- 7-21-2014 Self-Fulfilling Prophecy.** Kicking the can (postponing) rather than dealing with the problem at hand is becoming so common of a practice, it doesn't get much attention anymore. That's simply the way business is conducted... which is how the mess we're in with road repair/replacement funding has become such a massive problem. Rather than adjusting gas tax to match inflation, it remains at a fixed value... decreasing it's worth year after year. In the meantime, the amount of work and number of roads continues to grow. So, the entire system is under-funded and continues to grow worse. The issue continues to be political poison too. If you want to remain in office, you have to be against raising taxes. It's a disaster in the making... hence kicking the can, making it someone else's problem to address or get blame for later. Each time the issue comes up, other programs suffer as a result of money being taken from them to pay for what should have been collected through gas purchases. It's the robbing Paul to pay Peter dilemma. That gives the appearance of having solved the problem, but in reality just moved the consequences elsewhere. It's disheartening to witness the lack of action being taken. Rather than being responsible, we watch the problem get worse. Sadly, the excuse is there's no time to deal with it... which is ultimately what will be the case. The on-going delay will use up the time available. It's a self-fulfilling prophecy in the making.
- 7-22-2014 Opel Ampera Discontinued.** That was the big news in the hybrid world today. Online sources were all a buzz. Sales of that Volt counterpart in Europe have been quite a bit lower than the disappointing numbers here. So, it wasn't much of a surprise to find out it won't be upgraded to a next generation. It will simply be discontinued instead. That made me wonder what would be offered instead. Interestingly, that thought didn't stir much from others. The enthusiasts were in heavy defense mode. That intrigued me. What were their expectations? For that matter, what are they hoping for from Volt? They still absolutely refuse to identify the audience. Supposedly, GM was going to take middle-market by storm. Ordinary consumers would purchase Volt in quantities as much as double the mainstream minimum. Things fell apart when reality set in. In fact, the sales rate has remained flat for about 2 years now. We're still seeing between 1,600 and 1,700 per month... despite the dramatic price drop. That's obviously a concern, but we don't hear much about that anymore. There's no point. The next will have to be different to both attract buyers and deliver a profit.
- 7-23-2014 Double-Standard.** This was apparently an opportunity for the last stand: *"If you're going to try to paint a picture you need to back it up w/facts."* In just that thread alone, there were 3 rather blatant examples of others making statements as facts without presenting any data. Yet, I was the one who got called out on it. That was what I had been hoping for all along. Outright lies would be posted about Prius, obvious efforts to undermine Prius PHV. No one would question that though. Integrity was of no concern. They'd just look the other way. That's why I've been filming my drives. I knew at some point I'd be able to expose the greenwashing... and this was finally my chance. So, I did: How come others aren't held to that same standard? We see the same "6 mile" claim being made over and over again, a clear misrepresentation of the battery-capacity available. Yet, no data to back that is ever requested. The "fact" is simply accepted at face value without question. That's just plain not constructive. Some would call it a double-standard. Here's data to finally bring that misrepresentation to an end: [Prius PHV - Commute Work \(Deplete EV\)](#)

- 7-23-2014** **No Challenges.** That video certainly brought the rhetoric to a screeching halt. I now have undeniable proof showing the battery-capacity is far more than the 6 miles claimed. It absolutely amazed me how desperate certain individuals were to misrepresent Prius PHV. They exploited a vague bit of information by leaving out vital detail, with the hope people would make an incorrect assumption. In other words, they lied. It's dishonest when you know your portrayal is inaccurate... and they knew it. I pointed out the problem with their claims over and over again. On that one particular venue though, a few particular people just plain didn't care. They kind of behavior spoke volumes. Rather than compete directly & openly, they resorted to posting like that. It was quite frustrating to deal with at times... especially when others allowed it to continue. It happened time after time. But now they have to deal with be confronted by a rebuttal in the form of detailed video. It's a nerdy type of revenge. I enjoy that type of victory. The nonsense posts will simply end. There won't be any mention anymore... knowing I'll just post that same link again... which would expose what they are attempting... hence, no challenges. Gotta like that.
- 7-28-2014** **Lonely.** It's sad reading a quote like this: "*Well over a year of ownership and I have yet to see another PiP in the flesh other than my own.*" Even here in the Midwest, where none are sold anywhere within a 500-mile radius, I still have a sighting from time to time. The person making that comment was from Nebraska though. I guess that's far enough away from large populations to lower the chances. Even so, I just got back from a vacation out in a sparsely populated area. It was quite exciting. This is how I described that road trip: I was in Iowa last weekend for Nordic Fest. Had a blast, in a tiny Midwest town... where there were Prius everywhere! I was surprised as heck by the quantity. It got to the point where it was rather amusing. Not only was I seeing them all over the place, sometimes there were several parked together. Twice I ended up in a group of 3 and once a group of 4. And yes, there was even another plug-in model. Of course, if you think about it, Prius is a great long-distance travel vehicle. So, it does make sense seeing so many concentrated like that at a special event. Last year, a trip to Wisconsin had similar results. But in that small town, there were actually 3 plug-in Prius all within sight at the same time. We even saw a special edition model. It was sweet!

7-29-2014 **Wireless Charging.** Clarity about delay is becoming apparent. The word today is the next generation Prius PHV will offer wireless charging. That research & development we heard about from Toyota awhile back is indeed going to be a reality. Rather than having to plug in, you'll have the option of simply driving over a pad on your garage floor. It's like the induction charging long ago, but no longer requiring a paddle and the distance increasing. Unfortunately, there are certain people who just plain don't understand. They still think the audience is enthusiasts. Why they don't recognize the goal of appealing to the masses is even more of a mystery. Reading this particular comment really got me rather frazzled: *"You need to realize that many people buy electric cars for their efficiency. Taking a 11% to 14% loss on that, for a minimal increase in convenience, is pretty much opposite of what a section of the market is looking for."* This came from an EV owner who continues to argue with me and for some bizarre reason still hasn't noticed the message from other plug-in owners... who overwhelmingly state the number one reason for purchase is to help end our dependency on oil. How he can sight an increase in electricity usage as a deterrent is beyond anything I can fathom. We've even had a few owners openly state they don't care how many EV miles they drive, as long as no oil is used. In fact, I've complained many times about some not caring about MPGe values for that very reason. In other words, he still refuses to accept goals of the masses. Appealing to mainstream buyers is something he won't embrace. In a way, that is understandable. It would make the vehicle he currently cherishes just ordinary transport. Toyota wants that. Tesla is obviously striving for that too. Wireless is a convenience option which will help bring an end to guzzling dirty non-renewable fuel.

7-31-2014 **New Owner Assumptions.** The opportunity came up, yet again, to point out screen comprehension issues. With detail displays, it's far too easy to jump to the wrong conclusion. We often see that with the Eco-Meter. This is how I respond: The misconception that the PWR zone should be avoided for the sake of efficiency gain is very, very common. New owners misinterpret that RED color as bad. It never crosses their mind that the purpose is actually to inform you to minimize the time spent drawing high power, rather than avoid it entirely. So naturally, we get posts on a regular basis about how driving that way irritates those following behind them. The best advice is to *"Just Drive It"*. That's what long-time Prius drivers have been telling new owners for over a decade, because it's what delivers the best results. Using the engine at a higher RPM is not a bad thing. In fact, the hybrid system takes advantage of the situation by splitting the power. Some of it is used for generating electricity, so you actually end up using the electric motor more and topping off the battery-pack. That's counter-intuitive. You'd think consuming more gas would result in an overall efficiency loss, not a gain. The assumption comes from having grown up with a vehicle not having the ability to split power. Prius can and does frequently. That's a major part of how it achieves higher MPG even without plugging in.

7-31-2014 **New Owner Advice.** The same suggestion will likely be needed for many years to come still. New owners assume slower acceleration is better. We have to provide the advice pointing out that isn't the case, that faster can actually be more efficient. That's a difficult concept to accept, especially for those without any engineering background. It's too easy to jump to the conclusion that using less fuel will result in higher efficiency. The idea that bigger MPG numbers can result from stepping on the pedal harder goes against everything they were taught... back when an engine was the only power source. Adding a battery-pack and 2 electric motors complicates the equation to such a degree, many owners don't have a basis to even try those calculations. It's too complex to easily visualize the benefit. That's a simple matter for a computer though, which is what the hybrid system takes advantage of. Simply altering the speed of each of those devices interacting with each other is easy with sensors & software. That's far more sophisticated than your foot interacting with just a single tachometer. However, you can actually use that engine in the hybrid to influence the motor operation, letting the computer do the rest for you. So, the experienced owners offer this advice to the new: Accelerate briskly (a brief engine spin-up to 3500 RPM) and watch what happens. You still get outstanding MPG, even with the quick speed burst in ECO mode. It's counter-intuitive. But since traditional vehicles don't possess the ability to split power, most people haven't ever taken the time to think about how an alternative approach could yield very different results. The PSD offers flexibility well beyond what just an engine alone can deliver. There's 2 electric motors and a battery-pack that it connects & controls. That gives it far more efficiency opportunities. It's why the hybrid system delivers both much better MPG and lower emissions. Try it. You'll be surprised.

7-31-2014 **Falling Behind.** When it comes to the interpretation of competitors, having a background in economics really really helps. Unless you've studied the business aspect, the trap of engineering-blinders will catch you. It's far too easy to focus exclusively on the achievements of engineers and assume that will result in great sales. There's also the problem of how long change actually takes. The acceptance process is inevitably way longer than people hope. Sadly, even the rollout of technology improvements is riddled with business barriers having nothing to do with the design itself. It's a complicated beast. With billions of dollars at stake, taking well thought out steps should be acknowledged as vital. Sadly, that too isn't given the credit it deserves. This closing part of a post today caught my attention: "...the end of next year (December 2015) is when they are saying it will be available. 1 1/2 years away. That is a long time in my book and with the competition catching up, Toyota may be falling behind." When all aspects of business aren't taken into account, there should be reason for concern. Fear of falling behind and others catching up doesn't do that. The market as a whole must be considered. A single automaker cannot stand alone. My thoughts to this were: There is nothing that says "*falling behind*" is a bad thing. Marketing has convinced us that the most of something is a sign of leadership. That's called advertising, when they make you purchase something with greater capacity than what you actually need. They appeal to want and make the others appear to be falling behind. Fortunately for us, Toyota isn't playing that game. They've told us repeatedly that cost-reduction is a very high priority. Sadly, many haven't actually heard that message. People tend to listen to the "*most*" promotion instead; consequently, they get the wrong impression. Lithium batteries are indeed available, but they aren't in high-volume nor are they cost-competitive. That's a big issue some people overlook and others aren't aware of. If you listen to enthusiasts, they tend to dismiss that reality and focus on range & capacity instead. Talk to an ordinary consumer, someone who would otherwise purchase a Camry or Corolla. They're the audience, the market Toyota wants to capture. They're big deterrent is price. It's not whether or not other automakers are "*rushing ahead*". There will obviously be cross-shoppers, but attracting them isn't as important as making the hybrid a stronger product in Toyota's own production-line. In other words, the "*competition*" isn't what you think it is.

8-02-2014 Sales Interpretation. There were 3,019 Leafs purchased last month. That alone was enough to mute the Volt enthusiasts... since it was 999 more than Volt. Looking at the situation is the interesting new though. The 2,020 included a heavy push to get 2014 models off the lot, since the slightly improved 2015 is already available. To further erode hope, some of those purchases were the result of current leases expiring and owners leasing a new one in its place... which counts as a sale. In other words, there isn't really any growth for Volt and Leaf is doing better and better. Remember the "*range anxiety*" fear? That approach clearly wasn't effective. Anywho, it's nice not having to deal with spin anymore. In the meantime, I can only find listings for 273 Prius PHV, with the closest 912 miles from here. Toyota is obviously trying to clear out inventory before introducing the next model year. We still don't know how that will play out either. Expanding to other states remains a *wait-and-see* situation. The dependency on tax-credits is a liability vehicles collecting the full amount (\$7,500) cannot afford anymore. Next generation offerings must be able to survive without, which isn't looking promising based on the current market. That's why there is much less of a concern coming from those supporting Prius. With the plug-in model just a package difference from an already profitable high-volume hybrid, the odds of the next generation being self-sustaining 2 years from now is fairly realistic. Though, even without that \$2,500 assistance, it's still a challenging sale. The business of selling hybrids is difficult in itself. But at least the progress coming from Nissan & Tesla is helping open up opportunity. The other EV offerings aren't stirring much attention. Ford is making some progress with their plug-in hybrids, but sadly the depleted efficiency mislabeling debacle set them back some. It all leaves you wondering. There is lots to interpret, but not much of a point in doing in yet.

8-03-2014 July Sales. Failing to recognize the true competition has serious consequences. Toyota, Honda, and Ford all recognized that right from the very start. That's why Prius was introduced as a model choice between Corolla & Camry. That's why Honda introduced their Civic hybrid as a traditional vehicle variant, then re-started with a new hybrid system. That's why Ford struggled with Escape and ultimately chose to abandon it in favor of directly competing with Toyota. It was only GM who didn't see the need to address the market with something realistically competitive. Two-Mode was a disaster from the start, grossly over-priced and targeted at a tiny audience. Volt wasn't much better, also well out of reach for ordinary consumers. That's why posting these numbers are so humbling. At least some of the automakers are better off. But when you look at others, like VW and Hyundai, it makes you wonder what they'll end up doing. There's also Chrysler, which is a complete unknown. The point is, traditional vehicles dominate and their reign of waste & filth will continue on for quite awhile. The sale counts speak for themselves. The top-6 sellers for GM: 25,321 Equinox; 20,926 Cruze; 13,537 Malibu; 9,961 Camaro; 9,636 Impala; 6,430 Spark. The top-6 sellers for Ford: 26,558 Escape; 23,842 Fusion; 17,724 Focus; 7,545 Fiesta; 6,564 Mustang; 5,587 Taurus. The top-6 sellers for Toyota: 39,888 Camry; 30,833 Corolla; 26,779 RAV4; 12,866 Prius (liftback); 11,357 Highlander; 11,661 Sienna. Thankfully, Prius is holding steady in third place here. In Japan, the smaller C model (known as "*Aqua*") is the top-seller for the country, not just Toyota alone. The second most popular vehicle there is the regular (liftback) model of Prius. Clearly, our market is less receptive. But there is hope. As each automaker invests and delivers next-generation improvements, overall interest should grow. In the meantime, sales here are basically flat.

8-04-2014 **13.1 Miles.** That was a moment to savor. It was what the EV range estimate stated today. That's the high value I see at times during Summer. This year, it's been a bit elusive though. It doesn't reflect actual results well anyway. The number is nothing but a calculation based on recent driving. And since I don't have a pattern of any sort, especially during the warm season, expectations are hit & miss. The other day I carried 2 kayaks on the roof, but traveled exclusively in the suburbs. That meant lots of EV driving, but in a very inefficient way. Who knows how the computer interpreted the results of all that aerodynamic drag added to the vehicle. I used the A/C at the same time, further complicated matters. Of course, that was exploiting the flexible nature of such a dynamic system. It handle the big demand increase quite well. Perhaps it knew that. With so many factors to take into account, it's amazing the estimate value is even close. After all, the EV range goes down quickly when you're cooling the interior using electricity but not actually driving. Wanting a comfortable interior after loading up the kayaks onto the roof is a very worthwhile feature. It lowers MPG overall, but no where near as much as if the engine had to run to provide that same cooling instead. The electricity is used in the best way... sometimes for EV, sometimes for HV, sometimes for blending of both (called EV-BOOST mode). The point is that 4.4 kWh battery-pack is taken advantage of. That plug-supplied electricity helps reduce consumption & emissions, but not necessarily by just delivering a range of EV alone. So, that number really doesn't mean much. Just ask other owners. Some see higher estimates. Others see lower. It works out nicely regardless. Just drive it!

