BEV must be included. Toyota has already achieved that. They are now in the process of refining the technology.

Warnings of doom for supposedly ignoring the market are meritless. It's just spin from those who don't bother to consider the bigger picture.

1-12-2020 **Denial.** It's becoming even more difficult to push that *"laggard"* narrative. In fact, that label has fallen out of favor as a result. Antagonists keep trying though. They provide a convenient means of measuring progress. The harder they struggle to send a message of supposed failure, the easier it gets to see that isn't true. At times, that can be very informative. It's like a gauge for change. Anywho, today I dealt with yet another attempt: Getting real is to ignore the continuous dismissal. No matter what is presented, you'll refuse to accept it and cherry-pick to feed the narrative. Reality is, the moving forward of their largest production facility is a clear sign of preparing for large-scale change. It's not a token effort when you take your top-seller and begin offering it with a plug. The PHEV model of RAV4 will offer a 39-mile EV range, along with an impressive 302 horsepower, 5.8 second 0-60 acceleration, AWD, and towing. Rollout will begin this summer. There's simply no reason to listen to rhetoric claiming *"a company in full denial of the transition"* when evidence to the contrary is becoming obvious.

- 1-12-2020** **So What?** I pushed back, on a very familiar topic but with a 2020 view: That narrative is beginning to fall apart. Top-Down has been presented as the only viable means of achieving EV growth. It's proving incorrect, an absolute pushed by purist. Reality is, bottom-up approach can be a powerful way to reach ordinary consumers. It's not as exciting, but it works. The company pursuing that is Toyota. So what if Prius Prime "only" delivers a 25-mile EV range? With only overnight charging, that's still a potential of over 9,000 miles annually using nothing but electricity. With a \$27,750 base price, it's clearly aimed directly at middle-market. More expensive, but still on target with pricing for the masses will be RAV4 Prime coming this summer. Knowledge & Experience gained from the motors, batteries, controllers, and software to provide EV driving from those plug-in hybrids will provide a major contribution toward long-range EV offerings later. Cost & Production on that scale simply isn't realistic yet, but what can be learned from the production of those plug-in hybrids right now is priceless. Later is only a few years away. Profit from repairs & maintenance is still a concern, but if something with a plug can be a compelling choice for a dealer, there's still hope. It takes very little effort to get a customer already interested in the popular RAV4 hybrid to consider a RAV4 hybrid with a plug. That's a major step in the right direction. Too bad GM didn't do the same. Imagine how popular an Equinox or Trax using tech from Volt could have been.
- 1-13-2020** **Choice.** This sentiment is becoming more common: "*Why GM didn't put a plug on the current design of Equinox is still a mystery to me.*" It's a feeling of dismay that will likely grow in a rather profound way as this year plays out. I piled on by adding some historical perspective: The predecessor to Volt was Two-Mode, which already had a plug-in upgrade in the works on a SUV platform. Rollout was expected back in 2009 as a Saturn Vue. All lot of effort has been expended to conceal that past, to pretend none of the effort to electrify larger vehicles ever took place. Instead, GM decided to rollout a diesel model of Equinox post dieselgate. Two problems brought this about. One was Innovator's Dilemma. Success of gen-1 Volt praised by enthusiasts enabled GM to make gen-2 Volt even more of a niche, rather than making it into something for mainstream consumers. Two was the Osborne Effect. Any type of reveal like Toyota just did with RAV4 Prime could cause a great deal of harm to their profit from their traditional Equinox. Since Toyota has a hybrid model of RAV4, which is both selling very well and produced domestically, they don't face the same problem. In short, GM got itself into this mess by choice. Seeing the next step will be a reboot of Hummer is just digging even deeper into the same hole. Ugh.

- 1-13-2020** **Attack!** There are a few who just plain cannot stand their idea being challenged. Their word is what dominates the venue. So, when something is posted contrary to the narrative, watch out... especially if you do it repeatedly. I have, which meant getting personally attacked today. The most lame way to do that is claiming the person must be getting paid, with the hope that will draw attention away from the content itself. I take that as an invitation to make sure the message being conveyed about the topic gets focused on even more. In this case, that came with a terse insult. Sometimes, you just shouldn't let the local enabler get away with stuff like that: It has been interesting to watch you go after Toyota because you don't like their approach to BEV delivery. Having to co-exist with fuel-cell technology and building from the bottom-up is too much to accept. Now, you are attempting to spin a lie about me to cover up how poorly that has been going. Well, too bad. It's not about you anyway. Toyota has two EV models in the works for this year and a new PHEV that's looking to be a very strong seller, all nicely targeted at their respective market. That will set the stage nicely for the eTNGA platform to expand to offer more variety and very high-volume. Again, too bad if you don't like their approach to plug-ins. It's all about getting their customers (dealers purchasing inventory to sell) wanting to carry those choices.
- 1-14-2020** **Wanting To Sell.** This sentiment about PHEV sales is understandable, but lacks context: *"The Toyota salesman talked him [my father] into a hybrid one, without a plug. I don't think they want to sell these things."* Not wanting to sell hybrids was the problem in the past. I pointed how the shift away from traditional vehicles has taken hold:
- That's called progress... which unfortunately, is painfully slow. Some of us remember that very same sentiment for hybrids. Salespeople didn't want to have to answer a flurry of questions, wasting their time trying to convince a customer to purchase a vehicle that they would get less commission for. Now, 25% of RAV4 sales here are hybrids.
- The same will happen with plug-in hybrids as the Prime offerings expand. It started with Prius, extended to Corolla in China & Japan, and next will be available for RAV4. The catch is waiting the many, many years it takes for that information about how they work becoming common knowledge and the intentional spread of misinformation finally squashed.
- There's also misconceptions... which sadly, are spread by salespeople. Think about the wide variety of configurations in the market. Unless a person really makes an effort to learn about the technology, it's quite easy to misunderstand how it operates.

1-14-2020 **Much Sooner.** When stuff like this gets posted, it's like poking a sleeping bear: *"500,000 hybrids saving at least 20% fuel over equivalent ICE is currently displacing as much oil consumption at 100,000 full EVs."* There's anger that quickly emerges from the reality of such a statement. Dealing with the reality of impact across the masses is a far more difficult equation than the usual *"mine is better than yours"* argument. They are pretty much doomed to lose every time. The numbers don't lie. It's an inconvenient truth... which I also like to point out:

Oil displacement is what stirs ugly behavior from some who once proclaimed *"no plug, no sale"*. Some have become EV purists, speaking out against PHEV offerings despite the significant usage of electricity. Some Prius Prime owners, like myself, experience a 100% all-electric commute. So what if its a vehicle with a gas engine? That daily drive results in an outcome no different than an EV.

As the market advances forward, new choices like RAV4 Prime will become a very easy purchase for the masses. 39-miles of EV per charge from nothing but an ordinary 120-volt household outlet is simple, something basic enough that a showroom shopper will consider without much trepidation.

PHEV will pave the way forward too. After awhile, the owner may become interested in upgrading their garage. You don't have to at the time of purchase as with any long-range EV. That delayed install of a 240-volt charger may result in a better outcome too, adding capacity to support multiple vehicles... an important an often overlooked aspect of oil displacement.

If a household can only support charging of a single vehicle, that's a very real problem. Those who praise early-adopter sales don't want to acknowledge that low-hanging fruit. Having a second 240-volt charger for the second vehicle in the household can be an expensive next step for consumers.

There's the very real problem of battery production/supply too. A pack with a 17.8 kWh capacity (the rumored size of RAV4 Prime) requires far fewer cells than that of a long-range (300-ish miles) pack. In fact, that's enough for 4 plug-in hybrids. That makes the PHEV a much more effective means of phasing out traditional vehicles than EV quickly, representing a major reduction in oil much sooner.

1-15-2020 **Expectations.** Enthusiasts tend to lose touch with ordinary consumers, without being aware of it. So, from time to time, you have to remind them: Know your audience. It's not a matter of being a *"who will buy"* issue. The problem is finding a way to appeal to the *"who will sell"*. Lexus dealers are in an entirely different category too, having shoppers looking for something not Tesla like. True, that will change with the next-gen battery, but it most definitely isn't the case now. So, they are appealing to their base by establishing plug-in offerings with familiar design in low volume. It's no different than what happened 20 years ago with Prius. Remember the sedan model? We know the dedicated platform EV designs from Toyota are coming in a few years. By then, Lexus dealers will be more familiar with the technology and have a better understanding how to compete in the newly emerging market. Don't forget, the audience here is made up of supporters who are well informed and have much higher expectations than showroom shoppers.

- 1-16-2020 Neglect.** How many times did I foretell this outcome: "*Voltec died of neglect. If they'd put it in other platforms they'd have cleaned up.*" Even with the less efficient and more expensive system than Toyota, they still had an audience. It was missed opportunity. It's amazing how many years of blogs entries I have pushing for the spread of that technology. The enthusiasts kept fighting against that though. GM wasn't taking the next step. That situation was so ironic too. They'd complain that Toyota was resting on it laurels, calling them laggards, while that was exactly the situation playing out with GM. Even more ironic is the fact that Toyota really wasn't. RAV4 Prime is overwhelming proof of that. Makes you wonder what will happen now. GM has been painfully quiet. I just said this about the situation: That is exactly what enthusiasts were warned about. GM kept missing opportunity after opportunity. They became enablers, showering GM with engineering praise rather than pushing for spread of the technology.
- 1-16-2020 Adopting ZEV Standards.** It has been interesting to watch my state go through the process. They are on an accelerated calendar too, hoping to adopt the standards within just 15 months. Minnesota will commitment to CARB-established rules, just like the 12 or so other states that already have. There will be a phase-in period, of course. It gives the automakers & dealers an opportunity to adjust to meet the expectations. For consumers, it means a easier time actually getting a green vehicle. Just like with what originated from California, the credit formula will apply. So, there should be a variety of choices. For many automakers, there's not much to choose from yet. But you have to start somewhere.
- 1-16-2020 ZEV Credit Formula.** The formula for adopting ZEV standards is a simple one. My multiple EV range by a reduction factor, then add a standard value. For Bolt, the ZEV credit is 2.88. The formula is $[(0.01 \times 238) + 0.50]$. That 238 is the EV range in miles. The 0.50 is a value added since it is a BEV. With PHEV, that value is 0.30. So for Prius Prime, the ZEV credit is 0.55. The formula is $[(0.01 \times 25) + 0.30]$. For Volt, you get 0.83 using $[(0.01 \times 53) + 0.30]$. In other words, there's flexibility with what is being sold. Dealers could favor a vehicle with a shorter range; yet, they would still achieve the required ZEV credits. That's why when an antagonist claims "*compliance*" vehicle, they really don't know what that means. It's intended to be an insult. But if enough are sold, what difference does it make? Heck, there are some situations where you are actually better off with a lot of PHEV instead. Long EV range only matters if you actually use it. The upcoming RAV4 Prime will deliver 39 miles of EV range. $[(0.01 \times 39) + 0.30]$ Each one sold will earn 0.69 credits. Think about how much potential Toyota has with such a vehicle. It could be extremely popular.
- 1-17-2020 Video: Prius Prime - To An Evening Meeting.** Minnesota EV Owners' Group has meetings every 6 weeks or so. This one in January just happened to be one an evening cold enough to be below the heat-pump threshold, which meant the opportunity to show how the engine joins in to provide heat. Watch the overall efficiency climb as it cycles on & off. You can see the coolant being heated for cabin warming, then circulated until it isn't able to provide any more warmth. That entire time the engine is off, you get to enjoy EV driving. When the engine starts back up, the hybrid system is run in the most efficient manner... which means if there is excess load (due to RPM remaining relatively constant for maximum MPG) some of power is directed to the generator to create electricity for charging the battery. It's a system that seeks out opportunity. Even if brief, it really adds up. This video helps to demonstrate that capability... [Prius Prime - To An Evening Meeting](#)

- 1-17-2020** **Video: Prius Prime - Snowy Commute Home.** Roads were getting bad. All that snow meant a slow drive home. That extra time reduces EV range, since electricity is also used for the heater. Watch as the battery-capacity is used up and the engine joins in to provide a mix of power & heat. Once the coolant is warmed, the engine shuts off and you resume EV driving. It turned out to be a really good example of what Winter can do to alter driving circumstances. I quite pleased to be able to share footage like this... [Prius Prime - Snowy Commute Home](#)
- 1-18-2020** **Short Distance?** This was the commute posted on the video from yesterday: "*15.8 miles in EV is a very short distance.*" This is how I responded to that: 38 minutes of cabin heating and window clearing using only electricity is actually pretty good. Keep in mind the outcome. MPG was still well over 200 and the entire supply of electricity was taken advantage of. That's the point. In the summer, EV distance is well over the 25-mile rating. In fact, seeing low 30's is quite common. Also, this drive didn't start with a full charge; it was short 3% since charging had not completed yet.
- 1-18-2020** **Sales Spin.** I especially enjoyed responding to this comment: "*BEVs are doing well and growing! What suffered was PHEV sales.*" The perspective comes from unknowingly cherry-picking. They are looking at just a slice of the market in just a slice of time. When you step back to look at the what is to come, that conclusion doesn't make sense. I pointed out:

Drawing conclusions about the entire market based on limited data is very misleading. Neither BEV nor PHEV have enough variety available yet, the choices are far too limited for even a generalization. In fact, it's basically just cherry-picking still.

Tesla was scrambling to deliver their long-awaited price-target prior to tax-credit phaseout coming to an end. They did an excellent job too. Kudos! But that provides us nothing to set expectations upon. Reaching out beyond early-adopters is far more difficult than the low-hanging-fruit stage; mainstream customers are far less accommodating. So, even for that single choice, there is uncertainty... which anti-plug propaganda will exploit. Be careful.

GM was DOA right from the beginning of 2019. Volt was already declared dead and Bolt didn't appeal to GM's own customers. So, comparisons to 2018 sales don't tell us anything meaningful.

Toyota was limiting Prius Prime to just initial rollout states, making any conclusions about nationwide potential a guess at best. There was simply no reason to risk entanglement with GM's mess, especially with RAV4 Prime on the way and a mid-cycle update for Prius Prime.

All that provides perspective for the stage which has just come to a end. This new stage just starting requires significant growth at prices directly competitive (no subsidies) with traditional vehicles. So, even lessons learned from the past only apply in limited fashion. Appealing to showroom shoppers is a major challenge to overcome still. Having proven technically viable isn't the only step toward mass acceptance.

1-18-2020 **Amazing?** Comments like this are especially interesting: "*It is amazing to me that GM and Nissan in particular have nothing worth raving about.*" It wasn't just the comment itself, it was who posted it. He was a well-known troublemaker in the days of daily Volt blogs. I bumped heads with him quite a bit; ironically, it was on this very topic. Think about how many times I pointed out GM not doing anything with their technology, the need to spread it. Ugh. So, I posted:

Amazed, really? We knew even before Volt gen-1 rolled out that GM had the engineering know-how but not the executive desire. The disastrous Two-Mode history overwhelmingly confirmed enthusiast praise would enable the same behavior to continue.

I was amazed how many Volt enthusiasts attacked me for pointing out the technical achievement was giving a false impression of what to expect upon market saturation. And sure enough, when that happened with the steep price-cuts midway through gen-1 sales of Volt, the pattern played out. Sales didn't grow. Overall flat was a very bad sign, a warning gen-2 needed to be dramatically different to appeal to the necessary wider audience. Same problem repeating.

No matter how many times the obsession (engineering blinders) of power & range was brought up as a barrier to growth, I got shot down. The idea of spreading the technology was looked upon as a means of diluting intention, sending a message of defeat rather than being a natural next step. In fact, you can see that very sentiment playing out now with Toyota. We see many spinning the successful migration of their technology to RAV4 as a message of Prius struggling to survive. Evading the topic of what the next-gen Prius Prime will bring is evidence supporting a narrative of struggle. Think about what Toyota's next step will be.

GM has no next step. Evidence of that comes from the Hummer focus. Why aren't we hearing anything about a plug-in aimed at Equinox buyers? Nothing at all for middle-market buyers is a dead giveaway of problems to come. Remember the "*Who is the market for Volt?*" question getting asked repeatedly over the years? It's more neglect, missed opportunity to deliver something appealing to their own showroom shoppers. This is history repeating, yet again. Perhaps that's the amazing part. Could any automaker really be that stupid?

1-18-2020 **More Spin.** They keep at it: "*PHEV sales are not keeping up...*" Must of that rhetoric comes from BEV purists, those who don't believe PHEV have a place in our market. It's sad, especially when PHEV make such a great first plug-in vehicle. You immediately gain the benefit of all-electric driving (some, their entire commute) without having to do anything special or any extra expense. They don't see it that way though. In fact, they often quarrel amongst themselves about range. I jumped into that discussion today with:

Range isn't the only factor at play, as the countless sales articles continue to portray. Price plays a major role in what happens with the reach out to mainstream consumers. That's where PHEV will thrive, especially as tax-credits expire. Settling at upper 30's for range seems a good balance. It covers most daily commutes and doesn't necessitate a level-2 charger.

Toyota's effort to diversify will work well in that regard. Prius Prime targets the affordable pricing (nicely under \$30,000) and RAV4 Prime will capitalize on those wanting to spend more on a loaded SUV but don't want any plug-related risk or expense. Being able to just use an ordinary household outlet for a full overnight charge is an easy sell for timid consumers.

As for timing, waiting until GM's fallout from tax-credit phaseout still makes sense. No one really knew what their next step would be and surprises can be costly. Remember, it's about how the dealers respond, since they are who purchase vehicles from automakers, not consumers. Keep in mind, that is also how regulations are factored (dealer inventory, not consumer purchases).

1-19-2020 **Stages.** It makes you wonder if some people online have any clue how new vehicles come about: "*I think that any company designing hybrids of any flavor now is making a mistake.*" We witnessed Toyota's design evolve as battery-technology improved. The long-term goal was to deliver EV driving, which is exactly what we are seeing now from the PHEV rollouts. I stated the situation this way: Fortunately, Toyota is long past the design stage. In fact, they are so far into the mature stage, the technology is returning a profit dealers desire. RAV4 hybrid is overwhelming proof of that. RAV4 plug-in hybrid will help bring about the phaseout of the non-hybrid model. (Again, remember PHEV use smaller & lighter engines, while also eliminating complex geared transmissions.) It's the S-curve you mention above, but misunderstand the timing. BEV will follow, but that's many years off still due to infrastructure and battery technology limitations. It will happen, but that stage will take quite a bit more than the single generation you claim. Transforming an entire fleet of choices takes a lot of effort. The diversity of vehicles means a variety of configurations, which complicates matters across the entire production/sales spectrum. A simple look at what ordinary consumers have for priorities makes that a bitter pill to swallow. It's far more than just a matter of delivering the necessary technology. There's a very delicate balance at play that's easy to overlook.

1-19-2020 **Change.** Some people just don't get it. He just threw a bunch of statistics at me, without any explanation how it applied going forward. What happens in a subsidy stage, one that targets early-adopters and fails to establish any type of standard, is nothing to build mass-market expectations upon. It does a great job of identifying what is capable technically, but by no means does it represent the mindset of ordinary consumers. Measuring change is complex. You must continuously strive to see the big picture, because it keeps changing. Knowing that the target itself is moving is something enthusiasts fail to understand... because they assume it is always in the same direction. That's why knowing stating goals is vital. You must reaffirm them on a regular basis. When something in the market changes, you must evaluate impact. Those darn enthusiasts put blinders on, assuming focus on the destination would allow them to someone avoid obstacles along the way. Eh? That makes no sense. Yet, they'd argue it doesn't matter. Volt died as a consequence, taking along its technology in the process. Hoping production cost will get reduced enough to justify an insufficient design isn't a solution. I fired back today with my own rant: There's more to the GM cost equation than just simply reaching a tipping point with BEV. The system GM delivered after 3 generations of trying was still too expensive and too inefficient compared to what Toyota had delivered. There was simply no way to compete in that market, especially with Honda and Hyundai/Kia also showing potential. Imagine if Two-Mode, then Volt-1, then Volt-2, had finally delivered something competitive. An Equinox with the same characteristics of the upcoming RAV4 Prime should have been GM's ultimate achievement. Watching Toyota patiently wait for that fallout to pass while setting the stage for their next step sure has been interesting. There are still many naysayers are not paying attention to what is actually happening in the market and not aware of what it actually takes for mainstream change.

1-20-2020 **New Narratives.** I was stunned to come across a published article with an entirely new twist. My guess is this came about from anecdotal observations, since nothing about it relates to statements about the past. In fact, much of it doesn't make any sense. Read it for yourself, then consider the actual history: *"Toyota believes batteries and the precious earth metals used to make them will always be bad for the environment. The charging infrastructure will be costly and electric cars will always have severe limits on their range. So, it restricts battery use to self-charging units in a hybrid combined with efficient petrol engines. This is a stop-gap before making hydrogen cell cars, possibly by 2030."* What does that "bad" even mean? Toyota's effort to make as much of the vehicle recyclable as possible, including battery-pack components, has always been a priority. How does striving to reuse become an "always" problem? The second statement is just blatant rhetoric. Using words like "costly" and "severe" are dead giveaways of that. They are so vague, the intent to make you assume exaggerated scale. Following that was great. It's just an outright lie. The writer clearly hoped you wouldn't discover the PHEV already available (Prius & Corolla), the PHEV coming this summer (RAV4), and the BEV models in the works for late this year (UX300e & CH-R). That last statement is the clincher though. It appears to reveal this is really some type of anti-hydrogen propaganda at play. Typically, that comes from a source unwilling to accept a world of diverse choices. Watching Toyota gain success in their effort to reach fleet & commercial vehicle use of fuel-cells, as well for industry power, frustrates them to no end... since starting with ordinary passenger vehicles is the most effective & affordable means of achieving a wealth of real-world data. So, they invent new narratives with the hope of preventing people from noticing the goals Toyota is really striving to achieve. Ugh.

1-21-2020 **Video Quest.** I don't expect a lot of views. It's all about teaching the teachers. Each one strives to deliver higher quality. To achieve that, I have to carefully consider details of what I'm trying to show and how I'm going about presenting it. The content itself gets refined along the way in the process. I'm now to the point where I can look back and not have any upset or regret about basically starting over. The past 10 years of effort was practice, my own schooling. It's was learning about the technology available at the time and making the most of it. Those 10 years prior to that worked great for photos. I was on the bleeding edge of digital photography, watching it become an everyday tool along the way. The same is happening now with video, as impressive resolution & lighting in the 4K realm becomes common. That puts some perspective on the 89 videos I ended up publishing over the years. I wonder how many attempts it actually took to get that many worthy of keeping? And now, I'm looking to recapture the same drives with far more detail & quality, along with informative narrations. Again, I don't expect a lot of views. But for those who watch to learn, I was enjoyed putting together that content to share with you.

1-22-2020 **Should GM Have Kept Volt?** That was the question asked yesterday, originating from an article in a popular financial publication, on the big GM forum. This was the standout comment on the discussion thread made from it: *"The Volt was never a big seller, but while it's a shame that GM ended production, the Volt-Tech components really should have found a new home - perhaps in the Chevy Equinox."* I find it incredibly ironic how someone stating that now can get 27 likes right away and I got attacked in the past for saying the very same thing. I pushed and pushed and pushed for enthusiasts (those terrible enablers) to use their influence on GM for that very thing. Diversification is an absolutely essential part of growing a technology. A one-hit-wonder like Volt is not sustainable. That's how you get attention. Spreading to the rest of the fleet should have happened long before the obvious deadline of tax-credit expiration. In fact, that's what the federal subsidy was for... to help fund the establishment of a new technology. Automakers were free to use the money on whatever technology they deemed viable for sustained profit, to help then into the greener market. Instead, GM wasted the opportunity and everyone now sees it. That same wisdom shared years ago was treated with hostility. Ugh. Reading through several pages of posts, a pattern emerged. Those GM supporters never really understood what Prius represented. In fact, its purpose still remains a mystery. They so blindly followed the rhetoric, there was never really any critical thinking. They just blew off advice thinking it was just Toyota obsession coming from outside commenters, not actual suggestions for helping GM. We now have an archive in blogs & forums showing how wrong they were to blindly believe the hype. Lack of substance should have raised warnings for them. Merit is earned by actions, not posting *"vastly superior"* claims. My takeaway from reading through all the posts is how much detail has been forgotten; specifically, that sales of Volt were always a struggle. It never delivered upon its own original goals... 40 miles of EV range, 50 MPG following depletion, for a price nicely under \$30,000. That promise unfulfilled made it a contradiction to the promotion we got all throughout development. It wasn't efficient, which made affordability a major challenge. Now that Toyota is on the precipice of achieving those fundamentals, game over for GM. Keeping Volt was pointless, since those goals were abandoned. That made any next move, like offering the tech in Equinox, a daunting challenge... one far greater than they could handle.

- 1-23-2020 The Test Of Time.** That's the ultimate measure of success, especially when longevity is an essential aspect of developing a technology. That discussion thread went from being fairly constructive to an outright rant. GM enthusiasts don't take criticism well... hence being enthusiasts, rather than supporters. Anywho, it came to this: "*The Volt is gone, yet the Prius is still around; I think the answer is right in front of our noses, the Volt was a money-loser.*" A well-known antagonist felt the need to vindicate himself upon getting called out by one of the more sensible-headed contributors. That ultimate price was paid (yes, I say that ironically). Volt was never affordable. The design sacrificed too much for range & power. That wasn't a tradeoff to achieve balance. It was greed & obsession. They didn't want to admit it; yet, the only thing we're hearing about from GM now is that their upcoming EV offerings will be profitable right from the start. The reason Prius survived is it was designed to be profitable right from the start. It wasn't, since the early 2000's was a very different time... before "*climate change*" had even been coined. Heck, that was even years before "*global warming*" was given any attention outside of green discussions. Nowadays, that's a liability insurance companies and investors talk about all the time. The reason why is simple, money. So when Prius achieved profit with its first-generation design, it got noticed. That was just prior to the second-generation rollout. It's what sparks the fires of animosity, which we saw get quite ugly years later... still before Volt was even a concept. Now, Volt is dead and we have rants to deal with. Getting acknowledgement of the source of the problem is nice, but we'll never get an admission that he was among though feeding that fire. It's nice to know that time eventually reveals the true story, even if he doesn't want to. Having someone step up to help prevent aspects of history from re-igniting would be nice.
- 1-23-2020 Video: Prius Prime - Full Winter Commute, part 1.** With the outside temperature below the electric heat-pump minimum and such beautiful weather, this was the ideal opportunity to film my commute to work. Watching the resulting video, you get to see the engine cycle on & off while the system takes advantage of as much EV driving as possible. The lower-left shows the dashboard of my Prius Prime. The lower-right shows an aftermarket app reading data from the OBD-II port of the car. This provides a wealth of information about engine, motor, and battery use. Pay particular attention to the coolant temperature, which reveals a lot about how very cold conditions affect electricity use. When the drive concludes, I park in the ramp without plugging in. Part 2 of the video shows the commute home, without the benefit of using the electric battery heater while away at work... [Prius Prime - Full Winter Commute, part 1](#)
- 1-23-2020 Prius Prime - Full Winter Commute, part 2.** After having been parked all day in the ramp while I worked, the battery got cold. Notice the temperature indicated by the device shown in the lower-right. Despite those affects of winter, driving in EV is still available. Watch as I enter the highway and climb out of the river valley. Then later when the engine starts, witness what happens as the coolant is warmed to provide cabin heat. The engine shuts off and stays off for a surprisingly long time. Notice how low of a temperature it is able to utilize that warmth from coolant. It's quite an efficient commute, even without the benefit off plugging in while away at work... [Prius Prime - Full Winter Commute, part 2](#)

1-24-2020 **Bothered.** I kept my response to the point: "*What bothered me was the narrative to spin short-term marketing for the luxury market as representative of the long-term plan for the Toyota brand.*" It was about the on-going trouble we get from antagonists clearly not interested in anything beyond the current hot topic. Difficulty toward dealing with such narrow-minded views is quite a challenge. They simply don't care about taking the time to spread the technology across an entire product-line or the consequences change has on dealer support. It's like they expect profit to come effortlessly from anything carried in stock. The logistics of properly training staff are blown off as no big deal. They really don't have any clue how challenging it can be to ensure information is understood & conveyed well. Remember how many problems I had trying to get the message across to Volt enthusiasts? That type of resistance is far too much for any dealer to want to address. Not only is their many assumptions to overcome, there is also the very real problem of coming across as condescending. That's why the "*bother*" topic needed to be intercepted immediately. They've been spreading the same story for years. What did it accomplish? What do they hope to accomplish? Notice how it always comes down to stating goals? They feel it isn't necessary to bother. Ugh.

1-25-2020 **Time & Money.** When cornered, an antagonist will attempt to change the topic. When it comes to Toyota, they'll draw attention to fuel-cells, spinning a narrative of EV neglect. That almost always results in several bites. It's a classic troll move. They simply introduce something to undermine the discussion. Fortunately, the slow & steady success of fuel-cells is messing up that effort. Ignoring certain facts is a dead giveaway of struggle for them to come. Fuel-Cells have their place, a position of co-existence with plug-in vehicles. Antagonists hate the idea of multiple solutions for a diverse market. It's always of one-solution-for-all from them. That's why Volt died. Their inflexible approach prevented support of anything outside of their narrow focus. From their point of view, that was thought of as a sound choice. Their focus would result in a well-proven technology. Problem was, the world is constantly changing and there's a wide variety of needs. So, they ended up backing themselves into a corner as a result. Oh well. Their loss. All I can do is just continue pointing out how diverse our world really is and how many solutions will be necessary to satisfy everyone's requirements. Long story short, I hit back with a simple post: It's called advancement through real-world data. Personal transportation is only one application of hydrogen. There is also fleet & commercial use. They don't provide anywhere near as useful data as just letting enthusiasts randomly drive around though. The resulting fuel-cell technology can also be used for industrial power. Starting on the small scale with Mirai is an effective means of exploring a diverse opportunity.

1-25-2020

Audiences. Watching them change is fascinating. There is a growing sense already of an entirely new crowd coming on board due to RAV4. Those terrible enthusiasts of the past had no clue just how complicated the real-world actually was. Existing within their niche and fighting to prevent outside influence was a suicidal move. There's no way to win in the end when so much deception was used to appear victorious from battle to battle. Eventually, the truth is revealed. I expressed that sentiment with: It's a mixed blessing that people don't pay attention to long-term or big-picture issues. We do indeed have issues with dirty sources of electricity. We also have an issue with the perception of Prius. Fortunately, that's all changing. In fact, if you look at the situation, that's been the destiny all along. Thing is, the "*Tortoise and the Hare*" playing out in real life is easy to overlook. Starting now and looking back, you see Toyota's reputation with hybrid. Prius is king, but thought of as slow & gutless. Mid-2020, here comes RAV4 Prime. It's like the anti-Prius, fast & powerful. Attention will turn to it. Toyota knows their audience. Those who never paid attention or simply even cared will get a twinkle in their eye. That's an option those loyal customers never saw coming. They'll be thrilled by the idea of an AWD choice with a plug. A few years later, we'll get the next generation Prius Prime and it will be amazing. So, everyone wins. The point is there's a diverse audience out there, many from traditional markets have a lot to lose, and the technology isn't quite there yet for direct competition. We're getting close though. It will happen. But in the meantime, we still have to deal with that rabbit.

1-26-2020 Teaching Moments. With so many elements at play, it's really hard to figure out what is truly happening with the hybrid system. You end up scratching your head, not really certain if the outcome observed was truly the result of what you seemed to have identified. Even the best of us get hung up on the uncertainty: *"From actual miles driven on EV mode and miles/kWh data from the car, my full EV range SOC always comes out to be 5.4-5.7kWh. I have no explanation for this discrepancy."* What detail is being overlooked? Why a variance? It can be maddening. It can also be a teaching moment. You just share what you know, adding to the collective knowledge overall. I added:

What does the miles/kWh value actually represent? Is it overall efficiency or the measure of efficiency only while you are moving? In other words, sit somewhere parked for awhile. Does the value go down for the trip? We know that Hybrid Assistant provide the option of display either of those values.

That's why reporting a number is so screwy. If a person is picking up their child from school, sitting there with the system on but windows open would still consume some electricity but would be far easier to overlook than if they had the A/C or Heater running. That's an exaggerated example of a long commute with lots of stoplights, but still easier to measure than the randomness of red-lights and stop-signs. And of course, all that varies with temperatures.

In other words, those of us with extensive hybrid history have seen the same efficiency-measure problem play out over and over again. You never can nail down a solid answer to provide new owners or an expectation with prospective buyers. Making matters worse, we have the added problem of different generations having profoundly different software, hardware, and battery.

The song *"Let It Go"* comes to mind... hence, just teaching those interested how to retrieve that data for themselves. And yes, I will be doing exactly that with my videos. Teaching moments.

1-26-2020 Measuring Progress. An article was published yesterday about Toyota's plan to achieve 90% electrification in Europe by 2025, with the remaining 10% being sport, off-road, and commercial vehicles. This was a post that obviously stirred attention: *"Toyota's suicide note. Sadly I expect the obsessive Japanese need for consensus to pull all their car makers in this doomed direction."* I found that a great opportunity to ask for some perspective: What percentage are you expecting from other automakers by 2025? Toyota's plan to wean both consumer & dealer off of their obsession with non-electrified is going remarkably well. Any legacy automaker can cater to the low-hanging-fruit crowd, but reaching out beyond that audience becomes harder & harder. Achieving 90% in just a few years from now is remarkable. Once their audience has experienced the benefit of having an electric-motor & battery, the desire for more is a natural next step. Some will transition from HV to PHEV. Others will skip a step and go from HV to BEV. The point is, those steps are being achieved in a quick & profitable manner. While other traditional makers are still struggling to get consumer & dealer to move beyond vehicles with nothing but a gas engine.

- 1-26-2020** **Outdated Information.** When there are several generations and a wide variety of configurations, it is very easy to mix up specifications. Being vague makes the situation even worse. That's one of the reasons I continue to capture & improve videos. Increasing detail & quality helps document the history. Rebuttals to false claims afterward are really easy when you have that level of proof contradicting what they insist is true. Anywho, this is what I posted in response to such a situation today: That distance & speed stated is quite outdated. Prius Prime delivers far beyond "*city speed*". 135 km/h (84 mph) has been available since 2017. The upcoming RAV4 Prime (available in roughly 6 months) will deliver the same speed, but range will be more than that arbitrary ">50 km" expectation. The EV rating should be about 62 km (39 miles). Also, the "*should have*" doesn't take into account being profitable. Just because the technical achievement is there doesn't mean the technology can compete directly with well established choices. That part takes time, quite a few generations to reach a wide audience, since the technology much also diversify. Vehicle generations tend are typically 5-6 years each. Did you know that Corolla is also being produced as a PHEV now?
- 1-26-2020** **Sleeping Giant.** The response to my post about being outdated ended up with a claim of Toyota resisting change and not doing anything. Ugh. I fired back with: As for your claim of "*sleeping*", that's also quite outdated. Toyota has been aggressively converting their entire fleet of passenger vehicles over to the TNGA platform. It has been a quiet effort, basically impossible to actually notice, but fundamental in the move forward. It lowers costs and sets the stage for e-TNGA. That is Toyota's platform for dedicated all-electric vehicles. With TNGA rollout nearly complete, the "*nothing has happened*" belief will vanish. People will be stunned, most likely spinning the situation as if Toyota had to rush to catch up. But in reality, they have been working hard all along. Narratives to make you believe otherwise simply drown out the truth.
- 1-26-2020** **Stating Goals.** I especially like seeing this post on the discussion thread about Toyota's 2025 plans for Europe: "*We don't have yet all the specs to know where the trade-offs are on the RAV-4 Prime vs the HEV.*" I called out his edit after posting, but wanted to point out the importance of focusing on goals. People get too hung up on stages, forgetting what the overall purpose is. Hopefully, I get something constructive in response to this: It's nice to see you changed the word "*compromises*" to "*trade-offs*" (since the stigma of balance has been lost through years of rhetoric), but that still doesn't change the pattern of that reply fitting "moving goal posts" replies. To be objective, you must state what is hoped to be achieved. Anywho, we already know many specs. We have been told it will share the 135 km/h (84 mph) maximum EV speed as Prius Prime, has an anticipated range of 39 miles, and the battery-pack will not intrude the cargo area. We also saw a leak of a 17.8 kWh capacity for the battery-pack. In addition, we have been told it will feature AWD standard, provide 0-60 acceleration in 5.8 seconds, and delivers an overall power output of 302 hp. Heck, it even comes with predictive-drive and paddle-shifters. Want more, how about a 10yr/150k battery warranty? There's an advanced heat-pump too. What else do you need to know? What are the goals?

1-26-2020 **Never True.** It's always a pain getting told what you believe. Getting beyond that stereotype others see is challenging, but it can be done. Somehow just need to get them to take a little time to listen, rather than assume. That mean choosing words carefully so the chance to do that isn't spoiled. Unfortunately, the same doesn't work for automakers. That's why I was basically doomed when it came to the Volt enthusiasts. They had certain assumptions about Toyota and transposed them over to me, assuming I'd see GM the same way. I didn't, but their efforts to make excuses for everything rather than addressing the actual issue... which is exactly what we've have been witnessing with the impeachment trail... makes that impossible. There isn't any interest in determining intent or agreeing upon limits. That stupid trophy mentality has a proper term... it's called zero-sum. I win. You lose. Ugh. That's the long explanation and summary why dealing with this is pretty much futile: "*Once Toyota gets over their electrophobia...*" Refusing to even acknowledge that could have been a mischaracterization is all the more you can expect to get. Most of the time, they'll just pretend you didn't even post anything. I get annoyed, but use their claim as an invitation to reply, as I did in this case: That was never true. Toyota's stance has always been it was cost prohibitive, that dealers & consumers would not be receptive to the high prices. Even now, we are just barely reaching the advancement of battery technology enough to make them somewhat competitive. Look around. See how unrealistic direct sales against traditional vehicles will be this year without tax-credits available for Tesla or GM. Do you really think ordinary consumers are willing yet? Batteries have a little bit to go still. Fortunately, Toyota hasn't been just sitting around waiting. Don't listen to the antagonists. RAV4 Prime is an undeniable example of making a huge investment in the refinement of hardware & software necessary for EV drive.

1-30-2020 **Patterns.** It isn't surprising that most people don't see the pattern of repeated mistakes. Not being attentive long enough to notice the same thing happening again should be an obvious problem. People have other important things in their lives to tend to. That's totally understandable. But when a few fight back, absolutely insisting there is no pattern, you have to wonder. Why are they pushing back? There is something they fear related to change. Repetition confirms a strong possibility of the same outcome. Yet, they hope for a miracle to break the pattern. It would be nice to find out what is the true source compelling them to resist. Just like we are seeing play out with the political situation, their dishonesty will eventually have consequences. Despite that, they try to continue without accountability. It's bizarre to witness such destructive behavior. Go down fighting instead of accepting defeat. Watching others witness this payout is an added level of intrigue. Will they notice the pattern too? I expressed my inquisitiveness this way: GM's reputation for "*over promise, under deliver*" was well established by the time they had revealed the Volt concept, way back in early 2007. At that point, Two-Mode was already proving a disaster and they desperately needed a distraction. Fast forward a decade, we witnessed that with Bolt following the disastrous upgrade for Volt. And now that Bolt has fallen that same pit of the forgotten, they need yet another distraction to build up hype without substance... yet again. It's a repeating trap enthusiasts continue to fall into, despite the obvious pattern. Ugh.

- 1-28-2020** **Filming Drive Videos.** I have been asked how my progressively improving quality is achieved. When it finally gets warm out (Spring seems so far away still), I'll take the time to show what I actually do. Only recently having reached my own goals, it was a moving target not worth the effort yet. I want to share simple solutions. It's amazing how much work it takes to find the "easy" method. Fortunately, I enjoy the discovery process. Who knew so many videos making the cut, good enough to publish, would really just be practice until now. I certainly have plenty of opportunity. The new computer and new software has brought about new excitement. I can use that previous experience to create better quality content, complete with informative commentary. That's more than many hobbies provide in return for countless years of effort. I have something to share & inspire with. Sweet! For the moment, it's just a listing of hardware. In a few months, I'll follow up with the other detail... like photos. Right now, it's too cold for that. I have a hard enough time coordinating the videos. Lots must happen and I'm quite familiar with the situations when something goes wrong... hence the quest for simple. Stay tuned. In the meantime, here's that list: GoPro 7 for the dashboard, capturing video in HD. GoPro 8 for the window, capturing video in 4K. Android S5e for the OBD-II data, capturing video in QHD.
- 1-30-2020** **Tough Sale.** That says it all. It was the sentiment being passed around today. This next stage of sales... reaching out to ordinary consumers... is going to be far more difficult than the enthusiasts were ever willing to acknowledge. But now, they have to. Not only is that early niche market saturated now, the choices are becoming confusing. Whatever the heck an EREV supposedly was in the past, it is meaningless now. That obscure & uncertain difference carries no weight anymore. This audience simply doesn't care. Appealing to showroom shoppers means identifying with the most basic of priorities. Things like affordability are far more important than those antagonists of years ago ever imagined. They could never see beyond the tax-credits. So, having to finally acknowledge just how expensive their favored choice really is doesn't work. That's why so many of the rats abandoned ship. Those still hoping for the journey to be rewarding are left to wonder: "How?" It's the question beginning to draw attention... since the "Who?" is now undeniable. The market must expand, significantly. That means reaching out to an entirely new group of potential customers... which is why we see RAV4 Prime on the way. Although it still could be a challenge initially, the tough part should be easier to overcome simply because the hybrid model is already so popular and Prius Prime is proving to be an effective means of demonstrating how well thought out the technology is.

1-31-2020 **In Good Faith.** I watched an example of social change play out entirely, from its origin to its demise, with Volt. Enthusiasts made excuse after excuse to justify the unjustifiable. This can happen at any scale. You can witness communities change. In our case today, we all saw it playing recently on the national level. Rather than just stepping up with sincere & honest intent, there was always a competition to win the moment. It has become about declaring individual battle a victory, rather than focusing on goals. The very idea of simply doing something in good faith is gone. Witnessing such an attitude of short-term gain importance without concern for what happens next taught me so much about what to expect from other disciplines. Evidence of that hinting at how our political crisis would end up playing out was easy to see as a result. It was the same old cherry-picking, obvious efforts to spin a narrative, rather than seek out the truth. Some truly only care about surviving the moment. Showing some trust that losing this one battle would not mean the end of everything they know & love wasn't an option in their mind. It was fight, fight, fight, fight without any real meaning or purpose. As with our clearly dishonest & selfish president, direction is lost. The society becomes polarized and the mindset one of absolutes. Looking at wins & losses as an equation is unheard of. There's no effort to move forward, only immediate zero-sum outcome. It was inevitable we get to the point. The problem supersedes any particular leader. That's why removal of the president only reduces damage. It doesn't actually provide a cure. We'll see evidence confirming the current "win" in Congress really was an overall loss. They made a sacrifice for a momentary victory. Dismissing what was presented so far, rather taking the chance there was more still to find, is that blind-eye I complained about so often with Volt enthusiasts. They simply didn't care what came nice. Their choice was "*vastly superior*" and that's all that mattered. Look what that got them. Ugh.

2-01-2020 **Lowering The Bar.** Watching the absurdity of the presidential defense scramble to spin a narrative to defend acts clearly not of the high moral ground we expect is evidence of a decline. We've lowered the bar so much, the president is no longer someone to look up to. Statements like "*rising above that*" can be taken with their obvious parallel to height. Standards fell with the campaigning. He simply didn't care. Whatever it took to gain the upper-hand. It was sad to witness. Now as our supposed "*leader*", we are being led to a lower position in world standing. Respect is dropping. Credibility is falling. It's now easier to see the bottom than the top. Sound familiar? That same thing is what I watched play out with the EREV nonsense. That was supposedly a "*vastly superior*" technology. There was no substance to actually support the claims though. It was all shallow & limited observations used to portray that false narrative. Sales were never impressive. Change wasn't actually happening. It was just low-hanging fruit, short-term gain sacrificing long-term well being. That's exactly what we are seeing play out in the political scene. Like the automotive market, there are far more elements at play. The attorneys are just like the enthusiasts, formulating a perspective to support their win rather than actually addressing issues of integrity. Grrrr!

- 2-02-2020** **Free Charger.** Someone shared a link to a dealer providing a level-2 charger with a plug-in purchase. That's interesting. I'm quite curious what type of discussion that will stir. Here's how I commented about the article: It's a different twist toward the encouragement of charging at home. Getting dealer's involved is obviously an important step forward. But I would be concerned about the spread of misinformation from a source with basically no experience or accountability. How will they ensure proper detail is shared from salesperson to potential customer? My electricity provider (a local co-op) has it nailed. \$50 sub-meter added to a dedicated circuit for the charger, along with signing up for either their TIME-OF-USE or OFF-PEAK discounted rate program, gets you a \$500 rebate. Knowing that electricity will automatically be discounted using a charger of your choosing, without having to ever do anything beyond just plugging in at night, is simple & painless. Our local EV owners group has been working with local providers, doing all we can to provide feedback and help spread the word. Chargers are by far the question I get asked any detail about. It's quite encouraging to have witnessed (we routinely have public showings) consumers stepping beyond just the initial "*How does a plug-in work?*" inquiries to now wanting to know what it takes to own one.
- 2-05-2020** **Subtle Fallout.** News about plug-in vehicles as we knew it is gone. That's great with respect to rhetoric; those horrible antagonists hyping expensive & inefficient choices as solutions for the masses have vanished. They thrived on meritless attention. It was a nightmare for those of us trying to be constructive. Ultimately, that nonsense approach was how Volt died. Enablers basically killed it by spreading misinformation. They became victims of their own smear campaign. But trying so hard to mislead & confuse, they undermined their own progress. In other words, the audience found nothing compelling to draw them in. No incentive to take the next step spells doom for any initiative related to the spread of technology. To increase marketshare, you must appeal to a wider audience. Staying within the realm of enthusiasts meant being trapped in that venue. There simply was no way to expand. We're seeing fallout from that now. This next stage (the one beyond tax-credits) is showing signs of very real trouble already. Who is the audience now? The big EV blog isn't publishing anything to attract those doing basic plug-in research. There's just a flurry of articles highlighting concept & exotic vehicles. Nothing for ordinary consumers is a very real problem. Keep in mind how vital it is to have "*showroom shopper*" content at the ready, something to entice the curious searcher. Not having anything of that nature anymore is fallout those hoping to grow the market cannot afford to experience. Something must be done to prevent this loss of middle-market targeting has brought about.

2-06-2020 **How?** We are seeing attempts by GM to stir hype. With their tax-credit phaseout about to conclude, that's no surprise. Also not a surprise is how many enthusiasts there are online who really don't have a clue what GM is capable of with ambiguous announcements. For example, this came about today as a result of hearing some big reveals are on the way for early March: *"I'm excited to see what GM has planned!"* Ugh. Notice how there is no setting of any type of expectation, that it is left wide open despite this reader supposedly being somewhat informed (by the act of participating within an enthusiast venue). Even those Volt troublemakers set some type of target. Nothing whatsoever is a bad sign. Of course, that *"nicely under \$30,000"* goal still haunts many who backed GM. It's a sensible target to have set all those years ago for the market now, which GM was never able to deliver. Achieving cost low even to make a technology both affordable & profitable is far more difficult than those enthusiasts ever imagined... hence being enthusiastic, rather than realistic like a supporter must be. That difference is profound... which is why I ask the *"How?"* question now instead of *"Who?"*. Needless to say, I don't expect a constructive response to this reply I posted: It's all about actions, not words. Watch for vague & ambiguous statements. We've see the pattern of the *"over promise, under deliver"* game being played by GM repeatedly. This is yet another example of how they build hype without substance. Sure, GM could step up to the plate. They have the engineering expertise. The catch is their dealers simply aren't interested in supporting that. So, ask how these new plans change that paradigm. In other words, what will GM be doing to stir interest from their dealers. How will want they announce actually change the inventory stocked?

2-07-2020 **Not Charged.** Over the years, rhetoric involving the purchase of a PHEV just for the sake of HOV access has spread. Claims are that the owner never plugs in. Looking beyond whether or not that is actually true, we see the reality that the purchase resulted in another PHEV being put on the road. If the motive was indeed that HOV access, that means the vehicle is very likely to be sold 3 years later when it expires. That addition of a vehicle into the used market is great. Someone wanting to heavily discounted plug-in would get their wish. So, it is a win overall anyway. But the odds of an owner not plugging it ever is rather slim. Why wouldn't you take advantage of the cheaper fuel? Heck, there are places you can find electricity for free. For me, that's every time I visit the local grocery store. Anywho, the antagonist can never explain PHEV purchases in states where there is no incentive for HOV access. So, there argument falls apart one way or another. They keep trying though. The latest effort is: *"PHEVs consume 3 times more fuel if not charged"*. Seeing that as a title on an article was troubling. It was spin to get you to overlook the reality that the better PHEV operate as extremely efficient hybrids following depletion of the battery. Dancing around that fact is difficult. A plug-in Prius is still a Prius, so MPG is higher than other vehicles regardless of plugged-supplied electricity. Seeing results around 60 MPG even without plugging is an easily fulfilled expectation. How is that *"3 times more"* than the implied comparison to traditional vehicles? In the article, claims of the extra weight due to the large battery-pack certainly gives you that impression.

2-08-2020 **Video: Prius Prime - Electric Heat-Pump.** Electric-Only driving in the winter is made possible using an electric heat-pump. This is a device that compresses air to capture & transfer heat from its surroundings, an exchange of cold for warm. So even with temperatures in the teens, you can comfortably enjoy EV driving. This video shows me on an ordinary daily commute to work in February in Minnesota. It's quite uneventful, exactly what you'd want for a routine morning drive. The gas engine never starts, despite the cold. All the propulsion & warming came from electricity. Here's the latest in my quest to share technical info in a KISS format. The detail is there if you're interested. If not, it's just an entertaining time-lapse video showing what a non-eventful winter commute is like in Minnesota. With outside temperature in the teens, the entire drive is in EV. You can easily see the electricity trade-off of range for warmth. It serves well for those driving short commutes or (like me) have the opportunity to recharge while at work... [Prius Prime - Electric Heat-Pump](#)

2-08-2020 **Charge Time.** I posted this: *"It takes up to 6 hours to completely recharge a Prius Prime (25 miles) using a standard 120-volt outlet. That means it will take around 10 hours for RAV4 Prime (39 miles)."* You wouldn't think such a concise claim backed by real-world data would stir outrage. Someone was angered though, that I'd make post a statement so obviously incorrect. It was bizarre... until I discovered it was just another troublemaker on a newly created group. Ugh. It's sad to think a topic as simple as charge-time would draw those hoping to undermine. But then again, even among EV supporters there has been issues related to things as simple as charging. In fact, that's a big contributor to why PHEV will dominate for years to come. Sure, EV will hold the spotlight and capture the hearts of many, but stuff like this jerk today will be fighting against that progress. At least with a plug-in hybrid, you can start on your own. No special knowledge needed. Just plug in the charging-unit that came with the vehicle into the nearly ordinary outlet in your garage and don't even worry about the time it takes to charge.

2-08-2020 **Meaningful Adoption.** Sometimes, my blog entry will be created using a secondary computer. I forgot to send the following, from nearly 2 months ago... which was an important time, since it was prior to the tax-credit end becoming a reality. There was a claim of "*meaningful adoption*" without any context. I knew it was from a source who routinely evades constructive His posts focus on at-the-moment victories with a total disregard for the market as a whole. Forcing the perspective of only plug-in vehicles mattering isn't the slightest bit helpful. In fact, that stance often comes across as that "*vastly superior*" attitude we had so many problems with years ago. Allowing that to persist wasn't acceptable then and certainly isn't now, 5 weeks following Tesla's end of tax-credits and 7 weeks until the same happens to GM. Intent of that subsidy money was to achieve meaningful adoption. I pointed out:

Certain people have danced around what that really means. They are those who refer to sales as "*EV Market*" rather than acknowledge the consumers who legacy dealerships actually serve. Reality has since crashed down on them... as confirmed by their silence.

It was interesting to watch them turn a blind-eye to what the quantity of 200,000 really represented. That's less than 10% of Toyota's production for just a single year in just the United States. Spread over an entire decade (from 2009 to 2019), those truly in support of reaching mainstream buyers in any "*meaningful*" way, they knew volume & profit must be achieved prior to triggering phaseout.

The antagonists upset to see Toyota doing exactly that declare "*laggard*" to make their misunderstanding of market not sting as much. It's a vindication for those who pushed for genuine change, not just praise for technical achievement or short-term gain. This is why any next-step to subsidize adoption should be focused on infrastructure instead. Again, new money as an incentive to choose a plug-in vehicle should now be used toward upgrades at home. Where you park overnight should get those funds. That is a permanent investment which will deliver benefit for decades to come, well beyond just the purchase of single vehicle.

2-08-2020 **Intentional Misleading.** It is somewhat remarkable how certain people will just repeat the same lie over and over. This individual gets called out on it each time to, but simply doesn't care. He tried it yet again today: "*Glad my taxes helped to get you a refund.*" It makes you wonder. Is this a willful ignorance or a just plain doesn't care situation? Either way, there's always someone who steps it to point out the incorrect claim. Today, it was me: That isn't how tax-credits work. It isn't ever money from someone else. It is a reduction of what you would normally pay, a portion of your own liability. In other words, you get to keep more of your paycheck.

2-09-2020 **Returning Troublemakers.** There is a new group on Facebook created specifically for those interested in RAV4 Prime. Right away, I got quite suspicious by an individual posting what seemed to be gloating about GM. He made comment efficiency in relation to the size of the battery, following an unfounded claim of 12-amps from an 120-volt outlet being unrealistic for charging despite overwhelming evidence to the contrary. That was a big red-flag. Quite a shocking number of people equate capacity to efficiency, rather than the actual rate of consumption. It's a misconception that has propagated throughout the EV community, stemming from the belief that more is better. That's an easy trap to fall into. He obviously did. So, I posted this to test his integrity: *"Efficiency is measured in terms of kWh/100mi, not size of the battery-pack. In that regard, Prius Prime is rated at 25.9 and Bolt at 28.0, showing the Toyota is clearly more efficient. RAV4 Prime likely also has an edge."* Sure enough, he got angered and lashed back with a weight argument. Suspecting he was already unwilling to hear anymore, I figured it was pointless to address him. Instead, I just provided some background. This situation reminded me of the first battles, back when people compared Insight to Prius. It made no sense whatsoever comparing a 2-seat aluminum-body manual-transmission hatchback to a 5-seat automatic sedan. They had nothing in common beyond both just being hybrids. Yet, that comparison happened on a very regular basis. Ugh. Anywho, he was clearly trying to stir trouble when he brought up his Volt ownership in the reply, attempting to directly compare it to RAV4 Prime. Ugh, again. This was my response: That *"RAV4 Prime likely also has an edge."* means the Toyota design will likely be more efficient than that GM design. In other words, EV drive for a RAV4 will likely be more efficient than that from Equinox. That's comparing a similar size & class of vehicle. Knowing how much more experience Toyota has with motor, controller, and software design from so many generations of hybrids, it makes sense they have found a way to squeeze out greater electric efficiency.

2-10-2020 **More Fallout.** There was an article published a few days ago that started with: *"Put simply, GM was finished with hybrids. There will be no follow-ups to the Volt, no long-rumored plug-in hybrid crossover, and even no more hybrids on the way."* Comments posted about it were all over the place. Many said it was a shame that GM didn't do anything with the technology... exactly what I complained about shortly after gen-1 Volt sales confirmed it was a disaster already playing out. Even way back when, if you were familiar at all with how GM responded to Two-Mode sales struggle, the pattern was familiar. Taking the next step wasn't going to happen. Diversification wasn't being treated as a priority; instead, rhetoric to hold it back became the overwhelming theme. Evidence of that still is strong. Some were arguing in this very article that Volt was unlike the from Toyota, never directly powering the wheels. Despite confirmation that isn't true, that it did indeed operate in parallel for engine/motor propulsion, that false information continues to be spread. It's quite bizarre to see such blatant misrepresentation taking place. But then again, it isn't like the narrative is uncommon. Even GM's president pushes the belief of complexity: *"I just - from a physics and engineering standpoint - just can't get my head around making money doing that in the long haul, even as a stopgap."* That recent comment feeds the perspective of cost & complexity. There's good reason for taking that stance too. Toyota is about to prove it so wrong, GM will be set way back for even attempting to compete. They feel they are better off just pretending Volt served to demonstrate it was impossible and they moved on without any pressure to the contrary. Ugh.

2-11-2020 **Giving Up.** It is interesting to see articles posted about GM giving up on hybrids. They never had their heart in it, ever. The efforts were obviously not sincere. Audience was a dead giveaway of that. Sales & Praise came from conquest, not actual change. In fact, there is nothing at GM dealers to even indicate anything happened. We see traditional guzzlers on their lots. That's it. Had hybrids been of any interest, there would have been a push to spread the technology. RAV4 hybrid AWD delivers 40 MPG. Highlander hybrid AWD delivers 35 MPG (the FWD will deliver 36 MPG). If Toyota is the laggard, how come GM doesn't have anything comparable... or better? Volt technology was abandoned. Imagine what it could have become in an Equinox or Trax. Ugh. Here's what I posted as a comment on the article in the big EV blog's article about this topic:

Volt's claim to being "*vastly superior*" was a futile attempt to build up a false idol. It depended upon hope & assumptions. Even comments in this very discussion portray its design incorrectly to persist that narrative. In reality, Volt was an expensive approach to delivering a plug-in hybrid. GM clearly didn't want it to compete directly with traditional vehicles.

Toyota hit the problem from the opposite direction, doing everything right from the start with low-cost being a very high priority. That meant it would take several generations of design refinement, but in the end Prius now delivers to-the-floor EV acceleration and that same affordable technology will now be passed on to RAV4.

In other words, GM was the laggard. There was no push forward. It just died with an early-adopter audience and a heavy dependence on tax-credits. GM enjoyed the enthusiast praise, resting on its laurels rather than bothering to put that technology in a configuration their own customers would actually purchase.

Think about how Volt got its start. There was a plug-in version of Two-Mode already being demonstrated. It was a SUV, specifically a Saturn Vue. Taking a detour with the technology by modifying it for a hatchback should have only been a short-term effort. Abandoning the idea of putting it in an Equinox was the big mistake... one that RAV4 Prime will make quite obvious.

It's no surprise at this point GM has given up.

2-11-2020 **Disadvantaged.** Every time GM is brought up in a discussion, someone complains with a "*disadvantaged*" complaint. With complete disregard for what actually happened, they cry foul. It's really annoying how lack of critical thinking has become so common. I posted: 200,000 vehicles is not that many. It's just enough to help get momentum built up so sales can continue strong on their own. Tesla saw that intent with the tax-credits and did exactly that. GM turned its back on that same opportunity. Toyota will follow the Tesla approach, taking advantage of the tax-credits to build demand, then exploit the unlimited aspect of the phaseout period. That proved very effective for Tesla. It will propel the "Prime" offerings into the mainstream. GM now desperately needs something to move forward with. They literally have nothing for showroom shoppers to consider. When a loyal customer comes to the dealer looking for a SUV, they'll have nothing but a vast array of traditional guzzlers to choose from. That's a very real problem.

- 2-11-2020** **Priorities.** Spin of priorities is as simple as disregarding facts. You just portray a situation in a manner you want the activity to be perceived. That's the basis of a narrative. Hope is it will get passed along without question, just assumed to be true. The claim today was that Prius Prime couldn't deliver power without the engine running. That's false. But with such a statement repeating over and over and over again, it ends up a belief. That's why I try to capture so much detailed video. It's very difficult to deny content of that nature; though, antagonists certainly try. Anywho, I fired back on the power claim with: What difference? You drop the pedal to the floor in Prius Prime and it sucks up the battery-capacity. That full EV acceleration is what? No gas used for typical daily commute is a running cost of \$0 that some Prius Prime owners already enjoy. With RAV4 Prime bumping the EV range to 39 miles, focus will turn to time-of-use discounts to recharge. Understanding that will bring about a paradigm shift. In other words, Toyota priorities were to strike a balance to make their plug-in hybrid technology capable of directly competing with traditional vehicles. GM's priority with Volt was to exploit it as a halo.
- 2-13-2020** **Wow!** I was beside myself with this comment, unsure how to respond: "*When EV's are ready for the masses, every convenience-store will put in charging stations at no cost to the taxpayers.*" It makes no sense. A convenience-store is somewhere you only spend a few minutes stopped at. To make that viable, the owner would have to spend an obscene amount of money to deliver power that faster. Those super-high-speed DC chargers are extremely expensive; most plug-in vehicles cannot take advantage of those rates either. And why must the electricity be free? It's impractical attitudes like that we always have to deal with. Every step of the way, someone will draw an arbitrary line stating they would be supportive if. It's really just a rouse to get you to not push them to be more practical. Finding a balance is not for those who favor want though. And sadly, our society has become so negligent of need they simply don't care anymore. So, the sentiment expressed is to be expected. We have grown complacent. Ugh.
- 2-14-2020** **Master Plan.** A repeating theme is to now misrepresent Toyota's mission. I find it quite eye-opening how Toyota gets relentlessly attacked with those misrepresentations, yet other legacy automakers are allowed a free-pass with no plan at all. Not having anything at all is somehow more acceptable than having something you don't agree with. In what world is evading a problem the better choice? Ugh. I jumped into a new thread on the topic, knowing it will quickly become confrontational: Toyota has a master plan for transitioning their product-line away from traditional vehicle. They are already well underway with architecture change necessary to enabler. Few are paying attention to that though; instead, we're getting short-sighted rhetoric. That comes from an audience obsessed with top-down approaches. Toyota's business doesn't operate that way. They work bottom-up. In other words, we will also be getting plug-in hybrids and electric-only choices, but the industry spinners focus on the rest of the fleet for Toyota and disregard that as important for the other automakers. It's so hypocritical, I'm really surprised so many people get suckered into the propaganda. It's an effort playing out right before our eyes with enablers more than willing to feed the narrative. To that, my response is "*Ugh!*"

- 2-14-2020** **Good Business.** I had to fire back. Right away, the attacks began. It's the same player every time too. This is what I selected to respond to: "*Nothing wrong with good business, I just don't agree with the premise.*" Annoyed at such a vague response, a posted complaint without a suggestion just wastes everyone's time. What do suggest for a 2030 target with regard to a majority of each automaker's production? What premise? Notice how everyone, except Toyota, is only focusing on the low-hanging fruit? The absence of anything for the bulk of the business should be a red flag... in other words NOT good business.
- 2-14-2020** **Accountability.** He made it worse, replying with: "*government should be incentivizing plug ins of all types, with an emphasis on bevs, charging stations and renewable energy*" That's so horribly vague, it tells us nothing. This is what we call an enabler response. This are indigenous trolls. Every forum has them. They stir & provoke to keep discussions alive, doing whatever it takes to prevent conclusions from being drawn. Why is obvious. They thrive on those posts. Allowing them to come to an end is the last thing they'd want. So, you see the behavior of undermining for the sake of endless debate. I find that incredibly frustrating, but often choose to ignore it. Don't feed the trolls. Sometimes you have to, especially after he repeats attempts so often to provoke. I took that action with: That's not a target or even anything quantifiable. In fact, that was just another vague response. You're contributing to the lack of accountability problem.
- 2-14-2020** **The Point.** That same indigenous troll keeps at it. Post after post, all vague. He still doesn't quote or capitalize either. Comments are always of an ambiguous nature. He thrives on the chaos that creates. It's quite intentional, an undeniable pattern. That activity is for the sake of entertainment, attempting to retain rewarding elements of the past. In other words, his point is to fight change. I felt it was time to let him have it... not for the sake of expecting any type of change... but for those lurkers reading with curiosity wanting to learn why such an exchange was taking place. That's why this short & sweet response was so appropriate for the circumstances: The point is to rise above the rhetoric, not to contribute to it.

2-14-2020 **Choice.** I liked this, which came from another troll: "*Tell that to Toyota.*" He is another who thrives on the trouble he stirs. It's all about keeping the status quo, doing whatever it takes to prevent progress. I'm always amazed at how much effort is expended to defend nothing. He really doesn't have a position. There is only spin to prevent change, another pattern easy to notice if you watch posts. Anywho, I saw that as an invitation to climb up onto the soapbox. So, I did:

Tell what to Toyota? I'm calling you out for being vague too.

Toyota continues to refuse to play the game, forcing other legacy automakers to recognize they have no actual plan to convert their fleet.

GM is by far the biggest offender. Volt exploited the tax-credits, seeking praise from conquest sales rather than actually doing anything to change what happens with dealer inventory. It was a colossal waste of opportunity... one that Toyota has been working hard take advantage of, the very opposite of GM.

We see Toyota striving to phaseout their entire product-line of passenger vehicles in favor of hybrids. That establishes a culture of change at dealerships, where they learn to address showroom shoppers curious about the technology. It builds upon itself, once the shift away from traditional becomes obvious... which is exactly what we are witnessing now.

Toyota's next step in that master plan is to stir interest across the board with PHEV offerings, showing all audiences how adding a plug and more battery to their wide array of hybrids is a practical & affordable option. That pushes a paradigm-shift of choice. Rather than loyal customers simply replacing their old Toyota vehicle with a new Toyota vehicle, they see variety. That no-pressure approach is priceless. You need to support whatever your vague claim is with substance. How are the other legacy automakers going to move their offerings forward?

2-15-2020 **Video: Prius Prime - Sub-Zero Commute.** That -8°F speaks for itself. Watch how engine cycles on & off to use as much electricity as possible. Not much else needs to be said. In great detail, I captured my morning commute on one of the coldest this season. Although it came out fairly well, it wasn't without challenges. I tried the day before, on both the commute to work and the drive back. Both failed with technical issues. Camera setup is challenging. I ever forget to reset a configuration, causing a quality reduction on the dashboard feed. But it wasn't enough to prevent keeping the footage as with the previous attempts. That's video of this nature works though. You keep trying to get it all right. Sometimes it works. Other times, you write it off as a good effort... maybe next time. It's part of the refinement process. You learn from both success & error. Today, it was success. Phew! Watch how well Prius Prime copes with the dead of Winter here in Minnesota... [Prius Prime - Sub-Zero Commute](#)

2-16-2020 **Spinning Toyota's Stance.** There certainly is a lot of that lately. It's a good sign when the constructive nature of discussions vanishes. That's how you know they have nothing to argue with, that they're previous line of reasoning has fallen apart. In other words, it broke their pattern. This was the statement the antagonists have been struggling to overcome recently: "*Carbon reduction can only be achieved by consumers deciding to spend their own money in ways that deliver a practical return for themselves.*" It came from a Toyota executive in Canada... which seemed a great quote to attack. But lacking substances, the antagonists have been struggling to keep focus in their favor. I find that incredibly telling. Their spin isn't working. This is what I had to say to that:

After a decade of watching failed incentives from government efforts, it makes sense to stop beating that dead horse. We can obviously still invest in infrastructure, but focus on the vehicle itself simply wastes time & money toward reaching the masses. Have you ever considered how when each state that decides to adopt ZEV requirements must face a mountain of litigation? Those fighting the advance forward expend an enormous amount of resources to prevent that progress. Toyota recognizes this and has the balls to acknowledge it. Too bad if you don't agree with that. Facts are not subject to debate.

We must find a way to deal with that reality. Again, this is why "know your audience" is so important. With 17,000,000 new vehicle purchases annually here alone, its up to the automaker to find a means of delivering. Dealers will supply focus on what they can sell with minimal effort and maximum profit. That's a cold, hard reality. Our contribution is to make that process easier. Infrastructure is the monetary investment to encourage. We can make things happen with regard to charging. We can also provide the knowledge transfer to others. That will help the process along.

Watching consumer behavior, we have witnessed obsession with the SUV become normalized to the extreme of it now being an expectation. Sedan production is ending for Ford & GM. That blatant abandonment on their part is a response to the self-deprecating message they have been spreading for 25 years. Toyota found a way to adopt, adapt, and improve. RAV4 Prime is an undeniable solution to the problem, one that focuses on consumer decision.

2-16-2020 **Skeptics.** That was the identifier a good friend of my help to provide with his perspective, having moved on to the top-down offerings. From Toyota, to BMW, to Tesla, his explorations have been quite enlightening. That type comprehensive exposure can be very informative. It's what you need to balance technology with what the market will actually accept. We all hear about technology that's exciting & inspirational, but that isn't what the majority actually purchase. This is why Toyota's work to establish a technology for mainstream choice right from the start has been so successful. It's easy to build something when expense isn't a concern. But when you must squeeze out cost to make the offering both profitable & affordable, that's an entirely different matter. This is why I bring up GM so often. All those years of gloating, with so many enthusiasts feeling empowered to insult & belittle, the lesson learned from that having failed should not be so easily dismissed. Those antagonists really try hard to do that, hoping to sway skeptics away from consideration. It's who we need to appeal to... hence bring up "know your audience" so often. They are it... which is why I get so confrontational with those attempting to undermine that reach out to those still uncertain. Anywho, it was worth the volley this time. I saw there are some who still hope for a miracle, rather than doing what needs to be done. Identifying who & what is key to moving beyond this stage.

2-16-2020 **Credit Limit.** It was a nice change of pace to have this question pop up: "*What is Toyota's magic USA plug-in sales number?*" He wanted to know how the tax-credit would come into play with regard to Toyota's master plan and the rest of the market. I enjoyed getting to provide an answer:

When phaseout is triggered (reaching the 200,000 limit), there is an additional quarter (3 months) of full tax-credits available after that current quarter completes. Following that, the volume restriction is lifted but tax-credit value is reduced by 50%. After 2 quarters, the value is reduced to just 25% of the original full amount.

That process worked exceptionally well for Tesla and the same should be true for Toyota. The reason why is simple, intent of the tax-credit was fulfilled. Demand for the technology was established and brought up to the level of sustainability. In other words, the automaker takes advantage of the unlimited volume aspect of phaseout... which contributes to consumers accepting the offering as the next natural step forward.

The cold, hard reality of GM having exploited tax-credits for conquest with a terrible disregard for their own loyal customers became undeniable as their triggering of phaseout grew near. They had not established their technology. Showroom shoppers at GM dealers had nothing desirable. Volt had failed to grow beyond a niche and Bolt was struggling to survive. So naturally, there's a lot of downplay about the resulting fallout... especially with regard to Toyota's progress.

Toyota will face phaseout with 2 models of Prime already well established and the expectation of new & updated offerings to follow. There will be no doubt among showroom shoppers that change is underway. That confidence in those steps forward is vital for both dealer & consumer. So regardless of any future government incentives, progress will have already taken place. It's not magic. It's just a lot of careful planning and a mission unbroken by endless rhetoric.

2-17-2020 **PHEV Bridge.** We are really seeing an increase in the "*bridge to EV*" sentiment now. The role plug-in hybrids will provide toward bridging the electrification transition and it is becoming very difficult to just brush away now. It's becoming evident how little people understand EV technology. Through no fault of their own, there's much ignorance. Exposure is very limited and misconceptions are abundant. That makes undermining progress very easy... and we're seeing that being exploited in many ways. Choices like RAV4 PHEV should help turn the table though. Being able to so easily stir interest will be a game-changer. Remember how that was supposed to be Volt? This is why I pushed "*Who?*" so much. It was obvious whatever technology that came about and was proven would necessitate spreading for growth. The ultimate irony of "*laggard*" will be playing out in the next few months. The enthusiasts have all by grown entirely silent already. They saw the bridge but failed to find a way to across get across. It's all about reaching mainstream consumers on the other side. Bridging from enthusiast to the masses is how you achieve the advancement forward with technology. Engineering alone is not enough. People must accept what you present. Appeal to what they can do: PHEV are an effortless bridge that encourages upgrades at home. It's a painless decision being able to simply drive off the dealer's lot and recharge at home using nothing but a standard 120-volt outlet. After doing that overnight routine for a while, the owner becomes compelled to look into the 240-volt upgrade. No pressure on the when & how is key. After all, most households are simply not capable of recharging 2 plug-in vehicles overnight without an upgrade. Somehow, that bridge needs to be crossed without intimidation. Know your audience.

2-18-2020 **Illogical.** Reading this made me sigh: "*I'd like you to ask PHEV manufacturers standardize a light in the upper rear part of the vehicle that is ONLY powered on when the car is in pure electric mode. That is absolutely necessary for PHEV's to be considered a green alternative. If those cars have an ONLY ELECTRIC external indicator, you can consider them green to enter the city as long as they turn their engines to only EV.*" This is what you get from some newbies, those who haven't really ever given the circumstances or technology any real thought. They just make up something on-the-fly that seems sensible, but really doesn't equate to any benefit. That's just like the insistence upon more range being better. It sounds logical, but nothing is actually gained from having more capacity. In fact, beyond actual need can turn into a negative. Want can be costly to fulfill. There are tradeoffs. Anywho, I responded to that with: That is an illogical request. To ensure a PHEV has enough EV capacity available for restricted-city access, it must have a means of preventing that electricity from being used up during the initial drive to the city. Having a "hold" button means the toggle between EV and HV is at the control of the driver. So at any time, the engine can be turned back on after entering. More importantly, what if the owner lives in the city and that's where they plug in. If EV capacity is used up prior to reaching their recharge destination, then what? It sounds like a planning issue, but getting stuck in city congestion with the electric-heater running presents a problem the owner simply cannot predict. Surprise inner-city delays happen. Lastly, keep in mind that when the engine runs, it is actually cycling on & off. So, there is a mix of EV and HV while you drive even following depletion.

2-19-2020 **One Year Ago.** This was posted a year ago, as the death of Volt was unfolding. That reality hit enthusiasts hard, it was beyond their worst nightmare. Besides their beloved vehicle being abruptly discontinued, there was the fact that I was right about the investment in the technology all along. GM's heart just wasn't in it. They were content fulfilling a niche to relish in praise from those whose opinion was really just a facade. They had lost the war with me. All those battles didn't actually accomplish anything. But what they hated most was my message never changed. I was always pushing for the spread of clean & green technology to the masses, disinterested in glory. Their "*trophy mentality*" meant nothing to me. It made them crazy. I find it fascinating. A great example of that is how relevant my post from one year ago has become. I nailed it with the prediction and even back then they knew it:

That attempt at damage-control is pretty lame. The advertisement for RAV4 hybrid features the second-generation now being rolled out, not the first as you imply.

I have been talking about a "*Prime*" upgrade to that platform for years, just add a one-way clutch and more battery the same way Prius was augmented. It's a simple & affordable way to offer a plug option.

Each time I brought up the larger and more powerful hybrid, I got attacked. In fact, I expect the same with this post... especially when I remind everyone of how GM recently chose to offer Equinox as a diesel, rather than a hybrid.

See, with the RAV4 hybrid becoming a popular choice, due to the regular RAV4 being Toyota's top-seller and the hybrid being so affordable, taking the next step by offering a plug in a no-brainer. Those loyal showroom shoppers will see the plug-in and seriously consider the purchase, simply by association.