8-06-2014 **EV-Boost Mode - Video.** Watch this morning commute to work as I take advantage of the plug-supplied electricity while traveling at speeds faster than the EV limit. We call that "*EV-Boost*" mode. There isn't really much to say about it. The outcome speaks for itself. MPG is much higher, even when the engine runs. You can see detail in the video showing the gas-engine running at a much lower RPM than usual. That's due to its power be blending with output from the electric-motor. It's a simple approach to achieving great efficiency. In fact, that's what Prius has been doing from the very beginning. The only real difference now is that there's more electricity to take advantage of and most of it comes from a plug. So, no matter what speed you go or what the driving conditions are, the result will be a boost over the regular model. See for that for yourself... [Prius PHV - Commute Work \(EV-Boost mode\)](#)

8-08-2014 **Misinformed.** There is a particular individual, who posts very frequently on technical threads, still doesn't understand the detail. On the big Prius forum and being a PHV owner, you'd think he'd study the data provided. Instead, he's becoming a conveyance of misinformation... which sadly, makes the posts a source of greenwashing. Obviously, stopping that has been a priority. I jumped on this today: *"Actually once the vehicle exceeds 62 mph, full EV mode is no longer possible, because the maximum RPM of the MG electric motors has been reached. The gasoline engine has to kick in to prevent over-speed of certain parts of the transaxle."* It makes sense why he originally jumped to the wrong conclusion. But after awhile, you'd think one of the sources reaching out to help would finally get heard. Overcoming beliefs about EV aren't easy. So, we keep trying. The stigma created to make people dislike any engine running was part of a major effort to undermine. It will take work to changed the minds of those already convinced, based on what they were told by so-called experts. This is how I tackled the situation: That's a very common misconception, based in part on outdated information. The design has been improved over the years. That is clearly not the case anymore, as the videos confirm. MG2 has a maximum RPM of 13,500. You can see the spinning doesn't come close to that, even when cruising at 60 mph. The actual reason for the blending is to not sacrifice efficiency. Rather than wasting electricity to spin the motor extremely fast, especially since power fades as RPM increases, the system takes advantage of having an engine available. Running it at low RPM is a much better for overall efficiency. It uses very little gas that way, while also better using the electricity.

8-08-2014 **Next Volt.** Today was the big pre-announcement for Volt, so the daily blog was quite active. The next generation will be revealed at the big auto show in Detroit this coming January. Supporters still have no clue what to expect. Profitability and no more dependence on Tax-Credits is a very big deal, but never discussed anymore. Those topics have become taboo. So, we get other attributes discussed instead. That's not bad. After all, getting more legroom in the back seats and having having 5 of them has been an improvement many are hoping to see. The request for increased EV range is another popular item. Someone did actually bring up the topic of sales though. The mention of *"mainstream"* really stirred the pot too. I was intrigued when this popped up in response: *"Why the big uproar over the 'not a mainstream' comment? What is everybody afraid this means?"* It was my pleasure to point out why: Mainstream has been concisely defined in this market as sales of 60,000 per year (5,000 per month). That was the target the industry had established prior to Volt rollout and what GM embraced as a benchmark to achieve for the first generation Volt. Since the results ended up well below that clearly identifiable milestone, the topic is avoided... hence the skittishness when *"mainstream"* is mentioned.

8-08-2014 **Fools.** I saw this today and just plain couldn't believe it. I certainly wasn't expecting an attack on the competition. But one of the troublemakers on that daily blog couldn't resist. He wasn't happy about someone posting constructive information and retaliated with: *"The biggest lie is the PiP, which promotes a 11 mile EV range, but only gives six, because the other five is with the engine on! Those buyers were fools, and you are becoming one of them!"* Reading such blatant greenwashing and such shameful smug was quite a surprise. You wouldn't expect anyone to go to such extremes anymore. Oh well. That provided me with the opportunity to present data: Biggest lie? Yes! Though, it is becoming quite telling by how often it is repeated. Lack of clarity about the EPA label is being used to mislead and some people are spreading that misinformation. No matter how many times that 6 value gets addressed, pointing out that it really is 11 miles and explaining how the results are misinterpreted, the incorrect posts continue. Again, here are 2 videos clearly showing the 11 is indeed a correct representation of the electric capacity available. The commute in the one direction delivered 12.4 miles of consecutive EV driving. The other direction delivered 14.1 miles. [Prius PHV - Commute Home \(Deplete EV\)](#) and [Prius PHV - Commute Work \(Deplete EV\)](#). It's too bad more people don't understand how PLUG-IN HYBRIDS actually work. They make assumptions without checking facts. The engine will start at times of high demand, then shut off or cut fuel when not needed. It will also take advantage of the plug-supplied electricity to allow the engine to run at a low RPM for optimum efficiency. That available capacity is used to improve MPG. It may or may not be achieved through EV driving alone. It doesn't matter. The goal of reduces emissions & consumption is still achieved. Notice on this video how the engine shuts off and EV resumes after the high-demand request and warm-up cycle are complete. On that particular drive, there were 13 miles of EV. [Prius PHV - Lots Of Data](#)

8-11-2014 **Denial.** I watched the posts get increasingly more desperate. It has reached the point where there's no way to take them seriously anymore. The lies are absurd. One reply to me referenced something I didn't even say. Anyone could see that was a blatant slander attempt. Normally, implying what you meant through the use of misquoting provokes a rebuttal. But when I mention sales and the response to that was claiming I had complained about EV range and HV efficiency is downright hysterical. I didn't say anything even closely related. Then there's that on-going "6 mile" nonsense. They know it's a simple equation to figure out range based on kWh capacity. Yet, they try to mislead by excluding that vital information. The hope really is that we're fools. The point of this recent exercise was to expose the reality of denial. Marketing based on emotion didn't work. The focus on "*range anxiety*" assumed people would have a fear of running out of electricity. Turns out, they don't. Leaf has been selling well despite that and the outstanding depleted MPG of Prius PHV satisfies even the most stringent need. They are in denial that their favored approach failed to take the market by storm. Rather than being the celebrated leader, Volt has become just another offering in the variety of plug-in choices available. That's why I knew trouble was coming years ago. When I sought out an ally, their exclamation of being "*vastly superior*" sealed their fate. They were doomed. Rather than accept a partnership, they chose to face the challenges alone... which is why some are so desperate now. Pride is a very large obstacle to overcome. Too bad some still don't what join the rest of the team trying to end the reign of traditional vehicles. It's really quite sad.

8-11-2014 **All-Electric Range.** Statements like this are so close-minded, it's hard to know where to begin: "*CARB should base their rules on all-electric range, and nothing else.*" It has been overwhelmingly proven that goals should be set based on outcome, not the means. What good is that electric-capacity if it isn't utilized well? After all, the BMW i8 just got certified with an all-electric range of 0. Yes, zero! That's so far off of the expected 22-mile rating people had hoped for, it invalidates all previous arguments. Another automaker took another approach. They didn't choose to design for the test, a troubling practice of the past... which a few still endorse... as those pushing "*all-electric range*" still don't understand. So what if the engine runs briefly or in an extremely efficient state. The point is the outcome, not how it is achieved. Copyright law prevents similar design anyway. I sounded off to the narrow perspective saying: Certain people have requested data. Then when they actually get it, with video samples comprehensively detailing operation, they find excuses to dismiss that as an extreme or anecdotal. Fortunately, organizations like CARB don't play games like that. For your example, they won't end up settling on something as simplistic as just "*all electric range*". We all know the "*6 mile*" nonsense is nothing but a testing scenario being exploited with the desire to greenwash. Anyone taking time to look at the numbers will easily see that the 4.4 kWh battery-pack will deliver much more electricity, hence the actual distance of 11 miles. The calculation to confirm is quite simple. Those wanting to mislead will hope you don't actually do the math though. CARB will include capacity in the determination of qualifying vehicles. How could they not? After all, it is when & where you choose to engage EV mode that's important, not whether the engine is utilized at some other time.

8-14-2014 **Next Step.** We're seeing the same speculation emerge again, where want overshadows need from those posting not showing concern or even any supporting material. That's interesting, especially since the "*too little, too slowly*" was so well confirmed for that very reason. This explains why we got the quote the other day that GM considers Volt "*not a mass-market*" vehicle any longer for the chief marketing officer. It's a way of satisfying both audiences going forward. For those who focus on want, they will indeed get the Volt they've supported all along. It will be a premiere plug-in vehicle to showcase what the technology can deliver. For those who focus on need... in other words, the mass-market... they'll get that second model some of us have been pushing to get since before rollout began. We knew priorities differed so much, a single choice wouldn't be able to appeal to a wide audience. After all, diversification is a fundamental aspect of good business. Odds are very good that new plug-in choice will get a unique new name, to disassociate itself from Volt, since it will differ so much. Clashing directly with some of the principles enthusiasts haven't wanted to compromise isn't a bad thing. This is why the "*goals*" and "*who*" questions were asked over and over and over again throughout the years. That acknowledgement how the next step is taken.

8-15-2014 **Better Late.** Firing back is usually pointless. Since the audience is unreceptive, that type of sparring goes no where. But in this case, we now have the hypocritical stance as an element of change. We're seeing statements being made which agree with what used to be dismissed. But rather than that past coming back to haunt them, they try to present the idea as new and from them instead. These blogs clearly confirm that's not the case. Winning an argument isn't the point though. It's to get change to actually happen, regardless of how. So, claims like this are more of a footnote in history rather than effective debate material: "*We can certainly all have our differences of opinion and even engage in some heated debate but throwing fire bomb statements is always counter productive.*" In other words, things like pointing out the fall well short of goals doesn't help anymore. That message has been received. Finally. There is a struggle to take the next step though... and there is an opportunity to re-try to create that partnership they summarily dismissed in the past, show how the playing field is level. I posted: So is down-voting facts, yet we see that all the time still. Personally, I find it quite interesting to see the "*constructive*" comments of recent to simply be recites I what we've been saying for years, but got labeled as trolls for it back then. That's confirmation of having been right all along. In other words, there were business realities dismissed that are finally acknowledged. The goal of mainstream acceptance is a whole lot more difficult than those blissfully posting years ago had ever imagined. Heavy emphasis on engineering with wide disregard for the market has consequences. It's nice to see that now being addressed. The "*too little, too slowly*" has turned into "*better late, than never*".

8-15-2014 **The Same.** What antagonists hate the most is having it pointed out that goals are the same. That's why when Prius isn't even mentioned, they bring it up... claiming that's what you were talking about all along. Today, it was: "*Are you talking about the PiP again?*" I found that vindicating. That daily blog still hasn't learned. Years ago on the big GM forum, they discovered their own members were trolling by doing exactly that. They'd drop bait, posting insults and incorrect information with the hope of a rebuttal. Some just liked to debate. Others used in as a means to distract. None were happy to hear that the statements made applied to them too. They didn't want to face the reality that each for-profit business faced the same challenges. I simply pointed out that reality with playful banter: That's an example of not even trying to be constructive, just a joking effort to divert attention away from Volt's business struggle. But since you provided an invitation to post about PiP, noting that I didn't make any mention, it will be replied about & compared. Toyota designed a platform able to support battery augmentation. It allows them to leverage something already profitable, by just switching to a larger pack and offering it as an upgrade option. That's genuine progress, pushing forward a high-volume choice even further into middle-market. GM bet the farm on an approach which didn't work out. Simply reducing cost is not enough to reach mainstream buyers. They have even stated that, quite clearly. Despite that, certain individuals choose to disregard goals and just flaunt EV range and EV speed instead. Talking about not even trying to be constructive. Keep denying, making excuses, and diverting attention all you want. That won't help GM advance though. Their own traditional production will continue to grossly overwhelm their hybrid offerings. That's the true competition and it's far more difficult effort than imagined to overcome the barrier it presents. No matter how appealing Volt becomes, there will be countless consumers who will simply keep purchasing Malibu & Cruze anyway. That's why a profitable choice which doesn't compromise the priorities those buyers have must also be offered. In other words, don't mock Toyota for already doing what GM will end up having to do too.

8-16-2014 **Know Your Audience.** Buried in a stream of Prius insults coming from a Volt enthusiast who enjoys belittling, something somewhat constructive emerged: *"If that's the goal, OK."* That was unexpected, especially considering how the rhetoric is ramping up again. Though, there is no expectation of that having much of an impact this time. With each automaker taking a different approaches and GM itself changing their tune, the same nonsense as before won't be possible anymore. A bit uncertain how the information will be accepted, I responded with this: Middle-Market buyers couldn't care less about those descriptions or labels. They just want something that's affordable, reliable, and comparable to what they currently drive. Things like EV purity are not a priority, which is the very reason they are part of the mainstream rather than being an enthusiast. It's no different than other appeal factors we've seen as a draw for low-volume vehicles. With a plug-in hybrid like Prius, they'll see the instant MPG gauge at +100 while traveling at 65 mph on the highway and be pleased. Arguments of whether or not the engine is running then would fall on deaf ears. It's pointless. They'll see the efficiency gained from the electricity and understand the benefit for plugging in. That's the goal. Achieving high-volume sales to the level where reducing traditional vehicle replacement becoming noticeable requires far more than trying to selling the benefit of being cleaner and not dependent on oil. The high-efficiency vehicles must be directly competitive on the aspects ordinary consumers find important. Things like comfort & convenience cannot be sacrificed. They simply won't be interested. The lesson of "who" has been taught many times since the introduction of hybrids. It's vital to understand what the audience will actually purchase, not what they find impressive.

8-18-2014 **Change, acceptance.** The situation is getting ugly. More and more evidence is emerging that Toyota's approach was correct all along. GM's scramble to remake Volt in a fashion suitable for the masses is an admission of error. A few can't stand the idea of falling victim to the very thing they claimed Prius had suffered. They don't want to admit having misunderstood mainstream buyers. That question of "who" has burnt them severely. The importance of knowing your audience has become painfully obvious. So, starting the morning with this was a sign of trouble about to erupt: *"Here on a slow news day, we've already seen a re-report that the Bolt name seems likely for a down-market Volt. How this was arrived at was not explained, but the story went on to unequivocally state the new Bolt "will" cost around \$30,000, have a smaller battery, and less content than the Volt. This, "will" reportedly combat customer complaints that Volt is too expensive and let GM price the next-gen Volt higher."* That wasn't liked at all. It basically cancels out any advantage GM made have supposedly had, resetting customer expectations from 2010 to 2016. Meanwhile, they know next year will bring improvement to Prius. The news is a bitter pill to swallow... which means anyone pointing it out is in for some serious retaliation. Remember the lashing out we saw at the end of 2012? Basically, the fear that GM would "kill" Volt has been realized. They always knew it would actually live on in some way. Seeing the model they cherish no longer be the emphasis of sales was the true concern... and that's exactly what will happen. The original will remain a niche for enthusiasts and the new will get lots of attention from ordinary consumers. Acceptance of that is difficult. Finding a scapegoat is easy.