All the senseless efforts to undermine Prius and attack me were in vain. Enthusiasts here failed to heed the warning, despite being told hundreds of times GM must diversify their plug-in hybrid technology. It was never spread to a SUV... and clearly should have.

2-22-2020 **Video: Prius Prime - Sub-Zero Commute (alternate route).** In the quest to get a variety of data to share, I took this alternate route to work. It's another sub-zero commute. But unlike the other vehicle, this alternate route completely avoids the highway. With temperature much lower than the 14°F threshold for the electric heat-pump, it's another example of how the engine cycles on & off to provide cabin warming. The drive itself is rather pleasant, lots of hills & turns. The extreme cold doesn't present any challenges. Watch the temperature of the coolant as the engine heats it. When it reaches a certain level, the engine shuts off. When it drops below the minimum, it starts up again. As the system warms, that minimum drops. So, the engine stays off longer the more you drive, despite the cold outside. Overall MPG goes up and the drive proceeds. Plug-Supplied electricity is used for propulsion when the engine is off. You can see that detail on the aftermarket app (a device connected to my tablet via bluetooth from the car). It's handy to have more information available than just what the display on the dashboard shows.

Here's a link to that video... [Prius Prime - Sub-Zero Commute \(alternate route\)](#)

2-23-2020 **Preparation.** Expecting RAV4 Prime to take the market by storm, I have been preparing by creating informational videos to share about how that plug-in hybrid technology operates. Our recent super cold day provided a great opportunity to capture a commute with my Prius Prime. I took a non-highway route to highlight how the engine cycles on & off to give you cabin warmth while also allowing for short jaunts of EV driving. That turned out great. Good thing too. With changes of extreme cold dwindling as hints of Spring start to enter our forecast, this was basically my last opportunity to film. Work schedules and nice lighting don't often coincide nicely with weather patterns. So, I considered this opportunity a fortunate one, something not to be missed. It worked out nicely too. Knowing that even Tesla is playing catch-up, since they have not offered a heat-pump yet, any data showing how that technology will benefit all the extremes is helpful. Under ordinary Winter driving, that's all you need. The less efficient resistance-heater is only necessary during the limited times when it really is the cold season's peak. I have been enjoying that benefit for 3 years now. It's interesting how that makes a difference. Most people won't have any idea. We do though, the people watching for detail on technical videos. So, I'm glad to have created a collection to share prior to the desire for that knowledge from the curious.

2-23-2020 **Interesting Requests.** I especially like comments posted about the videos. This one in particular stood out: *"Have you or could you please do a commute with EV-Auto, where the car determines the best option between electric and engine? I'm thinking you would obtain better mileage if it choose for you?"* It was a request. I like those. Coming from an audience beyond the reach of the online forums, they are often quite compelling. After all, hearing from those outside your peers is the best way to get new ideas. And now that I have covered the essentials, it would be nice to be able to provide some other information. The suggestion of EV-Auto is a worthwhile one. At some point (meaning the warm season, when it's a lot easier to setup all the equipment), I could see myself following up with that request. Ideally, I would do the same drive twice for good measure. We'll see. In the meantime, this was my reply: With this particular type of drive (temperature well below heat-pump minimum), the use of EV-Auto would make no difference. The engine would cycle exactly the same way. In warmer conditions, if your destination is within the charge range, keeping it in the default EV mode is best. The only situation where I could see EV-Auto as having any benefit is on a long trip when there will be several demands for high power, which is when having the engine available (already warmed up) would provide an overall savings. On my commute, in all but the extreme cold (as in this video), my entire drive can be in EV. Switching to EV-Auto, would be a waste. Being able to recharge at work negates the need for engine running at all. For me, it's there for longer trips.

2-23-2020 **Next Step.** At what point does the next step become obvious? Some people still wonder: *"There is a rumor on the Bolt EV Facebook page that there *might* be a reason that Bolts are being heavily discounted and that they are being cleared out."* Knowing that Bolt was never profitable and there is no expectation for profit until GM's next-gen platform is rolled out, it simply makes no sense carrying forward with this offering. Without any tax-credit to leverage, just clearing out stock is a subtle way to allow the failure to fade away seems the best choice. After all, who is there left to speak out in favor of Bolt? All of the Volt enthusiasts have vanished. It's rather strange for all of them to be gone now. Their constant antagonist activity was always such a pain. Now, it's difficult to even convey the gravity of their influence. How could a supposed group of such massive underlying effort now be entirely absent from discussions now? That's just the way it is. The next step required abandoned the terrible path they were on. Forward was not the direction they favored. They endorsed a niche, something to reign over others rather than being an actual game-changer. Ugh. I responded to that *might* comment with: Seeing GM move to another platform for their EV offerings shouldn't be a surprise. The very idea of an automaker dominated by the sales of Pickups & SUVs having their premiere plug-in a small hatchback or wagon was a bit absurd. After all, GM had a prototype plug-in SUV over a decade ago. There's the reality of RAV4 Prime from Toyota becoming a serious draw too. So, starting fresh by moving away from Bolt is a sensible next step.

2-23-2020

First Post, Prime Curious. When you see a "1" in the counter for someone on the forum, there is good reason to give extra attention to their particular post. We often see extremes from the new... either someone innocently joining to ask a genuine question or someone joining with the hope of stirring trouble. Suspicion is easy to raise by just reading what they provide and watching for the reply. That return on whatever comment you provide tends to reveal motive. You can detect a pattern to satisfy misgiving. Here's what caught my attention: *"To give a quick background, wife and I are ready to upgrade from our 2006 Acura TL (that recently needed a rebuilt transmission) and we have been very intrigued by the Prius Prime..."* Was that from a person truly researching a purchase? I posted:

Interesting. That's what my wife traded in for her Prime. She bought her TL used, with a replaced transmission. I think the previous owner didn't know how to drive with a clutch. She also had to have it rebuilt after the back corner got struck by a careless driver. It made a mess of the navigation system, which was stored in the trunk. Anywho, she drives a Prime now and loves it.

There will inevitably be a new Prius Prime in the next few years that will be a huge step forward with the technology. I have been upgrading with each new generation of Prius for 20 years now. Toyota's investment toward electrification advancement is. We see hints as parts of what is to come from what gets rolled out with their other hybrids. Ultimately though, Prius has been a great platform for the greenest of us. And as the "car" slowly vanishes from this market, it makes sense to see Prius evolve into a strong choice for those not interested in something that resembles a truck.

As for your choice of when to purchase, how long do you intend to keep this Prius? There is always something better on the way. That's how new technology works, especially in an emerging market. To take advantage of whatever the next-gen Prius Prime offers, you should consider charger setup. Recharging with an ordinary 120-volt outlet should work fine, but the charging standard at that point will almost certainly be a speed step up from 3.6 to 7.2 kW. If you don't ever intend to provide a dedicated 40-amp line for a charger, a feature of the new tech would be missed. Supplying electricity faster isn't necessary, but that is what you'd be paying for as part of the next-gen offering.

It goes without saying (though I will), that EV range (efficiency/capacity) will increase and the battery will become more robust. That's just another natural step forward with the progression of any maturing plug-in technology.

This generation of Prius Prime has been a wonderful choice for us. We have two. Long highway trips to visit family and the countless drives to grandpa's stuffing the cargo area in preparation to sell his house has proven worth of the technology. Our commutes are entirely electric too, since we can recharge at work. I'm hoping to upgrade to the next-gen Prius yet again. But in the meantime, I'm thoroughly enjoying the EV driving experience this generation provides.

I hope my ramblings helped. Good luck with your decision.

- 2-23-2020** **Differences.** To some, the choice isn't clear. So, they ask: "*Why did you choose Prius Prime and not Chevrolet Volt 2, what is the advantage of prius?*" That sounded sincere to me. It makes sense that there are many who have no idea what the difference are. This is why I really try to focus on actual data, rather than getting pulled into the rhetoric. Hopefully, I did a good job of that this time: Volt offered less efficient EV drive (31 kWh/100mi) compared to Prius Prime (25 kWh/100mi) and less efficient HV drive (42 MPG combined) compared to Prius Prime (54 MPG combined). Electric heating from Prius Prime was also more efficient, offering a vapor-injected heat-pump rather than a basic resistance-heater that Volt used. It was also obvious Toyota was investing in other important design aspects of efficiency, as the carbon-fiber hatch in Prius Prime clearly confirms. Another easy decision-maker was the simple fact that Prius Prime was larger inside. Looking at the bigger picture, it was obvious Toyota would be spreading their technology to other platforms... as we now see with both Corolla PHV and the upcoming RAV4 Prime. That greening of the entire fleet is very important. GM seemed to be all bark and no bite, which has since been proven good reason for concern about actually moving forward.
- 2-26-2020** **Priceless.** There are some who have no idea how we got here and where we are going. That comes from not really understanding what is involved with a vehicle as a whole. Much more is required than just motor & battery. This particular comment provided an invitation to point out some of that: "*Funny how VW was able to develop a sophisticated software program to cheat emission testing but can't come up with something to basically control a vehicle.*" Recognition of what's really involved isn't easy. So much of that can be overlooked by the masses, and often is. Even this extreme example involved the diesel scandal didn't do much to raise the knowledge of many who believe to know a lot about the automotive industry. I pointed out a few things this person most likely had no clue about: Simply programming a disable isn't sophisticated; ironically, not wanting to be sophisticated is how the cheat came about. VW mocked Toyota hybrids with its diesel technology, somehow claiming efficiency was superior. In the meantime, Toyota advanced their hybrid programming to deliver full EV driving. So what if range is limited? That's software operating in real-world conditions deployed in several markets used for several years now. That proven reliability ahead of the larger capacity offerings is priceless.
- 2-27-2020** **Huh?** A fairly new owner of a Prius Prime posted 2 photos. He was confused. How could the MPG be so different on those 2 different meters if the distance was the same? He had no idea. I did though. That's not big mystery, if you know enough about what the system has to offer. I pointed out what he was likely completely unaware of: The car could have been run in place for awhile. Was it delivered with a full charge? If so, it's entirely possible the dealer used Charge-Mode because a level-2 charger wasn't available. After all, that is by far the fastest way to recharge. You get 7.2 kW from the engine, which is twice as fast as the usual rate from level-2 and more than 3 times faster than the factory charger.

- 2-28-2020** **Videos.** I want to film more driving video. I am looking forward to that. I don't see a good outlook for anything Winter related though. The snow is vanishing and predictions are for dry weather above freezing. Arrival of an Spring already was quite unexpected. That's not the normal way we experience March. In fact, even April can be quite inhospitable with regard to what most people expect as the end of the cold season. I do actually look forward to those warm snow storms that pile up lots of the fresh white stuff which melts away quickly... several weeks from now. It looks like that won't happen this year. Oh well.
- 2-29-2020** **Marketing Labels.** Rollout of the SERIES hybrid from Nissan called e-Power beyond just Japan is about to begin. You can imagine the stir that is causing. For example: *"The shocking part is the misinformation happens in the EV community... Imagine how much worse it is in the general public."* Strong emotion to certain labeling comes from limited foresight. When you focus entirely on a single offering, it's easy to fall into the trap of marketing. Labels are an especially problematic aspect of that. The topic from yesterday made that obvious. I jumped in hoping to provide a bit more perspective on the situation: The self-inflicted problem started a decade ago when Volt enthusiasts attempted to coin "EREV" as a type of battery/engine vehicle. Problem was, they kept changing the definition as PHEV offerings advanced. Those new plug-in hybrids would fulfill their criteria, negating the claimed uniqueness of their preferred technology. In the end, they had to succumb to the reality that it was just another way of configuring a PHEV. It's really unfortunate they didn't just adopt the *"No Plug, No Sale"* motto right from the start. The simplicity of that overcomes any type of marketing label.
- 2-29-2020** **Divide & Conquer.** It continued: *"This is the second Japanese company to come out with a "self-charging hybrid"."* I just kept right on going on that: This second entirely different offering from a different automaker makes it clear why a *"self-charging"* hybrid identifier is informative. It's another way of stating it doesn't have a plug, but still takes advantage of motor & battery. Anyone who portrays a narrative that people will someone believe that approach is superior to offering a plug is not taking the situation seriously... or is poorly informed about how the market actually works. Know your audience. Even the most out-of-touch hoppers will recognize the benefit of having a plug. The green aspect goes without saying. Rhetoric from the oil industry falls apart when you see the vehicle presented on a dealer's showroom floor. Misconceptions of power & reliability have been fading away. It's a matter of selling them on cost & practicality now. In other words, worry about *"self-charging"* is what those hoping to undermine the advancement of plug-in vehicles hope you will waste your time on. Don't take the bait! It's a divide & conquer trap. Instead, devote efforts toward spreading the word about how plug-in hybrids offer more.

- 3-02-2020** **Ugh.** There is a small number of individuals dead set on preventing anything else from getting attention. Only "BEV" matters to them. If it isn't a "Battery Electric Vehicle", it doesn't matter. So naturally, Toyota's effort to phaseout traditional vehicles by drawing attention to their regular hybrids is still causing quite a stir for them. It is quite remarkable to see such narrow-mindedness. They have no clue how to get to that majority of vehicles becoming a plug-in. Just like those Volt enthusiasts, hope is upon a miracle battery breakthru. Ironically, we now know that even that isn't enough. People will still fight a viable solution. It's the natural resistance to change. Toyota is well aware of that, hence their marketing. They understand who & how... something enthusiasts tend to be clueless about. It's the classic problem of being so focused on engineering, they neglect the business aspect of the vehicle. We've seen this many, many times in the past. I've learned an effective means of dealing with it too: Self-Charging = ordinary hybrid. Plug-In Hybrid = hybrid with a plug. It's bizarre how some are so determined to twist that into being misleading or deceptive. The battery-pack in an ordinary hybrid doesn't offer a plug, so the only means possible of charging is to use its own engine from within. The difference is obvious, not anything to make such a big deal about. Know your audience. Mainstream consumers recognize the benefits adding a plug provides.
- 3-02-2020** **Analogies.** Sometimes, they just plain don't work. He certainly tried. It was a constructive poster who sees the value in exchanges that make an effort to reach beyond the rhetoric. That's rare... and in this case, ineffective. I'm not sure what he saw connecting the dots for the analogy presented. Lack of a concise message is how the nonsense thrives. So, I jumped in to help: That analogy doesn't work, since it has nothing to do with what people expect from the product. Because "*charging*" is an aspect of design that is implicitly recognized, Toyota is explicitly pointing out their "*self-charging*" hybrids are not the same as their "*plug-in*" hybrids. In other words, this is an effort to differentiate offerings. Notice how no one complaining bothers to acknowledge the necessity to provide such a distinction? Ironically, those complaints are helping to establish a standout marketing term. They are their own worst enemy. Fast-Forward a few years from now when traditional inventory is dropping off and there's a mix of hybrid and plug-in hybrids on the lot. Remember the disastrous "EREV" campaign? The use of "*self-charging*" avoids an abbreviation and briefly informs of design, something quite useful to those shopping at the dealer.
- 3-02-2020** **Let It Go.** They won't, hence the previous ugh. When you find the antagonist just plain doesn't care, you just consider them a troll and move on. That means conclude in some brief & concise manner. This is what I posted in response to the self-charging arguments they obviously will continue to refuse to compromise on under any circumstance: Even novice consumers know "*hybrid*" means it is a gas vehicle that somehow uses electricity to be cleaner and more efficient. After 20 years of being available, arguing that is somehow not the case isn't constructive.

3-02-2020 **Rant.** You pay attention to names, learning from previous exchanges. And sure enough, there's a payoff. Another Toyota topic was starting and right away the attack was launched. They tend to be in the form of climbing up on the soapbox and preaching. They push a narrative, reinforced by repetition... hence watching names. They watch too, fighting back with canned responses. I'm always looking to be constructive. That means addressing change, something their perspective has a difficult time defending. They can't handle offensive moves that don't follow their script. This is where Toyota shines. Volt enthusiasts absolutely hated Camry hybrid, even more so than Prius. You could tell every time I brought it up. Being larger and more powerful, as well as being diverse, there was nothing to compare with. GM was clearly struggling with their hybrid technology and the electric-only effort didn't offer any encouragement. I saw that coming and knew RAV4 would become a serious issue for them. Ignoring Camry was easy. Ignoring RAV4 wasn't possible. Some are still trying though. I asked: Who are you trying to appeal to? An ordinary mainstream consumer couldn't care less about that enthusiast perspective; it just sounds to them like a niche rant. They have grown to recognize Prius as a +50 MPG green choice that was affordable & reliable. Toyota's leadership of pushing the masses forward has been carried over to RAV4 hybrid, which is taking the SUV market by storm... even before rollout of the plug-in model. RAV4 Prime... 0-60 in 5.8 seconds... 302 horsepower... AWD... towing... 39 miles EV.

3-02-2020 **Clear.** Everything they can do to shut us up: "*There is already a distinction. Hybrid. And plug-in hybrid. It's pretty clear.*" That downplay is amusing. Their behavior pattern is quite predictable. That's a telling response to watch for. It's a sign of growing panic. They see change coming. The idea of hybrids becoming the norm from Toyota means an unstoppable paradigm-shift. That's unwanted. They want to skip over steps entirely, jumped straight to BEV. That doesn't work. Skipping steps rarely ever does. With that knowledge, you do the best to minimize... making that step a quick & easy one instead. Here's I put it... well aware of how 20 years equates to "quick" in an industry well over a century old:

The word "*hybrid*" has been so diluted over the past 20 years, it really doesn't tell us anything anymore. Toyota is well aware of history and remembers how effective it was when "*full*" was coined to differentiate its hybrid from "*assist*" and "*mild*". It was a simple means of conveying the message... and worked remarkably. Taking the chance is what leadership is all about. Toyota sees the need and has very effectively drawn attention by coining another. That's what good marketing is all about. Think about how many times Microsoft took advantage of similar opportunities with technology advances.

Just imagine how upset people would be here if all vehicles with a plug were given an "*EV*" label. That is what you are attempting by lumping all types of non-plug hybrid into a single category. Have you ever considered how many different "*EV*" configurations there actually are? At some point, someone will coin a new term to describe DC fast-charging above a certain threshold to differentiate it from others with slower kW rates. It's a dangerous precedent to set by claiming "*already*" in such a vague manner.

Lastly, how can anyone possibly claim "*clear*" in a market so rapidly evolving. Even some here struggle to keep up with all the changes and the wide variety of approaches. Expecting an ordinary consumer to be up on all that is crazy. How could they possibly recognize if their own information is still up to date? It most definitely is not clear. All you have to do to confirm it is ask how efficiency is actually measured. How many here really understand what "*MPGe*" or "*kWh/100mi*" tells us? In short, those making a big deal about "*self-charging*" don't recognize the challenges of marketing. They are focusing on the wrong thing.

3-02-2020 **Loads More.** There was a random tweet from some random Toyota executive. An antagonist took advantage of it by only posting the first sentence. Such a blatant effort to mislead is not something I will just let go. That's an invitation to go on the offensive. So, I did:

Pointing out the omission of the rest of the quote tells us the real story. This is what you intentionally excluded: "*We're introducing the RAV4 Plug-In Hybrid this year, with loads more coming. Thanks.*" Spinning the situation to make it appear they were being disingenuous required leaving out that important part.

Toyota took the time to create a flexible platform, one that could be profitable by offering a variety of choices. We already see Prius Prime and Corolla PHEV. In a few months, RAV4 Prime will join the mix. It's only a matter of time before the "*self-charging*" hybrids gain the attention of the masses to the extent that traditional production can be phased out. What helps that process along is consumers seeing the endorsement of "*plug-in*" hybrids also playing out.

It's the step forward we haven't seen from other legacy automakers. In fact, all this attention toward Toyota could really be an effort to take attention off the other them. They have only presented niche solutions, nothing to replace their business-sustaining vehicles yet... quite the opposite of what Toyota is doing. Watch what happens with RAV4 Prime. Then think about what comes next... the loads more coming.

3-03-2020 **Shame.** The attacks on Toyota are telling. It's the only middle-market legacy automaker that actually delivered. VW has bold plans, but nothing at all to leverage. GM supposedly has plans, but seriously lacks credibility. Nothing else in volume for the masses is expected. So, much of the effort to divert attention is based on hope, not anything of merit. The result is to attempt shaming them. Supposedly, convincing supporters to recognize shame will somehow get them to abandon their hope based on actual successes. Ugh. This is how I dealt with that episode today:

It is quite telling to read posts which so blatantly turn a blind-eye to other automakers and the market as a whole, then claim progress can only be measured in terms of BEV offerings. That defies business logic to such an extreme, it's almost absurd to have to address.

Toyota has been able to deliver a profitable means of EV propulsion on platforms able to reach a wide array of customers. Both the PHEV and FCV being produced offers a clear road to the future. There's no arguing the power, efficiency, and reliability set the stage for high-volume sales. The variety of hatchback, sedan, and SUV demonstrate the potential.

So what if battery-capacity is small still? The durability & chemistry is proving itself as the technology continues to advance. Toyota was able to deliver all those components necessary to build a BEV without using up their tax-credits, or worse squander them on conquest as GM had done. That patience has positioned them to take advantage of the phaseout stage on a grand scale. Attempts to shame Toyota won't change any of that.

3-04-2020 **Moving Forward.** Some never let up. They continue trying to push a perspective that doesn't take into account all the elements at play. That's how you know. Being constructive means not omitting what you don't like. In days long ago, they would "*spin*" stories. Now, it is called pushing a narrative. The intent is the same. Both are attempts to undermine. Neither tries to usher in a spirit of cooperation. That's the tell. When focus becomes some specific technology rather than a goal to move forward, you know they don't have advancing the masses forward in mind. It's the trap enthusiasts fall into. They become so focused on a niche, they have a very difficult time accepting anything else. That's how we end up with that narrow-mindedness. I punched back at today's nonsense in that regard with: You are pushing the narrative that Toyota is not moving forward, that their emphasis on hybrids is not to phaseout traditional vehicles but rather an excuse to not have to offer plug-in choices. That's a load of crap, since the reader must turn a blind-eye to how PHEV delivery was achieved. The fundamental design is shared. To make their already very appealing RAV4 hybrid a RAV4 plug-in hybrid, it was basically just a matter of adding a one-way clutch and larger battery-pack. That's an approach proven very effective for Prius. It's a solid business approach. In other words, attempt to downplay the rise of Prime models all you want. Perhaps this audience may embrace the claim, but it will be meaningless to ordinary shoppers doing their purchase exploration at the dealer. Seeing hybrids become a common choice makes consideration of a plug-in hybrid much easier for everyone... dealer... salesperson... customer.

3-04-2020 **Complete Opposite.** We're fighting the good battle now: "*The self-charging moniker makes it clear from the start where the electricity is coming from. Hybrid already implies the presence of an ICE, the power source. It's the complete opposite of misleading.*" As time goes on, you notice the pattern of rhetoric. They try bringing up the same weakness over and over. Each time, shortcomings of the argue tend to stand out. Confirming the pattern becomes easier. In this case, it was the observation that the self-charging attacks never have any follow up. Lack of any substantive reply provides an invitation to post a comeback with attitude. I didn't even have to say anything this time. Someone else felt comfortable with that offensive. It was nice to watch. Expecting the same scenario to work endless is madness. We learn from watching the mistakes they make. After so many failed attempts, there is eventually some type of reveal that weakens them even more. In other words, the enthusiasts accidentally reveals their hand. That's what I watch for, patiently. They wonder why I would persist to such an extreme, only coming to find their answer when they realize what they had done. Too late. This is a good example. The ability to survive a chaotic situation, one with so many factors of influence as we see in the automotive industry, is to observe, prepare, and wait. It may seem misleading, until...

- 3-04-2020** **Promotion Irony.** Some see how what is being said today is what should have been said years ago. GM's supposed genius was really a facade that didn't actually account to much. Volt looked like a green movement, but was really just a symbol of what could be... not what will come to be. That difference was subtle then. Now, we get comments like: *"Perhaps they could have done that half a dozen years ago and promoted their own products."* Later today is anticipated to bring that, finally. Hope is GM will finally address their own products, promoting their movement forward with electrification. Arguments of whether or not Volt would have done better if advertised more have died. It was a small hatchback. No one would have cared. What mattered was what dealers offered... the SUV. Seeing a future where they include a plug is what changes the paradigm. With "EV Day" hours away from reveal, perhaps that step in the right direction will solidify. It's been a long time in the making and so much wasted opportunity has passed by, it's an incredible irony. GM may promote what they implied their goal was way back in the days of Two-Mode.
- 3-05-2020** **EV Day.** The big reveal was that GM is planning to spend \$20 Billion through 2025 on all-electric and autonomous vehicles. Lack of substance puts this in the same category as all their other ambiguous announcements of the past. There's nothing to put any hope on. Such statements are so vague, they aren't even enough to stir "vaporware" upset. That's what happened with Volt all those years ago. Goals were so ambitious, they sounded totally unrealistic to anyone trying to be constructive. Too many unknowns sounded an alarm. It simply didn't make any sense with so many questions still. How? Who? What? Where? Those important starting points were such a mystery, the realities of cost & consequence wouldn't add up. Clearly, nothing has been learned. It's the same old desire to stir rhetoric, as the voice of GM (the Chairman & CEO for that automaker) made obvious: *"We thought it was time for people to understand that General Motors has a leadership position in electrification and we're moving fast."* That literally tells us nothing. Ugh.
- 3-06-2020** **Litigation.** It is nice to see others starting to recognize there's more to the participation equation than just offering an EV for purchase. So many focus on the product itself, forgetting about the massive collection of resources required to make it happen. Some become enlightened, exclaiming: *"Totally agree!! CARB is kind of a mixed blessing."* That came from recognition of what it takes for a state to commit to supporting the effort. Not everyone is happy about the decision. In fact, there's quite a bit of fighting that takes place. That resistance isn't in a physical form, which would be easy to notice. It's far more subtle. Legal action slows the process to a crawl. Sometimes, it even stops it entirely. Watching progress get trapped by some group with power is so disheartening. This shouldn't be a matter for courts. It should be the right thing to do. Unfortunately, the majority of those online don't see it that way. They claim the environment and energy independence is paramount, but fail to recognize the complete picture. Those elements at play Toyota is standing in defiance of are dismissed by rhetoric. It's sad. In fact, that is how I stated it: Sadly, it results in a ton of litigation from each state attempting to join... hence Toyota's stance. They see all those lawsuits as a wasteful distraction.

- 3-06-2020** **Delay.** It's nice to see questions emerge from comments on a new topic. In this case, it was about the legal matters: *"Okay, I'm still a relative noob as far as details about "carb" states (since we live in a non-carb state) so I'm guessing the litigation is by automotive corporations fighting to prevent any more states from joining CARB ?"* Unfortunately, there really isn't much to say about it. Those forces to hold back change have been incredibly successful. In fact, undermining efforts are so successful they have become the norm. People don't even question the supposed logic. That's just the way things are. The situation is deemed an essential component of our foundation, something unrealistic to change. That type of mindset makes delay easy. Some keep fighting it, despite the odds. I'm happy to be a small piece of that very large puzzle. I witness some of it firsthand. Today, I heard mention of it on our local public radio, an effort I readily recognize. You may be able to as well. It's basically a heightened aware situation. Once you know what to look for, it isn't difficult to find. That's key. That's how we'll overcome some of these terrible efforts to hold back change. These are my general observations here, recently: Minnesota is in the process of joining now. We are seeing pushback from a variety of sources. It has been Senate Republicans and Auto Dealerships getting the attention recently for their resistance efforts. More with a subtle approach is the massive undermining effort coming from the Oil Industry. The goal is to prevent movement forward by getting proposals tied up in a legal mess to cause delay.
- 3-06-2020** **Goals.** When I read this, I got really annoyed: *"As I read it, the Prius Prime's goal is to provide the largest battery they can without the added weight compromising HV-mode efficiency."* I knew all too well his response would be to change the topic, diverting attention elsewhere in an attempt to avoid having to answer my question of source. Many online cannot remember where they heard something, who the source actually was, or even when any of that exchange took place. It's how misconceptions come about and how misleading thrives. Knowing this particular individual has credibility problems (from posting contradictory information) and simply likes to routinely complain, I had to carefully think about my reply. At best, he would just dismiss what I said. More likely, he would use the squirrel response. (No surprise, he did the latter.) Here's what I posted: Not sure where you read that, but it is not correct. I suspect someone assumed that at some point and passed it along as fact which then readers never questioned. The real story is Toyota was targeting affordability. Using the robust stack they had available at the time made it a tradeoff of space & capacity. That cost-effective reliability was key, so they went forward with the configuration.
- 3-07-2020** **Battery Pouches.** I occasionally mention the build of battery-packs consisting of stacks of prismatic or cylindrical cells. Those have been the common automotive choices throughout most of hybrid & plug-in history. Looks like GM will go all out with pouches instead. They offer greater flexibility, since the dimensions can easily be varied. Cooling is a challenge though. The edges differ from the interior, making it a more of challenge to manage operation with regard to thermal control than the other types. This approach should be less expensive, so there's valid reason to explore the potential. How robust they will be remains a question. Can they really sustain a lifetime of vehicle vibration? It seems a strange gamble. But then again, GM strategy doesn't always make good business sense. With Two-Mode, Volt, and Bolt all major nothings, along with smaller failures like BAS & eAssist, there's a history of progress stalls. That's why we should ask the same of any new technology, what is the goal? In this case, according to the press release, it appears to be cost & flexibility. That's quite vague.

- 3-07-2020** **Measuring Progress.** All that supposed nonsense in the past from me about stating goals was for good reason. It was obvious at some point, well beyond the rhetoric, there would be a loss of perspective. People just naturally lose track of purpose & priority. That's understandable. Heck, just look at how little people actually pay attention to politics. Being so poorly informed makes enables a type of government we are now having to deal with. There's argument of legal standing rather than moral obligation. You do it because you should, not because you have to. That means having some way of measuring progress. It's how you know your effort was successful. That's seem obvious... until you actually try. Without a solid target, there's always a way to justify missing it. This is how the "*inconvenient truth*" comes into play. You want to congratulate yourself for engineering achievement but fail to recognize the lack of adoption. Change is far more than just proving a technology viable. You must sell it too. Counting the number of plug-in vehicles encountered on the road from an ordinary drive, like your daily commute, should result in a number growing on a regular basis. In other words, you should see more and more as time proceeds. Stating an expectation of how many is an essential accountability factor. With so much still needed for true change, we need to be concise about how that progress will be measured. What must happen and by when? I put it this way in today's discussion on that topic: BEVs are a long way off for the masses (when that becomes a choice made by the majority). There's simply no way to argue against the harsh reality of lacking infrastructure & support. True, the technology itself is rapidly approaching a point where that is the obvious path, the road to get there is still a very long one. The business, government, and society changes needed are enormous still.
- 3-07-2020** **Currently.** There have been a number of people online just saying: "*I am just saying the lack of batteries is a false narrative as any company that invests in production can have a supply of more batteries.*" There's far more to it than just the production itself. If you build it, they will buy it has been proven false quite well by GM. In this particular case, it is how to best use what is currently available. My reply to that statement was: To be a narrative, context must be disregarded. That context was a matter of timing... the best use of the battery production currently available. In 5'ish years, that will be a totally different matter. It's much like what we saw with the supply limitations when large LCD televisions finally became a mainstream product. Ramp up of the production process proven to provide the best yields took awhile. In other words, that's great timing for the upcoming EV platform Toyota is working on. In the meantime, we'll get a variety of PHEVs to choose from. That's a very real measure in the progress of reducing emissions & consumption right away, directly addressing the current situation. It is very difficult for those pushing ZEV as the only solution to disregard the very real damage taking place by allowing new guzzlers to be put in service while we wait for a "*some day*" vehicle to finally get rolled out in decent quantities at decent prices.

- 3-07-2020** **Red-Herrings.** The most common defense used online to deal with a shortcoming is to change the topic. I see that deflection all the time. Their refusal to address the issue is a solid confirmation of having identified it correctly. Some get really mad too, but try to hide it. For example: *"Several years ago Toyota made a public statement that it was going with hybrids and hydrogen and not electric vehicles. No conspiracies theories needed."* That was such a blatant attempt to divert attention, I couldn't help but to be amused... especially since the "argument" has been used so often, it really doesn't stir much attention anymore. I have found fairly effective ways of dealing with that particular red-herring too: That's an easy statement to take out of context. Just ask when, where, and how. We know hydrogen will be an energy storage/carrier for commercial use. There's much opportunity it both the transport industry and the power industry. So whether or not it also proliferates the personal vehicle market is more of a red-herring than an actual issue.
- 3-08-2020** **Never Plug In.** When an antagonist does finally address the issue, they'll attempt downplay. In this case though, it was outright dismissal. They have figured out that claiming a plug-in hybrid owner never plugs the vehicle in will create enough of a distraction to completely derail the topic currently being argued. So rather than a red-herring, they just provide false information. Just like any other effort to undermine, there is rarely any detail to actually support their claim. At best, you get outdated hearsay. Some study or someone they know tells you literally nothing; yet, they think that's all we need to draw a conclusion with about the entire category. Ugh. It's all quite vague & random. The best approach is to just rebut with facts that are difficult to dispute, as I did today: You are making a big assertion to claim that PHEV owners don't recharge every day. Since it only takes an ordinary 120-volt household outlet is needed for the included charger to recharge the battery, it is as simple of an effort to plug in the car as it is their phone. No big deal. The payoff is obvious too. Daily commuting with electricity saves a lot of gas.
- 3-08-2020** **Doubt & Conclusions.** The foundation of a narrative is to raise doubt and draw conclusions. We're definitely seeing that now. It's the result of GM's EV Day. That stirring of press is an obvious distraction effort to draw attention away from the upcoming loss of tax-credits. There is a little over 2 weeks remaining. Put another way, nearly 10 years of opportunity was wasted. That money was a subsidy provided with the intent of helping each automaker adopt, adapt, and improve electrification. Taking a look at GM dealers, the assessment today would be that's a total disaster. If you are lucky, you would find 1 or 2 Bolt available for sale somewhere in the vast offering of SUVs and Pickups. At many locations, you aren't likely to find any evidence at all of change. In fact, the situation has grown worse since the departure of sedans is well underway. So, the narrative of GM skipping plug-in hybrids because they have embraced a better way is pure rubbish. Better what? They aren't selling anything better. It's not even enough to be a halo effort. There's nothing and won't be for years still. Quite annoyed, I posted this as a reply to a troublemaker clearly not interested in being constructive: GM didn't skip PHEV in any regard. They learned from Volt that building an efficient & profitable plug-in hybrid was a monumental effort... too much to spread the technology to one of their popular offerings, like Equinox. That wasn't the case for Toyota though. Prius Prime has proven it is a viable path to follow. RAV4 Prime is that next step. As for claiming the public hasn't really warmed up to PHEV, how can you draw that conclusion when so little exposure has happened? They are still very much a niche and available only in limited markets.

- 3-09-2020** **20.0 Miles.** Seeing that as the estimated EV distance when I started the car this morning came as a surprise. Huh? There was a "*charge interrupted*" message on the screen to confirm something wasn't right. My thoughts dwelled on it being a charger issue. What if my EVSE (Electric Vehicle Supply Equipment, the proper term for that connector to outside power) was starting to die. Although that's highly unlikely, it is still possible. I wondered what I would get as a replacement if that really was the case. Taking the stats into consideration... 37°F outside... 79% start... 12% end... 3.4 miles remaining when I parked... and 18.1 miles driven total... things just weren't adding up. All seemed just fine. Then it hit me! It was a double-whammy. Not only had I departed for work an hour earlier than usual from having to attend a class that morning, it was also the daylight-savings jump ahead the day before. Being off by hours explained what was going on. Phew! That sure had be wondering what was going on.
- 3-10-2020** **Daily Blog.** Remember that nonsense? It was 2 years ago that it came to an end. Their rhetoric was on a truly remarkable scale. So much influence emerged from the propaganda they created, it was a force strong enough to shift the norm. People just accepted their claims without question. It became the voice for GM and the automaker was thrilled to have such a powerful group of enablers. Time after time, we would get an ambiguous press-release, resulting in that group spinning it to hype. That happened over and over. Not only wouldn't they listen to me, I became the scapegoat for problems. They said I had lost my way and was blinded by loyalty. That's called reflection, of course. I just kept pointing out the reality of the situation, how they became obsessed with a niche and lost purpose. In fact, here's one of my posts from that end: Too little, too slowly was the pointing out of opportunity being missed. It simply never made any sense wasting good tech like that, especially with so many sharing words of praise for the potential. GM management wasn't interested in reaching out to the larger market.
- 3-11-2020** **Reaching the Masses.** Looking back at yesterday's look back from 2 years ago, I can't help but remember the ultimate GM set for itself and failed to achieve. It was the "*nicely under \$30,000*" pricing. That was how they would be able to reach that larger market, the masses. Another quote I pulled from that hostile exchange which brought the daily-blog to a close was: "*To achieve & sustain high-volume profitable sales has always been the goal.*" Supposedly, that was GM's overall mission for the technology from Volt. So.... 9 months after that when GM pronounced it dead, there was resentment. Emotion which had been focused on me had been revealed to be an embarrassing mistake. They got confirmation of having fallen into the trap I warned them about. It was that innovator's dilemma played out over so many years, they lost sight of purpose. They fought hard for a niche, not something ordinary consumers would want. My repeated message of "*showroom shoppers*" finally sunk in. That was the "*Who?*" asked about over and over and over again.