8-18-2014 **Change, reaction.** It's bringing out the worst in a few. The pattern is all too familiar. Personal attacks went from annoying to terribly offensive. I summed up my observation by posting: The big GM forum didn't react well to the introduce of C-Max Energi. They could handle Prius PHV references, but Ford's new offering was too close to Volt. The long-time posters quickly discovered arguments of how the efficiency was achieved didn't matter. So, they lashed out at those providing the information. Moderators had to step in, not wanting the integrity of the forum to fall apart due to the poor behavior of their own members. It worked out well. That restored civil exchanges. This time, here on this daily blog, the situation is more complicated. Volt will retain premiere status, but a second model will emerge... one that's intended to be an option for the masses... which vindicates those who had pushed for that all along too. The potential of "*Volt lite*" makes certain enthusiasts very uncomfortable. They don't like the idea of Volt with a smaller battery-pack and less content to make it appealing to ordinary consumers. The very goal GM is striving to achieve, they don't want. That model of Volt will become common. It's success will draw attention away from the one they are quite proud of. It comes down to whether or not they will join the team. The idea of embracing other offerings from other automakers at a level, all competing against everyday cars rather than being a niche leader, is difficult to accept. They've spent years avoiding that, hoping the technology would somehow experience a breakthru to allow it to be cost-competitive without having to tradeoff any aspect of performance. The reality of for-profit-business is crashing down. Evidence of that is quite apparent. Change is coming.

8-18-2014 **Change, proof.** Confirming the end has arrived certainly was easy today. We had the paranoid conspiracy guy and the guy with a personal vendetta. Posts were from them were flying. Both trying to make myself and another feel so unwelcome, we'd leave. Of course, my posts prior to that were down to almost nothing anyway. It was the recent news of the "*lite*" model which stirred this particular pot. Both needed to vent their frustrations and we were the scapegoats. My final reply to that nonsense was: A moderator's handbook would call this the "*nothing to lose*" stage, where it is obvious the venue has run its course and those clinging on to what's left get rather desperate to prevent change. In this case, Volt was promoted as vehicle for middle-market, but an expensive niche was delivered instead. The hope by enthusiasts was people would be drawn to the above-and-beyond qualities. That didn't work, despite the generous tax-credit and large price-reduction. Knowing that Two-Mode fell apart after a few years, the strategy with this was to delay until the next generation. But when news of the next generation came and it also included an alternative choice, things got ugly. We now see excuses, chest-pounding, and a stream of insults, nothing constructive. That's the proof of change. It's over.

8-19-2014 **Change, desperate.** There's always one who hears the word "*Prius*" regardless of what you say. He's angry from having lost and wants to keep fighting. When you make no mention whatsoever about Prius or Toyota, he'll claim you did anyway. It's quite bizarre. The responses are blatant trolling. Everyone can see the posts were exclusively about GM or only had reference to another automaker (almost always Ford), but you'll still get blamed for defending Prius & Toyota regardless. I guess the hope is content of the messages aren't actually read, that people will assume that's what you met. So, we have to deal with that spin. It's seemingly endless. Until something like this emerges: *"How much \$ does Toyota make on a standard base Prius? It took 17 years for Toyota to even turn a profit. The Volt is only 7 years from concept and 3.5 years on the market. Yet you love to deem it a failure already. Conquest sales, along with painting GM as a hi-tech innovator are successes by themselves."* The other guy, who had joined into the fray with me, ended up responding with humorous dismay. How could anyone be so desperate they'd just make up a lie so obviously false? Toyota's hybrid sales reached the million-per-year level a number of years ago. That would be impossible if profit wasn't being made. Heck, Prius has been the top-seller in Japan for quite a long time now. To make such a wild claim in an attempt to defend Volt is remarkable. Of course, the reality is that Toyota achieved profit from Prius by the end of the first generation (way back in 2002), a whole year prior to the rollout of the second generation. That's what should be happening with Volt by GM now. So, there's obviously pressure building for that to happen soon... especially since we know Volt is much older than 7 years. GM experimented with EV1 drivetrain variations, showing prototypes back in 1998, including a hybrid approach... which would have given them a 10-year head start on Volt, had they not abandoned it in favor of monster-sized guzzlers. Remember Hummer? Long story short, that is quite upsetting. So, people like myself are recipients of their frustration that this latest effort didn't amount to more than just conquest sales and a bunch of trophies.

8-20-2014 **Change, profitability.** Ultimately, it always boils down to that. A for-profit business must earn profit. It's that simple. What's complex is how profitability is calculated. Some people like to include development cost, especially when it comes to hybrids. They exclude them for traditional vehicles though. That's how you know they aren't be constructive. They also exclude advertising budget, which is almost non-existence for Prius but enormous for traditional vehicles. It's basic accounting & economic misleading by omission. That's quite frustrating, but not remarkable. We get remarkable from the desperate. To my surprise, it was the anti-Prius individual who couldn't let the profitability argument cease. He posted a rebuttal today, with some rather obvious points excluded. It was the usual spin. I responded with pro-Volt information. He won't like that, since the offering of another model will wreck enthusiast support. But since the goal is mainstream accept, who cares? (Notice how "who" comes into play again.) Anywho, this is how I responded: 2002 is when profitability was achieved, a year prior to second-generation rollout. It's well documented. As for the "after conception" spin, it's easy to see how that's being avoided with Volt. There were EV1 variations, including those with engines, shown way back in 1998. Also, let's not forget about Two-Mode and its plug-in prototypes. That confirms GM's efforts were on a similar timeline. Yet, those years aren't counted to make Prius appear older. Of course, we already knew the true situation from the PNGV program. All automakers were pursuing the same goals at the same time, starting in 1993. That Toyota profitability was achieved in-part by offering a variant of Prius, known as Echo. The hybrid system was replaced with a traditional transmission and the engine detuned. It was a clever way of reusing what was already available, taking advantage of high-volume to help reduce overall production cost. That is also why the third-generation was designed from the start to utilize a larger battery-pack. It could take advantage of lithium cost falling without requiring a generation upgrade. GM will be offering a variant with the second-generation, attempting to take advantage of high-volume for profitability in a similar fashion.

8-20-2014 **Change, question.** I chose to conclude by stating... Get use to the answer to this question becoming the focus of discussions: What do the KWH and GALLON values tell us? It's a clear effort to take the next step, a constructive effort to look forward. We know there's nothing in the past to prove that will make an difference anymore. Marketing claims about engineering approach won't either. We know driving patterns vary so much there's no consistency in results. Automakers are a for-profit business. EV purity is an ideal of enthusiasts, not a purchase priority of ordinary mainstream consumers. The desire for higher MPG through the use electricity is appealing, but there is no evidence that middle-market is willing to pay for the absolute of no engine use until all the electricity is first consumed. Promoting a high-efficiency vehicle by informing consumers about their KWH and GALLONS usage is the proper way to tell them the outcome of their drives. After all, the MPG value doesn't actually provide any information about GALLONS consumed. It's only a relative measure... which has contributed to many, many problems over the years. So what if the upcoming "lite" version of Volt has a smaller battery-pack and offers less EV in favor of blending. The point of GALLONS reduction through the use of more KWH is still achieved and far more will be sold due to it being better matched to the traits of high-volume vehicles. Offering increased interior room and an affordable price is a required tradeoff, a necessary balance to appeal to the masses.

8-21-2014 **Change, answer.** To my dismay, the response was blatant greenwashing. But when dealing with someone who's got nothing to lose, it wasn't a surprise. Agreement of any sort means the end to what he's been desperately trying to retain. Holding onto the last bits of "*vastly superior*" is something we've witnessed before. Two-Mode was the first colossal letdown, where expectations were built up so high it just plain wasn't realistic for any type of triumph. We saw the same mistargeted approach then as we do now. It appealed to so few, how could it result in high-volume sales? So naturally, posts in defense of it kept getting worse and worse. Eventually, the same thing played out with Volt, on the big GM forum. So, seeing a repeat of that very behavior on the daily blog was inevitable. It's still hard to believe someone would attempt to mislead like this though: "*Mainstream consumers don't even know how these cars work let alone start thinking about MPGe or Kwh.*" See what he did? I call that being dishonest. Others may say it's being disingenuous. Whatever the case, it certainly wasn't constructive. That change of "GALLONS" to "MPGe" was reprehensible. But it's not really worth the effort without someone who doesn't care. It's also redundant, since purpose of the Miles-Per-Gallon-Equivalent value is to take kWh into account. Stating it twice adds to the confusion consumers are already struggling with. In fact, that new measurement approach has been so misleading, those wanting to inform people about plug-in basics don't use it. They refer to fuel quantities instead. This Volt enthusiast intentionally made it appear as though I had used it too, hoping others reading his post would dismiss my information just as quickly as he did. Misquoting is a deliberate act used when someone is attempting discredit. Rather than debate fairly, it's a dire final effort to prevent change.

8-22-2014 **Groundwork.** Reading this from a Ford spokeswoman today made me wonder: "*Ford has done more technological development in the last 10 years than Toyota*". She went on to add that Toyota's latest Prius redesign failed to provide a significant increase miles-per-gallon. Sadly, I don't have the exact quote for that, though there was this which followed: "*Basically, give me the Fiesta they have now with the 1-liter engine, and I think they can get 60-plus mpg ratings, which Toyota needs to get with the next Prius. Ford has laid more groundwork for its next hybrid than Toyota.*" That's obviously far from the vague comments provided by GM, but what difference does it really make... since that large of a MPG increase wasn't even a goal. Toyota clearly stated their primary objective was cost-reduction. Who ever said 60 was needed in any regard? For that matter, who said it is later either? The market has been begging for competitive prices. A large increase with efficiency won't sway those who have a budget. Mainstream buyers shop with price as a high priority. Efficiency is nice, but it's far from being a compelling feature. The attitude of being good enough is all too clear. As for those "*more*" comments, since when does quantity of work make any difference? In fact, having less is the point. You want a well thought out platform to build upon. The buzzword for that is "*future proofing*" a design. It's how business is effective and risks are minimized. Stepping up to the challenge is worthy of praise, but already having prepared for it is often overlooked. It often results in criticism too, from those who don't consider the industry as a whole. Hopefully, Ford will end being in a position to compete directly. Everyone will benefit from having a variety of choices for middle-market.

8-24-2014 **Final Post?** That daily blog is nothing but a shell of what it had been. The scene of the last stand is there. But with no more battles to be fought, the war is over. Volt is not "*vastly superior*" to all other plug-in offerings. Supporters are not looking at it as a major player in the team instead. That irritates enthusiasts, who have all but entirely lost their audience... including me. They are without a goal. There is no purpose there anymore. It's just a venue to repost the same topics already available on the parent website. So, I gave this parting message a try: I'm well aware that it's not in good form to use "*you*" when addressing a volatile topic; however, that is not the case at this particular time of transition... which we have arrived upon just recently. Having friends who own Volt, Leaf, and Tesla plug-in vehicles, it is quite obvious to me that the few here who continue fighting against change are not at all representative of the majority. That's why taking the time to address them directly is worthwhile... even if it does stir the pot the wrong way. They will be helpful later with the effort to demonstrate viability to the mainstream. Talking to ordinary consumers about hybrids, it's disheartening to hear how quickly they still dismiss them. The same old arguments about payback and replacement are sighted as their reasoning. It's quite sad, but understandable. That's why the importance of having a good relationship with those who truly want to move the industry forward is being addressed now. The high-volume vehicles are what will end up swaying the masses. A vehicle like Prius PHV will contribute quite bit to the reputation of lithium batteries. Nothing elaborate is needed. It's just an option on a familiar platform. The push to get GM to do the same has been a challenge. All along, there's been resistance to the idea of less being more, from Volt enthusiasts... those who feel more is necessary, even at the sacrifice of cost & space. Fortunately, more and more Volt supporters are helping change that turn by endorsing a "*lite*" model. They see the true opponent is non-hybrid sales. Too bad for those few who still want to Volt to stand alone. The goal is to make the platform common, to replace the popular traditional vehicles. That means seeking out a balance, not trying to convince people to spend more for more than what they actually need. The second model will indeed dilute the spirit of the original, but that's called progress. It will still accomplish the ultimate purpose of reducing emissions & consumption. We are now seeing attention getting drawn to Ford, as they attempt to compete directly with Prius, while also advancing their current hybrids. We see Toyota diversifying, investing in fuel-cell technology while at the same time improving their hybrid platform with a next-gen rollouts, while also experimenting with a dedicated plug-in. There is no standing alone anymore. Change is happening and market offerings will become far from clear. Each will be somewhat different in operation. What they'll all share is reduced use of non-renewable fuels and reduced smog & carbon emissions. Their adoption will be hypocritical & abrupt too, just like we saw with handheld devices. Remember the PDA years? Most people were clueless about their potential. Then suddenly, we see them everywhere in the form of smart-phones. That's because they changed to become extremely practical by being made to closely match ordinary consumer interest and were offered in a wide array of choices.

8-25-2014 Heat Push - Video. Any hotter outside, you'd just turn on the A/C to stay cool. Since the battery-pack in the car also uses the cabin air to stay cool, it benefits when you're comfortable. So, this particular drive with the windows open instead was the ideal for demonstrating effectiveness of cooling without the A/C at a high. To add to the observational opportunity, I started the drive with the battery-pack already warm. Recharging had just finished shortly before and the car had been sitting outside in the sun since parking that morning. Pushing the limit, I kept the engine off, climbing out of the river valley on the highway. That meant speed of travel was a little over 55 mph with the engine not running, all the power coming from electricity supplied by the battery-pack. All that combined equates to lots of heat being generated. The system is well thought out and tolerances should stay within the normal tolerances of lithium battery chemistry. But this was a collection of circumstances most people would normally avoid. Turning on the A/C when the temperature exceeds 80°F is an ordinary thing to do. Allowing the engine to run briefly when merging onto the highway or climbing a long, steep hill is too. None of that is a big deal, but I didn't for the sake of collecting data about what actually happens with the battery-pack than, by allowing a heat push. The data itself was interesting. Rather than starting with the usual battery-pack temperature in the upper 80's, it was the upper 90's. Specifically, the drive began with an extra 9°F degrees to have to deal with. The 45 to 50 mph drive out of the city to the highway was uneventful. Heat only went up by 2°F degrees. It was the merge onto the 55 mph highway with an immediate climb out of the river valley which pushed the temperature into uncharted territory. I hadn't ever observed it beyond 102°F. Driving on the flat for the next 2.5 miles using just electricity only bumped it up another degree. That was nice, especially considering the speed. Then I hit the 70 mph portion of the drive. That stretch of highway meant the engine would join in. When that happens, the battery-pack continues to be drawn from. I was curious what that would do to the temperature. Turns out, that is what pushed it to the highest I had ever seen. Watch the engine RPM when has heated coolant (for emission cleansing) to the HV warm-up temperature of 145°F, at 9.4 miles into the trip. Though brief, you can actually see the battery-pack had already reached a peak of 105.8°F and was starting to fall, even though electricity draw was continuing (as indicated by the SOC value). I don't ever plan on driving that particular scenario again. Taking advantage of the engine to climb out of the river valley is a better use of the available fuels. That way, more electricity would have been saved for while driving on the faster section of the highway, so the engine uses less gas then. The point of capturing data was well served. That peak temperature was nothing to be concerned about. But even so, it's best to keep the battery-pack cool, by doing things like turning on the A/C while driving and parking in the shade. Not recharging during the afternoon when the car is already warm is an obvious thing that's easy to avoid too. That's how the battery-pack will last the entire lifetime of the vehicle... [Prius PHV - Commute Home \(Heat Push\)](#)

8-26-2014 **Clear Progress.** The newest video and feedback to is has been quite encouraging. I added more to that sentiment, pushing even more for closure acknowledgement from others. Change is exciting... to those who embrace it. For the few who aren't ready, they either turn hostile or simply disappear. That's quite an extreme, but a pattern we're very familiar with. Other chapters of the past ended in the same fashion. In fact, that's how you know it's over. The start of the next is then filled with new voices. That progress is very encouraging. We don't want to forget how that was achieved though. You want to build off of that success, to take what was learned the next step forward. This was my contribution to that today: It's nice to have that level of detail available now. There was quite an effort in the past to undermine Prius PHV, claiming it was necessary to have a liquid cooling system for the battery-pack. Yet, those making those statements never actually provided any data. The hope was that you'd assume they had supporting evidence. In reality, they were just passing along vague & outdated bits of information. I found that rather frustrating. They were clearly trying to convey a message of superiority based on people's lack of background. It sounds likely, so it must be. But what tipped me off early on was that those same individuals would also claim Prius PHV could not climb hills using only EV. This video not only shares detail about battery-pack temperature, it also shows they were intentionally trying to mislead. After all, how many times must owners point out what they say isn't true before you have to resort to actually showing it? Thankfully, owners of other plug-in vehicles have joined in to help. That's a very positive sign that the market is changing. We're past that initial rollout where there was something to prove. Now, it's a matter getting the attention of ordinary consumers, sharing our stories of day to day experiences.