3-12-2020 **Sales Pitch.** The effort being put forth to undermine RAV4 Prime is getting noticed. But rather than me fighting battles at the forefront, I'm instead providing reinforcement. It's nice not being a lone voice like much of the past. Prior to rollouts, there were very few of us well informed enough to play offense. We'd be forced into defense. But now with Prius Prime having provided so much real-world data already, it's not difficult. In fact, I have even seen some Model Y enthusiasts turn on Model 3 with the simple sighting of cabin warming. That difference is profound, but far from obvious. Tesla finally made the switch from relying exclusively on resistance-heating to actually including a heat-pump. The advantage Toyota had must have been quite annoying, in general. But now there's that differing technology within Tesla itself. There's no argument to be made either. It's common knowledge that heat-pumps are more efficient. Using less electricity to achieve the same goal is obviously better. How do you sell that though? The online fighting makes it clear audience matters. Showroom shoppers couldn't care less about what's posted in discussion threads. The nonsense in those venues is meaningless compared to the in-person encounters. That's why it is important to have your sales pitch ready. Enthusiasts generally remain clueless in that regard, not cluing into the importance of appealing to a prospective buyer. He tried to dismiss. That doesn't work when you are trying to draw interest, which is why I fired back with: 0-60 acceleration in 5.8 seconds is slow? That 39 miles of EV is enough range to cover daily commutes. It comes with an effortless sales pitch too, just plug the charger into the standard outlet you already have in your garage. Your attempt to simply dismiss such obvious appeal isn't going to work well with ordinary showroom shoppers.

3-12-2020 **Potential.** Change of attitude comes in odd ways at odd times. All of a sudden, there's some turning point you never saw coming. Things like this reinforce the abrupt shift: "*So when GM talks about caring about the environment..... I call BS. They care about the fat pockets of the shareholders and stakeholders.*" That's not even hypocritical. It's a statement of fact... now well proven. Back when it was mostly just the "over-promise, under-deliver" problem, there wasn't much evidence to support true green intent. Now, such a stance is obvious. That pattern can be detected with little effort now. My arguments long ago had lots of enablers fighting to suppress what I was pointing out. Those same observations are being made by others now. Though it all sounds new, it isn't. Keeping quiet about it is a wasted opportunity. Like before, I want to prevent the repetition. So, I keep drawing attention to the situation: Those were fighting words in the past. Bringing up the concern about GM squandering the opportunity they had resulted in "*laggard*" claims about Toyota. It was always an effort to distract, rather than take the situation seriously. The technology in Volt, praised by owners, never spread to GM's primary product. No SUV. No Pickup. Nothing but a small hatchback. There was so much potential... lost.

3-12-2020 **Could.** It certainly is interesting to hear others state what GM could do. There was a lot of that today. The situation is surreal. Battles I fought long ago are now being repeated, but with very different outcomes. Rather than being attacked relentlessly by Volt enthusiasts, it is mostly just agreement. In other words, the enablers have abandoned ship. They finally saw the inevitable disaster coming. And now that it did indeed sink, what can be said? There is much, and I'll say it: GM's reason for abandoning that path was a matter of not being able to figure out how to make that choice profitable. It had nothing to do with the technology itself. That emotion you mention was an opportunity wasted. Purchasing a plug-in hybrid SUV was something that their customers would have found sensible. It's a simple choice... and quite the irony. Driving around a "guzzler" delivering an EV commute and 40 MPG following depletion negates most of arguments from voices of the past. Going all in now with BEV doesn't change any of that. In fact, those conquest sales with Volt may likely work against GM. That audience has moved on.

3-12-2020 **Remember.** Watching GM failed to recover from ruin, despite their huge statements made only a week ago, has been interesting. Again, what's being said now is what I had been attacked for in the past... even without that attitude, like this: *"This is hilarious. Does nobody remember the Saturn EV-1? GM had their shot at electric vehicles several years ago."* They were so smug and simply didn't care. It started with *"vastly superior"*, then became a narrative taking them in a direction of self-destruction. Pushing a technology by telling people it is worth the tradeoff doesn't make sense. Paying a premium to move from a large SUV to a small compact is absurd. That's no how mainstream consumer think. In fact, many of those large SUV owners sacrificed efficiency and paid more, to avoid having to drive a small compact. Pretending that wasn't the case was a horrible waste. That's why I say *"Know your audience."* so often. They clearly didn't. I pointed that out to help those in denial remember: Enthusiasts tend to dismiss the past. Those pushing Volt worked extremely hard to suppress Two-Mode history, hoping those more recent hybrid to plug-in hybrid mistakes would carry over to GM's next endeavor. Instead, they ended up becoming enablers. It was fascinating to watch that denial play out. It comes down to setting realistic expectations. They were so obsessed with the hope of a better future, they turned a blind-eye to the warning signs. Hype fed the "over promise, under deliver" problem. Volt fell well short of expectations and excuses were made to downplay barriers, rather than actually address them. The situation about to play out with regard to plug-in hybrids is the class "Tortoise and the Hare" story. Could the same happen with BEV too? You better believe it.

3-12-2020 **Solid-State.** Ugh. With so many new chemistries now being tested, I shouldn't have to deal with stuff like this: *"What battery new tech? Main battery-makers are all at the same level and there's no sign the future will be different from the recent past."* Even without any obvious breakthru, the investment in research alone should indicate just how much of a desire there is for a better future. But then again, there are some who ignore & dismiss signs. After all, I routinely encounter a few who absolutely insist that no specs for RAV4 Prime have been released yet, therefore it should be treated with any credibility. That's just plain wrong. Not only has Toyota pointed out the 39-mile expectation for EV range, the 0-60 acceleration in 5.8 seconds, and the 302-horsepower, we have also got the leak of a 17.8 kWh expectation for battery-capacity. Heck, we even know that carbon-dioxide emission will be below 29 g/km. We also know there will be 520 liters (18.4 cubic-feet) of cargo-capacity. For that matter, we also got a confirm that this system will have the same top EV speed of 135 km/h (84 mph). Lastly, we have been told *"The battery is cooled by refrigerant of the air-conditioning system."* Pretending all that isn't known takes quite a bit of desperation. What is especially interesting though is the 230-volt outlet available in the cabin of the premium European model. That makes you wonder how many will take notice of where battery technology will take them, quite literally. Anywho, this is how I responded to the *"future"* comment: Huh? The entire industry is striving to eliminate the electrolyte. In fact, we got news just yesterday from Samsung about their progress toward solid-state batteries. Watch what happens with the phone industry for a general idea how the auto industry will be able to commercialize those advancements. No longer having current constraints of heat & density is a paradigm-shift that will tip the balance heavily in favor of exploiting electricity.

3-12-2020 **Safe.** I find stuff like this annoying: *"Just remember, Toyota does not care about you or EVs. If they think they need to protect the company they will axe anything..."* Everyone should reminded that no legacy automaker has a mission-statement to be green. That's mixed somewhere into the priorities, but don't pretend that profit isn't very important. That makes is conclusion pointless: *"Toyota plays it safe."* What automaker is truly taking a risk? We hear bold statement, but their really isn't much to speak of in terms of actually changing their business. Rolling out a new vehicle with new technology doesn't guarantee anything. Look no further than VW. Despite all the encouraging new, there's nothing yet to support their EV investment in terms of dealer acceptance. For that matter, we have no clue how their own showroom shoppers will react either. Heck, we don't even know about the risk. It seems like a big financial gamble. Is it? How much is really required for payback, to ensure a steady stream of sales after the low-hanging fruit is gone? Sustainability is a big deal often not regarded as important. That comes from the belief of mainstream sales being just a matter of delivering enough range at a seemingly competitive price. How exactly will that be gauged? It's all so vague. Sound familiar? That pattern recognition is why I don't take the *"safe"* claims seriously. GM provided the appearance of taking risk, but detail contradicted the narrative. That's why I kept my response to this brief: Do you really expect readers to not notice the very real progress Toyota has demonstrated with making their hybrid platform available across their fleet without compromising profit or performance? It's a win for everyone involved. The fact that the design carries over so well to a plug-in offering adds to the success. What is their to worry about? That's true progress forward.

- 3-13-2020** **Model Y.** The first one got delivered today, on Friday the 13th. Ironically, this appears to be the official start of a new recession. With so many businesses making plans to shutdown, scaleback, or switch to work-from-home, there's a lot of uncertainty growing. How long will this abrupt shift to avoid a sickness outbreak on the pandemic scale last? The automotive industry is incredibly complex. Technology is only a part of that equation for success. Many, many other aspects of business & industry are involved. Anywho, with respect to Tesla's progress, the only version of Model Y currently offered is the long-range with all-wheel drive. That start at \$52,990. So, any hope of it attracting mainstream sales are just a dream... especially with the financial sector showing so much instability. Now is not the time for expensive choices. Focus on ordinary consumers is more important than ever. Remember how the "*nicely under \$30,000*" target came about and why it was so important?
- 3-13-2020** **Continued Attacks.** It's a renewal of the Volt enthusiast nonsense now coming from EV purists. I find those efforts even more desperate than in the past, since they are so much easier to disprove. The videos resulting from those battles in the past are very effective ammunition for rebuttal posts now. For example: "*But its EV range is low, only about 26 miles. That hampers its EV only efficacy.*" Not only was I amused about the misunderstanding of how efficiency actually works, I was pleased to have that video to refer to as reinforcement of how easy it is to achieve those 26 miles and how much 26 miles of driving really is. In this case, I'll save that reference for a secondary reply, should I need it. His thinking that more range equates to greater efficiency is what I want to initially deal with. That's better material to address attacks with, since it is well beyond just misleading. It is just plain wrong. So, I posted: EV efficiency is a measure of consumption, not battery-capacity. In other words, range doesn't matter. It is how the electricity is utilized that matters. For Prius Prime, it has a rating of 25.9 kW/100mi. That puts it among the top for EV efficiency, far from anything that could be labeled as hampered. In other words, if you are driving within the range available, it will use less electricity to travel that same distance as most other EV choices.
- 3-14-2020** **Deal With It.** He didn't care; instead, I got this in return: "*Which is it, striving to support a backward narrative or facing the truth or facing reality. If the truth hurts, wear it on your chest. The i3 EREV is history in Europe. The Volt is history. Deal with it.*" That was actually a lingering comment from a previous posts, something obviously difficult to let go. Seeing it come up was a nice confirmation of the message getting through. He's upset by the past and blames growing success of PHEV as the cause. I just fired right back, using his own sentiment against him: Continued claims of "*most PHEV owners*" is a desperate attempt to push a narrative based on the past, going out of your way to avoid mention of what is to come. I keep pointing out how power (hp), capacity (kWh), and charge-speed (kW) continue to increase. The upcoming RAV4 Prime is a undeniable example of that and will inevitably be a popular new choice as a result. Technology improves over time. This generational upgrade is a clear step forward. Change happens. Deal with it.

3-14-2020 **Not Plugging In.** It's very difficult to follow ongoing attacks. Antagonists hit multiple fronts all at the same time, hoping to find a weakness. I do the same thing, but my desired outcome is to learn what their narrative... since I already know their weakness. In this case, I just followed the thread. Choosing to respond to someone else also getting attacked provides an ally as well as a new front. The troublemaker is desperately trying to portray PHEV as just a gimmick with the hope of painting a picture of BEV being the only viable means of significant oil-consumption reduction. This was the quote from that other online combatant: "*Regarding not plugging in PHEVs, I cannot fathom why anyone would buy one and not plug it in...*" He was having the same trouble overcoming the nonsense. I jumped in with:

Those claimed studies of "*many people don't bother to plug them in*" lack merit. Notice the absence of when, where, and who detail? That's a red-flag, a warning about the content being misleading. It's really easy to publish a study based on a small sampling in a limited market and continue to quote it many years after any relevance it may have had has faded.

I own a Prius Prime, recharge at work, and like you also live in Minnesota. My commutes on all but those days when the temperature drops below the 14°F threshold for the heat-pump are in EV. So, the benefit from plugging in is rather blatant. And with range increasing, as we see with the upcoming RAV4 Prime, it becomes an easy sell. In the warmer months, EPA rating can effortlessly be exceeded. I routinely see range in the low 30's for the 25-mile rated battery.

Long story short, there's no reason to believe the studies. Overnight charging with just an ordinary household outlet works just fine. For those who do choose to invest in a level-2 charger (and take advantage of the tax-credit for one this year, in addition to whatever rebates & discounts their local electricity supplier provides) can recharge significantly faster.

Think about it. The sustained 3.6 kW rate I see from my JuiceBox means I can replenish 28% of my usable capacity in just 30 minutes. That's 7 miles of EV. Knowing the rate has doubled for new PHEV offerings, that means you'd get 14 miles in just 30 minutes. Why not plug in?

3-14-2020 **Narrative Questions.** This is how you undermine: "*Why would one champion a fading compromise technology with more emissions than an EV and ever fewer advantages?*" That type of question forces a narrative. The antagonist sets you up to lose. If you choose a defensive position, you are reinforcing the supposed message. If you choose an offensive position, they will simply claim you are refusing to acknowledge the supposed facts. If you choose not to respond, they'll just continue on with the narrative any way they want. Needless to say, I had to respond in some fashion. The post prior to that was a taunt, using cherry-picked information, sighting 2 examples to reinforce his perspective. So, I decided to lead in with that: Know your audience. It should be blatantly obvious that Clarity and i3 have nothing to draw any interest from someone wanting an AWD crossover. You're making the same mistake countless Volt enthusiasts made. They were so focused on a specific configuration of a technology that they convinced themselves it could be the only choice offered. RAV4 Prime is a prime example (excuse the pun) of that. The configuration contradicts many claims made about Prius Prime, proving the technology was far more capable than they portrayed it. In other words, the narrative of "*compromise technology*" falls apart when looking beyond just cherry-picked examples and ordinary consumers clearly see that.

3-14-2020 Marketing & Education. Discussion with regard to VW rollout is quite different from what we saw with GM. A lot of attention is being put in the financial aspect. For Volt, it was technical... which was a joke, since we knew what GM was to deliver was proven already. The spin was that approach was "*vastly superior*" to what others would supposedly compete with. Ultimately, the colossal waste of time & resources will be look upon as a scandal. Proof of that comes down to the lack of any real support. The product was produced, but nothing came about with regard to actually promoting it. That's why I'm bringing up the same concern for VW approach. What is the plan? This is how I asked today:

With regard to this article, I'm quite curious about BEV advancement in the next few years. There's a great deal of potential long term, but barriers to overcome... like charger availability... are far bigger of a problem than enthusiasts care to address. We simply don't see many at public locations and most people don't have any exposure to them in homes.

That lack of knowledge makes any type of investment a monumental challenge, something pretty much impossible to deal with on the scale and at the pace VW is hoping for. That sure would be nice though.

Realistically, that sweet spot you mention just happens to be the capacity RAV4 Prime is said to deliver, 17.8 kWh. That a little over double the capacity for Prius Prime, which means the time for a full recharge will be about double with 120-volts. That does indeed put it in the 11-12 hour range. It's the maximum an owner can squeeze out overnight and exactly what's needed to stimulate level-2 charger purchases.

With only a 20-amp circuit, you could fully recharge in 4 hours. With a 40-amp, that time could get cut to about 2 hours... which is the ideal setup for BEV as the next vehicle purchase. That same 40-amp setup delivering a steady 7.2 kW rate equates to about 200 miles of range in around 8 hours. So if the owner is willing to invest and has the time available, a recharge of the acceptable "*280 to 310 miles (451 to 499 km)*" range could be achieved.

Catch is, how will the consumer learn enough of that to embrace such technology? Can we expect to see VW push marketing & education enough for that to happen? This reaches well beyond just their own production. Heck, just getting their own dealers on board will be a monumental effort. What is the incentive to take such an aggressive stance?

- 3-15-2020** **Unrealistic Suggestions.** I got this from someone in Germany on that thread discussing VW prospects: "*The US should really consider to raise their voltage in light of increased electrification.*" It's easy to see how a suggestion like that comes about, but it's uncertain how a not realistic reply would be taken. So, I leaned toward the understanding aspect of constructive exchanges this this instead: That's an interesting misconception. The US already has 240V service pretty much everywhere. It's basically just a matter of combining two 120-volt lines. The issue is having under capacity and poorly located service-panels. That's something each homeowner must upgrade themselves. There is a \$1,000 federal tax-credit available for that through the end of 2020. Problem is, people don't understand the benefit. That is why I ask what VW plans to do for marketing & education. Look at how GM failed at that vital task. Even die-hard fans complain about how little GM did to promote their technology. This very category is where Toyota excels. Think at how the success of RAV4 hybrid has been achieved. Consider how that will contribute to RAV4 Prime sales. That why VW is getting flack already for setting such high sales expectations even before rollout has begun.
- 3-15-2020** **Constructive Exchanges.** That reply to the person in Germany went well. This discussion continued: Residential is split-phase. Commercial is 3-phase. That's the way our infrastructure was built here and that's the way it will remain for generations to come. With respect to vehicle charging, it works fine. Without any supply upgrade, I was able to setup two 40-amp lines. That's good for providing steady 7.2 kW charging to both of our vehicles at any time. The SAE spec does support all the way up to 100-amp lines, but that would be overkill. The affordable 40-amp setup will deliver 200 miles of EV range in 8 hours. Do you feel a household would benefit from faster?
- 3-16-2020** **Working From Home.** It is no big deal for my wife or I. We routinely do it anyway. So, the request for non-essential travel to be halted is fine. The cats will enjoy having us around more often too. Since my job involves the development of computer software, with part of my team on the East Coast and some offshore, the concept of remote access is what we have been doing for many years now. That's new for others. They will get a crash course in virtual meetings and not being able have in-person contact. It is something that becomes natural after awhile. You learn there are other ways to share. Think about how much interaction I have had with others online, for decades, without ever actually meeting them. Being able to do that is quite empowering... and it saves a whole lot more gas than any type of vehicle technology. Think about what that can do for plug-in hybrid interest. If all you are primarily doing is just short-distance travel for basic necessities & entertainment, there's no need for massive battery-packs. It's an interesting rethink opportunity about want verses need. Forced working from home, as well as schooling from home, is an unexpected teaching moment for our rather stubborn country. I wonder what we'll learn from this experience. Hmm?

- 3-17-2020** **Not Paying Attention.** Stuff like this makes you wonder: *"It would be nice if Honda and Toyota could see fit to add them to their larger SUVs as well."* Most people don't pay attention and even fewer make an effort to research. It is a sad statement about our society, but quite accurate. Just listen to comments about the presidency. Sound familiar? It's the same old nonsense I've been pointing out about vehicles for decades. Fortunately, the same advice still holds true. Keeping hitting them with facts: Toyota's newest generation of hybrid system just rolled out for Highlander AWD bumps the combined rating from 28 to 35 MPG. That's quite an upgrade and a heck of a big difference from the traditional model only delivering 23 MPG. With sales here at 239,438 last year, that choice for such a large SUV is definitely a noteworthy effort to improve emissions & efficiency.
- 3-17-2020** **Conquest.** There is nothing like reading this on the Volt forum: *"Thanks everyone for making this place a great forum. I sold my Volt two weeks ago and bought a Tesla Model 3, going fully electric. The 2013 Volt was a great car."* It is the ultimate confirmation of failure. Tax-Credits were intended for subsidizing change, to make the process of moving forward with electrification easier. That meant dealers would feel less at risk welcoming in a change to some of their inventory. That didn't happen with GM; instead, it was a blatant disregard of purpose. Their goal was to seek conquest, selling to those from outside their customer base. In other words, there was no actual pursuit of change from within. Loyal GM customers would just keep buying the same old guzzlers, replacing their aged vehicle with a new model of something similar. This attitude & disregard went on for years, with fierce defense of the approach claiming change would come. It never did. Volt owners have been abandoning GM. Conquest was a terrible idea, doomed to this outcome. You can't just ignore your audience. Showroom shoppers got nothing. So, nothing happened.
- 3-18-2020** **Game Changer.** That shift in attitude & perspective is happening. The signs are becoming obvious: *"With gas prices diving well below \$2.00 a gallon, I can't help but wonder what the immediate impact will be on EV sales? Fuel cost savings are a major selling point."* I never thought I would see the price of a barrel of oil drop below what it was 20 years ago when I ordered my first Prius. That was under \$40, which equated to gas being less than \$1. Without the usual consumption demand... like the daily commute... supply is piling up. That means processing & pumping of oil will slow. At some point (supposedly around \$22 per barrel), it become a loss. That opens up opportunity for green technologies, but this really isn't the ideal for change. But then again, progress is progress. Somehow the game needed to be changed. I guess this is what will push some to the other side of the fence. After all, posting this seems to not have much of an impact anymore... despite the cold, hard reality of the situation: With the exhaustion of tax-credits for Tesla & GM, combined with all the low-hanging fruit being picked (early-adopter demand satisfied), a pause in sales was inevitable. The forces against electrification saw that coming. Also having this surprise oil surplus resulting in gas prices well below minimums needed to justify plug-in choices definitely puts our support in a regroup & replan status. Hopefully, a game-changer like RAV4 Prime will mess up arguments for those hoping to undermine our efforts.

- 3-18-2020** **Complaining.** Some people like to. The infotainment system is a common target of that. Problem is, the complaints are so vague there's really no point. All we essentially get is just: "*Still no Android Auto?*" That complete absence of any reasoning other than the software isn't available doesn't tell us anything. It's like complaining about the radio without any context. What the heck is missing? What do you want it to do? I get complaints like that a lot as a software developer. You hear complaints about making it "better" but have no clue what they are actually asking for. In their mind it is clear, but the need to convey any detail is missed entirely. They think it is obvious, that you should somehow magically know what they specifically want. Ugh. That's why delivery of a next-generation interface in an entirely new medium is a complexity they overlook. They see a screen and expect the same user-experience, despite function & operation being different. Usually, I just let them complain to vent. It doesn't do much good to try to explain platform differences to those unwilling to take the time to recognize the engineering challenges. Today, I did actually reply: It's coming... but not well understood. There has been much confusion about why simply adopting the older version never intended for that type of use isn't just used anyway. To transition from phone-centric software to something actually designed for automotive application, it's basically a start over. That's just like when tablets were introduced. People didn't recognize how an interface for a phone could differ so much. In fact, some never do until seeing why firsthand. In other words, Toyota wants to do this right. So, they have been slowly making it available as the software matures. After all, who should address confusion with the interface or unrealistic expectations? Knowing it is a Google product, think about how Toyota fits into that equation.
- 3-19-2020** **Curbside Service.** What a fascinating turn of events. The interiors of stores & restaurants are being closed to customers, to keep the staff safe and prevent virus spread in general. People still need provisions & food though. That has brought about curbside service on a massive scale. We're seeing all sorts of business switching to delivering what they sell that way. Today, we experienced that firsthand. I drove out to get dinner from a place my wife and I like to spend an evening at on special occasions. I called to say I was there and the order we had placed over the phone was pushed out on a cart. I was able to grab the bag, while still keeping the "*social distancing*" necessary. It was a surreal experience. I suspect there are many more to come. You don't realize how natural close proximity is with other humans until you are forced to prevent it. After several weeks, how will that change the way we interact? I already see ordinary people scrambling to figure out how to socialize online using tools my profession has used for years. When we first got the ability to video-chat and hold meetings on our computers, rather than going into a room to all share the experience in-person, many were lost. There was no basis of comparison and no expectation. Given time, they figured it out. We don't have time in this case. You must immediately adapt. Hopefully, with everyone participating for a shared goal, this should be easy. Curbside is a necessity. Think about plugging in your car. You already have electricity. You see the struggle the automotive industry is about to face. What could we do as a society helping each other to make that easier?

- 3-20-2020** **Staying Home.** We are able to make the best of it, quite unlike so many who cannot. My wife and I can work from home. We have hobbies to keep us plenty busy. The cats absolutely love having us around continuously. So, it's easy for us to stay out of the mess. I imagine it will be quite difficult for some. Many are not as fortunate. Of course, there are a few who simply don't care. Think about how oblivious to need those troublemakers of the past were. They pushed want to such an extreme, it became an immense effort to deal with their loss of priorities. That wasn't life or death though, in the short term. Right here & now, it is necessary for us to do as much as possible to prevent the spread of the virus. People are dying. Seeing how some are still refusing to do their part is unbelievable. With such extreme examples, why aren't they? Will they ever figure it out? Will others observing that reconsider some of their positions of the past? This is far from the only planetary problems we have to address at some point. Sooner is obviously better. People tend to avoid. People make excuses. People delay. It's quite ugly... and well documented in these blogs. We must grow up and become more responsible. The long-term consequences of actions & inactions eventually become evident. Learning from this terrible chapter in our history would be great. We could... make a better world... if we want to.
- 3-21-2020** **Trolls.** After dealing with their posts for awhile, they end up getting blocked. That works well on the computer. But on my phone-app, I still get post notifies when they reply directly to something I posted. Fortunately, the content itself isn't shown. So, I don't have to tolerate their undermining efforts unless I feel up to dealing with that nonsense. Today, I did. His post read: "*A potentially new Prius owner on the oil guy forum when mentioning Prime just knew it had 4 seats and he needed 5.*" It was in response to a comment I made awhile back, but intentionally omitted detail of the situation. It was a blatant effort to mislead by excluding something vital. He only quoted the first sentence. Anyone reading that would have no idea they needed to page back in the discussion thread to discover there was a second sentence, the one stating my point. He was vague too, by not including a link to his source. I was annoyed, firing back with: Talking about quoting out of context! You cannot just leave out the part explaining the response. Here's what I actually posted: "*That's not the audience. Focus is on showroom shoppers, not random on-the-street people.*" That's why it doesn't matter what some random person says on some random forum. At the dealer, none of that would be an issue. It would be obvious to see there are 5 seats.
- 3-21-2020** **Gas Prices.** They are dropping. It's interesting how not filling up the tank for several months changes your perspective. Today, it was a friend with this remark: "*I stupidly filled up at Costco this past December at \$2.559.*" Being able to avoid carrying around winter-formula gas during the warm season is nice. Combine that with the reality of price naturally falling a little anyway due to the transition back to summer-formula, you have a face-palm situation... as was that post. Oh well. I normally use gas a lot faster. But now with the stay-at-home situation, I find myself in the same predicament. Nonetheless, it doesn't stop me from also participating in the discussion: I saw \$1.997 the other day. That struck me as truly bizarre, focusing in on the partial cent rather than the reality of gas falling below \$2 per gallon. When have any of you ever seen that fraction as anything other than the 9/10th value? Of course, it doesn't really matter. With a job that allows working from home, it could take me a very very very long time to use up the current tank of gas. Even our far away restaurant now with drive-up service is within EV range.

- 3-21-2020** **Flat Tire.** Working from home and not going anywhere in public doesn't mean you can't use the local coffeeshop drive-thru, especially when the short drive uses nothing but electricity. That was the only escape from our exile today. So, I was looking forward to the experience. As I was pulling out onto the main road, I noticed the low-pressure warning on the dashboard was illuminated. Hmm? I plugged the OBD-II reader at the next light and prepared my phone to open the Tire-Assistant app when I got to the waiting line. There, I fired up the software. 3 of the tires reported exactly the PSI they should. 1 showed it was only at 10. Ugh. Sure enough, when I opened the door and looked out, the tire was squishy. My decision was to just hope for the best on the way back home. It was only a few blocks. When I parked in the driveway, what had happened was obvious. A screw for sheet-metal had nicely wedged itself between the tread that still looked new, on the tire purchased just late last Fall. That allowed it to be pushed directly in, creating a slow leak. After jacking up the Prius in the garage and taking a closer look, the hole appears to be one that should be easy to plug. Phew!
- 3-22-2020** **Survival, change.** We know the "zombie" businesses will be gone. There's simply no way for those small independent places struggling to survive prior to this will have the resources or desire to continue, even with special grants or loans. They'll move on to something else. Pressure to rebuild will be too much. Combining what's left for talent & ambition works well for long-term outlooks, those willing to suffer through the lean years of recovery will be what emerges from this mess. It's an inevitable reduction/reshuffle. It reminds me a lot of what I have witnessed over the past 25 years with family businesses downtown, where I would eat my lunch from time to time. Patronizing their establishments, which had been there for a very very long time, was always pleasant. There was history I recognized but wasn't really ever part of. They faced challenges over the years. Some adapted. Some closed. However, none had the kind of accelerated timeline we see right now. It's a reality quite unexpectedly aggressive. This isn't just the usual small shop closing up after decades of service either. We'll also see it play out on the grand scale, watching the automotive industry get hit especially hard. It grew dependent upon people willing to spend a large portion of their income on an inefficient means of transport. That's not the situation anymore. Overnight, we now have re-evaluation of that choice taking place on a monumental scale. Just how intertwined those decisions made were part of our lives will become quite apparent, not something to just brush off as in the past.

- 3-22-2020** **Survival, blame.** The tie of the economy into the automotive industry is important. So much of what we do depends upon those vehicles. The catch is, different cultures address survival differently. What we see here is a lot of blame. That is especially obvious with regard to our president, which trickles into his party and supporters. Rather than do something about the problem, they complain about something. Sound familiar? That's exactly what I witnessed over the years with transportation advances. The technology not going anywhere came from GM, a business that played the victim so often goals were forgotten. There was plenty of blame. Look at where it got them. 10 years after Volt, there isn't any progress. In fact, dealers are actually in a worse position now. That advancement to serious emission & consumption reduction will be even more difficult. Quite the opposite is the position for Toyota... an automaker who has had to endure several economic collapses. In fact, most people here aren't even aware of the recession Japan had when the United States was thriving. Toyota learned discipline. Toyota learned patience. Toyota made sacrifices and invested. It was about a better future, not a better bottom line. Ironically, they have no one to blame but themselves for not having anything of substance still. Survival is about finding a way to move forward.
- 3-23-2020** **Survival, recovery.** Throwing money at a problem won't always fix it. In fact, most of the time that doesn't result in the best choices being made. You want to do more than just survive. You want a recovery that will bring you forward. So, it should be no surprise that the rush to get a massive recovery bill voted for will have some opposition. Wanting to do it right means thinking through and discussing options. That's not happening; instead, there's a clear effort to invest in the past. Not a single penny has been allotted for clean energy or anything renewable. Rather than looking at this as an opportunity to take a joined step to better ourselves, there's an obvious effort to help the industries already struggling to survive. Prevention requires doing more than maintaining the status quo. You invest in the future to protect against slipping back. Look at the instability we have seen with oil prices. They have been all over the place... even before the bottom fell out. Seeing \$1.79 today for a gallon of gas is an undeniable sign of trouble... especially as we are witnessing solar & wind technology advance to become cost-competitive. Think about how much will be spent on just covering lost payroll due to this virus outbreak. That's just an effort to keep things afloat. Nothing to build upon what was lost is a very real problem. You can't just expect aged industry to recover without anything to push it forward. After all, we saw witnessed how GM exploited government help, using it for profit & praise rather than investing in the future... as those funds had been voted on for. Remember how the tax-credit money came about? Sadly, the automotive industry is only a small piece of a very large puzzle. However, the energy & emission aspect of it affects many other industries. In fact, they are so tightly knit, we are going to see a lot of unraveling soon. It's not going to be pretty.

3-23-2020 **Survival, facts.** Some are showing willingness to do what is necessary for immediate survival, but I am still not seeing anything with regard to climate change or oil dependency. Not only does that sentiment remain intact, despite the pressing new circumstances, it looks like there may be excuses brewing to do just the opposite. Rather than take responsibility for what needs to be done, there is a very real possibility of relaxed regulation. The idea of moral or civic duty means nothing to a society already stressed. That makes the new problems even worse. Ugh. An interesting perspective though is that only applies to our culture, here in the United States. That sentiment has been true for Japan. Remember long ago, before the Great Recession? They had their own economic collapse. Recovery from that was quite a struggle; however, it taught them well about how to prepare and deal with future economic & social challenges. We are now looking at the start of a new Depression, the real thing. Countless businesses will close. Those that survive will likely have to completely rethink their strategy. This will directly impact the automotive industry, in many regards. Toyota is one of those businesses with a good understanding of how to plan next steps and to implement them with knowledge of how to deal with surprises along the way. The chance of GM being able to do that is what? They are barely surviving their own undoing as a result of failing with PHEV advancement. The concept was sound. The approach was flawed. Having just abandoned that for supposedly an all-out BEV investment sounded doubtful even before this virus turning the economy upside-down. Of course, rolling out a small hatchback to an audience of SUV buyers never made sense anyway. Survival is not a strong trait for some...

3-24-2020 **Survival, accountability.** My biggest gripe with GM was sighted right from the start with Volt. It came from having watched Two-Mode become a mess. There was no accountability, transparency, oversight from within. So when the government bailout came along and the success of Volt became intertwined in that effort, I worried about the very same thing. We had no clue what the program deliverables were, there were no timelines, there was no one to ensure progress was made. The same thing is happening with our "bailout" of the country now. I'm seeing the same no-strings-attached approach. Remember all the tax-credit money being wasted on conquest sales rather than being using to actually improve the company? Heck, what about the corporate windfalls a few years ago? All that relief money from the lowering of taxes resulted in lots of stock buybacks. How did that actually help consumers? How will any type of money given to automakers now be used any different? There is still no accountability. Without specific milestones agreed upon, what incentive is their to strive for the overall goal? No penalty for falling short or not delivering anything at all is a very real problem. Survival depends upon always making some type of progress forward.

3-24-2020 Rivian, Ford, Porsche, Tesla. Remember that daily blog for Volt, my look back 2 weeks ago? I kept wondering if the website that had turned into a venue for rhetoric would change as a result of GM's recent affirmation of purpose. Hope that the rapidly approach end to their tax-credits and the obvious new market challenges would bring about perhaps some type of rethink. Nope. It was the same message of intent, GM would go all in with BEV by abandoning PHEV entirely. Of course, that leaves you wondering. It's the same lack of commitment we saw with Volt. Sure, they were endorsing a technology, but there was no accountability... hence the "*too little, too slowly*" concern that came about way back in 2009. That turned out to be exactly the problem too. GM delivered the minimum, a halo product. The irony of that situation is profound. Repeating that again is stupidity. Doesn't anyone else see the pattern? Not learning from history... Anywho, back on that website and speaking of repetition. I was curious if it would somehow turn into a propaganda machine again. Nothing new had been posted since June 19 of last year. All those nasty antagonists have vanished. Not a single one of them comments anywhere I frequent anymore. They either stopped participating online entirely or started a new identity to hide behind. It was always a dead giveaway they really didn't care when they'd launch an attack on you by posting personal information about you. They realize a revealed identity means being held accountable for comments... which is why they would always make sure theirs was never revealed. Needless to say, I was surprised to discover 4 new articles had popped up within the span of just 2 hours. I had checked at exactly the right time. The previous 4 distressful articles had rolled off the rotation. All that was left was the awkward & abrupt final post. The new ones featured Rivian, Ford, Porsche, and Tesla. That was telling. Nothing about GM on a website dedicated to Volt. There was no comment section anymore either. It was simply given a "*closed*" label. The end had come. It was truly dead... exactly 1 week prior to the end of tax-credit exploitation. The hope conquest sales of a supposed "*game changer*" would bring about an embrace of that technology had failed miserably... and everyone knows it.

3-24-2020 Deny, Distract, Deflect, Divide. Speaking of conquest, our horrific president is failing miserably too. Trouble is, the situation with the spread of the virus is trouble for our immediate health, not the long-term as with emissions & consumption. People are dying from his employ of the same tactics those terrible enthusiasts had used. I most definitely recognize that pattern. The deny, distract, deflect, and divide is very much what I had to deal with over the past decade from them. It was a relentless fight to stay on target. They would do everything possible to undermine those efforts. In other words, rather than focus on the actual goal, it's a game of blame. That is so upsetting, with regard to vehicle production & sales. Think about the magnitudes worse it is with regard to people suffering from a sickness we have had the power to significantly reduce. It comes down to prevention. Some see it as expensive & unnecessary. They prefer to brush off the risk as insignificant. Look at what happens as a result. So much opportunity wasted... Sound familiar?

- 3-25-2020** **Sienna.** This shouldn't be much of a surprise to anyone. Sienna (Toyota's large minivan) is due for a next generation. It will be last of the TNGA upgrades, which brings about a number of big improvements. The most obvious is to make hybrids directly competitive with traditional vehicles... in every regard... to the point where phasing out the traditional is no big deal. And that is exactly what we have been witnessing with the other vehicles Toyota produces. But with the minivan, it's a market with a very limited audience and fading competition. Simply outright abandoning the traditional model, to offer only the hybrid, makes sense. That's the rumor we heard more of today. Supposedly, there was a dealer preparation meeting for the 2021 product-line and that information got leaked. It immediately fed speculation about a "Prime" model. The system used for RAV4 Prime would lend itself well to the minivan platform too. That would be sweet. We'll find out... and that could be abrupt as well, since the 2020 model year is coming to a screeching end. When production resumes after the virus shutdown, it will be time to start watching inventory to avoid having to clearance out too much. That will be quite challenging this model-year... but a welcome fresh start for an all-new Sienna.
- 3-26-2020** **Intentional Misleading, part 1.** Today was off to a good start... ugh. The title of the article was "*Why Would Anyone Buy a Toyota Prius Prime When You Could Buy a Tesla Model 3?*" The opening paragraph highlighted affordability. That was a bad sign. Sure enough, the next paragraph stated "*Carfax says the Prius Prime starts at \$34,600...*" Yup, this was an article with the intent to mislead. I wasn't happy. I did a search to find out where that number came from. Turns out, that number came from Limited model, the fully loaded edition. It also included the destination fee. The reality is, starting price is actually \$27,900. That's significantly lower than we were led to believe. And since the premise of the article was why and focused on affordability, that means there should have been mention of the tax-credit still available. That can reduce the price by up to \$4,502. The story changes dramatically when you discover starting price of a Prius Prime is actually \$23,398. You don't even have to look up the starting price of a Model 3 upon finding that out. But if you do, you'll find it is \$39,990. That's such a drastic difference, there's no possible way the writer of such an article could be considered a journalist. That's outright deception which only took me a minute to confirm. Internet searches aren't rocket science.
- 3-26-2020** **Intentional Misleading, part 2.** Midway through the article, this was added to the mix: "*Additionally, the Model 3 will come with Tesla's semi-autonomous self-driving feature...*" That doesn't come with, it is an extra. That package upgrade is \$5,000. No where is that mentioned though. You are lead to believe it is included as part of the car's usual features. Stuff like that is very frustrating to encounter. If you're lucky, there is a comment section. The odds of someone reading what you post is slim too. So, what's published is usually all the reader ever knows about. They don't question industry writers. That information is implicitly trustworthy. Ugh. This isn't anything new. We saw the same deception practices 20 years ago. Having some type of recourse is nice. That's why countering it with video has become so effective. That is a fact which is difficult to dispute and easy to share. I still get tired of the endless battles. Honest debate is asking too much. The lazy and those with something to lose will just follow the crowd, helping to enable misleading along the way. Fortunately, sticking with the cause ultimately results in victory... as I have blogged about many times here.

3-26-2020 **Detroit Transition.** An article in the EV blog posted about GM and Ford outlooks certainly was interesting. I was intrigued what the perspective of others was now, in the light of new pressure on business & consumers. So, I jumped in with the hope of stirring some discussion:

It was obvious back when gen-1 Volt sales started to tank and GM did that big price slash that the desire to electrify had faded. Follow up to that move should have been an announcement of an upcoming SUV using the same tech. After all, we had already been shown a prototype of a plug-in hybrid Saturn Vue back in the Two-Mode days. That next step was long overdue; instead, we got news of a gen-2 Volt that would further refine traits enthusiasts had praised the vehicle for. It was a step in the wrong direction. Focus was on a niche audience. GM's own loyal SUV buyers would have nothing to actually buy.

All these years later, we now see the rise of the SUV in plug-in hybrid format, but not from GM. Specifics from the upcoming RAV4 Prime are leading that revolution. If Ford truly has sincere intent with their SUV offering, it would become a complementary offering... since those two PHEV are configured quite differently. There will be nothing from GM in that category though; instead, there will supposedly be a competitive BEV model of SUV a few years from now.

Watch what happens in the meantime. If Toyota really does kill their traditional model of Sienna, making that minivan hybrid only, it will set the stage for another +300 horsepower PHEV offering. That puts Detroit at a clear disadvantage. Just look at how some jumped over to Chrysler for the Pacifica. The status quo is definitely on the verge of being shaken up.

3-26-2020 **Piecemeal Data.** The topic about Detroit's future brought about this: *"GM has declared no more PHEVs. We'll get a RAV4 PHEV and Ford has several HEV and PHEV SUVs coming this year. Given the poor sales of the Outlander PHEV, I doubt Americans will buy many of these. And the take rate of Pacifica PHEV was only about 2%."* Seeing such a jumbled & disconnected grouping of information was annoying. It's worse than cherry-picking. They were just random facts. That type of piecemeal data only serves to feed a narrative. There's no critical-thinking with such vague assertions anyway. You don't build a line of reasoning from such disorganized statements; yet, that's what thrives online. Ugh. I fired back with: RAV4 is Toyota's top-selling vehicle and the hybrid version is around 20%. The PHEV model will offer 39 miles of EV versus Outlander's 22 miles and around 40 MPG for HV efficiency versus Outlander's 25 MPG. Comparing the two as if they were in the same category isn't constructive. No one is going to buy that line of argument. As for the attempt to compare a minivan to a SUV, that's absurd. Understanding audience & market is very important. GM can declare whatever it wants based on whatever it wants. Missing that opportunity is their loss. If you choose to doubt the potential, so be it.

3-26-2020 **Market Narrative.** It continued: "*Yeah, GM should have done PHEVs earlier, but now the tech is too obsolete to invest too much into. And they are going the right direction with battery only solutions across their brands and vehicle segments.*" I got a kick out of seeing the "*obsolete*" argument being used. After watching that nothing-to-gain approach fail countless times, you have to wonder if that was nothing but a knee-jerk reaction. After all, there are some who participate online without ever practicing critical-thinking. That from-the-gut type of response makes them feel better, that's it. Amused, but hoping not to sound close-minded or condescending, I posted:

The label "*obsolete*" doesn't actually mean anything, since it has no relation to sales. People continue to use & buy technology that has been replaced with better solutions for decades. The reason why is simple, there's a balance of cost & benefit. That's a bitter pill to swallow for those embracing the newer technology. But that's the cold, hard reality of business. Like it or not, that's the way it is.

With regard specifically to PHEV verses BEV, it is especially difficult to convey information. Comparing a PHEV driven with only electricity for the daily commute to a BEV presents challenges, since the results are the same. How do you up-sell to the BEV when there's the obvious advantage of having a gas-engine available in the PHEV for longer trips?

Arguments of design or complexity are meaningless to a consumer with priorities not matching those here participating in discussions like this. When they walk the showroom floor, their exposure to the technology is profoundly different. Most enthusiasts have a very difficult time accepting that... hence their opinion of "*obsolete*" not matching your definition at all.

In short, the should-have-done and going-the-right-direction don't mean anything either. It's all about sales. That's the measure of change, not what marketing tells us.

3-26-2020 **Complicated.** Ugh. Someone went off on some rant about how simple the process should be, upset by how people are making it way more complicated than it actually is. It's understandable that they don't have the background to have a constructive exchange of knowledge. But to argue that everyone is making a big deal out of nothing is quite counterproductive. If it was really that simple, how come there's so much struggle still. Why isn't that next step naturally taking place, especially with such generous subsidies helping to encourage change? Annoyed, I pointed out:

There's more to it than that. GM failing to deliver anything whatsoever with regard to a plug-in choice yet means a truly compelling BEV could potentially destroy their ability to sustain a transition. In other words, without any type of phased approach, they face the Osborne Effect. It's ironic how much Toyota gets hammered for investing in PHEV, when such an approach helps protect against that very problem.

Think about it. By the time Toyota rolls out their dedicated BEV platform, they are expected to have at least 4 choices of PHEV in production (Prius, Corolla, RAV4, Sienna) and 2 choices of EV in production (CH-R, UX300e). All those will help to build up sales knowledge and service experience in the meantime. It also gives dealers variety to offer that already have a plug, instead of just adding to a massive backlog of orders to fill.

Tesla had the advantage of having basically no competition and an eager early-adopter audience. That made limited choice and high sticker-price far less of an issue than it will be a few years from now. That low-hanging fruit has been picked. Legacy automakers also have the challenge of legacy dealerships, needing to appeal to their inventory desires and sales practices.

In short, it's far more complicated than most people realize.

3-26-2020 Recognizing Data. I was captivated by the opportunity to respond to this on the discussion about Detroit reaction to change: "*Just have to look at the numbers. BEV sales have been on more of upward trend than PHEV.*" I knew his view was limited & outdated. What happened in the past doesn't tell us much about what to expect coming up, if you don't recognize the variables. Sometimes, even that isn't actually needed to see how off predictions can be. His statement is actually false in Europe. The trend has swayed in the other direction there. I didn't bother to mention that, since his focus was just on the United States. Here's what I did say:

Recognizing data source tells a different story. Last year had 2 major events for the plug-in sales here. One was the scramble for Tesla to ramp up production of Model 3 and the scramble for consumers to purchase them prior to tax-credit expiration at 2019 year-end. The other was disappearance of Volt, a vehicle which had exploited tax-credits for conquest sales prior to 2019. Both tipped the scale heavily in the favor of BEV and focused entirely on the early-adopter market.

2020 will bring about a major player in the PHEV category. RAV4 hybrid is already a strong seller, which sets up the nicely configured upcoming PHEV model to draw in an entirely new audience... one that Tesla has yet to reach. And since Toyota is a legacy automaker, there's the potential with this new offering to stir interest from their dealers who previously didn't see demand.

In other words, trend of the past tells us nothing about what to expect from an entirely new audience. It's how market growth works. That next level doesn't necessarily resemble the prior, since purchase priorities of the next differ so much. Put another way, selling a plug-in to a well-informed enthusiasts has basically nothing in common to the approach needed to appeal to a mainstream consumer.

3-26-2020 Disappointing Outlook. Shortly after the press started sharing projections from Detroit about EV expectation, there was disappointment. It was almost as if the EV community did a collective sigh. The numbers were far lower than anyone ever anticipated. This great revolution of new BEV choices was only to bring a 5% penetration in over 5 years time. What kind of change is that? Seeing such an outlook so poor left many without words. How do you support being let down like that? The production of ICE (Internal Combustion Engines) was to have a grim future at that point, with plans of discontinuation by 2030. It was the wildly optimistic enthusiasts hyping up expectations again. Ugh. I posted this wake-up call: The problem of "*over promise, under deliver*" speaks for itself. It has a long history. What's even more interesting though is the Reuters detail published today that he's referring to. It states a projection of the two biggest American automakers producing 5 million SUVs and Pickups in 2026, with only 320,000 of them electric. That falls well below the expectation of major change... and certainly not the "*options for consumers will be there from GM soon*" you hope for. Look at Toyota's top-selling SUV for some perspective. RAV4 sales for last year totaled 448,071 here. That's just one vehicle from one automaker. 320,000 split between two automakers and split between SUV & Pickup makes that number really disappointing in terms of the supposed revolution they were hoped to represent... especially when that's projected for 6 years from now.

3-27-2020 **Repeating History.** It's fascinating to witness the repetition: *"On the other hand, if consumers don't come to the party, you can't expect manufacturers to churn out BEVs that customers refuse to buy. The public loves their gas cars, global warming be damned."* Remember the excuse GM made for ending EV1 production? Full of ambition to fire back, I did with:

So rather than push GM to advance its fleet forward, you're choosing to be an enabler. Just allow loyal GM customers to continue buying their guzzlers without any accountability. Ugh. We have seen that entire life-cycle play out already with both Two-Mode and Voltec. It's fascinating to watch history repeat, yet again.

Notice how much Toyota gets mocked for doing the opposite, transitioning their entire fleet of passenger vehicles to hybrids? That sets the stage for a very easy next step, getting them to consider a plug-in hybrid. And as you have heard countless times on this website, PHEV is the gateway to BEV. Once the consumer begins to enjoy the benefits of plugging in, their interest in the gas-engine sours.

The irony of those here turning a blind-eye to the obvious solution for legacy automakers is amazing. It's such a natural path to reach the mainstream audience. Yet, many choose a path of purity and consequences be damned.

In other words, you're making the same mistake CARB made 20 years ago. Remember that mandate? Remember why it didn't work? You're focusing on a technology, not a goal.

3-27-2020 **Exaggeration.** You know you have an antagonist cornered when they reply with an extreme, some type of response grossly exaggerating what you actually posted. For example: *"And your solution is for all automaker everywhere to stop making all ICEVs right now. Yeah, I'm sure that would work."* Of course, I said no such thing. I had posted several comments about automakers have some sort of transition plan, an approach to phaseout the out with a next step technology. Stopping cold wouldn't make any sense, period. The dealer business couldn't support such a drastic change across the board. With a particular vehicle, sure. In fact, that makes sense if there is some obvious succession. But if it is a step backward or requires too much on the consumer's part, not a chance. Know your audience. It wasn't that complicated in this case. He just simply either wasn't paying attention or didn't care. So, I kept my reply brief and without any point to argue: Ignoring the wide variety of HV and PHEV options available for transition to BEV by replying with an exaggeration...

3-27-2020 **Dealing With Rhetoric.** When arguments fall apart for the antagonist, their next step is to attack you personally. Most of the time, it takes a form like this: "*But that IS your solution, isn't it? Aren't you saying that manufacturers should stop producing and selling ICEVs?*" They simply make something up and ask if that is what you meant. It is an obvious divert technique, right out of the troll playbook. They hope you'll take the bait. Sometimes, I do... but with a twist. Since he wanted to make it personal, I looked up one of his own quotes to use in the reply to frame the discussion: To quote your own post from the previous GM discussion: "*What they don't want to do is waste resources developing more efficient ICE instead of developing their EV platforms. ICE is dead, won't be around much longer, and it makes little sense to dump billions into new engines that are on the way out.*" That looks like a continued misunderstanding what a PHEV is and has to offer. Nothing is needed to develop a more efficient ICE. You just take whatever is already available and supplement it with electric-motors with batteries powered by plug-supplied electricity. GM did that already to create their Voltec system. This is what everyone expected to be rolled out in a SUV platform, like Equinox or Trax. Development was already complete and real-world proven. The approach worked, but GM abandoned it anyway... despite leveraging so much of what GM had already established. That was GM's phased approach to BEV offerings. Toyota, Honda, Ford, Hyundai, BMW... many automakers are following a similar path to reach that ultimate goal of no longer producing ICE. It is a natural transition which should appeal to the masses.

3-28-2020 **Simple Advice.** We have people working from home, not driving their vehicle anywhere near as much. Apparently, this person wouldn't be driving at all for quite awhile. I'm not sure how that's possible. Never going anywhere for several weeks isn't something we're hearing. Even with the reduction to essential travel, people still travel. If nothing else, they'll need toilet paper eventually. More realistically, they'll need food. I can't imagine too many people going to the grocery store and purchasing a supply of things to eat for several weeks. Some will, but that won't be the norm. Significant reduction is the expectation. And in that case, there's nothing to do. The longevity of your battery-pack is just fine in that circumstance. In that regard, I provided this simple advice: The advice is to drive the car from time to time. Use electricity or gas. You have that choice with the HV/EV button. At home, plug in randomly rather than every night. We have been patronizing local businesses. They are still working to provide food services and they still need money. So, it's out to get something to eat. The improvised curb-side delivery has been working great too. There's the drive-thru for the local coffee shop too. Eventually, you'll run out of some supply (toilet paper), so you'll need to run an errand for retail anyway.

3-28-2020 **New Misconceptions.** The start of the weekend brought this: "*For long periods without use, apparently the best is keep the charge to HV level (no more than the 20% HV charge). Read that here somewhere.*" I was curious where that new member to the forum came across such misinformation. I also wanted to intercept that before it becomes a new misconception. After all, many of those situations can be turned into a teaching moment. So, I posted: Incorrect. You have any recollection where you read that? It's helpful to find out the source of new misconceptions. Think about it. Toyota's hybrid system has strived to maintain about 65% since for longevity since the very beginning, over 2 decades ago. That balance has proven itself well for a wide variety of uses & conditions, even with different chemistries. So out of the blue reading that HV level is better makes no sense, especially since that is below 14%. Keep in mind that there's a lot of anecdotal comments passed along on the internet, some never confronted by critical-thinking, just accepted as fact. Don't be afraid to ask for links or detail to support a claim.

3-28-2020 **Facts.** Things change over time. The best of sources back in the past may no longer be up to date or even relevant years later. So, it best to check. That new misconception stir brought this about: "*Good to get the facts, we may need to research a bit...*" That's the kind of reply you like to get. I added to the discussion"

When doing that research, the comment posted is revealed to actually be part of a question... someone looking for confirmation of that being a valid suggestion. It's a good example of how hearsay gets passed along and later ends up becoming assumed fact.

In this case, it is easy to see a red-flag about the supposed advice, because the second sentence doesn't make any sense: "*After confirming that EV mode has switched to HV mode, turn the power switch off.*" It's an illogical step. EV mode is always default. Switching to HV just prior to powering off achieves nothing. There is no point stated for doing that either.

The first sentence tells us more about the circumstance of the post though: "*Leave a low level of charge in the hybrid battery (traction battery) when leaving the vehicle undriven for a long period of time.*" What was stated as the "hybrid battery" has been misunderstood to only represent the HV quantity, not including the EV quantity. It doesn't state whether that "low" represents the usable portion of the pack or the entire capacity either. So, you end up with a confusing mess of numbers the reader must interpret on their own.

This is why I share those driving videos with the OBD-II data added. That extra information provides insight to nudge people's brains for desiring a closer look. You discover there's more at play than a simple value being stated at any particular time. It's a complex system Toyota worked hard to create a "*for dummies*" interface.

3-28-2020 **Owner's Manual.** The on-going discussion got really good: "*I can understand your criticism, but the sentences quoted are a direct copy of the PRIME owner's manual.*" That type of bewilderment is easy to figure out if you work in my field long enough. It's simply the issue of not keeping documentation up to date. In fact, it sometimes isn't ever accurate. You have a different person or group writing up the manual than the engineers handling the software. Somewhere in between is an analyst figuring out details of the interface. That may or may not sync up with design and it most definitely does not get maintained well. Investing in the resources required to keep a manual, which only serves as a general audience guide anyway, rarely ever happens. In fact, that is why some of the references aren't as concise as you'd like and they come with a disclaimer about how what you see may actually differ. That's why what we do online has been so engaging & rewarding. As owner's we become part of the process... putting the "*manual*" in manual. Taking it literally like that isn't for those unwilling to commit. But some of us do get a bit enthralled... I had a conversation with the woman who oversees Toyota University training materials. She was well aware of what I do. We discussed the content I provide as a consumer, having no connection to Toyota other than having purchased their product. Her feedback is why I am taking so much time to research Prime prior to creating a User-Guide for it. I also wanted this particular document to span the technology, rather than a single vehicle. So, it could be quite timely for RAV4 Prime rollout... especially with me working from home now, no longer spending time driving the daily commute.

3-28-2020 **Is the Prime Advertised?** I was surprised to stumble across a video for RAV4 Prime. I believe it was for consumers Norway. Knowing how progressive that country is, been the world leader in EV ownership, that should have been expected. I was astonished by the timing though. It seems rather early... or is it? Supposedly, we'll see it here and in Canada. So there, earlier is entirely possible... or was prior to the virus. Anyhow, I found an old thread to revive that would serve well to post a link. It was about advertising Prime, back when that label was used exclusively for Prius. Now having it also refer to RAV4 is great. My comment was: 2 years later... a new "*Prime*" advertisement has emerged. Mention in the video is "*Elektrisk Rekkevidde: 65 km*" which translates to "*Electric Range: 40 miles*". Here's a link to watch the video... [Toyota RAV4 Plug-In Hybrid er klar for bestilling hos Toyota Bilia](#)

3-29-2020 Denial. We have seen it in many forms. A new aspect of denial is finally starting to get some serious attention in the EV world. That is long, long overdue. With my career in software development now quickly racing toward a 30th anniversary (40th if you include my education), there's much I can contribute toward the topic. Summarizing all that is simple... maintainability. For software to survive the test of time, it must be well designed. To quickly deliver refinements, flexibility should have been part of the fundamental approach to how it was constructed. Most new to programming don't have a clue how to achieve that. I often find having to present architecture-layouts and process-diagrams to explain how that can be delivered. It is often a major challenge, since speed & cost are big tradeoffs for that. Needless to say, my background makes me well informed on the topic. So, when hearing about VW struggles to now deliver on schedule due to software issues, none of that is a surprise to me. In fact, much of it was quite predictable. This is the same reason I was so hard on GM. Knowing what it actually takes to make hardware operate well and support upgrades, you must understand what it takes to provide the software for it. Anywho, this is what I posted today with regard to the denial issue VW enthusiasts now face: Who is in denial? On a very regular basis, we here claims of how many years Toyota is hopelessly behind and scrambling to catch up; yet, there's never any detail provided to actually support that. Reality is, we haven't ever been given reason to doubt they aren't on their game already. After RAV4 EV, Mirai, Prius PHV, and the Prime family have all delivered a variety of EV operation without any trouble. The software works fine. Denial comes from those focused entirely on EV range. They make jokes about a BEV not being available and divert attention to hydrogen with the hope no one will take the time for a closer look. When a closer look is taken, we see refinements to deliver more using less. That requires mature software to handle such a continuous flow of upgrades. Think about all the interplay which occurs between battery, motor, inverter, charger, cooling, heating, and of course safety. Clearly, some cheering for VW haven't until recently.

3-29-2020 Sloppy Writing. Most who write review articles are just industry writers, contributing their own observations. None are really ever a journalist doing extensive research. So, it's good to know what you're reading. Today, I ran across the same media source that published a very misleading article last week. Then, it appeared to be intentional misleading. This time, it looks just like sloppy writing. It was an article titled: "*How Capable Is The RAV4 Hybrid?*" I immediately got suspicious when the starts-at prices were listed. Hybrid = \$28k. Non-Hybrid \$25k. Quickly scanning through the article. Why no mention that AWD comes standard with the hybrid but not with the non-hybrid? To get AWD from a non-hybrid, you have to choose the \$33k model. That's \$5,000 more than the hybrid, never mentioned! Similar issue came from the towing-capacity. It listed the hybrid as 1,700 lb (which is incorrect, it's actually 1,750) and never mentioned anything about the base non-hybrid, only a maximum of 3,500 lb. Again, there was no way to know that base non-hybrid didn't offer that. In fact, it's only 1,500 lb. Sloppy? In the end, it did declare RAV4 capable. But from reading what was written, there's some assumptions & misleading at play. You are clearly not provided with quality reporting by any means. Blah.

3-29-2020 **\$1.64 Per Gallon.** Watching the price of gas fall has been surreal. We all knew the stay-at-home orders would bring demand down to such a level that supply issues were inevitable. There's simply too much gas now that people are no longer driving a daily commute. Only driving to the closest grocery store and maybe retail is a dramatic reduction of miles. In fact, that's so low all of the napkin calculations fall apart. Suddenly, the 25-mile range for Prius Prime is more than enough. Even the farthest out destination for curb-side pickup of food is just 10 miles away... which means starting the engine to use gas costs way more than electricity. That warm-up cycle usually gets washed out due to distance. Since there is no distance anymore, the penalty is obvious. Electric-Only driving is cheap, even in times of dirt cheap gas. Will we see lower than the \$1.64 from last night? Who knows. At this pace, I certainly won't need gas anytime soon. Heck, I may not need it for a few months now. Makes you wonder how this will impact the oil industry. For that matter, the airline industry. I wonder how much all the lack of travel will allow our air to cleanse. Living in an area where there is usually air traffic (about 12 miles from the airport), lack of overhead traffic is noticeable. Empty streets are beyond bizarre. These are strange times.

3-30-2020 **Critical Thinking.** There isn't any. The political disaster we are now dealing with makes that obvious. Relating that lack of cognitive enough to automotive choices, it's easy to see how we got in this world of hurt. Without even considering vehicle type, there are blanket statements being made about the future. Today, it was this nonsense: *"Once batteries are available in sufficiently large numbers and formats this whole PHEV intermediate step can be forgotten."* Sound familiar? It's the same old vague. Lack of any type of quantitative measure or even some milestone expectation, there is just a general dismissal of concern. More importantly, there is no one to be held accountable. Meritless steps are taken without any justification or even target set. It's just a move taken that is supposedly for the better... and people accept it at face value. Ack! That's just so bad, I don't know where to begin. We have become lazy, stupid, and uncaring. Needless to say, that type of audience has no clue what critical thinking is. It's just like the days of that daily blog, they'd climb up onto the bully-pulpit and say whatever was wanted. Each day was a fresh attack on principle & logic. Ugh. I keep pushing back though. Here was my rebuttal: Think about the product life-cycle investment and the shortcomings of infrastructure, not to mention how long it takes for mainstream buyers to embrace a "new" technology. Typically, that's several generations. Lacking the variety of choices currently, it isn't just battery supply either. In other words, we're looking at around a full decade of PHEV offerings still. Put another way, how long will it take for a vehicle purchased tomorrow to need replacement? That statistic alone reveals a picture of just how many years the general mindset takes to get a majority to shift. Like it or not, that is the reality of the situation... without even addressing all the forces that will be fighting against having any type of plug offering.

- 3-30-2020** **What !?!** That same confusing publisher had another article on RAV4 Prime today. It blew my mind. What the heck was this suppose to mean: "*The Prime's hybrid engine allows for 25 miles of driving with electric use only before the engine kicks in. It has a 31-mile range for electronic use only and a combined estimated 90 mpg.*" Reading it was so confusing, so bewildering, I didn't know what to make of it. He used the word "engine" two different ways and quote two different "*electric use only*" values. Huh? Even more strange was the 90 MPG estimate. Where in the world did that come from? It simply made no sense. What message was he even trying to convey? I was left baffled. How would others reading such a mess interpret the article? With an upcoming plug-in hybrid SUV also coming from Ford, having such grossly inaccurate reports from supposed journalists makes you wonder. Was that intentional? If so, was it to undermine the RAV4 or all PHEV offerings? Ugh.
- 3-31-2020** **Oil Prices.** They are falling and the stir to reduce output as demand plummets and supply overflows is getting heated. This was the big news today: "*US crude plunged nearly 7% and finished at an 18-year low of \$20.09 a barrel Monday as the coronavirus pandemic continues to deal a devastating blow to energy demand.*" Something will happen. I suspect some of the smaller drillers will just join the large pool that has already filed for bankruptcy. My guess is there won't be anywhere near the recovery anyone could hope for either, since it's this type of event that causes irreparable damage. Too much depended upon a constant flow. Too much depends upon the price being higher as well. Not having a profitable business makes continued investment a problem. More and more drilling was expected for a variety of reasons from a variety of sources. None of that matter though when the resulting fuel isn't being used. I can imagine the workforce re-evaluating the benefits of working from home after this... especially since investments toward infrastructure from setting up hardware for employees is taking place right now. Not having to lease or maintain as much office and is an obvious gain for business. An obvious gain for employees is not having to commute as much, or ever. There's a lot of travel that won't ever happen again either. This is a rethink moment for everyone involved. Oil won't be as desirable afterward.

3-31-2020 **Rolling Back.** News of the inevitable came today. Those climate policies set in place by the previous administration are no more. Automotive emission standards have been weakened with the excuse of saving money, which makes them more accessible... as stated by U.S. Secretary of Transportation: "*By making newer, safer, and cleaner vehicles more accessible for American families, more lives will be saved and more jobs will be created.*" That has never made any sense, especially this time when the claimed savings is just \$1,000. The report I found from Consumers Reports on this topic states the opposite. It will increase fuel cost by \$3,200. It will increase vehicle cost by \$2,100. And it will cost to nearly every state (45 of 50) at least \$1 billion in net consumers losses. That impact from dirtier air is significant. Ironically, we are dealing with the worst air-borne virus spread in human history right now. So that last thing you would want to do is make a decision to add pollution to the air, making it even more difficult for our lungs. Yet, that is exactly what's happening. There's simply no excuse for allowing more carbon and more smog when hybrids have proven quite worthy of reducing those emissions and PHEV & BEV are actively proving even more. The solutions are already established. Heck, even solar hit the tipping-point last year, making it price competitive with fossil fuels... well, until the stay-at-home paradigm shift anyway. Rolling back is absurd. I can't believe so many cruel & evil people have been put in place to empower greed. This legacy will we pass down to our children is shameful.

4-01-2020 Predictions, bankruptcy. They are especially good when it comes in the form of an assertion: *"In ten years or so Toyota declares bankruptcy, the subsidiary get's spun off to pay off creditors, and the subsidiary buys the Toyota name. This way the Toyota brand lives on without the legacy factories weighing them down."* I was amused by that. It was confidence without substance. Not liking the approach is no reason to call it a failure. There is no merit to drawing that conclusion. If Toyota is to fail, what about all the other industry players in no where near as good of a position? It makes no sense, especially without any reference to what the industry stance will be in that timeframe. I fired back with:

Toyota recognizes & responds to what is actually happening to the market here and you declare their doom. Nice.

Reality is, neither their dealers nor mainstream consumers care about BEV choices. Cost is still far too high and infrastructure far too lacking. That will changes throughout this decade and Toyota is preparing for that... as evidence of this article confirms. They are using compliance to refine future all-market offerings. Remember, the goal is to offer something that is both profitable & sustainable without subsidies. Initially focusing on a specific market supportive of that makes sense.

Meantime, Toyota is pushing EV technology into the market here which legacy automakers been reluctant to pursue... the SUV with a plug. That upcoming RAV4 Prime is exactly what mainstream consumers have been begging for. Heck, even supporters of Voltec overwhelming validate it is what would appeal to ordinary shoppers.

It's really unfortunate so many BEV enthusiasts have turned a blind-eye to what the business truly needs. A powerful SUV offering 39 miles of EV travel, while also delivering AWD and basic towing, is that product this market has been waiting for. Toyota has acknowledged that and will soon be fulfilling the demand with a product which will significantly reduce carbon & smog-related emissions. Attempting to spin that to a bankruptcy outcome is absurd. You do realize the electric technology in PHEV is the same as that for BEV, right?

4-01-2020 **Predictions, suddenly.** This is the response I got: "*In three to five years you'll start seeing all-electric SUVs that cost considerably less to manufacture than the RAV4. Suddenly there will be zero reason to buy a hybrid.*" That of course stirred my attention to being vague. Start is a meaningless term. There's no scope whatever from that. From the time a person first sees a Prius to the time they see one sitting in a driveway somewhere in their neighborhood or a few times on a daily commute could be quite a few years. That already puts us at something like 6 to 8 years out. There's nothing "*sudden*" about that. Sure, it might alter perception of industry, but it doesn't change what people drive for a long time. Transition is painfully slow even when the technology is readily available. Cost plays a major role and typically takes a few generations to finally squeeze out the well-established technology. I pointed out:

3 to 5 years! No, that's not at all realistic. In fact, you've lost your mind. The 2020 RAV4 LE has a 14.5 gallon tank, delivers 30 MPG efficiency, for a 435 mile range. That means the customer is going to expect at least a 300-mile potential to be considered competitive. That requires a 75 kWh battery-pack. That RAV4 has a sticker price starting at \$25,950. How much is the price of an equivalent Model Y today? Answer: it starts at \$52,990.

Toyota will be giving customers a taste of EV driving. It won't be cheap, but it require any compromise. At the same time, Toyota will be building up production of the same cells that will be needed for BEV choices. So what if they start their real-world experience inside a PHEV instead? The experience & relationship with a supplier will become well established while the battery market takes shape.

Sorry, but your rosy picture of a soon-to-be-future isn't based on any type of substance to build upon. It will happen, but no where near as fast. That isn't even taking into account the forces against the technology either, like dirt cheap oil.

4-02-2020

Predictions, capacity. The requirement of roughly 100 kWh capacity as a minimum for BEV to take on traditional vehicle replacement should be obvious to anyone studying the market. It comes down to the cold, hard reality of expectations. People will want an effortless 300'ish miles of range, period. No matter how much that defies logic, it is what will be demand. Want overpowers need. We have seen that play out over the past 2 decades. What people believe is more important than the facts saying otherwise. That's how we ended up with giant guzzlers. People just plain did not care about what we truly important. Their priorities didn't have to be logical. It is driven by emotion, not critical thinking. So, even when there is seemingly sound argument, the detail tends to reveal shortcomings. For example: *"Price parity estimates generally assume a 60kWh battery pack at \$100/kWh. That price point will be reached within 4 years. If you feel that parity requires 75kWh then it's still only 6 years out."* It seemed a sound reply to my reaction to the suddenly claim. He tried to convey consumer reaction based on trends of the past, with regard to early-adopters. That's the trap enthusiasts easily fall into. He clearly did too. I tried to present reason to second-guess his own reasoning: That price parity generalization misses the point. 75kWh is a minimum for acceptance. It delivers 300 miles in nice conditions. In the winter, between heater consumption and longer commute times, the resulting low 200's will not appeal to the masses. That means we are realistically looking at 100 kWh capacities for something competitive. To be able supply enough vehicles with that at a competitive volume is very wishful thinking. Trend data shows us how slow ramp-up & acceptance on the scale (a sizeable chunk of each automaker's production) will take awhile, without even taking into consideration the disastrous economic situation currently playing out. We're talking end of decade.

4-03-2020

Fighting Fire. It is interesting how some will place blame elsewhere, like on an executive or corporation for the sake not having to actually deal with the problem... or so it would seem. But when you look deeper, what they are really doing is shifting attention to you. Notice that from this subtle message: *"Well, sorry if I don't go along with poisoning my fellow Americans so the ultra rich can make more money. But yes, if cheering on someone who will *** over the little guy for the sake of the super rich becoming richer, conman president is certainly the guy. Rolling back the automotive mileage standards will only help Big Oil CEOs. Period."* In other words, by not agreeing, they feel it disassociates them from any responsibility or obligation. That is basically a "bystander" defense, providing an excuse not to have to do anything. It's why there was always such a fundamental hate for Prius. Continued success of the technology Toyota had employed meant change throughout the fleet. In fact, that is why the Volt enthusiasts kept making Prius the focus of attacks and pretended no other hybrid existed. By ignoring Camry & RAV4, hope was that would hold back market growth. Ultimately, those efforts fail. We're seeing it now with arguments like the one mentioned here. That comment doesn't actually achieve anything. He was upset at Toyota's seeming forgiveness of what's happening with EPA regulation. In reality, the situation is quite the opposite. I doubt he'll open his eyes enough to see it. But maybe someone following the thread will:

Looking at the bigger picture, the real problem can be seen. Rules get tied up in litigation. It ends up wasting resources, time & money that could just be otherwise used elsewhere... like for advancing battery tech. In other words, there are many who have fallen into the trap of thinking regulation what brings about innovation. Forcing change doesn't work.

Try looking at it from another perspective, offering incentives. The tax-credit was exploited by GM, used for conquest sales rather than actually bring about change to their dealerships and loyal customers. It was just another way to waste resources. Not only did Voltec fail so bad it was abandoned, that also served as an excuse to abandon cars too.

We see the self-destructive efforts to push SUVs and Pickups growing. People will fight intensely to own that type of vehicle. This is why Toyota is about to rollout an impressive plug-in hybrid SUV. The narrative of greed doesn't work when we now see that they are fighting fire with fire.

4-04-2020 Denial, Dysfunction, Delay. Leading to the election of this president, we heard him complain about how terrible the current administration was, that he would fix mess when he got in office. 3 years later, we are far worse off and all he can do is blame his predecessor. There's no accountability whatsoever, despite so much time and so many warnings since getting elected. That complete absence of responsibility is exactly what I saw play out with GM. Anyone who served as an excuse would be dismissed, so there would be no one to actually fulfill an obligation. Goals themselves were always ambiguous, where there wasn't any good means of measuring progress. It was a mess for the automaker and is now a mess for the government. In other words, failure of leadership can happen on any scale... using the very same techniques. Watching those familiar tactics successfully remove checks & balances, systematically until there's nothing to provide resistance anymore, is so disheartening. It's not the act of that happening, it is the enablement. So many people turn a blind-eye to those activities. Some even claim they are beneficial, accepting mixed messages and missed milestones as part of the process. None are willing to face the consequences. Remember the disaster Volt enthusiasts encouraged? Remember why they did that? Notice how none of them are around anymore to help GM get out of the mess their support made possible? This all too familiar pattern is easy to see, if you look for it. Most people don't. That is your warning of problems to come.

4-04-2020 **Behind?** I found this intriguing: "*If GM is one of the 3 furthest behind in electrification, then how come they were just 3 months behind Tesla in having their cars phased out the U.S. Federal EV tax credit?*" The reason why should be obvious. There is a new audience now. All the apologists are gone. In fact, it is as if Volt itself is dead. You simply don't hear from owners anymore. That's because many have moved on and the rest don't see any point. Why support a technology GM itself has abandoned? There's nothing to achieve anymore. No matter how much of an endorsement an owner provides, it falls on deaf ears. No one cares anymore. So, my intrigue comes from hearing what others think GM's next step should be. Volt enthusiast absolutely hated Toyota and refused to acknowledge there would ever be a next PHEV offered. Now that there will be, I'm really hoping someone will provide constructive feedback. I tried to stir discussion on the thread addressing EPA rollouts and how GM fits into that:

GM isn't really behind, it's just suffering from self-inflicted wounds. Their tax-credits were wasted on conquest, rather than using them to transform dealers and loyal customers. Think about who purchased Volt. Those buyers were just outside enthusiasts taking advantage of the opportunity, people who never owned a GM before just enjoying the early-adopter bargain. Most simply moved on to other brands as their lease expired or to pursue the next opportunity. So much was lost by not rolling out Voltec to something a current GM owner would likely upgrade to. It's sad the entire idea of a PHEV offering got abandoned. But that was the choice GM made.

Ironically, many made fun of Toyota for taking the time to target their own loyal customers instead and following the path of Tesla. So what if the narrative of "*behind*" gives an impression of struggle? Anyone taking the time to look at the bigger picture can see the long-term strategy of using the unlimited aspect of tax-credit phaseout is a very wise move. Look at how well that worked out for Model 3. Figuring out what will appear to showroom shoppers in the meantime is priceless.

As for the topic of regulation/mandate rollbacks, the expense related to litigation for establishing them in the first place requires a great deal of resources. It's simply better to stay focused on the goal instead. Even if there is no enforcement of it to push the rest of the industry, those other automakers will have no choice but to deliver something competitive in the end anyway.

4-05-2020 **20 Reasons Not To Buy, propaganda.** Today got off to an interesting start. It was obvious from the beginning it was an attack article written to mislead about Tesla. You could tell it had been circulating media sources for awhile; Model 3 was listed as "*recent*" and no mention of Model Y. Those electric vehicles have captured the imagination of consumers; however, there are supposedly 20 reason they should not be purchased. Coming from an enthusiast source... you know, those old-school collector & muscle publications... this was no surprise. In fact, that kind of nonsense is the propaganda we saw 20 years ago, unchanged. The comprehensiveness of their campaign to undermine is what we've come to accept. They simply don't care and willingly circulate incorrect information. It's really unfortunate, but understandable. There is no way to compete with electric. The performance from motor & battery is impressive. Tesla has exploited that, fundamentally changing the "*sport car*" experience. The silent speed & power is difficult to compare. Making a gas-engine capable of that is far more difficult. As for responsiveness, there is no way to deliver such an experience. Tesla is a clear winner in that regard... and they don't like it. In fact, this is a case where "*vastly superior*" actually has merit. Whoa!