8-27-2014 **Vastly Superior.** In their spirit of closure, I gave the most irritating of Volt trolls on the big Prius forum one last bit of attention. He dropped this bait with the hope someone would bite: "*The normal Prius had a patch added by the factory.*" I obviously hit him where it hurt, because there was no response. It is now 4 days since I replied too. People like him can sometimes be helpful, as with this particular argument. Posts get refined after repeated attacks. We learn how to rebut the undermining with simple & concise messages. They eventually give up. Of course, that sometimes results in a new argument being started. But at that point, reputation for not wanting to be constructive is easier to see, like the dismissal of facts. Our bite on the bait is rather fierce. Why hold back when you know ordinary exchanges of information are not enough. Rather than accept vague, we overwhelm with detail and point out elements difficult to dispute. It typically works nowadays too. That certainly wasn't the case years ago... which is even more evidence of that chapter having come to a close. We've moved on. Will he? The lack of anything following this post is a positive sign: The regular Prius comes with a 60 kW electric motor, yet it has a small battery-pack which only delivers a fraction of that. How do you explain such obvious under-utilization? Toyota built a system that could be upgraded when cost of the battery dropped to a competitive level. The strategy of planning ahead to minimize financial risk and to fully test the system ahead of time is called good business. Calling that a "*patch*" is inappropriate. We can clearly see how the extra power from the larger battery improves the regular Prius without having to do anything other than pack upgrade itself. It's a package option, in a market where using electricity is still a niche and is still dependent on tax-credit incentives.

8-28-2014

Victory. Our compulsion as a society to hold out for victory rather than accept any type of compromise is a major fault. We've seen the terrible consequences of that mindset from the wars we've been involved with. Heck, we even see it with the game was play. Notice how professional sports here don't end in a tie, how overtime is required to determine a victor? The idea of congratulating both teams for a game well played isn't acceptable. One must win and the other lose. That's what we've been taught. So, achieving closure with the current generation of plug-in vehicles is quite a challenge. It's why certain individuals would rather fight to a bitter end than to welcome the opponent as a worthy adversary. Oh well. I summed point-in-time we are at now this way: The nonsense of the past is over. Most of that is due to having such thorough data available now. With so many owners sharing their real-world experiences, the hype is just a bad memory. There were groups who would generate quite a bit of hope based on vague statements. When those of us trying to keep discussions constructive asked for support evidence, we got labeled as trolls and down-voted. They were actually the troublemakers. We even had to deal with well-proven facts getting dismissed... until it was discovered how effective videos could be. Words alone weren't enough. That's become very clear on the various forums & blogs. It is now quite easy to squash a false claim by simply posting a link to a video. Evidence of the change in focus became easy to see the start of this year. The shift of attention over to sales is the hot topic of discussion now. It's not exactly constructive in all venues though, as this quote from yesterday tells us: *"If even the PiP is now outselling the Volt with its pathetic range and performance, I think that leaves zero doubt that there'd be a market for a cheaper 25 mile Volt option in 2016."* That's still a bit on the insulting side, but at least it's progress. The posts which followed that topic-opening statement were a mix of helpful and misguided. That particular audience still doesn't want to acknowledge the reality that Prius PHV sales remain limited to just 15 states, that some Volt sales are the result of expiring leases being replaced by new leases, and that tax-credits will expire during the life-cycle of next-gen offering. Nonetheless, the true measure of progress is finally being recognized as important. We've moved from engineering bragging-rights to what discussion that includes being practical & affordable. They say third time is the charm, but to have to endure both Two-Mode and Voltec failing to draw sales prior to that was a massive waste of resources. All the time & money that was lost due to focus on want rather than need... Anywho, being able to sum all that up and declare closure on those chapters in history is great. The more-AER and anti-blending chants have lost their audience. The market has moved on. Remember how it was based upon the *"range anxiety"* campaign, which proved to be a non-issue. Sales of Leaf became undeniable evidence that having an engine available was not essential. Offerings will be a wide array of configurations, even the increasing talk of a *"lite"* version for Volt support that. We welcome the change, especially due to it having been so painful to reach this point.

- 8-31-2014** **Looking Back.** I wrapped it up with this: It's over. There is nothing left to debate/argue/flaunt about the first-generation Volt anymore. Attention has almost entirely shifted over to the second... and we're all wondering if the hype will begin again, or if it will finally become a realistic high-efficiency player. The last constructive comment I got from an enthusiast was the current served its purpose well as a "*halo*" vehicle. The catch is, we all know that is not what it was intended to be. The goal of being a mainstream seller by the third year fell apart quickly after rollout. Of course, those who refused to state goals prior to that were aware of the problems early on. That's why the "*too little, too late*" concern was so irritating. They knew what was delivered had veered far from both what was wanted and what was expected. What mess. To make matters worse, Prius ended up making so much more of a difference, accepting failure to make moving on to the next attempt was very difficult. Thankfully, we have now arrived at that point. Hearing that worldwide sales of Toyota hybrids came to 665,740 for the first half of the year, there's no way to deny how much "*gas saved*" happened as a result. The next step must be taken, but it will be in a very different market... one without tax-credits. The high-efficiency choice must be able to compete directly with that automaker's other offerings. It won't matter what choices come from elsewhere. It will come down to what's on that dealer's lot. That's why it has been so important for Toyota to focus on deeper penetration within the existing markets. Figuring out how to sell to consumers in an area already saturated is far more difficult than appealing to enthusiasts. That's why discussion of a "*lite*" model of Volt is no longer outright dismissed. Delay time is being used up. Being able to deliver high-volume and low-cost is becoming absolutely necessary. Toyota is already selling 1 million Prius annually. Improvements from the next-generation combined with increasing pressure on reducing emissions & consumption will make it a nice choice for ordinary consumers. Looking back, we see how Toyota stayed true to need and how GM decided to favor want instead. Looking forward, we certainly hope need is taken seriously.
- 9-03-2014** **August Sales.** Nothing new to report. Sales of high-efficiency vehicles are flat. Sales of traditional vehicles are strong and growing. Cheap gas and little to no concern for the air we breathe and dependency on oil makes for a very difficult situation. That's why it is so important for the high-efficiency choices to actually be competitive. Those who choose to measure success based upon sales of other plug-in vehicles, rather than looking at the market as a whole, are worse than cherry-pickers. That refusal to acknowledge the true situation has consequences. In other words, sales to improve quite a bit. Status quo is really presenting challenges. Sad.

9-05-2014 **EV-Boost - Video.** Unlike the *"heat push"* video, when I did everything I could to stress limits through ordinary circumstances, this was a demonstration of what an owner is more likely to actually do. Avoiding direct sun is the most obvious means of protecting the battery-pack for longevity. Since rain was in forecast for later that day, the cloudy conditions would ensure the interior of the vehicle didn't get too warm. Another technique is giving the battery-pack time to rest both before & after recharging, which I did. That gives it a chance to cool in the meantime. The humidity level had climbed nearly 100% by the time I was ready to leave work. That moist air was uncomfortable. A/C use was the sensible choice for interior cooling, for both myself and the battery-pack. My plan was to drive that same route under similar EV conditions as the *"heat push"*, but at a cooler temperature for summer had worked out. (Sometimes, you get lucky!) A few drops of rain had just begun to fall. The edge of the approaching storm made for a rather scenic situation to film, while also serving as a comparison video. The drive itself was indeed quite ordinary. Having started out with both a lower air-intake temperature and all 3 battery-banks on the cool side, the data expectation was it would be quite a contrast. Sure enough, that drive home was what I had hoped... other than I forgot to reset the display statistics before drive. So, you get to see my overall results for the work commute, morning & afternoon drives combined. Looking at the temperatures, the effectiveness of the air-cooling system is clear. It works well. Also, to my delight, that same route driving with the windows half open was barely any more efficient overall than just running the A/C instead. I now have data showing the penalty for being comfortable is negligible. It's nice to see results so revealing. Using the electricity for cooling and the engine for assisting delivers a clean & efficient drive. Gotta like that... [Prius PHV - Commute Home \(EV-Boost\)](#)

9-06-2014 **Good Questions.** This was asked today: *"Why isn't Toyota building more PiPs? Do they lose money on every car sold? Are they worried about reliability and don't want too many out there?"* The answer boils down to audience, no different than what we've been seeing for years. That aspect of business is absolutely vital. Simply building & offering a nice product isn't enough. That's the lesson GM has learned the hard way. You have to understand what they buy. I responded with: This topic has been discussed in great detail many times. The aspect which continues to float up to the top is: Staying within the initial rollout states has the advantage of learning how to penetrate a market which has already satisfied early adopters. In other words, Toyota wants to figure out how to appeal to ordinary consumers. It's absolutely vital. The reality of tax-credits expiring and HOV stickers running out is a very big deal. Toyota would like to be well positioned for when that happens, which means figuring out how to achieve mainstream sales. Knowing that in advance of rolling out the next-gen design will have a big payoff. Simply building more won't reveal that desired information.

- 9-08-2014** **Red-Herring.** It's easy to see how the fuel-cell offerings will be used to confuse & mislead. It's getting annoying already. In reality, it's really a distraction. What happens with fuel-cells doesn't have any bearing on what happens with hybrids. They will co-exist. But you know how certain people want to paint a different picture. For example: *"The three biggest reasons for car buyers not purchasing plugin cars are: high upfront costs, fear of new technology, and lack of public charging stations. Honda and Toyota's answer to low plugin sales is fuel cell vehicles. Good luck with that!"* Knowing how to respond is a challenge, since the comments will basically fall on deaf ears. They want you to waste time on the distance, hence being a red herring. It's much better to stay on topic, rather than follow. But sometimes, you can't resist: The effort to offer fuel-cell vehicles is in no way related to plug-in cars. They are mutually exclusive. They are a diversification of business product. They are not a replacement. Toyota has been working to reduce upfront cost at the same time. The question has not changed and neither has the answer. That's why Toyota hasn't been pushing the plug-in beyond just raising awareness and building up real-world experience. The choice to share a platform with the non-plug model is an obvious path to reduced cost from high-volume production. They are preparing to compete in a world **WITHOUT** any tax-credit incentives.
- 9-10-2014** **Reluctance.** This was a reasonable assessment: *"I'm starting to suspect, as some posters here have mentioned, that the reason Toyota is reluctant to release the PiP nationwide is because they don't believe there's enough demand in the states that don't normally sell them."* It's based on anecdotal evidence though. Observation of activity, rather than knowing background & purpose, can lead a person to draw an incorrect decision. So, you have to be careful when responding. Being made aware of missing information is part of the learning process. You don't want to alienate someone due to a simple misunderstanding. Here's my attempt at being constructive: That's not reluctance. It's smart business. There has been overwhelmingly confirmation that the mainstream market is not interested in any vehicle offering a plug. Even with great incentives, the plug is confined to just a niche audience. It simply doesn't make sense rolling out a product to the masses when the masses aren't ready for it. Look at how Volt's approach made no difference. Designed with the assumption that *"range anxiety"* would be a major purchase deterrent, the hope was it would crush the plug-only competition. Clearly, that didn't happen. It didn't come anywhere near close to anticipated sales volume either. The goal of being able to offer PHV as a competitively-priced Prius package option is especially challenging in a market that doesn't even embrace hybrids. Prius sales are flat and the other automakers face even more of a struggle. What would there be to gain by expanding rollout right away? It was smart of Toyota not betting the farm on a single choice. GM really backed themselves into a corner with Volt. No one knows what their next move will be or even what it should be. At least with Nissan, we see the commitment and a solid plan forward. The path for Ford is clear too. But none are in a position to compete now. Traditional vehicles pose far too great of a barrier to overcome still.

9-10-2014 **Change of Season.** The temperature here has plummeted. It's 30°F cooler now. Conditions have switched from being comfortable with the A/C to desiring use of the heater. That certainly will change the data for me to collect. Last night was the first taste of it. I set the timer, but forgot to actually plug in the Prius. That's what happens when you're in a rush. Anywho, the drive out from one end of the cities to the other... without any EV charge available... resulted in an average of 59 MPG. That's certainly nothing to complain about and it got me thinking about battery temperature. On the return trip this morning, I got 59 MPG again. But this time, I started with both an engine & battery that didn't have any hint of warmth. In fact, I had to fire up the heater. It was just 52°F outside and I was still dressed for Summer. The Fall conditions immediately revealed interesting data. The battery banks reached highs of only 79.12°F, 80.26°F, and 78.92°F. That's well below even the starting temps I had seen just last week with when pushing EV with it hot outside and no A/C cooling. HV driving clearly isn't anything to ever be concerned about. I'm looking forward to observations with plug-supplied electricity now that the warm season is just a memory. Winter will make things especially interesting. I sure am glad for having figured out how to share all that heat data before the cool arrived. It should be quite a contrast when you're required to wear a jacket & gloves.

9-11-2014 **The Turn-Around.** We've reached that point. Hold on. It's going to get ugly. You can tell something is amiss when "*this is what I meant t say*" is used in replies to a rebuttal. In other words, those who have discovered they've lost the battle are attempting to stay in the war by now finding a way to agree. That's been happening a lot recently, coming from those who have firmly stood their ground for years. An abrupt change of stance like that doesn't make sense. But with the real-world data so plentiful, clearly confirming they were wrong, what other path is there... other than to save face by backing down for now. It's quite hypocritical, though welcome nonetheless. Not fighting anymore is nice. In the end, it doesn't matter anyway. There's an entirely new audience waiting. I went through the drive-thru the other day and absolutely fascinated the employee who looked in and commented on the dashboard. He had no idea I was driving anything special until pointing out the current 81 MPG average. That certainly got his attention. So, the nonsense with Gen-2 of Volt will begin shortly. Wait for it, a bang after a delightful silence. This isn't a prediction. It's just observation and good memory. We've seen the pattern before. It will happen again. Lessons of the past will be completely unknown. They'll consider that a fresh start with no possible connection to errors of the past. It's a turn-around, but not necessarily in the right direction. Sorry to be so pessimistic, but stuff happens.

- 9-19-2014** **5 Years Ago.** The calm lasted just a little over a week. Ugh. The daily blog for Volt was basically dead, barely any mention of this generation anymore. It was just casual mentions of plug-in related topics, nothing even remotely like anything in the past. Then, bang! Something poked the sleeping bear. That same old hype from 5 years ago showed up again. Excitement about the next generation being superior to the competition emerged from the rubble. Nothing of any substance to support claims is available. Yet, the chest-pounding started. GM will crush the competition... even though who they're competing with is a mystery. It will be better and that's all that matters. There's no point in asking for goals this time. With the previous rollout, the avoidance to acknowledge and obvious back-pedaling made it quite clear that particular group was just a bunch of enthusiasts who wanted to celebrate some type of victory, even if it was hollow. Giving them something to fight about again is just a waste of time. The pattern is well established. I will post a few facts though, since now there is lots of real-world data to confirm the information. Hype grew due to blind hope. Stuff like driving videos show the true nature of the situation. That's a level of detail well beyond what we had available 5 years ago.
- 9-20-2014** **Questions.** It's refreshing to get ordinary questions, new owners taking notice of more as they drive, then asking for more information. The craziness from the supposed competition is annoying. Ordinary consumers aren't interested in bragging rights. They just want a nice experience from the vehicle they chose to purchase. Anywho, I enjoyed responding to this today: *"Is EV mode only available when the battery has been charged via the charging cable, even though the battery is fully charged via regeneration?"* The discussion already had quite a bit of activity by the time I jumped on board. That too was encouraging. I posted: It's available at other times, but that kind of side-steps the purpose of being a plug-in hybrid. For starters, the behavior of "EV mode" is different for the plug-in than it is for the regular model. The plug offers both more power and more speed. It also allows you to engage it without the emission system already have been pre-warmed, but will consume gas for the sake of cleansing emissions once you have exceeded the power/speed threshold. Put simply, the system is designed to take advantage of plug-supplied electricity. You'll see that by watching the MPG display. At times, it will be sustained at the max, even though the engine is running. That's achieved by taking advantage of the battery-pack to allow the engine to run at a very low RPM, which in turn is very efficient. Those miles of travel won't be counted as "EV" though, since the engine wasn't stopped. They'll be counted as "HV" miles instead. Over time, you'll observe when it's best to allow the system to do that. The "HV/EV" button lets you disengage that electricity boost. For long drives on the highway, you'll find saving the battery-pack for later better overall. You'll also discover there are circumstances that will allow you to top-off the battery through brake-regenerating, like when exiting off the highway. It's quite a dynamic system, very smart with how it utilizes the electricity available by taking advantage of the engine at times.

9-21-2014 **Meaningless.** This was the first of the superiority posts I chose to respond to: *"That EPA value is as meaningless as saying that your Volt uses 5 gallons to travel 200 miles, when every ICE users understand miles per gallon and few travel 200 miles in one day or trip. We have to educate correctly. A meaningless value confuses even more, and more questions will be asked. Keep it simple, straight, and related to something that has a cost."* I found it very amusing that his attempt to greenwash was so blatant. There's been a huge effort to educate which focuses heavily on how misleading the MPG value is. In fact, that was the very reason those new EPA values were created. Yet, he attempted to claim the opposite. It makes you wonder what other concepts he has a fundamental misunderstanding of. That would explain the constant arguing. Anywho, I responded with: Actually, most of the rest of the world uses QUANTITY/DISTANCE to measure efficiency, which has been overwhelming proven a more effective means of conveying that information. Our misleading system of MPG is being phased-out in favor of using QUANTITY/DISTANCE instead. For far too long, advertisers have exploited those MPG misunderstandings. People assume that the measure is linear, when in reality it's a diminishing return. That's why the difference between the higher numbers is less and less. See how the gallon reduction is less as the MPG increases... 300 gallons from 50 mpg. 200 from 75. 150 from 100. 120 from 125. 100 from 150. 86 from 175. 75 from 200.

9-21-2014 **Most Important.** Like the other post, I suspect the reply to this will fall on deaf ears too: *"And for plug-ins the most important number is the electric range, so that should be the largest text."* The only reason I even bothered to respond was these numbers didn't exist 5 years ago. There was no standardized measurement approach available back then. Now that there is a basis of comparison, it's not good to allow misleading to take place. It's like watching a bully. If you don't speak up, you're an enabler. In this case, these particular Volt enthusiasts are still trying to push the purist view. Any blending whatsoever is considered a violation of what they hold most dear. It's actually quite amusing, a source of entertainment at this point. When GM finally offers a lite version, they sure are in for a reality shock. No matter how much you point out the goal of reducing gas consumption doesn't require elimination, they cannot come to terms with electricity utilization actually being wasteful. How that electricity is consumed is more important than making sacrifices to prevent the engine from running, even if brief. Whatever. As time progresses, that real-world data will also become difficult to avoid. I simply put it this way: You mean KWH capacity, since RANGE is not a constant. Think about the impact temperature has. The amount of KWH the battery can deliver is always the same, but the RANGE you actually get from that varies significantly. Then there's the benefit of taking advantage of the engine at times. You're still consuming that same KWH, but it won't be counted in the RANGE due to the engine joining to contribute power. It's still the same plug-supplied electricity being consumed, which fulfills the purpose of plugging in.

9-21-2014 **Seemingly.** I liked the way that word was interjected in this quote: "*My sense is that many Prius enthusiasts are "dis-comforted" by Toyota's (seemingly) lowered expectations for a new Prius.*" It was from a 2010 owner who had looked forward to upgrading, rather than having to sell the Prius at a later age. Long product-cycles are tough under normal circumstances. But with the economy recovering at a far slower rate than anticipated and gas prices considerably lower than forecast, it's not much of a surprise the hybrid market is holding steady instead of anticipating change. So, again, I had to point out what should be obvious at this point: Know your audience. Toyota has stated they want to stir interest from those who have never considered a hybrid. That's far more of a challenge than appealing to enthusiasts. Toyota is aiming Prius directly at the mainstream, attempting to hit middle-market hard with the next generation. Offering a base model that uses a NiMH battery-pack will be a let down for an enthusiast, but a serious draw for ordinary consumers... who's looking for a well-proven efficiency technology that's dirt cheap. These are the same consumers who have no idea how an automatic transmission works and simply doesn't care. They just want something reliable & affordable that actually delivers. Toyota's expectations are high-volume sales, not breaking new ground for enthusiasts to thrive. Seeing a Gen-4 Prius easily exceed 50 MPG with a price that competes directly with other popular family cars makes it a big winner, for both business and the masses. That approach reinforces the path for an affordable plug-in model too. Again, that may not appeal to enthusiasts, but it is a choice which mainstream buyers will actually consider.

9-21-2014 **Events Today.** I missed both. There was a big one for Prius out on the East Coast. That just plain wasn't realistic this year. So, I looked forward to the local one for plug-in vehicle at the state capital. Being sick prevented participation with that too. In fact, the 3-day weekend I had planned was a total loss. It's sad. There were 243 owner registered to attend. That would have been fantastic to be part of. Oh well. It's an annual event, perhaps next year. But then again, the hope is for plug-in vehicles to become so common that won't be necessary. You'll just see the variety available on a regular basis over the course of daily drives. That's certainly not the case yet, but the spirit of cooperation is changing things. The ugliness from Volt won't have much of an appeal to ordinary consumers, who will just seek out the more affordable model anyway. They're a different audience... not unlike that of the other plug-in hybrids. For that matter, the electric-only vehicles will attract new newbies too. Put simply, the upcoming new generations will be a reset rather than an upgrade. Though, that does send a little feeling of regret for missing today's events my way. The market, the outlook, the expectations, (and obviously) the choices, will all be different. What's happening right now is a unique stage in history. Remember the absurd times when we had people comparing Hummer to Prius? Some nonsense is hard to believe. It's actually hard to believe close to 4 years have already passed since the calamity GM unleashed too. It turned out to be a disastrous outcome of the "*if we build it, they'll buy it*" approach. The events today set far more realistic expectations, addressing problems & limitations directly... rather than just hoping for the best. I get to meet with the group at the end of the week, for the Fall meeting. Hearing stories afterward are quite informative. That works for me. I'm quite curious to get more real-world battery information, especially with all the thermal research and video-documentary I've done lately. There's much to share and those real-world observations are priceless with so many detail-oriented owners trying to help progress along.

- 9-22-2014** **Brisk Acceleration.** It's interesting to read about observations made by new Prius owners. Experimenting with acceleration speeds can sometimes lead to really mixed up understandings of how the hybrid system works. It often comes from assuming slow acceleration is better. They grew up only knowing how an engine works. You press the throttle harder, more gas is consumed. That's not the case for Prius. It has not one, but two, electric motors. Having just one would make the "figure out" process based on anecdotal evidence fairly accurate. You draw from the battery to supplement the power demand. Prius isn't like that though. The power-split-device combines both a motor for traction and a motor for generating to the engine. That means all of the energy isn't used for propulsion. Some is used for the creation of electricity... which isn't always used for providing thrust to the wheels. Some is sent to the battery-pack. That means you must look at the consumption of energy over the span of time, not just a single acceleration event... hence common confusion. That's why we recommend: JUST DRIVE IT. You're better off letting the system figure out how to achieve the best efficiency instead. But if you really want to give it a nudge, you can. An owner today did figure it out on his own. Reading his observations was a nice confirmation that the system can be understood simply by watching it carefully, even without aftermarket instruments. I chimed into that pleasant thread with: That is indeed an efficient approach, excellent observation. The recommendation for BRISK acceleration came from the days of the classic model and had held true ever since. It takes advantage of the hybrid system, utilizing both engine & motor for an overall gain. Accelerating slowly actually defeats the intent of the design. That Eco-Meter is there to remind you to keep power-demand brief, not to avoid it entirely.
- 9-23-2014** **Just Plain Wrong.** Sometimes, you simply don't know what to make of what newbies post. I jumped into a thread that had taken a turn for the worst: There are indeed people who are able to maintain higher MPG. I just post extensive collections of real-world data and move on to other things... like correcting: "*Toyota system does not assist with highway driving*". That is just plain wrong. 100% of the time the gas engine is providing thrust to the wheels, it is also providing power to the generator. Sometimes the resulting electricity is used to recharge the battery-pack. Sometimes the resulting electricity is used to directly supply power to the electric traction motor. Sometimes both. Having a power-split-device adds flexibility a regular transmission can't even remotely compete with. That energy-flow changes frequently too, between 10 to 20 times per minute is common. The outcome is efficiency optimization a gas engine alone could not achieve.
- 9-24-2014** **No Highway Benefit.** Yesterday's post went no where. Some people apparently think they know, even without data to actually confirm their belief. It really surprises me how there are some still who don't understand how the system in Prius actually operates. The assumption of no assist and no recharge on the highway is not correct. There is quite a bit of electricity generated from normal engine spinning and from the reality that most highways aren't actually flat. With even the most subtle change of pitch downward, you can see the MPG spike. The system rapidly cuts fuel and routes excess power from the change to the generator. The power-split-device also shunts that power to the generator when the reverse happens. The result is energy which would have otherwise been lost... hence a net gain.

9-25-2014 **Being Competitive.** That more-is-better mentality is very difficult to overcome. It's far too easy to dismiss based upon a single attribute. Remember how computers we're rated solely upon CPU speed long ago? This is the message of being competitive spreading now: *"Whatever Toyota has planned, they need to increase the EV range just to stay on top cause the other manufacturers are catching up & passing Toyota."* Simply offering larger capacity batteries isn't a solution. Look at the mess we ended up in from cars & trucks growing larger. That wasn't actually an improvement. In fact, it made dealing with emissions & efficiency even more difficult. We don't need a step in the wrong direction like that again. Substituting one fuel for another isn't really a fix. Expecting that to be competitive is a setup for disappointment. This is how I put it: Seeing that greenwash message spread is disappointing. Do you just happen to know when or how that belief was passed along to you? More is not necessarily better and we certainly don't want to fall into the same trap as we did with speed & horsepower. This market is quite gullible, easy to convince that bigger is a sign of leadership. Misplaced priorities was a big contributor to automotive industry problems in the past. Let's not repeat those mistakes. Those plug-in hybrids with larger battery-packs already are faced with the reality of not having anything competitive to sell and heavy dependence on tax-credits. Traditional vehicles pose far too large of a challenge to overcome. An expensive plug-in hybrid compromising storage/seating space and delivering low efficiency following depletion isn't a solution. Toyota is working extremely hard to deliver a lot from a little. Convincing those who would otherwise purchase a Camry or Corolla is the goal, not trying to upstage other automakers.

9-25-2014 **Labels.** The topic of "EREV" got stirred up again. There are some dead set in their belief of what a vehicle of that type is. When you push for details, their definition falls apart. When you point out contradictions, they just brush them off. It's quite frustrating how they absolutely refuse to be construction. The reason why is obvious. Of course, when I pointed it out today, the reaction was explosive. No surprise. Labels have always been a really big deal, even if they don't actually amount to anything. Oh well. Here's what I posted... on that now quite hostile daily blog for Volt: Arguing semantics is a very old greenwashing tactic. The purpose is to divert attention away from the topic. Rather than address actual results of whatever technology, discussions end up chasing label red-herrings instead. Notice how specifics are avoided, how vague descriptions actually are? There is no official definition, nor should it make any difference anyway. It's the outcome that counts, not what marketing name is used. Thankfully, the emission ratings don't succumb to that nonsense. Rating categories are the same. How that level of clean is achieved doesn't matter. The point is the goal was accomplished. Hopefully, the same will happen with plug-in hybrids. It shouldn't matter how the gas & electricity is actually utilized. The goal is to significantly reduce emissions & consumption.

- 9-28-2014** **Brisk.** It's nice getting comments like this: "*In the Prius, accelerating quickly, especially above certain power levels, is slightly less efficient...*" But you never really know where replies will go. Some of the time, context simply doesn't match. Thinking big picture is often a problem, so you end up arguing with the person. People tend to focus on the moment, rather than considering final results. Hoping for the best, I replied with: That does NOT take OVERALL efficiency into account though. Prius is a hybrid with a power-split-device, adding into the system a generator and battery-pack along with the traction motor. So, that engine-alone efficiency assessment does not apply. When the engine goes beyond the most efficient state of operation, there isn't as much of a loss. It seeks a higher RPM to reduce that, which as a result creates power not needed for propulsion. The unneeded power is converted to electricity for use later, something a traditional vehicle cannot take advantage of. In other words, the penalty can actually be a wash or even a modest gain under the right circumstances.
- 9-29-2014** **In-Vehicle Internet.** When there isn't much else to attract customers, trying new things is reasonable. This one is a strange and doesn't seem to offer anything worthwhile. It's the option of having the car provide 4G LTE service. On the Volt blog, I asked: "*What's the benefit of having a separate plan tied to your vehicle?*" Now, 2 hours later, still nothing. That abruptly brought the thread to a halt, no posts since. Why would you pay extra for something you wouldn't be able to use much, especially when alternatives are already readily available? I followed with this: I already have a shared data-plan for the family. Each phone works as a mobile hotspot without any extra fee. You just flip a switch and have a secure internet connection available for your other devices to use anywhere you go. I can't imagine having to stay within range of the car. With the phone, you can be quite mobile, especially when carrying along a USB battery.
- 9-29-2014** **Fact or Rumor?** Reading this today was annoying: "*GM previously announced the second generation Volt will be able to travel on electric power between 50 to 60 miles (80 to 96 km) or even more whereas the current model can cover up to 38 miles (61 km).*" There was nothing ever but a vague mention about this option being explored. That's it. There was no promise of any sort. But then again, the same thing happened many times in the past with Volt. People built up hype based upon hope, nothing of substance. Even so, properly identifying what was actually promised verses what was thought to be a promise was quite a challenge... hence all the entries here documenting events & announcements while they played out, rather than trying to remember detail long afterward. It should be interesting to see how things play out as the Auto Show circuit proceeds. It's just starting now.