- 4-05-2020** **20 Reasons Not To Buy, highway.** The first reason setup the tone of the article: "*And since there isn't much braking on the highway, the battery rarely gets recharged, so the range is small.*" It also treated the audience as idiots by conveying a long-time debunked misconception. The claim was efficiency was the opposite as cars with a gas engine. They try to portray the use of electricity as a penalty. But to do that, you must disregard the past 20 years of real-world data from hybrids. If that was the case, there would be no MPG improvement from them. Reality is, there is no such thing as a highway that has neither hills nor traffic. Both engage regenerative energy capture, without ever touching the brake-pedal. That helps to prevent loss which traditional vehicles have no means of dealing with, that opportunity is lost... wasted energy. The other loss is from the inefficiencies related to city & suburb driving. That's obvious with a traditional vehicle. Even with start/stop ability, there's simply no comparison to the complement/supplement of power from an electric-motor. Of course, you must disregard the law of physics related to aerodynamics to believe any of the enthusiast gibberish anyway. The faster you drive, the more resistance there is. Air pushing against the car presents a greater penalty at faster speeds. It's not linear either. The cost to efficiency is quite dramatic as you speed up.
- 4-05-2020** **20 Reasons Not To Buy, hype.** The second reason was just plain stupid. It focused on the "*look at me*" attitude supposedly coming from owners. That's so hypocritical, it's hard to believe that was so high on the list. A quick glance on their homepage was exactly what they were complaining about. Every single photo screamed exactly that. They are major source for hype. Simply driving around a Tesla is not a statement for attention. Most owners are just endorsing what they believe by making that purchase. They are voting with their wallets. Driving around a muscle car, especially those featured in the photos with fancy paint & highlights, is a statement of what? Ugh. Sometimes, you are just left in dismay.
- 4-05-2020** **20 Reasons Not To Buy, environment.** Next came a rant about battery production. It was horribly vague and claimed: "*...their factories pollute the air as much as driving a conventional car for eight years.*" I found that especially amusing. Since when is the lifetime of a vehicle only 8 years? Why was the write so afraid of mentioning what happens in the following 4 years? After all, that is what vehicles tend to average now before being replaced. And why no mention of recycling? Even if the initial production pollutes, what about the significant reduction that comes from reused those same components again later? Of course, the whole "*pollute*" reference was rhetoric anyway. When there is no distinction between carbon emissions and smog-related emissions, be suspicious. That type of detail omission is a red-flag. Though with an article listed nothing but a paragraph for each reason, that isn't anything you'd call journalism anyway. Lastly, there's never any perspective given. How dirty is any of that compared to a traditional vehicle burning petroleum and the process used to acquire that vehicle & fuel?

- 4-05-2020** **20 Reasons Not To Buy, charging.** The usual lack of charging stations was brought up, as if that was the only place you could ever refuel. No mention whatsoever was made about the convenience of simply plugging in at home. Again, it was all horribly vague, nothing but a paragraph for each claim being made. Travel was emphasized to draw attention away from everyday use and multi-vehicle households. It's that mindset that a single vehicle must deliver absolutely everything you would ever need for transport. That's how we ended up with giant SUVs that never go off-road and never tow anything. You must always be prepared for an extreme. Ugh. Though, this is a know your audience propaganda piece. It appeals to those not wanting to actually consider want verses need.
- 4-05-2020** **20 Reasons Not To Buy, time.** Again, spin in the article required you to imagine charging only takes place at charging stations and is required for any type of travel. That made the "*too long*" narrative for timing easy to emphasize. No mention of any charger availability at home is key. If people don't ever realize a EVSE is available... or even see the acronym to wonder what it means... they'll just assume the worse. It stands for "*Electric Vehicle Service Equipment*". That non-descript label & term does actually serve a purpose. It draws attention to the fact that there is something else involved in the process. When you tell people it is basically just a large adapter, they can readily understand how it can be used at home. Just like plugging in your phone to recharge, it's all you ever need to do. That's simple and requires no thought about how long it will take. The device is ready whenever you are. So, conveying a message of overnight recharge is no big deal. It just works. No worries. No need to ever hunt down a charger when you are out & about your daily routine.
- 4-05-2020** **20 Reasons Not To Buy, scary.** Fear is a tactic I was surprised not to see right away. The message conveyed was service would be limited & expensive. If you have a problem on the road, it may be impossible to get help. Ugh. It went on to stress: "*Also, roadside service won't help you if you run out of electricity, which is the most common problem.*" That is an outright lie. Some services offer generator service to allow you to charge enough to get to an electricity source. Those that don't will simply provide a tow for the same purpose. It's not like you would ever be complete abandoned. After all, how far away is the nearest public outlet? It's not that big of a deal and it a rare circumstance anyway. Gauges in the car and apps on your phone make it very easy to recognize state-of-charge and where to replenish. After all, 100% of all vehicle service providers have electricity. If all you needed was to just plug in, they could provide that. It's amazing how fear is used to scare people into resisting change.
- 4-05-2020** **20 Reasons Not To Buy, spare tire.** At this point, I am already growing tired of reading such nonsense. Roughly 75% of new vehicles don't come with a spare tire anymore. So, it doesn't matter anyway. After all, there's plenty of cargo room in a Tesla. The frunk (trunk in the front of the vehicle, space available for a spare since there is no engine) is an option. There's the usual repair-kit that vehicles without a spare include. That's a jack, pump, and goo to seal the tire. Again, how often are you going to travel long distances anyway? If you are just roaming around the metro area and suburbs, help is always near by. Getting a quick patch or replacement tire can be done anywhere and has absolutely nothing to do with being a plug-in vehicle. This article tries to misrepresent electric propulsion as somehow being different. If your combustion engine dies while on the road, you don't expect the repair to take place on the spot. Towing to a shop for service is routine for any type of vehicle.

- 4-05-2020** **20 Reasons Not To Buy, tires.** The insane acceleration Tesla offers will cause the tires to wear out quickly. Since when is that a reason to not buy one? Will anyone be using that neck-breaking speed for ordinary driving? No. In fact, that is absurd to even mention. Yet, it was. And not only was that highlighted, they was presented as if there was no way to avoid the acceleration. The writer was attempting to create a misconception that the huge amount of torque available from electric motors was the only way they operate. It's too easy for a belief like that to be spread. They just over emphasize to make you forget about ever taking anything else into consideration. It's a common deception technique.
- 4-05-2020** **20 Reasons Not To Buy, cold.** I became irritated by this: "*It is long known that electric devices are not dependable under cold temperatures.*" It then went on to add: "*some systems may stop working...*" That is an outright lie. There is nothing about Tesla, or any plug-in vehicle for that matter, that has dependability issues in the cold. There is no concern whatsoever for operation to fail. If you have electricity, no different than having gas, the system works just fine. Such a blatant attempt to distort reliability is a clear act of desperation. At this point, there should be concern for what this article will stir. It is a source for feeding rhetoric. Misinformation written like this is for the intent of causing harm.
- 4-05-2020** **20 Reasons Not To Buy, slippery.** If you keep repeating the same message over and over again, people loss touch. The undermining takes hold. In this reason, the claim was "*Tough to drive on slipper roads.*" That is also an outright lie. The "*enormous torque*", as they put it, has literally nothing to do with driving on snow or ice. It went on to state "*even the slightest acceleration is a problematic*". Then it continued by including "*dangerous*" to make sure you feared the technology. Again, that is a crock. For me in the Prius Prime, there are buttons to adjust pedal sensitivity. If you want more play, don't use the POWER mode. Geez! This isn't rocket-science. It's just a matter of switching to NORMAL. You can even go further by switching to ECO. Then, it's no big deal on those "*challenging conditions*". What kind of people believe this crap they are shoveling?
- 4-05-2020** **20 Reasons Not To Buy, breaking.** This one was quite amusing. When a publication about vehicles calls it the "*Breaking System*", you have to wonder how that article was sourced & edited. But then again, perhaps not... since they wrote this: "*First, they use regenerative braking to recharge the battery and second they sometimes brake without stopping the wheels by cutting the power to the engine.*" That makes no sense whatsoever. There is no engine! And if cut power flow from or to the electric-motor, there is no longer any resistance. That's like shifting to neutral, which would do nothing whatsoever to contribute to deceleration. They were obviously just making up brake information to mislead & confuse. What I found most telling though was how it gives you the impression there are no friction brakes available. Omitting that information about the vehicle having the ability to stop using ordinary brake-pads is a major clue to intent. This was undeniably more evidence of wanting to deceive by dishonest means. You cannot just leave out vital facts, especially with regard to safety.

- 4-05-2020** **20 Reasons Not To Buy, charging.** Oddly, it was brought up again. Listed the same reason a second time goes beyond desperate. The emphasis was fear. It brought up "*range anxiety*" and stressed the problem of going somewhere with few charging stations available. It became clear way with this statement: "*Also, if you want a good charging station at your house, it will cost you and take time to install.*" The writer was being vague for good reason. He wanted you to get the impression recharging with an ordinary household outlet was impossible. You are lead to believe not only is a "*good*" charging station required, is that if you have a bad one there may be issues. Ugh. I can't believe I put up with reading this rubbish. But I will persist and find out what nonsense is to follow.
- 4-05-2020** **20 Reasons Not To Buy, purchase.** Blah. You are told the new way of selling vehicles by Tesla is "*strange*" because it is unfamiliar. That of course is yet another attempt to appeal to fear. To be new is to be bad. Of course, then came the outright lie: "*Also, there is no test drive. Dealers have no test cars and they are not allowed to take you on the promotional drives.*" That is so far from the truth, I don't even know how to reply. The writer was trying to portray a purchase experience of being forced to making your decision sight unseen. This is how an antagonist raises doubt. They spread misinformation that you would be difficult to verify. Unless someone actively seeks an answer, how you find out?
- 4-05-2020** **20 Reasons Not To Buy, cupholders.** Really! Not having any available in the back is a reason not to buy? Purchasing an aftermarket cupholder for rear passengers is such a complicated & expensive process, the entire decision should be abandoned. Ugh. Of course, that too may be another lie. A quick online search reveals complaints about the location in the armrests not being well thought out. So, either that wasn't available initially or you are lead to believe that hasn't ever been an option is really pushing it... because that search also revealed a wide variety of upgrades. You could choose anything from a cheap plastic window mount for just \$1 to a fancy aftermarket leather-wrapped \$350 console to fit between in the middle above the flooring. Needless to say, that is an absurd excuse for deciding not to purchase.
- 4-05-2020** **20 Reasons Not To Buy, finish.** Quality of vehicle assembly is very much a subjective element, if explained. Different people have different priorities. I could see how that may be a valid point to list, if there was any actual detail included. To just say "*lacking*" doesn't actually tell us anything. It's the same old spin we've seen for years with Prius. People would complain with claims of being unacceptable, but never really explain what they were referring to. It's the avoidance of detail that's a dead giveaway. Lack of substance tells the real story. So even if they have something legitimate to convey, they didn't actually do it. The message of disappointment is transmitted with the hope you won't question why. I don't find that helpful at all. It's no different than reading product reviews for anything else. If it is just a vague low-rating post without any explanation, there's no reason to accept what was posted... literally. What was the reason?

- 4-05-2020** **20 Reasons Not To Buy, software.** This one was pure gibberish, like when you listen to our president. The claim was the system gets regular software updates: "*However, sometimes, the updates are too advanced for the drivetrain. So, to keep up with the new version, you need new hardware or a new drivetrain.*" What kind of nonsense is that? For that matter, what kind of person is supposed to believe that load of garbage? The updates are just refinements to the existing system. There is nothing required physical changes. I find it amusing to see that "*too advanced*" in the claim. What in the world would that actually mean? Think about it. What would that refer to? There's simply nothing of merit to support the claim. Heck, you can even look up the software versions and see what was included. It's all improvements to what already exists in the vehicle. Like updates to your phone or computer, there's never any new hardware needed. Ugh.
- 4-05-2020** **20 Reasons Not To Buy, expensive.** Just when you thought you've seen it all, they make the "*too expensive*" statement. That seems reasonable too, reading further: "*...that is more expensive than comparable electric cars from other manufacturers.*" Huh? What else is comparable? The luxury features from Tesla are no match to mainstream offerings from GM, Nissan, or Hyundai. All are a lower grade of build, that way for the clear purpose of appealing to a mainstream customer... not someone willing to pay more to get more. Interestingly, another "*you can't even test drive*" comment was added to this reason. Again, that is just plain not true. So at best, we're dealing with vague references. More realistically, this is just more misleading by being vague and making implicit references with the hope you'll make incorrect assumptions.
- 4-05-2020** **20 Reasons Not To Buy, resale.** This reason stated off good, pointing out how the evolving market makes used values difficult to predict. But then the topic of worth diverted to recycling, with the claim that "*...this is not possible since the batteries aren't recyclable.*" They are nothing but a string of many, many, many rechargeable lithium batteries. Those are already known to be commonly recycled. There are collection bins for lithium batteries in many retail stores already. It's not a big deal and more definitely is possible. I'm quite annoyed at this point, but only having 2 reasons remaining, I'll stick with the commentary. Blah.
- 4-05-2020** **20 Reasons Not To Buy, repair.** The element of fear "*get stranded by the side of the road*" was added to the claim of it being impossible to repair. Overlooking the fact that a plug-in vehicle is far less likely to strand you anyway, since the design is much more robust than a combustion engine with hundred of moving parts, there's the reality of not being able to repair them on the side of the road either. If your vehicles somehow loses power and forces you to pull over, what would you be able to do right there on the spot to get it going again? Is there anything in a traditional vehicle than can be fixed easily, at the location, without any tools? I can't think of a single thing you'd be able to do with respect to needing a mechanic. Unless it is a flat tire, you're going to need a tow anyway. In other words, this reason was a red herring.

- 4-05-2020** **20 Reasons Not To Buy, self-driving.** It was stated this way: "*Self-Driving can provide a false sense of safety. And Tesla car had been particularly problematic.*" What does that have to do with the technology itself? We all know people have been mislabeling autonomous features, leading you to believe the technology is so advanced the car will handle everything for you. That has never been true and warnings are given on a regular basis to that affect. The "*full self-driving capabilities*" advertised are for future software upgrades. The advanced hardware included capable of providing "*no action required by the person in the driver's seat*" is clearly identified as a forthcoming feature. It isn't available yet! The word "*future*" was quite intentionally excluded from the reason... which is why it was labeled as a "*Self-Driving Scandal*". The only deception about how it works comes from those trying to undermine success.
- 4-05-2020** ***Phew!*** Reading those 20 reasons was painful. It was a great example of the extent some people go to for the sake of misrepresenting technology that brings about change. Focus of the article was Tesla, but it's easy to see how Toyota has been a target of the same type of efforts to impede progress. We have seen that same nonsense for 20 years now. A great deal of effort is used to feed misconceptions and to spin facts. Some won't even bother with that; they will just keep repeating the same lie over and over again until source is obscured and detail forgotten. You'll get assumptions and experiences confused as mixed messages come into play. A simple look at GM is all it takes to wonder what's really going on. If Volt was so great, how come no other plug-in hybrid will be offered? And if Bolt was proven to be superior to Voltec, why isn't it selling well and where are other BEV models? There's a lot working against advancement in the automotive industry and Tesla has emerged as the Apple equivalent. People that are willing to embrace the proprietary approach and willing to spend a premium to get it will be very happy with their purchase. That leaves the rest of the market vulnerable to narratives... which is how Tesla becomes a means of undermining everything. If it continues to be successful, it is labeled as a niche. If it shows any type of weakness, it is sighted to be the canary in the coal mine. It's a lose-lose situation, which is why I took the time to explain how the attempts to misrepresent come about.

4-05-2020 **5,873 Sold.** That's the total reported for quarterly sales of Bolt. Everyone knowing there was a scramble to take advantage of the final tax-credit opportunity, it didn't need attention. Instead, the posting started with a comment about the crazy discounts. I see this as much worse than the situation Volt was in. At least with it, there was still attention given to the effort of GM to push electrification. True, they were without merit. But nonetheless, there was a spotlight. Now, there's nothing. Everyone jumped ship. You simply don't hear anything about Bolt anymore. A few weeks ago, we got news of a mid-cycle upgrade coming for the 2021 model. But with stay-at-home severely impacting expectations for the industry, those plans were abandoned. Bolt will supposedly get upgrades in 2022 instead. Sales began in December 2016. That will its sixth year. With sales just barely above what Volt was able to achieve (an average of 1,600 to 1,700 per month), what would that accomplish? It represents no growth in a time when the rest of the industry is seeing new choices. Think about what RAV4 Prime alone will do for putting pressure on GM to finally deliver something their own loyal customers will be interested in. This takes "*too little, too slowly*" to an extreme. Voltec failed to achieve change, despite getting so much praise for being a game-changer. Bolt has done what? Remember, the goal is to find something to replace what's on the dealer's lot. All I see is growth for more SUV and Pickup sales. Why is their no push for something, anything with a plug? Here's what I had to say on the topic today about recent Bolt sales: We have been told Bolt doesn't make a profit, so the crazy discounts only serve to keep inventory moving. GM's own loyal customers aren't interested either. That is in no way a sustainable business model. What is the point?

4-06-2020 **Facing Insanity.** How would you deal with it? I now have 1,000 pages of personal log documenting 20 years of my experiences. It's rather amazing how the crazy debates grow to the point of insanity. You wonder how the heck a person can be in such deep denial, outright lying without any care or concern. People support that too, enabling even more. I'd face it both frustrated & bewildered. It's not the kind of thing you would ever want anyone else to also have to deal with; yet, here we are. My exposure was confronting antagonists fighting Prius and what it represented. Everyone else has forcefully been drawn into to the consequences of having elected a president clearly not interested in taking care of the country. I have learned to counter the appeal to emotion with substance. In other words, my best offense was to hit troublemakers with real-world data. The following is what a physiologist shared about the situation, a description I found all too familiar: "*The sense of grandiose omnipotence that he displays seems especially appealing to his emotionally needy followers. No matter what the world says, he fights back against criticism, continues to lie in the face of truth, and above all is still the president. What matters is that he is winning, not whether he is honest or law-abiding. This may seem puzzling to the rest of us, but when you are overcome with feelings of powerlessness, this type of cartoonish, exaggerated force is often more important than true ability. This is the more primitive morality, as we call it, of "might makes right", which in normal development you grow out of by five.*"

- 4-07-2020** **Volt Owner Review.** It was refreshing to look backward now, on a past that really was history without a twist. I wondered how long it would take to actually reach this point. A video review from a Volt owner was shared. This is what I posted as a comment after watching: The video was nicely done, an excellent footnote to what things were like back when GM still had lots of potential in that market. It is really unfortunate that opportunity to expand Voltec to more desirable platforms wasn't pursued. The most obvious next step would have been to offer a PHEV model of Equinox. With so much experience, so much of an investment, so much of market yearning for exactly that, the decision not to is baffling. True, it would have upset the fragile equation of profit. But then again, seeing GM push the tech out to more vehicles would have enticed dealers to endorse it. The mixed messages about its future and knowing other automakers were more interested made it a hopeless cause. When his lease expires, you think he'll get a RAV4 Prime? The better seating, the larger cargo, the more efficient heater, the AWD system, the faster acceleration, the ability to tow... It does make you wonder how GM will respond to such an offering.
- 4-08-2020** **Caught Unprepared.** I certainly have a lot to say on this topic. Over and over and over again, I repeated the "*too little, too slowly*" concern. There was years of downplaying the situation and use of every possible tactic available to try to get the speaker to shut up. Sound familiar? That same type of nonsense from both Two-Mode and Volt... it's hard to believe such terrible history could repeat like that... is now happening right before our eyes with our presidency... every excuse imaginable, along with finding someone to blame. Upon getting caught unprepared to such an extreme, what option is available at this point? It's the trapped-in-the-corner situation again. That's quite remarkable. Opportunity was wasted. Time & Resources were squandered. The very same reaction witnessed all those years ago... lash out at anything... the final act of desperation. This is the consequence of not preparing. Denial of the problem won't make it go away.

4-09-2020 **10 Miles.** That's the rumor circulating today about the EV range for an upcoming PHEV model of F150 pickup from Ford. This comment, in the long discussion thread, is what caught my attention: *"...it won't be worse than the first generation Prius Plug-in, which had an all-electric range between 0-12 miles. You ask how Toyota could possibly build a plug-in car that might have an AER of zero miles? I don't know; ask them! Seems like an amazing feat of engineering to me."* It came from a known troublemaker and was my invite to dive in... and I did:

AER (All Electric Range) was a marketing term coined to distinguish plug-in design like Volt from Prius plug-in. Since they served entirely different purposes, it made sense. Forcing an unfit definition on so many years later does not. So whether it delivered 0 miles or 12 miles was always a moot point, a red herring with the intent to mislead about how the system actually operated.

Having a larger battery and a plug was provided Prius with the ability to take advantage of supplemental electricity from a source other than gas. That provided more power for a MPG boost. The system was able to draw 38kW for propulsion. If demand was below that threshold, the engine would remain off. If it exceeded that, the engine would start to provide the additional power needed.

Prius Prime has a larger battery-pack, providing the ability to draw up to 68kW of power for propulsion. That's enough to accelerate onto a highway and cruise up to 135 km/h (84 mph) without the engine ever starting. Of course, calling that distance AER is a moot point now too, since Volt is dead, has no successor, and lacks what comes standard on Prius Prime... a heat-pump.

In short, your criticism of "worse" doesn't take into account what really matter. The vehicle will still be taking advantage of a plug, regardless of whatever rating or label it is given... using electricity instead of gas.

4-10-2020 **Guessing Operation.** Having a discussion about a plug-in hybrid pickup brings in an entirely new group of people into the mix. Some have no background whatsoever and just start wildly guessing about operation, how the upcoming new system will likely work. That means all the same old assumptions get stirred up again. In this case, it was about horsepower. I jumped in to provide some insight: Horsepower equates directly to battery size, not just what motor is available. We've seen that with Prius. As the pack grew, so did the power without any change to the hybrid system itself. The gen-1 model increased from 27kW to 38kW from nothing but capacity increase. The gen-2 model introduced a clutch, so that larger pack combined with a second motor distorts the calculation. Be careful when looking at numbers. In this case, that is correct, 44hp would be just an assist. Prius Prime is able to draw 68kW from its pack. The result is 91hp available for EV driving. That's enough to propel that size vehicle just fine without ever starting the engine. The same cannot be said for a much larger vehicle, like F150.

- 4-10-2020** **Building Narratives.** There are some who have questionable motives posting stuff like this: *"...it's because Toyota isn't interested in building anything more than mild hybrids."* then go on to include: *"...it's safe to say the percentage of electric-powered miles is far lower than it is in a properly designed and built PHEV, such as the Chevy Volt and the Honda Clarity PHEV."* It originates from being a Volt owner, then getting burned by GM abandoning the technology. But what was the purpose of becoming a plug-in owner if you don't want to see the market move forward? So what if your preferred approach failed. That's no reason to spin stories to build narratives about another that is showing genuine progress. Annoyed, I responded with: Trying to relive glory days of past doesn't change the reality that GM chose not to participate going forward. Voltec died as a result of the decision not to spread it to other vehicles... like a SUV or Pickup. Meanwhile we see this Pickup planned from Ford, along with a SUV. As for the nonsense of *"properly"* designed vehicle, the avoidance of addressing how Toyota's tech advanced is quite obvious. The effort to not mention Prius Prime's ability or its successor, the upcoming RAV4 Prime, couldn't be any more of a wish-GM-would-have-done-that situation. How will GM respond? It is all about targeting the core market. That's why Ford is looking into augmenting a F150. Owners will be thrilled to finally get an electrification choice that will return a noticeable gas savings. Whether or not it meets your approval as a Volt enthusiast doesn't matter.
- 4-10-2020** **Who?** It continued with a long, drawn out soapbox presentation. It was a pie-in-the-sky presentation without any scope. You know they type, where both audience & timeline is undefined but no one seems to have a problem with that. So it sounds credible, but there was no relation to how it applied to the situation at hand. In other words, it was a long-term prospective completely void of any relevance to what happens right now. That happened a lot with Volt in the past. They focused so much on the ideal, they lost touch with the moment... which is how so much opportunity was missed. Who was all that supposed to be addressing? I grabbed to of the basic conclusions draw without any supporting evidence to rebut with: Again, who are you trying to make a case that *"the days of the PHEV are over"* to? The painful lesson learned by Volt enthusiasts is that they had no audience. Their preaching to the choir meant nothing to mainstream consumers, those who shop the showroom floor. So, none of their claims of superiority ever reached beyond the niche. It turned out to be an approach that didn't appeal. Why? That question is what should be addressed, not drawing a conclusion of *"I don't think PHEVs satisfy anyone anymore."* simply based upon generalizations of simpler & cheaper. After all, that doesn't at all resemble the business of automakers or dealerships. Think about it. What is your sales pitch to a potential buyer? Remember, the audience. What does a SUV or Pickup shopper consider for purchase priorities in 2020? How are you going to convince an ordinary person that short EV distances from an ordinary household outlet for a reasonable price isn't better than the other choices there on the lot?

4-11-2020 **Sarcastic Insults.** This was inevitable: *"Gee, Toyota has "advanced" the state of its PHEV tech from "0 to 12 miles" all the way to... well, they are touting "39 miles" for the upcoming RAV4 PHEV."* I seek out that type of attack, where they try to put you on the defense, as an opportunity to take an offensive position. I certainly took advantage of that this time, creating a nice outline of what he was attempting to avoid:

Pretending to address the tech by throwing out one random fact is a dead giveaway of a nerve being struck, especially when the post ends with both *"sad"* and *"pathetic"*. The reason why is obvious, those other facts are quite relevant to this discussion as well. Those characteristics carry over nicely to a pickup.

SIZE matters. The offering from GM had a cramped interior, but included a technology lots of potential. Unfortunately, the opportunity to make it grow into a much larger vehicle was squandered. Toyota will soon be delivering that instead.

SPEED draws lots of attention. Whether it's useful or not, that is a selling point. Showroom shoppers are impressed by the ability to accelerate quickly. 0-60 in 5.8 seconds will put many vehicles to shame. That will indeed be impressive.

HORSEPOWER for those times you do actually load up the vehicle or find a need to tow, that desired power is there. The upcoming plug-in hybrid RAV4 will deliver 302. Having so much torque available is part of the fun-to-drive equation too.

AWD is a major selling feature, so much so, even a model of both Prius and Camry offer it. That is a purchase priority for many. Having it included as a standard feature for the PHEV in a SUV platform totally makes sense.

HEAT-PUMP offers cabin-warming efficiency many plug-in owners are envious of. That is most definitely advanced tech to avoid discussion about what you are trying to undermine the message of automaker progress.

EFFICIENCY when the battery-pack is depleted will be impressive. Just like the other Prime design, resulting MPG from hybrid mode will be substantially higher than its traditional size & power counterpart, about 38 MPG.

RANGE seals the deal. As much as enthusiasts tout the desire for more, real-world statistics simply doesn't support the claim. Ordinary consumers simply don't routinely drive beyond those 39 miles of EV it will provide. In other words, all those facts avoided add up to make a compelling purchase. And that's without mentioning the 10-year, 150,000-mile warranty or any of the safety features included on all models. You have been called out for attempting to undermine Toyota's best-selling vehicle soon to be available as a PHEV.

4-11-2020 **No Plan.** Regardless of what argument is using, ultimately, each automaker must have a plan. No statement of intent or even a clear investment should be reason for concern. Yet, those that support GM don't. Just like our current administration, there's just a mix of confusing messages, no accountability, and no obvious direction. Heck, for that matter, there isn't even a next step identified. That's the same old nonsense we've seen from years with both the troublesome automaker and certain people in office. We get these bold declarations of advancement without anything ever happening. In fact, it is often a slip backward. Ugh. I continued on with the replies to the rhetoric:

That narrative of "*GM killed the Volt because they think there is no place for PHEVs anymore*" gets more interesting each time someone tries to support it. The reality of the situation is easy to see once the perspective is backed away from the weak argument based solely on range comparisons.

Put simply, GM couldn't deliver something profitable. Their design was inefficient. That put it at a clear disadvantage for competing in the PHEV market. Neither the EV efficiency (31 kWh/100mi) nor the HV efficiency (42 MPG) of Volt made it compelling from a business perspective. Ironically, the "*vastly superior*" tech it had to compare to came from its nemesis, Prius. Delivering EV efficiency of (25 kWh/100mi) and HV efficiency of (54 MPG) meant it would use less fuel to travel the same distance. In terms of battery, that meant a lower cost since fewer cells would be needed.

Dealers seek easy profit. They refuse to carry inventory something that's challenging to sell. A high sticker-price without anything compelling beyond EV range is a very real problem. Not having any tax-credits remaining and having wasted the opportunity to exploit the unlimited aspect of phaseout means GM has nothing to work with anymore. Their squandering of subsidies for conquest, rather than transforming their own customer base, really does mean there is no place... for them. For the rest of the market, the PHEV still offers a great deal of potential.

4-11-2020 **Understanding Tax-Credits.** Some still don't, despite so many years of exposure. Much of that comes from so much exposure to intentional misleading. There's quite a bit of propaganda aimed at undermining the message of purpose. That confusion from mixed messages, spinning outcome, and just making up stuff is rather effective. Sadly, we get stuff like this as a result: "*The whole tax credit argument makes no sense. I mean, if Toyota is dependent on tax credits to sell the Rav-4 Prime, then what are they going to do when those credits run out?*" That came from someone who is well informed in the plug-in community, yet still uncertain. But at least he is aware of that lack of clarity and is asking for more information. I especially liked his look forward, a scope often avoided... because so many are just hung up in the moment. Finding out about the bigger picture makes it challenging because of that. I tried my best to convey purpose is a relatively short response: Those tax-credits are for breaking the status quo, to finally get dealers to embrace the technology. Getting them to establish momentum to create a new norm (inventory readily available) was the subsidy purpose. GM perverted it into a use for conquest instead, which is where the dependency came from. Nothing changed with regard to dealer interest. The reason why should have been obvious. Those purchasing Volt were not loyal GM customers.

- 4-11-2020** **Doubting Purpose.** Even when it is told directly, acceptance can be difficult. But hey, that's still better than the outright dismissal I have grown use to getting. So, this was a definite improvement over that: *"I'm not even sure they want to sell us PHEVs being how poorly the Prius Prime is stocked in the USA, despite the fact they could sell a ton more than they do."* It's easy to fall into that feeling of doubt when the sentiment is passed along so often. Undermining purpose by repeating a different message over and over again is the tool of an antagonist. They say what they want you to believe at every opportunity. Critical thinking is how to overcome it. I try to provide a means of helping that process along: That anecdotal reasoning is easy to understand, but doesn't match what we've been told or Toyota's goal. All along, we've seen an effort to move the entire fleet. That means having lots of patience and the willingness to not succumb to the easier path. Lots of Prius Prime simply doesn't make sense knowing there's a RAV4 Prime on the way. Why would they waste tax-credit opportunity like that? The goal of reaching the masses wouldn't be achieved by hatchback. Know your audience.
- 4-12-2020** **Range.** A new discussion was started, comments posted based upon range/price measures... which is as informative as something like horsepower/price. What purpose does it serve if some of that capacity is rarely or ever used? If you never tow anything that massive, what is the cost of having that ability? It turns into a penalty when you pay for far more than you actually need. Sound familiar? It's that same old want verses need problem. The oldest example is acceleration speed. Some people absolutely insisted more was necessary, but couldn't actually prove it. In fact, they were so desperate to spread such a narrative to undermine Prius, they just started lying. That's what pulled me into this mess. I was shocked how far they would take the dishonesty in the name of supposedly helping endorse cleaner technology. That's why they were so baffled that I would endorse more than just a single automaker. It made no sense from their perspective, since they were really just serving their own interest. So when I see stuff like this, I question motive: *"Meanwhile in the real world, range is often the most important metric with a BEV along with price and msrp/range metric is an excellent data point to show value of each model in a comparison chart."* Before I could even respond, someone else sharing the same concern as me jumped on that same statement. It's nice no longer being alone. It's also nice that range is finally getting scrutiny, which is long overdue. I sounded off by replying to him rather than the troublemaker with: Totally agree. If most of your driving is nothing but a daily commute, focus on range makes no sense. My daily commute is 36 miles. That makes a PHEV with a supposedly *"inadequate"* capacity of 39 miles reason to question the priorities of those against it. Increased range doesn't accomplish anything for the bulk of that vehicle's usage. It is a blatant example of diminishing returns no one sharing Price-Per-Mile statistics is willing to address. At some point, more is not better. In fact, it can be a negative. Why carry around capacity you will rarely ever need?

4-12-2020 **Change.** You can see some of the antagonist stance beginning to slip. My guess is the combination of a saturated market, ending of tax-credits, and the collapse of the oil industry has crumbled the foundation of argument far more than anyone wants to admit. Remember how GM fell apart? There was so much damage-control going on near the end that direction had been completely lost. They had no idea what the next step should be. That's exactly where some of the BEV enthusiasts are now. They have been so obsessed with pushing range further and further they no longer have any clue how much is enough or what to do when it has been achieved. That's why the rumor of a F150 as a PHEV on the way has them perplexed. Knowing a BEV would be so expensive direct competition with a traditional model would be impossible, they have nothing to promote. Hybrids offering a modest amount of capacity have always presented a glimmer of hope though. They don't like that at all... especially since that hope is becoming realistic. There's echoes of that too: *"Toyota will get this right with the new Tundra. They have the worlds best hybrid systems and I believe they will build a full size pickup with a gas hybrid that has class leading mileage."* Discovering the supposed laggard has a feasible means of advancing forward is beyond upsetting. Most people are challenged with facing the prospect of being on the wrong side of history. They don't know how to acknowledge having overlooked something. I do my best to get out in front of that, pointing out facts often to prevent such a predicament. Used as a teaching moment, it's easier for them to accept... defeat. But that's what change is all about. Today's example went as follows: Evidence of that is becoming difficult to deny. Toyota is inching its way closer and closer. 2020 Highlander hybrid delivering 35 MPG with AWD and a 3,500-lb towing capacity makes that quite apparent. In fact, knowing that helps to explain Ford's move forward with a PHEV model of F150.

4-12-2020 **Per-Mile.** What a contrast from the past. I have allies now. That's what I wanted all along. There were some who absolutely refused to believe a person owning a different automaker's vehicle could share the same goal. Ugh. Thankfully, their voices have a harder time stirring attention nowadays, due to stuff like this: *"I think range is important and price of car is important. However, I do not see why msrp/range is a useful metric."* It's easy to just dismiss that when I post. But when someone relatively unknown does, the enthusiasts is at a loss. I was more than happy to join in to point that out too: It is only useful to enthusiasts. Try presenting the same info to a showroom shopper. They'll walk away in dismay, surprised that you'd even bother to appeal to them with such a statistic. Know your audience. The ordinary wants to know how much the price they are willing to pay will provide in return. That's why GM targeted Volt for *"nicely under \$30,000"*. It was a compact hatchback and that's how much people typically budgeted for with that category of vehicle. That practice of delivering for a print-point is a very well established market approach... and has been extremely successful... which was a big reason why Volt failed to such extreme. It was too expensive, plain & simple. Belief that more range makes a vehicle better is futile. As you pointed out in previous posts, range increase provides a diminishing return. So, the idea of *"Per Mile Of Range"* pricing doesn't reflect the reality of what a mainstream consumer is actually looking for.

4-12-2020 **\$1.29 Per Gallon.** It sounds like there will finally be substantial cuts from oil producers. They were pumping so much beyond demand, it was putting the world in a position for serious problems. The supply isn't being used. In fact, consumption has dropped so dramatically we are hearing reports of air over major population centers clearing to extremes that haven't been witnessed in the lifetimes of many. Imagine being able to see a mountain range from where you live for the very first time. That must be an incredible experience. What's bizarre though is how cheap gas has become. That would normally be cause for celebration. I don't hear any of that though; instead, it is concern for loss of jobs and possibly parts of the industry falling apart. Certain operations are unsustainable when little to no profit is being made. In fact, holding on to excess inventory can be costly. Oil is so abundant, the realization that "*peak*" doesn't mean supply on downturn is becoming apparent. It is really what some of us have been screaming about for years... actually, well over a decade. What the term "*peak*" actually represents is the permanent loss of stability. When you can no longer depend upon the strong, on-going source of revenue, things start to get ugly. It progressively gets worse, but all the excuses coming from apologists obscure the warnings. They say everything will be fine and return to normal, despite the lack of merit to support such claims. This here, right now, is the turning point. Too cheap is a very real problem. Investors feeling uncomfortable tips the balance. Difficult decisions will need to be made. If not, losses become even easier to notice. Like it or not, permanent change is coming. There will be a new norm. It will be fascinating to witness how that comes about.

4-13-2020 **False Hope.** Its spread is a very real problem. How does one combat an idea? There is nothing to physically battle. The impossibility of victory becomes apparent very quickly... as is the reality that whomever is repeating it won't ever stop. I have witnessed that so many times with my support efforts, its an endless fight. All you have to do is just keep saying something, especially if there is a hint of truth in its origin. The most common of these is to point out the results of a survey. How old it is, how small or limited of a sample it was, or how relevant it applies to the topic makes no difference. Antagonists will just keep bringing it up as it is somehow proves their point. The purpose is to appeal to your emotion. If it feels right, it must be. That kind of manipulation is the old snake-oil bit. People fall for, simply by not bothering to check facts. Critical thinking is a lost art. The wisdom of something sounding too good to be true being enough to raise concern is just a memory from long ago. I see too many clinging on the hope without any substance to support it. Those meritless claims are something to cautiously watch for. In times like these, it is very easy to encounter someone trying to manipulate you for their own benefit.