- 9-30-2014** **No News, situation.** We're in that dead-zone now, where there's nothing for the spotlight to shine on. That's putting the "*upstage*" group at a loss. So, they pretend none of the previous rhetoric or hype ever happened. Obviously, it's the next-generation Volt enthusiasts attempting to draw attention. We'll be back to the "*vastly superior*" nonsense in no time. Flaunting EV range & purity is far more rewarding than having to address goals and acknowledge business need. In other words, high-volume sales to ordinary consumers is still a taboo topic. Somehow, GM will magically deliver a product they'll be proud of that will also appeal to the mainstream. Being 2 entirely different groups of buyers, with mutually exclusive purchase priorities, still isn't seen to be a problem. Ugh. The silence from GM makes it worse. The so-called transparency from before is no longer offered. They aren't saying anything anymore. In a way, that's good... since those vague hints of the past ended up doing more harm than good.
- 9-30-2014** **No News, reach.** It's a waste of time bothering with that daily blog. There's nothing new and the audience is tiny now. Reflecting upon the comments still posted worthwhile though: Saying that GM prided itself on its "*transparency*" is a good way of looking at the situation. Thanks for that perspective. They did indeed share quite a bit of detail on the design as it was being developed. The catch was, actual operation information wasn't shared. Certain things were clearly avoided. When the question of depleted MPG was brought up, there was an obvious effort to change the topic. When the question of cold-temperature was asked, it simply fell on deaf ears. When revelations of direct-drive and sticker-price came about, that was proof of the transparency not actually providing facts with respect to goals. Too many vitals hadn't been shared. Ultimately, it comes down to matching audience with expectations. GM had chosen to focus on enthusiasts for the first generation, but hoped somehow that mainstream consumers would be drawn to the same appeal. That didn't work.
- 9-30-2014** **No News, goals.** We all know the "*over promise, under deliver*" reputation and the "*too little, too slow*" concern. Like the vaporware claims, we knew early on something was wrong. There's simply no way to accomplish so much with such a lack of clarity. It starts when you cannot even answer the question of who. What's the point if you don't understand the audience? Of course, we've always known. Some just didn't want to admit the first-generation was directed at a niche. It should have been so easy to see that want had taken the place of need. That's because sales of mainstream vehicles are not exciting. Being common means not standing out. That was a direct contradiction to what stirred excitement. So, what mention it now? The reason is these upcoming announcements about second-generation plug-in hybrids are really important. The goal to survive without tax-credits or state-incentives should not be taken lightly. The designs must be capable of competing. No one will care about conquest-sales or bragging-rights. Success will be based upon acceptance from ordinary middle-market consumers.

9-30-2014 **No News, agreement.** Lack of consistency is a serious problem. There is no pattern with expectations for Volt, hence the concern now being raised. No agreement upon purpose means disappointment is inevitable. Someone won't be happy. We'll see a repeat of the same disenchantment as with the current generation. That rollout was filled with those abandoning support when they discovered GM hadn't followed the path they endorsed. With so many different paths now, how could that not happen again. Reading posts of those still active, there's arguments taking place about priorities. Some feel increased EV range is absolutely vital, while others still hold true to the heavily promoted current range. We see that with MPG too. Then there's lack of agreement about cost. That is all over the place. Feeling vary so much, there's no way to know what to anticipate. There certainly isn't anything in common about the points being posted. There is one aspect many do sound off consistently about. It's legroom in the back seats. Oddly, nothing has been said about this from GM. Providing another 2 inches to make it competitive wouldn't be easy. That essentially means switching from a compact platform to midsize... which increases cost and reduces efficiency. What a mess. Thankfully, we get a consistent message from Toyota. Prius engine efficiency will increase. Cost will be reduced. Capacity will be increased as battery technology dictates. Being 4th generation, the baseline is already established. We simply look forward to system improvements.

10-01-2014 **September Sales.** They weren't any surprise. Traditional vehicles are selling well. As usual, Camry & Corolla had a strong showing, with 28,507 and 20,530 respectively. Having sold most of their year-end inventory, that was anticipated. Prius still had 2014 leftovers, so low inventory from final clearance made its numbers on the small side. PHV was especially limited in stock, so the 353 sold was expected. Currently, there is only an inventory of 311 listed for the entire country. The new model-year rollout is a rough time. But then again, we knew this was coming. The true competition is a mighty foe. Trucks continue to be popular, very very popular. 50,176 sales for Chevy Silverado alone. That's a freakishly scary count. Talking about a reality shock for those still not wanting to consider the big picture. Even more so though is the new Ford pickup; their F-Series sales was at 59,863 for the month. How does a hybrid car compete against that? Fortunately, Toyota isn't so lopsided. Their total for pickups was 20,729 for the month, here. Over in Japan, Prius is a top-seller. So, it's this market that's trouble. We know that the attempted remedy to that was a disaster too. Two-Mode was expensive and no where near as efficient as hoped. And anytime you attempt to provide constructive criticism about GM, it turns into a defensive "*failure*" response. So, little opportunity awaits. It's a daunting challenge to face. Anywho, there is a glimmer of hope, but don't look forward to a miracle. Currently, there's an inventory of 7,632 listed for Volt. Setting realistic expectations is very important. Balance is vital. High EV range numbers may be appealing, but allowing them to offset other aspects of the purchase decision. Ask yourself why traditional vehicle are still selling so well.

10-02-2014 Encouraged Trolling. There really isn't a proper term available when someone from the inside drops bait. When someone from outside the forum does that, the behavior has been labeled as "*trolling*", since responses are disruptive. But in this case, the intent is to encourage participation, to stimulate discussion to keep the blog active. Today, the moderator of the Volt blog stirred the pot by posting this in the thread about September sales: "*Prius plug-in sales were a dismal 353 versus 818 in August, 1,371 in July, 1,571 in June, 2,692 in May. Talk about falling like a rock.*" Complete disregard for how many were actually available for purchase was conveniently omitted, giving a false impression of demand. That's both annoying and a little frustrating. I responded with: That's called good inventory management. Notice how Cadillac ELR has such a huge pile-up of unsold inventory that there won't even be a 2015 model-year? The plug-in Prius has a very limited supply. You cannot purchase was isn't available. There's nothing to gain from selling lots of the current plug-in model either. This generation Prius is at the end of its cycle, on the market 1.5 years longer than Volt. And within the next 3 months, the 20-year strangle-hold on NiMH will end. The patents expire, opening new opportunity for the hybrid market... which will inevitably stir the plug-in market. Looking at the big picture, we see 50,176 sales for the Chevy Silverado pickup and 59,863 sales of Ford F-Series pickups in the month of September. That should be a reality shock, a rude awakening, for those thinking sales of plug-in vehicles will gain major market-share, especially when the tax-credits expire. Much still needs to be done for the entire high-efficiency effort. The industry is not going to cooperate much either. Many challenges await.

10-02-2014 Nothing. The enthusiasts were quite angry, all half-dozen of them. So few are left, there's no real point of wasting any time anymore on them... with the exception of pointing out that there's nothing left... which the other constructive poster actually did: "*You've got nothing.*" They were not amused. I was. There's a sense of wonder how they can't see the change coming. We've seen so much already. But what comes next is big, really big... something they've been fighting against. I chimed in with: That's an excellent way to summarize the situation. We've been going in circles for years with the same old nonsense. We point out need, they come up with excuses rather than just address the situation. No progress. There still isn't a concise message or expectation either, after all these years. It's just an endless stream of wishes and contradicting statements. In the end, it doesn't matter. Those high-efficiency vehicles meeting the needs of ordinary consumers will become the usual choices; the others will be a chapter in automotive history... as will the enthusiasts who fought for attention. We've seen it already, several times over the past 14 years. This isn't any different. Automakers are a business. Being able to sustain profitable high-volume sales is what measures success. Period.

10-02-2014 **Change.** This year has been one of change. I remember when it started; there were arguments against any type of transition taking place. Now, there are so few still chanting "*leap frog*" and "*vastly superior*" no one cares. They've lost their audience. New enthusiasts are emerging who simply want no part of the first-generation nonsense. They understand the changes require and support them. It's quite interesting to observe. Too bad so few will take the time to read about what actually took place. Oh well. I pointed out to those still desperately grasping onto the past with this: It's like eating your vegetables and doing your homework. Some people hope they'll be able to get by without having to. The rest of us know the next generation of Volt will be quite different and the changes will be embraced. Those who opposed will just act as if that was the plan all along. We've seen it before. This isn't any different.

10-03-2014 **Interesting Timing.** I hadn't expected that change to arrive the very next day. The biggest argument about Volt acceptance has been engine efficiency, the MPG delivered following depletion of that battery-pack. Certain individuals got outright hostile about it sometimes, claiming it was meaningless, since most of the driving was in EV mode anyway. That put them in the stance of being highly against a "*lite*" model of Volt and showing outright hate for Prius PHV. What I found most interesting about that was they'd pretend the regular model of Prius didn't exist. It wouldn't ever be mentioned. It became quite evident after awhile the HV performance was a strength they despised. Some of that stems from the rush GM made to deliver Volt on time, postponing the high-efficiency engine inclusion until the next generation. That meant all publicity would have to focus on plugging in, since Volt reverted to traditional vehicle efficiency once the plug-supplied electricity ran out... rather than delivering efficiency a little bit better than a hybrid afterward. The long-awaited solution from GM was to be a 1.0 liter turbo 3-cylinder engine. That should bump up MPG, but it comes with the tradeoff of reduced power and added cost. It's the topic of today's daily blog. To no surprise, the contradictory claims of MPG are absent. We were told the increase from 40 to 50 was meaningless, yet the bump from 50 to +150 was absolutely vital. Looking at the data though, that was proven to be quite incorrect. Yet, they continued to argue it anyway. Not anymore. That is a very welcome change. Suddenly, they are very much anticipating the increase in HV efficiency. It's hypocritical, but it's also progress.

10-04-2014 Real Competition, comments. I was amazed to see such a post. So, I'm including it in its entirety: *"LOL. Then what the hell is the atrocity called the PiP? A weak attempt to compete with the Volt. Keep trying to drag the Volt down to the Prius level all you want, but it's in a league of its own, even among plug-ins. It still doesn't have a serious competitor."* The smug from certain individuals is really unfortunate. It gives a false impression of the other Volt owners possibly feeling some type of attitude themselves. They don't. Most are just those taking advantage of an opportunity to drive primarily with just electricity. In other words, consumers with EV interests, but not mainstream. That's why survey results from them are so different from the masses. They have a passion and seek out more than just reliable & practical transportation for a good price. Knowing your audience is absolutely vital. That was the lesson to be learned from several hybrid failures of the past... most notably: Two-Mode. Now, we see the same mistake was made with Volt. The design was sound from an engineering perspective, but there wasn't a large consumer base to appeal to. That's why I kept asking who. I was amazed they weren't seeing the business error being repeated. Amazingly, a few still don't. Most enthusiasts realized there was something horribly wrong when the founder of the daily blog & forum abruptly abandoned support shortly after Volt rollout began. That's why there are now only a handful of the originals remaining. Everyone else is gone. They've been replaced with the owners I hang out with, those interested in industry advancement as a whole and support my endorsement toward solutions for the masses. After all these years, my purpose still shines true: *"To significantly reduce emissions & consumption in a reliable & cost-effective manner."*

10-04-2014 Real Competition, reply. This is how I ended up responding to that smug nonsense: WHO IS THE MARKET FOR VOLT? That question was asked over and over and over again. The reason was to get enthusiasts to recognize the targeting of first-generation Volt was at them, not serious competition. It was a niche configuration, built with the hope that more than just enthusiasts would be interested. It failed to achieve that goal, specifically identified by GM as sales of 60,000 annually. Serious competition has continued to absolutely crush Volt, keeping it at just a minor fraction of monthly sales. Of the 223,437 vehicles sold by GM here in the United States in September, only 1,394 were Volt. That's just 0.6% of the total. For Toyota, their total was 167,279 sold, with 14,277 being Prius models. That's 8.5% of sales... much more, here. In Japan, the portion is even larger. Volt being in a *"league of its own"* is actually the problem, hence the on-going rumors of a *"lite"* model configured to increase sales. In other words, GM would be offering a *"Prius level"* choice to target that serious competition. The lashing out of a few enthusiasts at those who keep pointing out needed change is quite understandable. They feel let down and seek someone to blame. So, why not accuse the very people who correctly identified the market long ago of being the reason for their trouble? Automakers are a business. They require sustainable profit. The source of that revenue is on-going sales in large quantities. That won't be achieved from a niche vehicle. It comes from offerings which match purchase priorities of the masses. Increased fuel-efficiency is not an aspect they are willing to pay a large premium for. Price must be competitive with the other choices they have available. That means traditional vehicles will continue to present a significant challenge to overcome. No amount of choosing to only compare plug-in sales to other plug-in vehicles will change that reality. Pretending hybrids like Prius don't count either is a denial of true situation too. It's time to take the market seriously. Face the real competition.