4-13-2020 **Hummer EV.** Speaking of false hope, the promotion of the upcoming Hummer EV blows the mind. Next month, GM will reveal some detail, stirring excitement for a Fall 2021 rollout. The latest hype comes from a filing last week of a trademark for the new logo. Sound familiar? That is very much like the "*range anxiety*" excitement that came about for Volt. It's a showmanship type move to rouse excitement, not anything to actually bring about meaningful change. There's a sucker born every minute too, gobbling up the hype to build it into hope: "*Again, offsetting the fuel consumption of these 10mpg beasts will do more for the environment than switching an hybrid owner to a BEV.*" Obviously, I had much to say about that: That offset sounds plausible, if you don't take into account the market for it. The potential for sales of a 1,000 horsepower system generating 11,500 pound-feet of torque and 0-60 acceleration in 3.0 seconds is tiny. This is a niche vehicle, period. Ironically, those pushing the narrative of GM discontinuing their Voltec system to avoid wasting investment money in a platform that people won't buy have been painfully silent on this bitter reality. It's the same history repeating itself, yet again. GM craves the spotlight, neglecting their core product as a result. There's no balance. It's Volt all over again, but this time they aren't even trying to pass off the technology as a family vehicle. And yes, I noticed how you attempted to skip the category of PHEV entirely. Reality is, a pickup with a "*paltry*" capacity of only 10 miles of EV range will do far more for the environment.

4-13-2020 **Operating Costs.** It is such a disappointment when websites intended to help promote electrification fall short on the same thing, again and again. How many times must electricity amount be brought up before it is finally addressed? Fortunately, there are more of us pushing for that now. Today, I was joined with: "*MSRP per mile of range doesn't account for operating costs such as energy consumption...*" Seeing that was great. Of course, it's difficult to know if that will make any difference. I have been bringing up the topic for years now. I didn't let this opportunity slip by either: That statement is key to gauging motive of those who claim to be green. You can validate by simply bringing up the KWH/100MI rating. Guzzling electricity is not what we should be turning a blind-eye toward. Yet, the topic is virtually never addressed. Each time I try, someone attempts to divert attention elsewhere or make up some excuse. In fact, this is from a comment I posted back in January 2017 about that very topic...

35 kWh/100 mi = 97 MPGe = 2017 Ford Fusion Energi

35 kWh/100 mi = 98 MPGe = 2015 Chevy Volt

31 kWh/100 mi = 106 MPGe = 2017 Chevy Volt

30 kWh/100 mi = 114 MPGe = 2016 Nissan Leaf

30 kWh/100 mi = 116 MPGe = 2016 VW e-Golf

29 kWh/100 mi = 111 MPGe = 2017 BMW i3 PHEV

28 kWh/100 mi = 119 MPGe = 2017 Chevy Bolt

27 kWh/100 mi = 124 MPGe = 2017 BMW i3 EV

25 kWh/100 mi = 133 MPGe = 2017 Toyota Prius Prime

Naturally, the response was to attack me for that effort, rather than acknowledge the concern being raised.

4-14-2020 **Propaganda.** After dealing with those "*20 Reasons Not To Buy*" this comes across my feed "*20 Downsides Of Electric Vehicles Drivers Often Overlook*". It was nothing but an echo of the same propaganda from that other article. They just sorted & adjusted the content, repurposing it for reaching a different audience. Those same lies were repeated. Stuff like the batteries cannot be recycled is frustrating to read. It is blatant dishonesty. But coming from a society which has come to accept & dismiss at face value, it's no surprise. Loss of critical thinking has consequences... as we are learning a painful lesson about right now. Eventually, a snake-oil salesman will get caught. I watched that play out in slow-motion with the enthusiasts. One by one, they would finally either get exposed or realize things had fallen out of favor. The result each time was to flee. I watched countless individuals abandon ship when it came to the shortcomings of Volt... countless familiar names lost to history, which I'll never forget. They were so much of a problem, constantly fighting for a cause that didn't make sense. What they were endorsing had no path forward. It was nothing but hype to make you feel good. That lack of substance is exactly what we're seeing now with the presidency. He's telling people what they want to hear, not what is actually happening. That desperate need to retain the spotlight results in a frantic effort to rewrite history. This is exactly why my blogs are so extensive. I documented the what, when, and why is what they said. It serves as proof of how things got so bad and provides a means of detecting the repetition... because we all know the same old propaganda will be spread again later. Ugh.

4-15-2020 **Lexus NX450+** The reveal of a Prime model from Lexus happened today. That was unexpected, due to the stay-at-home orders. You don't really expect much nowadays until the economy gets going again. We're all waiting out the required time, hoping the worst of it is over. It's obviously not, but at least there's optimism... which I think this is what Toyota intended to contribute to. There are some things worth waiting for... as Prime taught us, many times. An interesting aspect of the reveal was to learn a little bit more about the upcoming RAV4 version of this same tech. Although not official, we have known about the 17.8 kWh battery pack capacity (of which 16 kWh is usable) since late last year. That was an accidental publish which was quickly retracted. What we haven't known about is price. Heck, there hasn't even been a rumor. There has been speculation though. Targeting a "nicely under \$40,000" price would make it highly desirable, a nice balance of price & performance for such a large & versatile vehicle. That magic number appears to be \$36,500. It provides a basis for luxury equivalent pricing, which is enough to hold us over for now. After all, other new vehicles are on the way too. I had to remind the hypocrites of UX300e. They were claiming this PHEV proves Toyota has no interest in BEV. Providing a contradictory reminder of their obvious omission felt quite vindicating. I even threw in basic specs for good measure... 54.3 kWh battery-pack. 150 kW of power. 0-62 mph in 7.5 seconds.

4-15-2020 **Critical Thinking.** It still doesn't happen. All we get is generic dribble: "*I would think that a Volt powertrain would be enough power for a '1/4' ton pickup, especially with a bit larger battery.*" How is that representative of thought? After an entire decade of hearing about the game-changing technology and watching it struggle to advance... and fail, what doubt remains? It's not like they couldn't see Toyota spreading hybrid technology across the fleet. Or are some really that blind? From a perspective of making sustainable profit, I know many are. They see great engineering and shut off the brain. Believing the "*if you build it, they will buy it*" mantra is business suicide. Being that naive is... well, an enthusiast... being optimistic beyond logic. I let the poster know that too: The reason GM didn't follow through with Voltec wasn't a technical issue. It was the Osborne Effect. That reality of such a "*vastly superior*" product would have been a paradigm-shift their business model couldn't handle. This is why topics... like a rumored F150 PHEV with 10-mile EV range... are getting so much attention. That approach offers a path forward without major disruption to dealer/consumer behavior or expectations. It is a natural next step forward. In fact, this is exactly why Toyota has transformed their fleet to offer a wide array of hybrid choices. With such variety validating the technology, seeing an upgrade to include a plug won't upset the fragile business balance. Think about it. There is a RAV4 Prime and a NX450+ PHEV on the way. Both target core Toyota & Lexus shoppers... offering power, speed, and range in a SUV platform... without asking much from the dealer. It will simply be a model upgrade choice to carry, like a package option. Not a big risk for anyone involved. The delicate reality of sustainable profit will be supported, rather than interrupted.

4-15-2020 **Concerned.** Sometimes, you run into someone with no knowledge of the situation or background to follow progression of need: "*If Toyota was concerned about the Osborne Effect, they would not be releasing a PHEV version of their BEST selling models...*" That would have been something just fine to let pass, if it wasn't the sentences that followed conclusion drawing of the claim plug-in hybrids don't have any opportunity. Generalizations like that are annoying in the first place. But when you are on the precipice already, looking forward to the journey down on the other side, it's almost farcical. There is concern where there shouldn't be. You prepare for years for such an opportunity. That's the point of all of this. Ugh! With some dismay, I posted: That reveals a misunderstanding of how the PHEV is actually designed. For Toyota, it is basically just the addition of a one-way clutch and larger battery-pack to the hybrid model... so simple, supplying more can be reasonably accommodated... a clear effort to avoid the Osborne Effect. To further provide evidence of Toyota setting the stage, look to production of RAV4 hybrid. It is being ramped up in Toyota's being plant in North America, the one in Kentucky which prior to this had favored Camry. Seeing that volume switch to RAV4 is an undeniable step preparing for an onslaught of increased demand ahead of time. As for your attempt to compare a high-volume legacy automaker to a success much lower volume new automaker, that doesn't make any sense. They are fundamentally different. In fact, their business models have almost nothing in common. With your comparison to GM or Ford, they don't have demand for a sedan. Know your audience. This is about offering a plug-in hybrid SUV.

- 4-16-2020** **Setting Traps.** Our president is a selfish troll. That's quite obvious. What isn't is why some so loyally follow him. It's fascinating to see such blind trust play out on that scale. I saw that same behavior with the fierce defense of GM. That didn't make sense either. Wild promises that couldn't possibly be fulfilled were supported. It got to the point of absurdity. People didn't die though. True, they would slowly be destroying the environment, limited resources, and our children's future, but the outcome was challenging to prove. This is blatant; yet, it is backed anyway. So, he feels comfortable setting traps to make an example of his opponents. Sound familiar? I went through that same nonsense. The similarities are remarkable. Such a vivid past makes recognition of the pattern undeniable. He believes any victory is a victory, even if won by dishonest or disingenuous means. Such a reckless regard for integrity never senses to amaze me. It's like witnessing a caricature come to life. Interacting with that results in some of those traps catching the person who set them. It's those psychological aspects of narcissism preventing the world around them from being perceived correctly. Learning how to deal with that is quite a challenge... as our society is now just becoming aware of. It eventually gets easier to address, but the consequences are just as real no matter how well you prepare.
- 4-17-2020** **Day Of Reckoning.** That especially nasty troublemaker from years ago emerged out of nowhere to defend the death of plug-in hybrids from GM. His comment provided an interesting stir: "*It may be too soon to hold services for Voltec.*" That got me to look up the statement he made once upon a time about this very event. I found it and felt a reminder was in order, telling him what was what now: That day of reckoning has come. In your own words at the close of 2017, when news came of Volt to reportedly cease production in 2022: "*How many here doubted that you'd be first to dance on the Volt's grave?*" It's time to dance. Refusing to accept what the data tells you won't change the reality of the situation. And after a decade of denial, no successor speaks for itself. From that exchange, the words "*too little, too slowly*" tells us why. No more excuses. It was all about goals... and still is. Each automaker much deliver a well-balanced solution. This discussion thread reinforcement the importance. Delivering 10 miles of range would indeed do that. Too bad if you don't like it.

- 4-17-2020** **Too Late.** He didn't like it, but I didn't care. The same old nonsense was attempted: *"I'll be patient a little longer. Future Voltec products have been promised by GM for whatever that's worth. If there's room for 10 mile PHEVs and the 25 mile Prime, there's room for better."* Each time in our history went something went wrong and a shortcoming came back to bite him, the response was similar. Except now, there's no reason to provide any resource. It's over. I let him know why too: Too late. Opportunity has been missed. GM squandered tax-credits on a configuration their own loyal customers have no interest in. Toyota did not make that mistake. Toyota still has tax-credits available and they will be used to draw interest for a plug-in version of their top-selling vehicle. GM also missed out on the phaseout stage, where tax-credits switched to unlimited sales quantity. Tesla did quite the opposite, exploiting that chance to deliver high-volume during a time of high-demand they created from the previous stage. It is incredibly ironic how all those *"laggard"* claims backfired and the concern for moving too slowly was validated. As for your claim of future products, that is just plain not true. GM has clearly & repeatedly stated they are going all in on BEV production and see no market for PHEV. Meanwhile, we are about to see Toyota deliver a RAV4 Prime... a fast & powerful SUV plug-in hybrid with decent range and priced reasonably enough to stir interest from their own loyal customers seeking a core product. In other words, what the heck are we waiting for from GM, especially after so many years of hearing *"be patient a little longer"* for something supposedly better?
- 4-18-2020** **One Month, No Gas.** What a strange situation. I haven't traveled outside of the EV range available to my Prius Prime for entire month now. So, I went out of my way to start the engine today. It was just on a run to the drive-thru for coffee, but that's more than enough to keep the system fresh. Of course, someone cut out in front of me on the drive there. I was annoyed how they simply didn't care. They never acknowledged my presence or even tried to speed up. Had I known, I would have passed them. Ugh. Oddly, the same thing happened on the way home. Driving 15 mph below the speed limit, why? You'd think with so little traffic, they'd been going to fast... and not cutting you off. My guess is people are preoccupied with other issues. That's not safe for driving. Being distracted is never good... especially when you have someone that got out specifically to drive. Coffee was a good excuse to get the use a little gas instead of electricity. That shop was further away than the usual, perfect for that purpose. Oh well. I can try again in a month.

4-18-2020 **Recurring Interest.** I certainly found this interesting: "*GM has certainly made its mistakes, but they are the company that got people actually thinking about EVs. They started with the EV1, next came the Spark EV, then the Volt and finally the Bolt. All those efforts were half hearted and somewhat disjointed, but it certainly shows a recurring interest.*" Of course, my interest was quite different. Mine was with regard to the halo we are once again watching GM manipulate people with. It's the same old propaganda, but no one else seems to recognize the pattern. Even that post completely missed what was truly taking place. I attempted to provide the detail, but who knows if it will make any difference. Excitement the Hummer EV is beginning to stir already resembles the same old nonsense we have seen several times already. I posted:

Actually, that pattern reveals disinterest. Look closely at your list of electrification projects. Notice what's missing? Understanding audience is key. None of those targeted their own loyal customers.

GM's first mass-market technology attempt was Two-Mode. That was to be a highly scalable platform, able to be resized for different vehicles and to accommodate a plug. Trouble was, there was no clear audience. Who was that technology designed to appeal to? It certainly wasn't those who were looking to replace their aged SUV from GM with a new one. The follow-up to that was Volt, which suffered from the same problem. That technology didn't have an audience of GM owners either. We see the same situation with Bolt as well.

Watching GM repeat the same pattern confirms it really isn't a mistake. True, they are indeed getting people to think about EVs. That isn't bringing about change though. Do you really think a 1,000 horsepower system generating 11,500 pound-feet of torque and 0-60 acceleration in 3.0 seconds is designed to target shoppers at GM dealerships looking to replace their old GM pickup? For that matter, how many will even be produced? It's the same old distraction tactic. Get people excited about something to appear technologically ahead of the competition, but don't actually impact the status quo.

4-18-2020 **Fighting Facts.** It only took 9 minutes to get this reply to that recurring interest post: "*Perhaps you can contrast and compare GM's history with Ford, FCA, Volvo, BMW, Porsche, Toyota, Honda, Nissan, etc. And maybe rank each company on history and level of interest and involvement. Until then, I'd say your argument is very weak and falls in the general category of reflexive bashing.*" It was a classic downplay & dismissal with an added personal insult. I was quite amused. That defensive posture in reaction to an offensive play was very much expected. He was appealing to emotion. I was pointing out facts. His instinct was to fight. It's quite bizarre how someone believes they can portray a different history as valid, without being called out, simply by omitting particular details. Of course, had he actually addressed them, I would have followed up with more history: BAS and eAssist. But it was clear that wouldn't be necessary. Ignoring what I posted and attempting to focus the spotlight elsewhere was the dead giveaway of intent I hoped to confirm. So, as usual, I made my response brief: Whether or not another automaker is guilty of the same thing doesn't make GM any less guilty. Judging it as "*weak*" doesn't change the fact that it is a recognizable pattern repeating either.

4-19-2020 **Declaring Victory.** Supposedly, I am required to admit defeat at this point. Ugh. My own text from 2 years ago sums up what actually happened: "*Now, some just declare victory without any supporting facts. They just plain don't care.*" With the declaration coming from someone looking forward to the upcoming Hummer EV, it was to be expected. Know your audience. Some enthusiasts block out all reasoning with a desperation to justify their choice under all circumstances. That approach of absolutes is the clue to look for. Focusing on specifications is the confirm. I saw it shortcoming after Volt made its debut. There was no flexibility whatsoever. GM would deliver precisely what had been promised, period. Victory didn't have to be waited for either. It was only a commitment to the technology, not actually doing anything to bring about change. Praise was victory. In other words, this is that same old "*trophy mentality*" all over again. This is why it was so easy to dismiss Prius. This is also why so many antagonists are struggling to dismiss RAV4 Prime. Watching them challenged by facts is interesting. You can only spin reality so much before the desperation becomes obvious. In fact, that is the point our president is at now. With each interaction being a flurry of lies, nothing is getting accomplished... which is exactly what I witnessed with Volt... hence the "*too little, too slowly*" concern. Victory of what?

4-19-2020 **Advancement Spin.** Since drawing a conclusion cannot take place without supporting evidence, I take stuff like this as meritless spin: "*...had a piece on LICE (legacy internal combustion engine) manufacturers making cuts to R&D budgets, since C19 has cut what little positive revenue they had. This does not bode well for their EV efforts, and that means it does not bode well for their future.*" To properly respond, I look at the few facts actually available and combine them with documented history. You can recognize patterns that way, which provides a basis to identify how advancement will likely take place. Notice how that keeps emotion out of the equation? The use of "*does not bode well*" is a clear attempt to avoid using logic. Making a statement of passion is usually much more effective than cold, hard facts. That's an unfortunate reality, but a good indication of intent. What for it. That spin is sometimes very easy to overlook. Here's how I dealt with it today:

Actually, it will probably mean the opposite. When money for R&D vanishes, you are forced to take some unexpected risk to capitalize on market opportunity. Most are quite reluctant to take that required step forward. It is necessary for recovery though. Watching this play out will be interesting.

With the case for GM, they have been quite timid about their existing PHEV and BEV tech, hoping to start fresh in a few years. So, it's a head-scratcher. Their strategy was calculated based on an auto-industry and oil-industry which have since both fallen apart. Complicating matters is the uncertainty of future income for consumers.

With Toyota, it's a very different situation. There is no R&D necessary. They are already positioned for this. It is now matter of ramping up hybrid production to phaseout their traditional models, which sets the stage for their plug-in hybrids. It doesn't involve a lot of risk, since the architecture is already rolled out and the tech is readily available. Being able to carry the entire fleet forward is exactly what's needed. It also makes the following step to BEV a shorter one, since their customers will see the electrification progress.

That's why the attention on a Hummer EV is rather absurd. What purpose does it serve with regard to the business at this point?

4-20-2020 **Whoa!** The price of oil had fallen to a 21-year low... as of this morning. Since then, the market has collapsed entirely. \$0 per barrel is bizarre. Soon to come are negative prices, when the infrastructure suffers from inventory problems. Where do you put millions of barrels of unwanted oil? Things are about to get ugly. This situation hasn't ever existed before. To abruptly stop using something usually in high demand is a real problem. It get worse when you give it some thought too. Each barrel of oil yields a variety of resulting product. The largest portions are the many gallons of gas & diesel. Since gas isn't being purchased much anymore but diesel remaining in regular use (for commercial deliveries to businesses & homes), there's a new imbalance to deal with. This is why the price of diesel hasn't been impacted but the price of gas has plummeted. What a bizarre and very unexpected set of circumstances. Who knew that the tipping-point for oil would arrive with such an obvious bang. There's no missing this moment in history. No debate... only concern for inevitable change... to discover what "*normal*" will end up becoming.

4-20-2020 **Behind Spin.** It will be interesting to see how statements like this change when Fall arrives: "*Actually Toyota is doing as little as they can to move the ball forward.*" Of course, we really don't know what the situation in either the automotive or oil industries will be then, but that's no reason not to keep looking forward. The key is knowing where to look. Forward is forward. That's progress regardless of how it is achieved. So, the conclusion to that dribble posted was just more of the same old downplay nonsense: "*...I'm not sure 39 mile EV range of the RAV4 prime is going to cut it when others can run silently for over 200 miles.*" The more is better mindset doesn't actually achieve much. For some cases, it doesn't achieve anything. In fact, this is why it can be referred to as rhetoric. Holding back progress entirely is a goal for some. They throw out claims like that to impede the entire process. It's quite frustrating when you notice the pattern. Anywho, I turned that narrative around with:

Those who do not believe in the bottom-up approach will get that impression. In reality, the perception of little (or "*behind*" as the narrative puts it) is a powerful means of moving the entire fleet forward. See, the challenge with top-down is it gambles the technology will rapidly drop in cost and the market as a whole will readily accept the technology. As we have all witnessed, neither is playing out as hoped.

With respect to a RAV4 Prime having to compete directly with a 200-mile EV, when are you thinking that will happen? Take some time to think about the specs. That size, speed, horsepower, and AWD offered in high-volume would come from who? That's where the bottom-up makes a difference. With RAV4 so popular and built in Kentucky, there's a supply/demand balance. Toyota won't be shooting themselves in the foot. Please explain how a 200-mile EV would be able to satisfy the pressures a large legacy automaker must deal with. The realities of business paint a picture of great barriers to overcome still, something only Toyota has addressed with regard to dealer & consumer. It's not all about engineering.

4-20-2020 **Dealing With Nonsense.** Some of it is so repetitive, there's nothing to gain from quoting the full text anymore. It has been torn apart to small pieces, proving no value in return. They had little to work with coming into this pandemic. Coming out of it, there's no point. Their nonsense has been weakened to the extent of not serving any purpose. Even just plain old delay has a no outcome. Rather than wait, people will move on. So, I was happy to respond to today's batch of it: Know your audience. That reference of "*tend to buy*" is data from the early-adopter stage, when enthusiasts took advantage of lease & tax-credit opportunities. It has almost no relevance to how ordinary consumers will behave and has basically nothing in common with their purchase priorities. With regard to "*one side of a scale*", that's just rhetoric. It is easy to confirm too. The claim of "*going to win*" is meaningless. Win what? In fact, the absence any stated goal or measure is a key component to rhetoric. Of course, anyone who understands the engineering sees the shared technology. To propel a RAV4 Prime you need the very same hardware & software as a RAV4 EV. The primary difference is one also has a gas engine and the other a larger battery-pack. Remember, the true customer of a legacy automaker is the dealer, not the consumer. They want to carry inventory of mature technology. Having hybrids so well proven, the stage is set for plug-in hybrids... which in turn, make the next step to BEV a very easy one. As for the "*it would be interesting to see the percentage of people that have PHEV plug them in consistently*", that's nothing but a propaganda feed. Who do you expect to believe such nonsense? 39 miles of EV is more than the first Volt offered and no one made claims of it not being plugged in. RAV4 Prime is larger, faster, and more powerful... better pretty much every regard, for that matter.

4-21-2020 **Calculating Expectations.** Unlike the crazy approach from enthusiasts, who build hope from hype, there's a better way. It comes from studying information available and collecting data to see if you can extrapolate anything from it. Someone did that today. I was thrilled to see a sensible post. So much of the EV mindset has been based up the niche known as Tesla, the group as a whole is at a lost about how that applies to legacy automakers with dealers selling to mainstream consumers. They have little in common... and let's face it, the status quo has not budged. That sets up for a terrible outlook just prior to the 50th Anniversary of Earth Day, but it's reality. That is what we learned from Volt... so much barking with no bite at all. The entire fiasco literally did nothing to bring about change. What difference is there between a dealership now and one back prior to rollout? The technology didn't advance the market forward... which was my point all along. Something needed to emerge from Voltec. Nothing did. Instead, it died. Supposedly, the solution now is to abandon the integration of engine & motor entirely for the sake of BEV focus instead. That means taking a closer look at what the technology has to offer and setting realistic expectations. Since GM has proven worthless, attention is shifting to Toyota/Lexus. This week brings about the first rollout, in China. People are attempting to figure out what that means in terms of range. What would that same vehicle be rated here? This was one such speculation: "*186 miles on WLTP. Under 150 miles EPA/real world.*" I took that and built upon it with the information I had, providing some calculations to support those numbers: NEDC rating is listed as 13.1 kWh/100km, which calculates to 21.1 kWh/100mi. Translating to EPA, you get about 30.17 kWh/100mi. That lines up well with ratings for Bolt, Leaf, Niro, Clarity and i3. Assuming 90% of 54.3 kWh total capacity, you get 48.87 kWh usable for EV. That comes to an EPA range estimate of 162 miles. Assuming 85%, you get 153 miles.

4-21-2020 Reality Check. Lashing out at Toyota is really just an excuse, a distraction away from the true struggle. That means we get this on a regular basis: "*How many electric cars do they make? Who cares of the death spiraling ICE.*" To them, it's a numbers game... not a measure of true change. Remember how GM played it? Volt sales were almost exclusively either leases or fleet. That's why I argued so often about the "*game changer*" not actually accomplishing anything. Neither of those "*owners*" were loyal customers who went to a dealer to replace their aged GM vehicle with a new GM vehicle. They were nothing but conquest with little to no business-sustaining profit. It was really just a shallow effort to game the system, one which focused almost entirely on ways to exploit the tax-credit. This is why there is so much rhetoric now with regard to how Toyota has instead focused on upgrades across the fleet. Their new architecture was rolled out almost entirely unnoticed. It sets the stage for phaseout of traditional vehicles while at the same to preparing for plug-in offerings. Getting such a massive audience to take notice is genius. They hate that reality. Highlander, RAV4, Camry, Corolla, Avalon... all well known Toyota choices available as hybrids, both affordable & efficient. They are directly competitive with their traditional counterparts. That annoys the antagonist to no end. Making matters worse, we see the possibility of a new minivan only being available as a hybrid and the next Prius only be available as a plug-in hybrid. That's real change. Needless to say, some of that underlying infrastructure shift is starting to get attention... by those who don't like it... which makes be quite delighted to punch back with a reality check: Toyota is a very strong industry player in the design & production of electric-propulsion components. So what if most are currently only used with systems that have small battery-packs? They are a juggernaut in the BEV realm, which is still very much in the early stages. Heck, we don't even know how the expiration of tax-credits will impact the market, because that literally just happened. The experience gained from hybrids, plug-in hybrids, and fuel-cells is priceless. All depend upon highly refined hardware & software for EV driving. Attempts to downplay that are futile.

4-21-2020 Progressive Rollouts. A series of upgrades is far more effective than attempting a big bang. In fact, significant change all at once is exactly what should be avoided. Toyota wrote the book on how to do it write, quite literally. They learned how to promote improvement and showed the world. It was quite fascinating at work to take a certification class and discover that process would be the basis of what we would be studying. That turned out to be one of the most enjoyable classes I have ever taken in my life too. Though challenging and quite a draining experience, I took away a lot from that. Some of it came from already having made so many real-world observations of Toyota's approach. It clearly works, despite all the claims those naysayers attempt to tell you otherwise. It works. That's why what we are witnessing right now provides encouragement of what will likely follow. I keep it short & sweet with: Don't forget there is a higher density chemistry on the way. Rolling out the platform to China with existing lithium makes a lot of sense. Refine the vehicle itself before expanding to other markets, with a battery upgrade. That is exactly what Toyota did with Prius 20 years ago. Gen-0 was for Japan only. It used D-cell batteries. Gen-1 was rolled out to the United States 2.5 years later, featuring prismatic batteries. That was quite an upgrade... which most people didn't even know about. In fact, I bet many just learned about it from this post.

4-22-2020 **Subaru Evoltis.** This is co-development effort with Toyota to deliver an EV by 2025 with a possible range target of 300 miles. That kind of news has been putting antagonists in a difficult position. They require an enemy to focus on, someone to attack & blame when things go wrong. Seeing Toyota break out beyond their carefully constructive narrative is a big problem. They are trying to spin the situation back in their favor though: *"Toyota could easily have pushed to adopt CA standards nationwide. That is not what they have done. All you have to do is adopt the highest standard and you are safe. Let alone being a leader and pushing standards forward. The only pure EV Toyota ever shipped in the USA was a Tesla designed RAV4. It is 2020 and over a decade since the first Tesla shipped and nothing from Toyota but hybrids. It is almost as if they said we innovated once in the last twenty years and that is good enough for us."* That was the full post, the attempt to belittle & mislead in its entirety. That's the kind of post I like to take the offense on. I'm more than happy to take on their nonsense. And, I did:

Completely disregard what was posted and respond with a blatantly false narrative instead. Ugh. The legal hurdles involved with that adoption is a trap and Toyota unwilling to take the bait; instead, they are just going ahead with the technology push anyway. There's a big difference, lessons learned which others also disregard.

As for the claim about RAV4, that's absurd. Toyota rolled out their new architecture throughout the entire fleet, enabling affordable upgrades with minimized overhead. In other words, a variant of RAV4 EV will begin rollout in just 1 week and a RAV4 PHEV will rollout in a few months. Both are undeniable efforts to fulfill that highest standard.

With regard to being a leader, that comes from actually changing the status quo... not just agreeing to do so. Phasing out their traditional passenger vehicles across the fleet, replacing them with hybrids that can easily be offered as plug-in hybrids is genuine leadership. They are focusing on their core customers, making a true difference. Downplaying that reality won't change it. Toyota continues to push forward, and as this topic confirms, they are helping pave the way for others to follow.

4-22-2020 **Is Tesla Thriving?** That is an interesting question to pose. It was not taken well though. Comments were argumentative right from the start. There was no sense of balance or any interest in being objective. It was very much an enthusiast response. That's unfortunate, Tesla has opportunity and has demonstrated an impressive ability to adapt. Those traits should be very helpful with the next steps. Problem is, no one really knows what that means... and the growing antagonism is evidence of that representing challenges to come. Uncertainty isn't the friend of those to focus too much on passion to sell a product. Mainstream consumers need more substance; want is less important. Anywho, I tried to give praise, among with some foresight: With regard to low-hanging fruit, Tesla did indeed thrive. Tesla had a lot of venture capital available, carbon-credits to sell in a market hungry for them, and basically a monopoly. All that is changing now. This next stage without tax-credits, needing to draw attention from those not enthusiastic about change... in a world with the oil industry now struggling to survive and other automakers attempting to grow in the market... is going to be very challenging. There is also the bitter reality of people in general having less disposable income even after the economic recovery. Think of the perspective of what legacy automaker dealers have. What are they going to want to push to bring in consumers with. Those business-sustaining sales are what keeps the industry going.

4-23-2020 **Watching It Again.** The start of the first day after the 50th Anniversary of Earth Day sure got off to a good start. I got the same old nonsense from 13 years ago. Remember how Volt started? It was literally the same thing I am seeing again. To watch that history repeat is remarkable... since I know exactly what to watch for this time around, and have the experience to counter it. This time, it was rant to me posting: *"Toyota's top-selling vehicle in just the United States alone last year was RAV4, which sold 448,071. That raises the question of what Tesla's growth plan is..."* That was in reply to a supposedly bashers of Tesla listing sales results from the past 8 years. 367,595 was the worldwide total for all Tesla sales combined last year. My interjection of reality stirred a rebuttal absent of any facts. It was just a repeat of the very same propaganda we saw for GM way back. That cheerleading without any actual leadership direction is a dead giveaway of a problem. How will such *"progress"* be achieved? I asked about such a future this way: It's ironic how you respond to a fact by appealing to emotion, then conclude with a remark about goals but don't actually state any. That type of posting is what turned genuine support for Volt into enthusiast rhetoric. They would do everything they could to stir a passion for the technology by focusing on its appeal, doing as much as possible to avoid reality of the business itself. Seeing you repeat that history is fascinating... especially since their posts ended up diverting so far from goals. The question of Tesla's growth remains. Avoiding any measure of quantity and mention of product diversity is a solid confirm of history repeating. How will Tesla achieve *"biggest automaker in the world"* with such an incredibly vague response? What are you endorsing?

4-24-2020 **\$1.11 Per Gallon.** I noticed the price while in the drive-thru at the gas station/coffeeshop today. Since my approach was from the back entry, that was quite a delight to see while waiting in line. After getting our coffees, I drove through the pump area to snap a quick photo to mark that moment in history. By dumb luck, a new Prius just happened to be driving through the scene precisely at the time. I hadn't even noticed it coming. So, there was nothing to prepare. Looking at it afterward, the sight of an in-focus white hatchback perfectly lined up in the capture was a very nice surprise. I highly doubt I will ever see prices that low again. That's a scene from 20 years ago, when I got my first Prius. What a surprise to relive such a memory now... well, kind of. It has been what, at least 2 months, since I last filled up and only 1/8th of the tank has been used so far. I won't be needing to fill up again for a very long time. That's fine. I can witness it from the eye of a lense instead.

4-25-2020 **Feeble.** It can be enthralling sometimes to read comments relating to the "*behind*" narrative for Toyota, for example: "*These feeble range numbers prove Toyota is way behind. If you're not passionate about something, you come out with stuff like this.*" Since when has Toyota ever focused on passion for the secret to their success? Even back when I was waiting for the delivery of my first Prius 20 years ago, I was well aware of Toyota's reputation for their "*boring*" vehicles. They were looked upon as family movers. Those who owned them were pleased about the affordable & reliable choice they had purchased. I worked great for getting from place to place. The reality that speed & power has been mixed into the equation now goes completely unnoticed... by those making an effort to downplay. That's no different than decades ago. They focus on a number that appears disappointing, then beat it to death hoping you won't notice anything else... which is where I come in. I point out those other traits of interest. But in this case, I was just on the attack. The post came from a well known troublemaker, burned by supporting GM to Volt's bitter death. Now, he wants to ensure Toyota has a difficult time advancing forward. I attacked back, injecting some logic into the on-going comments: Measuring progress based on range is either naive or doltish. It tells us nothing about the technology itself. Anyone can squeeze in a lot of capacity. Making it reliable & affordable is an entirely different matter... something Toyota has proven to deliver exceptionally well. Those of us who actually take progress seriously measure it based on how much that technology changes the status quo. Rollouts appealing to the "*passionate*" fail to achieve that. Mainstream consumers are fundamentally different from enthusiast. Know your audience.

4-27-2020 **Range Ratings.** There is a website which... up until recently... served as an objective source of plug-in related news. The growing struggle with Tesla has shifted a bias over to hyping video-footage completely unrelated to the promotion of electric vehicles and focusing on range. In other words, they have lost direction. That clear sign of goal uncertainty is a warning. Red flags like that in the past weren't taken seriously, so it is no surprise they get blown off now too. Disregard for actual market change is a very real problem... hence the Tesla issue. Sure, those vehicles are great, but they are proving to be an expensive niche. Reaching ordinary consumers has been far more pie-in-the-sky of a hope than anyone wants to admit. This obsession with range reveals how much further (pun intended) they still have to go. Even when some supposed threshold of distance acceptance is reached, there's much more to address still. That's where Toyota shines. Their approach is reverse. They are focused on those other factors, the priorities that become a major barrier when trying to reach out beyond the niche. Larger audiences require thought beyond a single mindset. What I find amazing is how many people need to have that brought to their attention. Most are clueless as to how business operates. In this case, there's far more to sales than just range ratings. Ugh. Rather annoyed, I jumped into the topic today with: These ratings reveal a serious loss of priority. Looking at range based on battery tells us what with regard to purchases? There is a very real problem of diminishing return that no one seems to want to address. We just keep getting more of the wrong focus. Attention should be directed to vehicle efficiency, not the size of the tank. It's really unfortunate when the "*kWh/100mi*" efficiency rating is completely ignored, disregard from topics like this as if it makes no difference. In reality, that's far more important. It is how much electricity you actually consume that matters, not how much can be held when full. Sadly, this is why EV supporters get labeled as enthusiasts, rendering their opinions to just that of someone out of touch with the mainstream. They can be their own worst enemy at times.

4-27-2020 **Early Majority.** I tend to avoid quoting very long statements, since the message tends to get muddled. This one was easy to ensure it would get followed up without confusion. So, I that's what I engaged in: *"You talk about "enthusiasts" and "mainstream", but highly efficient cars tend to be small and aerodynamic and look like the first generation Honda Insight, which doesn't appeal to the mainstream and driving one labels you as an enthusiast. EVs are approaching a transition from "Early-Adopter" to "Early-Majority" buyers. But to make that transition, EVs need to appeal to mainstream tastes that prefer larger, boxier, SUVs and crossovers. Pick your poison: do you want hyper-efficient EVs that are limited to niche hyper-milers, or do you want moderately efficient EVs that are widely adopted by the mainstream?"* It should be no surprise why I decided to pursue such an overly simplistic lack of thought. That's how misconceptions perpetuate. So, I replied with:

It's always intriguing to encounter someone who hasn't given the matter any thought. The assumption you are making is quite obvious... and quite incorrect. How will you respond is my curiosity. That's the type of feedback we can use to constructively inform others.

Consider RAV4, Escape, CRV, Equinox, Outlander, Tiguan and Rogue. All are Crossovers with FWD similar in size & shape. Despite having shared aerodynamics, they deliver very different efficiency... 26/35... 27/33... 28/34... 26/31... 25/30... 22/29... 26/30. Those city/highway MPG ratings are all over the place, not in any way what your *"poison"* implies. Reality is, there are far more elements of efficiency at play than just the generalization you claimed.

When it comes to EV propulsion, the situation becomes even more complex. Conversion from DC to AC is a matter of hardware, which varies profoundly from automaker to automaker. Did you ever consider that? What about the traction motor? What about the type of cabin heater? What about the software controlling it all? Then there aspect of performance, the trade-offs better power, speed, and consumption, most definitely have an influence. You ever think of that? There is also the weight of the battery-pack. In other words, you now have very good reason to take a closer look at what *"kWh/100mi"* ratings actually tell us. It most definitely is not just a vehicle size & shape category. That's how you know whether a similar looking vehicle is efficient or if it guzzles electricity.