- 10-04-2014** **Exact Same Thing.** It's nice to finally be stepping back to look at the big picture. For far too long, there was the "only plug-in vehicles matter" attitude. Arbitrarily dismissing the rest of the market wasn't constructive. Now, we are getting some perspective. Though not accurate, at least it's an attempt to consider more. I found this a bit frustrating: "*It is identical to the path Toyota took.*" That's the new version of those not-the-same battles from ages past. Had GM actually taken the same path, Volt would have been given aspects of performance to meet need, like Toyota did. Instead, there was an emphasis on speed & power want, sacrificing efficiency and seating comfort. There was obviously a big cost penalty as well. Remember, there weren't any tax-credits available back when Prius was rolled out here. So, that "*exact same thing*" we keep hearing is a crock. The tax-credits didn't appear until 5.5 years after Prius sales (the start of 2006) and the money was half what Volt gets. If GM had really followed the Toyota approach, Volt would have started with a modest battery-pack, then increased size as cost permitted. Anywho, I kept my reply simple. After all, acknowledgement from having overlooked something rarely ever happens: I have pages upon pages upon pages of blog entries pointing out differences observed over the years. I suggest you read them. It's easy to come to a different conclusion without that kind of detail available, especially when looking back long afterward rather than reading about the history as it was unfolding.
- 10-07-2014** **Refueling.** The topic of refueling rarely ever gets any more attention than just what you do at the pump. How the fuel itself is stored simply never gets considered. That's really unfortunate. Consider this food for thought: "*Renewables need a storage and H2 is a good choice. Both are important so I am dumbfounded why some are anally against it.*" I was quite pleased to see that posted. As much as people are in favor of using electricity for driving, the reality of not having a way to actually hold onto that energy until it's needed is quite a problem. Expecting a power-company to hold onto for your recharging use later isn't at all realistic. Power is generated, then sent out to the grid. They adjust the creation rate based on demand. It isn't stored. That's why there's such a supply & cost difference between daytime (especially in Summer when A/C use is heavy) and late in the evening. They generate & send. There isn't a means of storing it... unless you consider H2 (hydrogen). I added this to the discussion: Let's not forget act of refueling. As much as we'd like to dream of a time when all parking spots provide the ability to recharge, that just plain is not realistic... not by a long shot. It's sad to think of all of those apartment & condo dwellers who are at the mercy of landlord simply not interested or financially able to retrofit their property to support that. There's an obvious expense & effort for those owning a home too. It sometimes isn't logistically possible either. With H2, that population has a solution available.
- 10-07-2014** **Milestones.** A major one was reached recently, by Toyota, who doesn't have much fanfare. Of course, celebrating too often would be considered behavior like the you-know-who automaker. So, the excitement is contained to basically just a press release. Keeping that low profile has always been the choice for Toyota. Today, the milestone was 7 million hybrids. Back in January, the 6-million mark was reached. Only taking 9 months to reach the next is definitely noteworthy. Not bragging is a good plan. I chose to point it out, on the now hostile daily blog, this way: That know-your-audience is what led them to the decision to branch Prius into a smaller & larger model. The approach obviously worked. Worldwide sales of their hybrids just hit the 7,000,000 milestone.

10-07-2014 **Back to Basics.** It is very easy to step away from that small obsessive group of Volt enthusiasts now. All that could be learned up to the reveal has been. It was important to learn about their perspective well ahead of time. Today's topic heavily reinforced their attitude. It was about EV miles and saving gas. They just plain didn't care how much gallons were actually consumed. Their clearly stated they had no interest in how much kWh of electricity were consumed either. It was totally about bragging rights. I was astonished how they just plain didn't care... but not surprised, since that is why their group stands apart from those who genuinely hope GM delivers something for ordinary consumers. Another vehicle for enthusiasts is clearly not what they should be cheering for. At this point, I'm simply aiming for closure. Those few individuals caused quite a stir over the years and didn't actually achieve anything. Now, we see GM branching out with the plan to deliver a different design. Meanwhile, Toyota, Ford, Honda, and even Chrysler are pursuing a choice for the masses, a vehicle with mass appeal, striving to deliver the basics rather than having something to brag about. As I put it: Removing tax-credit from the equation levels the playing field. That absence of subsidies is what will reveal the winning approach, since success absolutely requires on-going profitable high-volume sales. Automakers will have less than 2 years of full government assistance available when the next-generation offerings are rolled out. So, it's best to plan to sustained sales without. As for battery-capacity defining whether a plug-in hybrid is PHEV or EREV, that's contradictory criteria... since the "*lite*" version of Volt wouldn't fit the definition. An increase for Prius could be done too, which would increase EV power and offer electricity for heating. In other words, there is neither specific nor even arbitrary measures to label type. That's just marketing... as effective as "*range anxiety*" was. Instead, they'll end up being categorized based on vehicle size, consumption ratings, and kilowatts available. Recent reveals from both GM and Chrysler further solidify that aspect of consumer awareness. People won't care what a technology is called. They'll focus on the results of using it. They won't even care about recharging. Overnight is overnight. Each morning, it will be back to full. They won't even care about when the engine runs either. Seeing MPG well above what a traditional vehicle delivers will satisfy their purchase choice. It's back to the basics. Is it reliable, comfortable, practical, and affordable?

10-07-2014 **Panic.** There's one individual on the big Prius forum who consistently uses adjectives to stir emotion. His words, like "*flaw*" and "*defect*", tend to make me crazy... especially when used to describe a well-proven operational behavior of the system used in Prius. My guess is he doesn't have much of an engineering background. Just picking up knowledge along the way is fine, but don't instill a sense of panic to others. Geez! Of course, some people thrive on the attention such actions provide. It's like a child using a "*naughty*" word. They know they'll get the attention of the parent that way. So, responses need to be well thought out and not demeaning... since he is striving to learn, just not in the most appropriate way. I ended up posting this: Neither applies to the plug-in Prius. A charge of "*full*" is actually just 85% and the "*empty*" level is really 23.5%. And when you want to save the maximum charge while out driving (after the engine has fired up), it depletes to 72.5% for optimal longevity. The battery is always kept in that happy place, automatically for you. Overnight charging is the best, since you take advantage of the lowest electricity rates while also minimizing grid demand, as well as recharging when the pack has had an opportunity to cold soak (rest).

- 10-08-2014** **Pointless.** That closure I was looking for was presented this way: "...*obviously comparing a hypermilers mpg with a fleet average is kind of pointless.*" It was a fascinating journey witnessing hope transform into hype, then disappointment become excuses. That's why goals were a continuous request prior to rollout, then following later as sales struggled. What could be said at that point to be constructive? Progress has to be achieved somehow. Toyota proved Prius was a solid platform to continue improving. As battery cost dropped and energy-density increased, the system would benefit. Reaching more and more consumers was the goal, not winning praise. Declaring victory from an online debate doesn't accomplish anything. It always comes down to sales. High-Volume & Profitable is absolutely essential. You'd think after all these years that particular group of troublemakers would finally see that. Clearly, that don't. So, I let them have it with this point and move on: Yup, that's why the certain somebody's here with the trophy-mentality can't use their own data. From me, it's a different story. I've published a collection of videos clearly showing results of just driving along with the flow of traffic. You can see for yourself how the system operates. And with my own data, I drive several 400-mile trips per year with the bikes on back and no charging. That certainly drags my average down. All the running around to see my fiancée and her family without charging does too. It doesn't matter anyway. This group refuses to consider the entire fleet. That cherry-picking isn't constructive. Whenever the rest of GM's production gets mentioned, their panties get in a bunch... which will certainly make things interesting when a "lite" model of Volt is eventually rolled out... since some statements made will end up becoming contradictory. The market will become more complex too. Reaching out to new consumers means new options. Things like wireless charging will certainly stir the pot. Even if it doesn't catch on, that will still get a new audience to take notice of the selection of plug-in vehicles available.
- 10-11-2014** **Unheard Of.** This is a quote to make you think: "*10 years is unheard of in consumer electronics.*" I was pleased to see that. Most people, including myself, don't look at the situation from that perspective. It's a great point. Imagine a phone or computer battery lasting even half that long and still delivering so much. We not only expect them to need replacement, we face the decision directly. The catch is the expense is much less. But then again, how many people do you know who still carry their phone from 5 years ago? Their computer? More often than not, that necessity of battery replacement leads to the decision to replace the entire device. So, it's rather hypocritical to hold an automobile to a much higher standard. The reality of Prius batteries lasting 10 years is truly remarkable. But then again, if you understand how it is utilized, that should be no surprise. The engine is used to protect the battery-pack, starting up at times to ensure longevity. Imagine if you had that ability available for your phone! So, it really isn't unheard of. It's well designed... to keep you from having to deal with replacement.

- 10-11-2014** **Sales & Who?** That question is finally getting some traction. Simply telling us about Volt owner satisfaction doesn't get much attention anymore, since we're seeing more and more comments like this: "*Tesla is moving product while GM gets more nervous.*" It's hard to believe how much effort was expended to distract from the purpose of sales. Fortunately, that isn't effective anymore. I pointed out and asked: While the rest of the industry strived to deliver something for the masses, GM launched a massive "*range anxiety*" campaign. They even went as far as trademarking the term. It was a gamble that battery capacity would remain low and cost remain high. The plan was to deliver a "*game changer*" product which would "*leap frog*" competitors. The hype was amazing. It was unsupported nonsense being spread like wild fire. How could so much be achieved in so little time? It ended up being a disaster. The design fell short of a number of goals. Any hope that was left turned into spin. Sales clearly revealed the game was not changed. In fact, quite the opposite happened. Both Tesla and Nissan demonstrated there was a market without anxiety. Volt didn't have an audience. This is why Prius so often got attacked. It weathered the publicity storm. Staying out of the spotlight by offering a modest (affordable) boost to emissions & efficiency was enough to demonstrate it too had a market. The next generation offerings are what will make a real impact. GM is scrambling now. Who will they target this next design at?
- 10-13-2014** **Decisions.** We have an interesting dialog going on about the next-generation Volt, in the big Prius forum. That's been remarkably constructive. People have been quite candid too. It's a very good sign of change. Too bad the daily blog is still quite hostile. I wonder how that will change over time. This was my interjection to the discussion today: I had countless arguments with enthusiasts about their engineering-only perspective, insisting they take notice of the business perspective. They were blinded by the performance and design. Consequences of refusing to acknowledge the market were provided and warned about, repeatedly. They didn't care. They didn't want to accept the reality that engineering skill alone wouldn't be enough. Management decisions made a mess of things. That's how we got to the situation we're in now.

10-13-2014 **Acceptance.** My issue with those decisions of the past was not addressing need. If GM executives had delivered a sporty type Volt in addition to one aimed at middle-market, good for them. It would have been a win-win. Both business & consumer would benefit from the platform being used in a diverse manner. Instead, GM gambled on the sport, hoping its performance focus would appeal to the masses. It didn't. They also hoped cost would rapidly fall as gas prices continued to climb... neither of which ended up happening. Toyota focused on middle-market, delivering a platform able to be augmented further as cost justified. In the meantime, there would be something relatively affordable without any dependence on gas prices. That's a very different approach from GM, especially when taking into account only get 1/3 of the tax-credit. The hope is GM will take that proper step, reaching out to mainstream consumers. Achieving profitable high-volume sales is absolutely essential with this next-generation. A configuration designed for the masses is required. If they also deliver and second choice, a more expensive model, good for them. But if that's all they deliver, game over. I see Prius PHV as the true game changer, since it focuses heavily on the low end. Yesterday, I had a bunch of weekend running around to do. After 84 miles with just a single recharge, the average came to 60 MPG. Providing an effortless efficiency boost like that is what will really make a difference. Imagine people pulling into their garage and having the system automatically recharge wirelessly. They set it up once, then JUST DRIVE IT. With such a small battery-pack to keep cost down and not compromise large cargo carrying or seating in back, that's realistic. Hopefully, other automakers will pursue a similar goal. Without gaining acceptance from the masses, what are we accomplishing?

10-13-2014 **Engineering Only.** This perspective is getting old; yet, it needs to be addressed again. I guess the classics never die. After all, we still see some of the really old greenwashing techniques being used... despite being exposed as blatant efforts to undermine. It never ceases to amaze me how some people fail to recognize the forest round them. That cliché of only seeing the tree in front is far too fitting. I suppose if you never take a business class, you have no idea what economic & accounting influences are and how much of a role they place. So many factors related to sustaining sales are simply disregarded, it's like having to listen to 30-second television commercials. All you get is hype about performance. Anywho, I tried to inject some sense into the discussion: I had countless arguments with enthusiasts about their engineering-only perspective, insisting they take notice of the business perspective. They were blinded by the performance and design. Consequences of refusing to acknowledge the market were provided and warned about, repeatedly. They didn't care. They didn't want to accept the reality that engineering skill alone wouldn't be enough. Management decisions made a mess of things. That's how we get to the situation we're in now.

10-14-2014 kWh & Gallons. On that surprisingly constructive thread today, they took a closer look at MPG. The comment was made that when in "*proper context*" that value tells the efficiency story. I was somewhat in dismay to see that posted, replying: There is no proper context. We all know the variance within EPA testing results and real-world vary dramatically. Beyond 100 MPG, that variance can be greater than the value itself. A consumer choosing a 300 MPG vehicle over one listed at 230 MPG may not use any less gas, based on how the vehicle is actually used. And even if they did get exactly what the sticker states for testing results, that's only a difference of 15 gallons over the course of 15,000 miles. That's just 450 miles of travel for a 30 MPG vehicle. That same "70 MPG" difference equates to 350 gallons of gas when comparing that same 30 MPG vehicle to one which delivers 100 MPG instead. That's 10,500 miles of travel for the 30 MPG vehicle. Context is far from clear and will basically never be represented properly in terms of MPG. The only appropriate method is stating KWH and GALLONS. For example: 300 MPG for 15,000 miles = 50 gallons; 230 MPG for 15,000 miles = 65 gallons; 100 MPG for 15,000 miles = 150 gallons; 75 MPG for 15,000 miles = 200 gallons; 30 MPG for 15,000 miles = 500 gallons; Notice how higher MPG doesn't actually make much of a difference? Notice how that MPG is achieved is not told? Then, there's the reality of how far a person travels before recharging. That makes comparisons even between like vehicles unrealistic. Between different vehicles, it's even more difficult. Since it takes a lot more battery usage to compensate for a less efficient engine, that mismatch complicates matters tremendously. It's a mess! How could vehicles appropriately depict efficiency without having kWh quantity information?

10-14-2014 Data Discovery. Someone with access to the large GM database posted this today: "*From the OnStar data average mileage is going 100 miles on a gallon of gas plus 22 kwh of electricity.*" That tells a very different story from the self-selected enthusiasts who expose their data on a public website dedicated to sharing Volt statistics. I quickly calculated my own 100-mile average. Go figure. It was much lower. In fact, I used the old 3.0 kWh per full-recharge value. It's long overdue that I switch to the 2.75 kWh value that ChargePoint has been routinely reporting. Knowing how much electricity is loss as a result of recharging is important. The battery-pack has a 4.4 kWh capacity and uses 61.5% of it, which means roughly 0.044 is consumed from the act of plugging in. In other words, only 90% of the electricity is actually used by the vehicle while driving. Anywho, it's part of the equation... sometimes included, sometimes not. Unfortunately, the amount of gas consumed is rarely ever stated by Volt enthusiasts. That recent thread on the daily blog overwhelmingly confirmed that. The choose to focus on electricity instead. Who knew that was so inefficient. I knew Toyota's system was more refined, but we really surprised to discover it was by so much. This was my reaction to that: Wow! That is horrible. My 100-mile average is 1.36 gallons plus 8.8 kWh. I had no idea Volt was so much less efficient. What a great example of MPG being misleading! Are you sure that is correct?