4-28-2020 **No Agreement, No Progress.** Trying to get people to recognize the importance of balance is extraordinarily difficult. This derives from our society no longer having an understanding of the difference between want & need. They have justified weak excuses for so long, that approach has become the norm. You simply reason your way to a decision. Stated another way, objectivity has been lost. The influence of emotion clouds logic. So, we get stuff like this: "*From a *practical* point of view, I am much more concerned about range than efficiency.*" It gives the impression of being thought, but the injection of opinion reveals otherwise. That's easy to confirm too. Get them to state a goal. At some point, range will suffer from diminishing returns. If no such milestone is identified, there is likely going to be a problem of endless pursuit. In other words, efficiency will never get any priority. Delay has consequences too. If you commit to much to one particular design without the consideration of all influencing factors, you end up backing yourself into a corner. This is how both Two-Mode and Voltec failed. Learning lessons from past mistakes is most definitely not a strength of online discussions. Ugh. I tried to point that out with the following: The point is to draw attention to the balance of priorities. Again, there is a very real problem of diminishing return that no one seems to want to address. It's the more is better mindset that will end up harming BEV sales. Unless the supporters can agree upon fundamentals like that, we're all screwed. Notice how disastrous public chargers have been due to that very same problem. No agreement, no progress. That brings up back to practical. What range is that? If you study the history of the BEV, you'll see it has been a sliding scale. Ask why. The answer will trouble you.

4-29-2020 **15 Million Sold.** I was wondering how long it would take to hit that significant milestone. It seemed to be approaching, but I wasn't seeking out the data. Assuming the announcement would be made upon reaching it was reasonable. And sure enough, Toyota did as soon as the worldwide count for purchases of their hybrids reached it. That number is absolutely amazing... and quite validating. Any technology to reach such a level, especially when it starts at such a significant price-point (greater than \$20,000 per sale), is a really big deal. This isn't like when people replace their phone. It is a purchase you will likely utilize for an entire decade. Whatever you decide upon has major implications too. Choosing a guzzler can be very expensive to maintain. The same is true for an unreliable brand or model. So when it comes to the broader category of technology, there is no easy matter of "size" to measure against. It is far more difficult to evaluate the value of. That's why the endorsement of 15,000,000 owners can become a significant influence. In fact, that plays a major role in what dealers select for inventory. They know their customers.

5-01-2020 **Listening To Science.** We are still dealing with the nonsense of negotiation, where the people opposing measures to address the problem feel it is possible to make a deal. You can't make a deal with a virus any more than you can with the climate. They don't understand what is at stake or how their decisions have no impact on the outcome. Watching reactions to the pandemic overwhelmingly confirm that. Whether or not you believe you are doing enough doesn't change the reality that you are not. We will suffer from the effects of smog & carbon emissions, period. No feel-good effort make up for not fulfilling a requirement. That's what stating goals was all about. We saw it with Volt. There should have been a spreading of the technology across the entire fleet, period. Even if milestones were not reached, it was still progress forward... which is the point. That momentum builds... once you have everyone in agreement about purpose. See the pattern? Both with the technology for vehicles and the medical advances for the pandemic, we need agreement. Next steps in the right direction are essential. GM did nothing to break the status quo. We're seeing the same with our federal government response. All these excuses, delays, and red herrings are a massive waste of resources... at a horrible cost. Both will have long-term consequences yet to even be imagined. We're in for a world of hurt by not listening to science.

5-02-2020 **Not Worth It.** Software upgrades were a hot topic like July, when I posted this: *"Google just began rolling out the new version today. Think about how complex software upgrades to just phones are. Carriers routinely take a very long time to provide a new OS. Having to wait 6 to 9 months is quite common... and quite unrealistic for a vehicle model-year. See where I'm going with this?"* Today, I posted a follow up:

9 months later, there have been many upgrades... 4.6 and 4.7 and 4.8 and 4.9 and 5.0 and 5.1 and 5.2 with 5.3 soon to be available... confirming much work still needed to be done to establish that different approach.

People didn't understand what it would take to transform an application not designed for that new platform. It totally makes sense that Toyota didn't want to deal with the inevitable flurry of customer requested updates to their vehicle. Just imagine what it would have taken to support an upgrade process. Waiting until a stable version becomes available and has proven effective of at-home upgrades, rather than having to burden dealerships with low-profit services, was the better choice. It simply wasn't worth being hasty.

As the Android Auto matures on the automotive platform, being able to seamlessly executes upgrades without interruption to the driving won't be a big deal. Think about what it takes on your phone. Will the car stay active and have internet access the same way to download software while not in use at home? Will you be willing to wait while the upgrade installs? Will you schedule the upgrade for later?

This is a paradigm shift, a new ownership experience for automakers to address. Delay until Google works out the kinks is an effective way to avoid issues the automaker has little control over.

- 5-02-2020** **Emotion.** The pattern is astonishing: " *Use information to determine action - not emotions, not politics, not what people think or feel, but what we know in terms of facts.*" That was the trophy-mentality I observed all those years ago with Volt, sighting concern over approach to its design favoring emotion rather than constructive goals. Supporters became enthusiasts as a result of that blindness, turning hope into meritless hype. It became a race in the wrong direction. So much of the resources went into favoring a niche, the effort was doomed. They kept praising traits which provided no value moving forward. That's exactly what we are seeing now with the pandemic. The focus on supposed "*freedom*" is not doing anything to actually help the situation. In fact, it is wasting resources on what will clearly become a fall backward. We'll end up having deal with losses which could have been prevented. For GM, there is no recovery. The project died. All that work to figure out how to blend motor & engine abandoned due to mismanagement. It was remarkable how much emphasis was placed on feedback from owners. That is asking the wrong audience... hence "*Who?*" It made no sense planning to appeal even more to a niche. You want mainstream acceptance, you must follow wherever that logic takes you... like it or not.
- 5-05-2020** **Lessons Learned.** The parallel continues: "*As the death toll mounted, the briefings became less about providing critical health information and more a forum for Trump to air grievances, shift blame, stoke feuds, spread misinformation and inspire false hope.*" That is exactly how Volt enthusiasts responded to faltering sales. They would never accept responsibility or take any action to provide direction. It was the same old nonsense we saw back with Two-Mode. No matter what happened, there was always something to deflect with. In other words, there was never any takeaway, no lessons learned. Each event was treated in isolation to prevent a cohesive story from ever emerging. This is why I kept having to deal with the same old nonsense routinely, they would do everything in their power to keep people from becoming aware of the bigger picture. Any distraction possible was better than allowing others from discovering what was actually happening. Our president and his administration are the same type of problem, providing excuses and feeding enablers for their own agenda. In other words, they just plain don't care. It's really sad.

- 5-06-2020** **Switch Narrative.** There is an on-going effort to portray the introduction of plug-in vehicles as the only solution available. Electricity sent from a battery is the future, period. It's a fear that continues to grow from BEV purists. They fear diversification. When a technology appears too weak to stand on its own, that is typically a sign of hiding weakness having been identified. I know that reaction far too well from Volt enthusiasts. Their fear was simply speeding the technology to other vehicles with other configurations. Their belief was that would dilute the message GM was sending. Ironically, GM itself did that with their many vague & ambiguous press releases. Those attempts to feed hype confused purpose. No one knew what the goals were anymore... which brings us back to the narrative. What does the "switch" to electric intend to accomplish? With hydrogen, it is obvious. We see diesel as a serious emission & consumption problem. Large transport needs an alternative. Advancing that technology through deployment of real-world tests with small vehicles is far less expensive and allows for far more flexibility to explore the opportunities. That's why we see on-going efforts from Toyota, Honda, and Hyundai in that realm. Whether or not those small vehicles become a standard part of the business later makes no difference to the experience gained for application on larger scale use. This is how I responding to the rhetoric attempting to spread the "switch" narrative today: Commercial & Fleet use of fuel-cells is inevitable. The hydrogen deniers attempt to spin a narrative of impossibility, that there's no way EV could co-exist. They refuse to acknowledge all the elements at play. That narrow-mindedness about the problems we have to address will eventually become too difficult to deny. In other words, there is no switch. It's really a matter of recognizing dual-path develop is necessary to serve the wide range of needs.
- 5-08-2020** **Compromise.** Notice how the effort to establish & reinforce a narrative requires being vague? Detail is how you confirm insincere efforts. If they refuse to respond or give you something unclear, it becomes obvious after awhile they just plain don't care. We saw Volt enthusiasts do everything possible to avoid addressing lack of change. They pretended the status quo would somehow magically be altered simply by the presence of Volt, that nothing actually needed to be done to get mainstream consumers to embrace the technology. Their choice had serious consequences. Now, we see some in the BEV community pushing to undermine plug-in hybrids with messages like this: "*The Volt is a compromise. All PHEVs are compromises. They work but are, by comparison to pure ICE and BEV, very expensive to design, build, and fix.*" That opportunity wasted is now quite obvious. But since virtually all have jumped ship, abandoning what GM had been praised so much for, there is no one to respond. They gave up. I haven't. That's because I have solid facts and real-world data to work with. It's very difficult to get me to shut up when so well armed with so much material, especially the videos. So, the online battle continues in this new war: Notice how that statement attempts to create a stigma for the word "*compromise*" rather than acknowledge what it really means is to deliver a balance of priorities. Also, notice how "*very expensive*" is absent of any perspective. It's that lack of attention to detail that allows people to just blow off comments from enthusiasts. Why bother taking them seriously when they don't take the time to explain what they are passionate about. In other words, those generalizations are what people see as rhetoric. They do nothing to impact the status quo.

5-08-2020 **Limited Supply.** It will be interesting as the year progresses to find out what kind of spin is stirred. That was often why I frequently that daily blog for Volt. They worked hard to come up with stories. None were ever strong enough to stand the test of time though. Limited duration & audience is key. When looking at the wider market and long-term plans, what they spin makes no difference. They certainly try though, as I was happy to point out today:

That narrative fell apart today. It was started by those who prefer the fast approach, race to get whatever has proven successful to market, then flood the market with it. That works just fine for startups. For established providers, it can be disastrous. We have a real-world example of that too. GM's effort with Volt was failure for that very reason. Sure, it worked, but it wasn't able to return a profit and the technology itself was terribly inefficient. That is exactly what you don't want as a legacy automaker.

Toyota has been taking the time to do it right, waiting for the technology to mature for delivering a high-volume solution that was easy to sell and returned a profit. There was no rush. There was no pressure to deliver. There was no limited supply. It was all just a load of nonsense stirred by those hoping to undermine progress.

That progression is easy to validate, as of today. Lexus UX300e (Toyota's new EV for China & Europe) will come with a 10-year/1-Million KM warranty for the battery, which includes a very clear capacity degradation threshold of 70%. Such an incredibly long endorsement of confidence tells us a lot about how much unseen success has been achieved by Toyota.

In other words, Toyota invested but has not ramped up yet. Production of the new format/chemistry is not needed until the vehicle it is for gets rolled out.

5-08-2020 **Misconceptions.** New audience. New participants. Same old misconceptions: "*Hybrids are only economical if driven in a certain way, if used for a lot of long distance driving then they're as bad as a regular ICE vehicle.*" We get new ones too: "*PHEVs with an electric range of at least 50km make sense as a stopgap to full BEVs if you don't have access to a good fast charging network for long trips, but otherwise hybrids are 1990s technology dressed up as the future.*" I was annoyed, but more than happy to confront the nonsense. So, I did: It is interesting how you expect an obviously false statement in reply to Toyota hybrids to be accepted. That "*as bad as*" claim is just plain not true. It's so easy to prove too. Toyota hybrids use a smaller engine... which in itself contributes to greater efficiency... combined with the use of the Atkinson-Miller pumping cycle, rather than Otto. Using that well-proven technology on their PHEV offerings is the next step forward. The best example is the upcoming RAV4 Prime . That will offer 62 km of EV range, then will switch to that highly refined HV operation following depletion. It's a win-win, before even taking into account how much of that technology is carrying forward to their BEV offerings. In other words, that supposed "*stopgap*" measure is a means of profitably moving the entire fleet forward. The focus on "*if you don't have access*" completely ignores that bigger picture issue. Think about what dealers will be willing to carry during the economic recovery.

5-08-2020 **Addressing Speculation.** There's a lot speculation with regard to Toyota's rollout of the new Lexus EV in China and the very generous warranty it includes. Lacking any industry standard or even a consistent expectation, it leaves much subject to wild guesses based on little to know information. Trying to get in front of sources which could generate & spread misconceptions is key... especially knowing there are some who intentionally create misinformation. With lockdown and the industry basically at a stop, along with the market in China showing signs of slowing, its difficult to find anything solid to work with. So, a good chance of speculation growing is likely. Ugh. Oh well, all you can do is address problems as they are detected:

Nissan's pack essentially didn't have any cooling at all. It only employed a radiant approach, simply allowing the heat to pass through the case to the outside. It was a sealed battery, so even just passive air circulating through it wasn't possible. That's why just pushing cabin-air through the pack for Prius Prime has proven worthy of longevity. The next step up is A/C cooled air being directly funneled along the entire casing to draw out heat. That's aggressive by comparison. So, the generous warranty seems reasonable.

As for the maintenance program, that may be more of a throwing-a-bone-to-the-dealer situation. They need to provide service in place of no longer maintaining a combustion-engine. They still need to make money. Bringing in your vehicle from time to time for a measure, inspect, and cleaning of the battery system shouldn't be that big of a deal. In fact, it could just become part of the routine when you bring in the vehicle for tire-rotation. After all, services like inspecting brakes & shocks, changing the cabin-air filter and wiper-blades will continue. You'll need to replace tires at some point too. And how exactly is that an "*unnecessary*" expense if you are guaranteed 70% capacity throughout 612,371 miles of ownership? It's like paying for insurance but never having to file a claim. Isn't the goal of a BEV to bring an end to the surprises that come about from maintaining a traditional vehicle? Think about what the confidence of a that guarantee does for resale value too.

5-09-2020 **One Week Later.** Not a single person responded to my software upgrade post. There were so many people angered about my response before, with many different ways of telling me I was wrong. None of them said so much as a peep this time. They were all passionate about a topic they had no background in. Their posts 9 months ago have proven to be hasty & anecdotal, the same nonsense I have to deal with in other disciplines related to the rollout & spread of technology. Those assumptions are costly at times. In this case, the belief was opportunity had already slipped away and there would be no way to make up for such a tragic loss. They truly didn't understand. That's typical. Being a software engineer for 3 decades now, I'm familiar with that behavioral pattern. Knowing what it takes to build, deploy, and support is a complete mystery to most people. Keeping up with the ever-changing technology makes it difficult even when you do have the background. So, this was no surprise at all. I waited for the validation. Unfortunately, no one wants to address next steps. They all abandoned ship when the challenge became far more than they had anticipated. Sound familiar?

5-09-2020 **Spreading FUD.** Right out of the classic handbook for spreading Fear, Uncertainty, and Doubt came this:

- Lose sight of the big picture.
- Divide & Conquer.
- Lie & Distort.
- Conjure up conspiracies.
- Accuse the accusers.

That list of tactics for misleading & manipulating was used to describe what the president has been doing. It matches exactly what I dealt with from the past with vehicle technology. From a wide array of antagonists, the same old nonsense had to be dealt with. Nothing in that list is constructive. So, none of that should be present in what we face. Yet, the frequency is abundant to an extreme... to the point when tolerating it becomes impossible. You either choose to ignore or confront. I'm distressed by the number who ignore. They just pretend there isn't a problem and nothing said is inappropriate. That is the goal, to get people to become disenfranchised, making they enablers. It's a sad reality when critical thinking doesn't happen anymore.

5-10-2020 **Supposed Facts.** People just make up stuff, not citing source or scope. They just post what they feel is right: *"To match Toyota/Lexus, Tesla just have to dial back the charge rate to 50 kW - but that would slow the transition to EV's as no-one really wants to double a journey just for charging stops."* Nothing provided to support such a claim gives me the opportunity to ask how that conclusion was drawn. That irritates some, calling me out as a troublemaker... and some not so polite labels. I turn it around with facts. In this case, I was armed with data: According to a survey of 8,500 consumers and industry experts conducted back in March by J.D. Powers, that is not correct. In fact, rate didn't even make the top 3 barriers listed. They were charging station availability, driving range and purchase price. A charging rate of 50 kW would likely do the opposite, since it would satisfy the availability concern. Think about it. 50 kW will deliver a rate of 167 miles/hour for charging. It requires 480 volts on a 75-amp line. That is a reasonable balance of cost & performance. Faster is much, much more expensive to setup & maintain. For that matter, who pays for the equipment and who pays for the electricity? Like it or not, overcoming the availability barriers by providing lots of chargers with lower rates will accelerate transition. It is counter-productive to believe that faster is necessary.

5-10-2020 **Priorities.** There are some who spread misinformation instead of FUD. Their hope is the same, to undermine progress. It's what happens when you don't like the direction a solution takes you. When you make a hypothesis, then discover you were incorrect, you are supposed to learn from the experience... not deny the outcome. Ugh. Fighting it makes no sense. We see it regardless: *"Why is Toyota selling this only in Chinese and European Markets and still saddling us North Americans with Hybrids and FOOLCELLS, do they take us for FOOLS?!!!!"* I had this to say in response: We have overwhelmingly demonstrated how our priorities are all screwed up. It is the outcome many feared would come about at a result of GM pushing its desire for range & power over the goal striving for a balance. Volt made it all too clear how that obsession sacrificed our original intent to change the status quo. A decade later, dealer lots look worse. Sedans are vanishing, replaced by traditional guzzlers. Think about covid will do to infrastructure investment. People here will be arguing for a supposed need to have ultra-high-speed DC chargers. Why sacrifice so much money for a few of those when you can instead get a bank of 50 kW chargers? That type of tradeoff makes no sense, especially when buyers at this stage will almost certainly have a second vehicle for long-range travel anyway. It never ceases to amaze me how the desire for more blinds so many to what is really important. Thankfully, Toyota knows their audience and simply ignores what just ends up as enthusiast rhetoric. After all, we have been acting foolish. Having to wait until the after markets with better priorities get rollouts is a sensible approach.

5-10-2020 **Barriers.** It is quite eye-opening to witness the contribution to barriers. Most have no idea they are doing it. A few notice though, asking: "What is not correct? Believe me, having driven a 2014 Nissan LEAF, doing a 0-100% charge to get to the next available charging station is a bummer." Having constructive questions come up is great. That's exactly what we should be getting as new rollouts take place. In this case, it was about the new EV in China from Toyota: Know your audience. Toyota/Lexus isn't targeting the long-distance traveler. They are well aware that most households will have multiple vehicles, that the BEV will be used for daily commute, running errands, visiting friends, etc. When travel out of that range is required, the other vehicle will simply be used instead. This requires us to recognizing priorities. Remember in the 80's when a truck was a truck? It was only used when necessary, parked on the side of the garage otherwise. Most of the time, you were using the car. Now, that older vehicle will become the "truck" and the BEV used for everything else. Think about how long those old trucks lasted as a result of the limited use and how little it took to maintain them. We're getting back to our roots. A daily driver does not need to fulfill every possible scenario. The narrative that is must is counter-productive, causing harm to BEV adoption. Don't contribute to the barriers.

5-12-2020 **New Crossover.** Hearing about something new coming from Toyota, while in the depth of a pandemic, seems counter-intuitive. The analogy given was: *"Isn't this like launching a cruise ship during a Hurricane? Seems like pretty bad timing to be launching two new hybrids... Then you had the seeming abandonment of that concept, with the birth of... Now it seems Toyota is gravitating back to..."* Coming from someone who has a reputation for stirring controversy and not open to criticism, I wasn't sure how this would be taken. It didn't stop me from posting it though:

That's called rhetoric and it "*seems*" you are happy to pass it along. Ugh. Stepping back to look at the big picture, we can confirm Toyota has stayed true to their overall effort to phase-out traditional vehicles and now is the ideal time to make that commitment clear.

Why wouldn't an automaker take a next step at a time when the entire world is forced to re-evaluate anyway? Change is necessary. That should be obvious. It would be bizarre not to take advantage of the opportunity.

With regard to this upcoming reveal. Think about where the market was heading before the pandemic. Sedans were falling out of favor and the industry required platforms which could easily accommodate a decent size battery-pack. Seeing a new vehicle emerge that fits in between Camry and RAV4 makes a lot of sense. It would start out as a hybrid while offering a very easy path to plug-in hybrid. That's sensible business. In other words, Toyota has weathered many hurricanes already. This is what being prepared for the big one looks like. What other automaker is so well positioned to shed their old traditional vehicles?

5-12-2020 **Diversification.** The basics of business are absent with many. It's much like what we are discovering from the pandemic. There are many who are science illiterate. Not having any background, yet drawing conclusions anyway is quite dangerous... as we are witnessing, with horrifying consequence. Thankfully, the situation with vehicle technology isn't that drastic: *"It seems that Toyota is all over the place and trying to see what will actually take hold in the market."* When you don't have any basis to gauge observations upon, it is easy to see how mistakes can be made. They have no idea why certain decisions came about, so understanding the next step becomes nearly impossible. I chimed in again: That is another "*seems*" example of rhetoric. Antagonists pass along the "*take hold in the market*" as a red herring, hoping you'll follow it without question. They don't want you to discover BEV will co-exist. Reality is, the need for fleet & commercial vehicles with fuel-cells is already there and the oil industry embracing it inevitable. Our cargo transport must shift away from diesel. So, there will be high-volume production of hydrogen anyway. Toyota is simply diversifying its business, seeing that obvious opportunity to share EV-related technology. Using the Mirai platform to help refine that technology is a sensible approach.

5-13-2020 **Continuous Improvement.** The effort to cut cost is often confusing and difficult to identify. The on-going discussion made that all too clear: "*The question to me, is with the death of the Prius family, should we ever expect a NEW from the ground up built hybrid or will the future for Toyota be continued introduction of Hybrids that are Hybrid versions of existing ICE models? I tend to think, the Prius model line alone will be the only truly from the ground up built Hybrid. But I could be wrong.*" Knowing whether or not what I post makes any difference to him will be slim, but at least it gives others information to consider:

You are forcing a perspective that doesn't make sense for bottom-up design. It's a challenge for those who have only known top-down. They want to see something to check a box on their checklist, even though that approach isn't the better choice. This is why the KNOW YOUR AUDIENCE comes up so often. Understanding the market you are targeting is key.

A great example of this is the "*waterfall*" methodology most software developers used for decades. It worked great. Why would you want to change something so well proven? That question is easier to answer now that we have many "*agile*" success stories. In other words, Toyota is demonstrating flexibility by making lots of adjustments along the way. That's a huge benefit from having a platform with that intent... especially when trying to adapt to a dramatically changing market.

To be specific, this is how TNGA came about. That is an architecture designed from the start to be a hybrid, but rolled out as a traditional vehicle. You see an existing ICE model without any realization that it is actually a hybrid with backward compatibility.

We have seen that flexibility for a long time, well hidden to those who don't look for it. Way back in 2003, the system in the second-generation Prius had an oversized traction motor and a PSD capable of delivering 100 km/h using only electricity. Although that opportunity to support EV was available, it was never exploited... and therefore assumed, impossible. The "*ground up*" wasn't acknowledged.

The same should be obvious now with TNGA-e intent. How much of that necessary design is already in place, already providing real-world data? Again, this is how the KNOW YOUR AUDIENCE comes into play. Toyota customers in general don't want a "*ground up*" vehicle. They want their own familiar vehicle to now offer a plug.

Put another way, Toyota can play the discreet game exceptionally well. After all, most people have no idea how a vehicle is designed anyway.

- 5-13-2020** **Basic Advice.** It's nice getting back to sharing knowledge. In this case, it was in an thread very actively discussing charge options for a new owner's Prius Prime. I jumped into the mix with: As already stated, NEMA 14-50 is by far the most common 240-volt outlet, an option heavily favored for level-2 charger sellers. Keep that in mind when shopping. Something else to keep in mind is getting a charger with Wi-Fi support. The very first no-meter-required program in the entire country available for all customers in the provider's district was just started by Xcel here in Minnesota. It takes advantage of Wi-Fi connectivity, which enables time-of-use discount on a non-dedicated circuit. In other words, you can get reduced electricity rates when charging your vehicle, yet share the same 240-volt line. The billing distinction is automatic due to the charger, not a stand-alone meter you would have to install. That means if you have other devices that can plug into a 14-50 outlet, there's no need for any separate wiring. For example, you may have a heater or compressor that also uses 240 volts. That same line can be used. It's a no-brainer advancement in EV support at home... if you have a Wi-Fi enabled charger.
- 5-14-2020** **OMG!** It's hard to believe stuff like this even gets posted: *"Tesla increased its production rate on average power of two within the last 12 years. Even with a slight slow down you get to a few million. My estimate is: 2019=365000; 2020=500000; 2021=900000; 2022=1.5 million; 2023=2.5 million; 2024=3.5 million; 2025=5 million; 2026=6 million."* Fortunately, a bunch of people voted dislike and started sounding off about how thoughtless that was. No automaker could ever grow to that scale with a single vehicle. Expanding to offer a wide variety at that speed isn't possible either. Of course, imagine if that could be. Many enthusiasts make the incorrect assumption that they represent mainstream consumers. That's why so many argue with me and I always repeat the same mantra... know your audience. Expansion beyond niche can be painfully difficult. They don't understand how different it will be, as was clear from this post. In fact, appealing to early-adopters seeking opportunity has very little in common with someone shopping the showroom floor. It's quite remarkable how what I dealt with from Volt hype translates so well with the EV crowd as well. They really don't have any idea how the business aspect works. That blindness from focusing entirely on the engineering is a serious pitiful. Almost all of them fall into that same trap. Ugh.

- 5-14-2020** **Dinosaur.** It took 3 weeks to finally get a reply. The post was nothing but attitude, more ignoring what was posted to continue on with a narrative. This time, it simply ended with: *"Sorry to bust your bubble, Toyota is a dinosaur."* He just plain did not care what was being said. It's that same old nonsense. Within the pointless rant, there was this: *"Toyota is traveling on well paved roads not blazing new trails or leading anything other than the adoption of twenty year old technology."* That's the familiar song & dance. Only focus on the spotlight. We watching that disaster play out so many times with GM, it boggles the mind. They engineer by press-release and enablers gobble it up. That hype they generate is dangerous... but they don't care. I fired back with: That's called a "feel good" speech, used as an excuse to turn a blind-eye toward the real problem. Attempts to validate emphasis on efforts that fail to address what really needs to be done is what we have all seen for the past 20 years. Some people clearly never learn what the lack of balance truly costs. Ironically, the reply of *"bury our head in the sand"* is a perfect describe for the situation. In other words, leadership must include changing the masses. Simply blazing a trail that only a few follow doesn't accomplish that. Put another way, look beyond the early-adopter stage. Reaching the mainstream audience requires a very different approach than just appealing to niche buyers.
- 5-14-2020** **Continuous Improvement.** So many people make anecdotal assessments, pointing out the bigger picture is quite a challenge. They know what they saw. That's the end of it. Not taking the time then, to see if more was really at play, solidifies their belief. Carried forward many years, it becomes almost impossible for them to let go of what had essentially become a narrative. To make matters worse, they have no way of confirming their oversight later. You're basically stuck with an *"agree to disagree"* situation... which I find absurd, since cherry-picking facts isn't objective. Anywho, this happened today with approach: *"Yeah, I'm not talking about kaizen."* He didn't want to widen perspective, despite the obvious need to when discussing overall goals. I was disappointed... which is better than being annoyed... but nonetheless, still a barrier. This was my reply: It is how Toyota's big picture comes together though. So, you must address it. That is a fundamental of how they operate. Set long-term milestones and use that continuous improvement process to help reach it. The beauty of that process is all along the journey there are rewards. In other words, if there is a pause for some reason (a block), it doesn't matter since much has already been delivered. Put another way, Toyota doesn't strive for a big-bang rollout. In fact, most improvements are so subtle they go unnoticed. Their focus on incremental upgrades is how they are able to invest in new platforms. TNGA and TNGA-e are simply steps to note, as were THS and HSD. Each contributes in its own way to get to achieve overall goals. People focus on the milestones though, not even noticing that detail... hence the misinterpretation of purpose or the perception of a course change... especially when they feel compelled to check a box. It's what keeps a forum lively. It doesn't change anything. The milestones still get achieved even if intent or direction is unclear.

- 5-15-2020 Battery Day.** Speculation about rollouts in China is what has been filling discussions lately. Everyone feels it necessary to post an opinion. My comments try to interject facts. In fact, I posted specifications for VW battery choices today. That quickly ended some speculation; however, the upcoming "*battery day*" for Tesla has lots of die-hard fans. So, it will be challenging to squeeze in detail. For example, a fundamental continues to get brushed aside. Tesla will begin including prismatic battery cells in their offering. That's a major departure from the cylindrical type; yet, it is basically ignoring as a contributing factor to performance & longevity. Why? Needless to say, I had a post of my own: Although the technology has indeed improved and more can be reasonably expected, something on that scale screams tradeoff. What did the engineers/chemists give up to achieve that? The first thing that comes to minds is charging speed. We already know that limiting rates for current lithium batteries to 50kW will contribute to longevity. Having lower tolerances would likely result in a cost reduction as well. In other words, the devil is in the detail. Perhaps the long-life packs are limited to tier-1 charging. Interestingly, a limitation of rate would prevent the Osborne Effect. Diversification of product is the next step in reaching out to a wider audience anyway. In fact, that is a fundamental of business growth. The idea of a one-size-fits-all solution is very much an early-adopter perspective. Seeing variation of offerings should not be a surprise to anyone.
- 5-15-2020 Tradeoff, Always.** There is a long-time member on the big Prius forum who refuses to acknowledge change. He has held onto the past and continues to push that perspective as a narrative. It's very frustrating... since the comments made are facts. Problem is, those facts are outdated and for a different audience. Recognition of that has been impossible. He just plain doesn't care. I got a glimpse into the reason why today when the "*balance of priorities*" was brought up. He was absolutely convinced that tradeoffs don't happen with great engineering. A few of us had to do a double-take on that one. Of course, the Volt enthusiasts were that close-minded too. By simply dismissing cost as a factor, the problem goes away. It becomes a issue of pure mechanics, with no influence of business whatsoever. My example caught him off guard. He had absolutely no idea what "*tier-1*" charging was, despite 15 years of participation adding up to over 16,000 posts. His complaints about Toyota and favoritism toward Tesla should have made that a central part of some arguments. That's a SuperCharger option. Tier-1 is slower (max 60 kW), but costs have the price-per-kilowatt than Tier-2. It's a tradeoff decision consumers must make each time they plug-in for a rapid recharge. You make the choice by weighing factors involved. What is more important, time or money? With such a simple example of a tradeoff, I'm hoping our flurry of "*What!?!'*" replies finally gets him to recognize he had been making comments based on incomplete information. Discovering you were poorly informed can be a great teaching moment taken advantage of.

5-16-2020 Rethink, audience. The idea of something for the masses is starting to come around. It's the effort from VW helping to push the industry beyond the niche. That challenge is far more complex than enthusiasts realize. In fact, most are still unaware of what the loss of tax-credits for some actually means. So naturally, confusion related to how that will impact everyone else results in wild guessing. That's unfortunate. You'd think that group would be the best informed. They are not. Know your audience. Anywho, I injected some sense into a discussion today when "rethink" was brought up in a thread about VW not bringing their smallest PHEV to the United State. Of course, focus had already shifted over to Toyota and its possible reaction to tax-credit phase-out:

When Toyota enters phase-out, it will be an onslaught to the industry making up claims about cost & market for PHEV. By then, Toyota will have a strong foothold in the market, being able to take advantage of the switch to unlimited quantity... just like Tesla did. This is the payoff for taking the time to do it right. Look at how disastrous the rush was from GM. Rather than focus on their core consumer (the SUV buyers), they squandered the opportunity by catering to enthusiasts. In others words, they provided an exceptional example of what not to do.

Watch what happens as the RAV4 production in Kentucky pushes a paradigm shift, one that is even more difficult to deny with the rethink our lockdown is stirring. It is a design targeted directly at an audience with very strong potential. VW is well aware of this, hence not even bothering to bring Golf PHEV here. They will rollout a Tiguan instead, but won't compete against RAV4 Prime. Its 13kWh pack and 1.4l engine will be less range & power.

The point is that we are starting to see a recognition of mainstream buyers. The focus on early-adopters was helpful initially with proving out the technology, but we are now well past that phase. It is more important to address other aspects of plug-in ownership now. The obsession with speed & power is becoming an anchor, souring the appeal by ignoring everything else. Again, this is what GM did. Just imagine if the tech from Volt had been spread to a vehicle like Equinox.

5-16-2020 Rethink, warranty. When you mention plug-in vehicles, the response back is almost always with regard to battery replacement. People express concern to such a degree, you really don't have an opportunity to mention anything else. They have already made up their mind. That's why I got a "*gasp!*" type reaction last Fall at the town meeting when bringing up the topic of Toyota pushing their hybrid warranties out further... proof of concerns being addressed. Today, it was online with more of the rethink posting: More evidence of rethink need beyond range & power can be found by looking at Toyota's exploration of warranty. The introduction of Lexus UX300e comes with 10-year/1,000,000km coverage. To get a guarantee that the battery-pack will deliver at least 70% of new capacity after so much time & distance is what ordinary consumers have higher on their priority list. True, the ability to go farther and recharge faster is important, but it most definitely is not what mainstream audiences voice concern about. Recognition of that reality is quite a challenge for early-adopters. They became so obsessed with the engineering, the business aspect of selling vehicles was neglected. The stage of appealing to a wider audience means addressing different priorities. That rethink is inevitable. Watch what happens with regard to such long warranties being offered.

- 5-16-2020** **Rethink, distraction.** Seeing our president now in a state of panic reminds me of the enthusiasts getting caught intentionally misleading. They do everything possible to change the topic. Distraction is their objective. Just like a troll, they throw out random bait hoping someone will bite. For Toyota, it's the same old thing... mentioned something about hydrogen. Enthusiasts tend to be enablers, so that tended to work quite well with the online discussion, especially general audience. We're starting to see evidence of that failing now. It's hard to tell why. Several factors have changed. The biggest is the economy taking a permanent turn. Days of plentiful disposable income are gone, as is the predictability of the oil industry. Just like our restaurants, anything struggling to survive before the pandemic will either close forever or find some new approach to survive. In other words, the rethink is obvious already. It will be necessary. That is exactly why our top executive is in serious trouble. He has no clue what to do. His only approach is failing. And since critical thinking is absent from his qualification, it's clear some type of end is near. Question is, who will do that rethink? With so much of the economy tied into the auto & oil industry, the overall of disciplines and knowledge to share is quite remarkable. I had no idea how much insight my past would contribute to planning for this new future. Having learned to deal with distractions is really paying off.
- 5-17-2020** **Explorer PHEV.** At a starting price (with taxes) of \$82,250 in Germany, it is clearly not a product for the masses. Heck, it doesn't even need a rethink. That's far too expensive to be taken as anything beyond a niche effort. Some will argue this is how you reach the larger audiences faster, by working your way from the top down. We know that doesn't actually work. There's simply no incentive. Thankfully, there is an Escape PHEV on the way already for the United States. So, any of the bad press from this beast shouldn't carry over. Looking at a range of 26 miles on the WLTP scale (European rating), it's difficult to see how the promotion will play out. What will be emphasized? The draw is not obvious. That was the same problem Two-Mode faced. You couldn't figure out who GM was targeting. Perhaps Ford will have better messaging. Looking at the online promotional flyer, it states "*Four EV Modes*". They are Now, Later, Charge and Auto. Explanations for each imply focus will simply be on the fact that you get advantages of having a plug. The degree to which it provides a benefit are absent. It will be interesting to see how that differs when Ford begins selling their next-gen PHEV offerings here.

5-17-2020 Both Worlds. You know I cannot resist spin like this: *"VW wants to switch to electric cars they don't like hybrids, as they have the worst of both worlds, it's a crappy EV combined with an overly complicated ICE."* It has to be addressed. Letting such an opportunity to provide exposition should not be wasted... and, it wasn't:

Once RAV4 Prime rollout begins, convincing the typical consumer that 302 hp delivering 0-60 in 5.8 seconds with a 39-mile EV range is the "worst" will fall on deaf ears. Toyota has over 20 years of well-proven hybrid technology. So, claiming "complicated" really doesn't equate to anything. They already considered very reliable. So, there's nothing to be concerned about. In fact, getting to enjoy EV driving with full confidence of an engine backup is the best of both worlds.

Put another way, how are you going to promote BEV purchases? Are you really going to mislead/misrepresent about what a PHEV has to offer for the sake of pushing electric-only purity? That doesn't make any sense. It is likely quite counter-productive, since the purchase of a PHEV often leads to charging upgrades at home and an interest in a BEV for the next new vehicle purchase.

This is why no legacy automaker is going all-out with BEV plans... though, GM (who has proven to be all bark and no bite) claims to be following that path. It's not good business yet. VW knows that. BEV still have many challenges to address, which early-adopters of ID.3 and ID.4 owners will help to overcome. People don't have the confidence yet. So, bridging to that end-state with PHEV in the meantime is a great solution. It dramatically reduces consumption & emissions right away, no wait for next-gen batteries.

As for the claim of *"selling hybrids would be detrimental as they create confusion in some buyers"*, where's the evidence to support that? Toyota is phasing out traditional vehicles, making hybrids their new base and plug-in hybrids the stage-setters for electric-only. Consumers see a benefit, not a detriment.