- 10-15-2014** **Competition.** I find it fascinating how Volt has become a competitor with no other vehicles. It makes claims pointless and serves as a great example of not taking a situation serious. It was quite unexpected watching it become the opposite of Prius. Ironically, it was supposed to be a direct competitor... which would have made it the same, attempting to fulfill the same goal but do it much better. Clearly, that's not what actually happened. So, we get stuck in non-sensical spin-debates from time to time. This was an attempt to escape from that, to bring back to constructive outlook: Efficiency measure a moot issue anyway. GM cannot sell a vehicle not making a profit and dependent on tax-credits forever, hence this discussion about Gen-2. Toyota is in a far better position to compete with the true competition: traditional vehicles. Whether or not GM will be able to substantially narrow that gap is the question. Getting crushed by their own production isn't a good situation. We see how Cruze, Malibu, and Impala sales dominate. Then when you look at the popularity of Equinox sales, reality sets in. Volt is just a tiny player on that very large game field. Sadly, GM considers the "*competition*" other plug-in offerings from other automakers. The recent confirmation of that in the article published at the start of this thread should serve as a red-flag for people, a warning that the executives are heading down a wrong path, again. They are about to repeat mistakes if they continue to ignore their own production. Ironically, GM is its own worst enemy. They keep spinning an "*every is fine*" message. How is that helpful? A teacher certainly wouldn't say that to a student when there is an opportunity for improvement.
- 10-15-2014** **What Market?** The answer to the WHO question overwhelming results in this answer: "*They want to compete in the 'alternative fuel' market, and in the 'advanced technology company' market.*" It's validation that GM continues to be motivated by want, rather than need. That's quite disappointing, especially since that means there will be backlash to deal with as a result of the next-gen rollout. It would be fantastic for something actually competing in the same market as Prius, but that becoming clear that won't be the case. That's unfortunate. Oh well. All I can do is prepare and hold on to hope that someone in management will come to their senses. There's no reason GM's business has to struggle. They just need to expand offerings to entice their own customers to choose a high-efficiency low-emission choice instead. This were my thoughts on the emerging situation: With gas currently \$2.89 per gallon here and nothing pointing to higher prices in the next few years due to increasing supply, expectations of a vehicle like Volt to compete in the mainstream without state & federal assistance is totally unrealistic. How some continue to evade acknowledgement of the situation is remarkable, but not as much as GM still not having a plan "B" to fall back on. Toyota has a popular profitable platform to leverage from. Offering the plug as a package choice is a great business move... so much so, we see other automakers following similar paths. It reduces risk significantly and provides the opportunity to exploit as the market shifts, by just adjusting production levels. What in the world will GM do? At some point, something will fall apart that won't be repaired with a clever press release. Think about how much the 30 million recalls will affect the bottom line. How much will they have to invest in keeping their vehicles competitive? The reveal of Gen-2 in January will certainly be interesting.

- 10-16-2014 Timer.** Proof that new PHV owners are not just enthusiasts comes in surprising ways. Of course, we already knew that from experiences with the regular Prius. This time, with the plug, it's not anything different. The most recent example was from an owner who never used the timer. For that matter, she didn't even know there was one. When it was pointed out to her, the question of "*didn't you wonder what that button was?*" came up. Since she didn't know what it was, her response was that she hadn't ever tried it or even looked up what it was in the manual. Having a plug-in hybrid appealing enough to make the sale but still a bit too intimidating to press a button is an interesting situation. Toyota went to a great effort to follow the KISS principal. But even with the "*Keep It Simple, Stupid*" approach, you can still overdue. As an engineer myself, I know all too well how much complexity it takes to provide a very simple interface. Apparently, even just a button is too much for some... hence the effort to deliver wireless recharging. Eliminating the plug itself removes another potential purchase barrier. Who knew? I did. But those on the big Prius forum are a diverse mix. Some do find it surprising. Others are pleased someone shared their feeling of it being too much. I find that fascinating and very good to know.
- 10-17-2014 Choice.** It's nice seeing how that Volt thread on the big Prius forum held on so long, constructively. However, it is quickly dwindling down to that particular individual who thrives on debates. So, his asking this today was no surprise: "*I don't understand this obsession that car A is a bad car because it isn't 'mainstream'.*" Either that was intentional to keep the posts coming or it is a case of terrible memory. Having been threw this several times with him already and knowing he's quite smart, I say it was an effort to stimulate thread activity. And since he did play friendly, why not play along? After all, that's how some of the best out-of-the-box ideas come about. I replied with: I never said it was bad. GM can build & sell Volt to their heart's content. That's fine. They must also deliver a choice for ordinary consumers too. That's the catch. What I've said over and over and over again is: CONSUMERS WHO WOULD OTHERWISE PURCHASE A MALIBU OR IMPALA OR CRUZE NEED TO BE OFFERED A CHOICE OF A HIGH-EFFICIENCY LOW-EMISSION VEHICLE. The purpose of replacing traditional vehicles will never be fulfilled if GM keeps delivering good to a small audience. Those other GM vehicles will just continue to overwhelm sales. Do they really have to wait until after Gen-2 ?

10-17-2014 **Expectations & Shortcomings.** After a few exchanges with others, he got back to me with: "*THIS is a VOLT thread.*" I found that amusing and took quite a bit of time to think through my response. It was obviously just a debate for the sake of debating thread now. Nothing else could be gained. Fortunately, I learned more than anticipated from the friendly exchanges. Actual useful information was conveyed. Gasp! The consideration of gas & electricity usage is clearly a weakness in Volt that many go to great lengths to avoid. Seeing that behavior pattern here too, though in a tame fashion, confirmed it was a good perspective to highlight. We even came up with a simple way to convey the data. Anywho, my attempt to conclude went as follows: This thread is about leap-frogging the "*competition*", as stated in the title. Yet, we have no clue who that actually is. The vehicle called "*Volt*" will be changing again too. GM originally told us that "*Volt*" would achieve mainstream sales... the same definition everyone else had been using for here for years: sales of 60k annually... by the end of the second year and that production capacity of 120k would be available for the third. Should we be expecting that for Gen-2 now? Will the next "*Volt*" be aimed at just the plug-in segment exclusively? Will the next "*Volt*" be a premiere technology vehicle for GM and there be something else targeting ordinary consumers? What's the plan? Too many questions unanswered does not set proper expectations. The resulting endless debates are pointless. At a time when gas has dropped to \$2.79 per gallon, sales are going to be a challenge. Betting the farm on a single high-efficiency low-emission choice is quite a gamble. Fortunately, I'm leaving this better prepared for the upcoming confusion. Refusals to consider both kWh & gallon consumption is a dead giveaway the technology, whatever it may be, isn't being considered appropriately... because, having those numbers available is vital for proper comparisons. They reveal shortcomings the odometer and MPG does not.

10-19-2014 **Waste of Time.** I get a kick out of some who draw conclusions without addressing everything. From their perspective, it makes sense. But not identifying all the factors at play leads them to make assumptions. So, who knows if having posted this will do any good: Stepping back, way back, to look at the big picture, there's something new to see. Very few have the background & experience to actually see the pattern though... hence the seeming waste of time and same 'ole GM responses. There is far less interest in Gen-2 of Volt than the hype would make it seem. Discussions drop off quickly on forums & blogs that actually hold any interest, which is much less than with the build-up to Gen-1 rollout. Volt gets the attention because GM attempts to draw it, to make it stand out among what has now become a crowd. The posts in a venue like this is what flushes out the argument points... which we can analyze and develop KISS response for proactively... rather than waiting for them to emerge as greenwash material later. Having to reactive after the fact is much more difficult to deal with and damaging in the process. Those are lessons learned which we should take seriously. I participated on the big GM forum and that daily blog for Volt on a regular basis having to "*defend*" Prius. What I was really doing was responding to the constant stream of misrepresentations. Much of it was blatant lies. But not having any effective way to share data, it was a seemingly endless battle. Turns out though, that waste of time wasn't. I eventually refined comebacks, leading to simple messages and detail video. Many of those Prius undermining efforts have ceased. That's why perspective has become a consideration of overall production. It's vindication of successfully having dealt with that stage of resistance. Preparing for the next is a sensible thing to do now... which is what this thread was truly about.

- 10-19-2014** **Vehicle Shape.** I particularly enjoyed responding to this: "*Prius (liftback) problem, I think, is so many people do not want to consider that shape of a car and be labeled as a 'Hybrid' driver. I still think Toyota's best bet is to keep the Prius shape and size and vastly improve...*". It's fun looking back and sharing how those observations resemble what's currently happening: Remember what came before the heavily stigmatized minivan? It was the heavily stigmatized wagon. Guess what is back! The wagon is becoming popular again. We could see it coming too. To make a SUV more aerodynamic without sacrificing a lot of the interior space, they transformed to wagons. Notice how sedans need to become more aerodynamic and how there's a demand for an increased interior space? Slope the front a little and raise the back a little, you've almost got hatchback. Look closely. You'd be surprised. The back roofline of the Hyundai Sonata already resembles Prius. The reputation of "*hybrid*" driver being a stereotype will continue to fade away as more and more are seen on the road. In areas with heavy saturation of them already, it's emerging as a non-issue. After all, there are more and more SUV owners who mocked Prius that we no longer hear from anymore. Prius will continue to be upgraded as it continues to build reputation. Just think of what the next-gen rollout delay will do for the older generation. More of them seen on the road will further reinforce its standing.
- 10-19-2014** **Ambiguous.** The guy who likes to debate is at it again. I nibbled at his bait. Curiosity got the best of me. Sure enough, his comeback to my reply was just more of the same. I've seen that many times in the past. He's just one of those who enjoys tossing conversation back and forth, going out of his way to ensure responses result in more replies. Never enough detail to draw a conclusion is the key. This is what he was trolling with: "*...and analysts expect plug-in growth to far exceed hybrid growth...*" It was a nice test-the-water quote. Maybe he'll get someone else to bite later. Post and move on for me: Ambiguous statements like that shouldn't be spread. It literally tells us nothing. The complete absence of detail gives reason for question. "*Growth*" could mean anything. No actual quantity estimate or even a percent is a red flag. The same goes for "*far*" being meaningless. "*Hybrid*" doesn't really mean anything anymore either. What is Prius PHV counted as? Fusion Energi? Volt? What about vehicles with start-stop? What about tiny assist motors? And of course, who the heck are the so-called "*analysts*" saying that? Are they part of the auto industry? Someone supporting EVs? Someone pushing fossil fuels? We learned long ago not to take statements at face-value. That one is an excellent reason why.

10-19-2014 **Small Steps.** The effort to consider more than just engineering & politics can fail too. Adding business typically need isn't enough either. That's why some seemingly endless problems never really get solved. Yes, you can get lucky. But betting the farm on that possibility obviously isn't a good plan. What you need to do is talk with someone like an anthropologist. Take a perspective of analyzing human behavior too. People are most strongly driven by fear & revenge. That's why I poke the leaders stirring that very mindset. Many simply cannot see beyond their own hate. That means the only way to deal with competition is to eliminate it. The concept of friendship is laughed at. Who would ever take the hand of a former enemy? That's why trying to get certain Volt enthusiasts to join the rest of the plug-in community is an absurd idea. They've been greenwashed to fight Nissan & Tesla and make fun of Toyota. So, when I send out an endorsement for plugging into lithium batteries, they remain suspicious and unwilling to even consider the thought that I'm fighting the foe I declare. Other plug-in vehicles are the competition in their mind, not traditional vehicles, period. This is the same reason why my suggestion for a second model of Volt falls on deaf ears. They just plain don't believe me. History is on my side though. Success from extremely difficult resistance has always worked best from taking small steps. For example, that's why Toyota overly simplifies the Energy screen. They didn't want to overwhelm. Look at the effort to deliver wireless recharging. Same thing. Not having to plug in makes it more like a traditional vehicle. That seems counter-productive. But looking back into our previous turn-of-the-century change, many social taboos and scary barriers were overcome from being introduced in tiny doses. Toyota will ask a small premium for a system that isn't in any way intimidating, yet it still delivers decent efficiency boost. Taking one step at a time was always good advice. Learning to walk before running was too. What about the size of the step? It went without saying that small was better. This time though, we actually have to say it.

10-21-2014 **Silence.** It's beautiful. An end has come to the superiority fighting from Volt enthusiasts. They have nothing to gloat about anymore. Volt sales have been flat and plug-in Prius sales have been supply-impaired. Forthcoming announcements tend to bring about a silence anyway... especially with the antagonist group. They are the ones who go out of their way to provoke, a step more than simply being enthusiastic about something uncertain. Being civil in response to someone that simply doesn't care can be quite a challenge. Fortunately, we don't have to deal with that right now. It's so quiet. Yeah! Anywho, there are press releases on the way to stir the pot. Activity online over the next few months should be interesting. Toyota has delayed the next Prius rollout for a variety of reasons. That clears the path for GM to do whatever they want with Volt in the meantime. Do you think they will chose wisely? Promoting a new offering isn't exactly their strong suit. The reputation for "*over promise, under deliver*" is very well established. Being realistic this time sure would be nice. Since the very beginning, the hope was to find an ally in the effort to replace traditional vehicles. Hype about Volt undermined that purpose. Enthusiasts turned on Prius, not the true competition. They lost sight of goals. Maybe there's hope this time around.

- 10-22-2014 Deciding After The Fact.** You cannot; yet, he believed that was totally acceptable. *"Will the gen II volt leap frog them? I think it has a good chance, but we won't know until it is released. After that I figure we can decide if it was puffery or real. It will be the first gen II so even if it does leap frog those models, those models may catch up in the next generation which is 2016 probably for the gen II leaf and next prius phv."* I was beside myself after having read that. It's not the slightest bit constructive. For that matter, it's so vague, it doesn't even tell us anything. It's simply more hype, coming from the very person claiming no such spreading of unsupportable hope ever happens. It's more feeding of the nonsense we've had to endure for years. Oh well. I'm still willing to fight it: There's nothing to decide. What is meant by *"leaf frog"* must be clearly defined prior to rollout. If that detailed criteria is met, then it succeeded. If not, it didn't. The nonsense with rollout of the first was inexcusable. We saw the goal-posts being moved after the fact. Volt clearly wasn't achieving sales goals, so focus shifted over to performance instead. The reality that it was in no way sustainable without a large subsidy was pushed aside in favor of promoting EV miles. There's nothing to debate anymore and spin falls on deaf ears. We want to know what *"leaf frog"* means.
- 10-23-2014 Oops!** My references in the previous post to *"leap frog"* were misspelled. They were oddly fitting too. You rarely expect anything like that to happen. But it did. So, we got a good laugh from the blunder: hehe! That's both a funny typo and ironically fitting. Gotta like the auto-spell feature on phones. Anywho, we all remember how GM hyped the *"range anxiety"* angle. They even went as far as trade-marketing the phrase. Their purpose was to show the world how EREV was vastly superior to EV. It was Tesla who stirred the pot, but the target was Leaf. We were told over and over and over how valuable having a *"range extender"* would be. As time progressed though, Leaf showed signs of consumer interest. The fear campaign was falling apart. That vital feature of Volt wasn't crushing the competition as hoped. So, attention was refocused on a seemingly weaker foe: Prius PHV. But it turns out, that wasn't as easy as hoped. Despite the limited market availability and much lower tax-credit, it still held on. I was surprised how much misleading effort the enthusiasts had to expend to save face for Volt. It's something they'll look back upon with regret... hence asking now what looking forward will bring. Instead, we are seeing the hype being encouraged again. That vague *"leap frog"* exclamation without any detail matches an all-to-familiar pattern.
- 10-24-2014 Fuel-Cell Debate Points.** Cost and overall emissions are the big ones. On their own, they don't provide enough justification either way. So, the debates tend to drag on and on. EV supporters love to bring up infrastructure as a shortcoming for hydrogen, but then end up being hypocritical about not wanting to address that very topic for plugging in. That lack of balance obviously rubs me the wrong way. Of course, the Volt supporters had been doing the very same thing up until recently. That refusal to acknowledge is frustrating. It's a red-flag about upcoming rollout issues... because you cannot just hope shortcomings will magically go away. Anywho, I brought this point up, hoping to at least bring the level of rhetoric down in the discussion: Refueling is a very real issue people seem to either dismiss or be unaware of. Fast to refuel should be obvious. The other is storage. The grid doesn't actually have any. That results in an efficiency penalty most fail to acknowledge. When the electricity is generated, it is sent out for immediate use... since there isn't any way of holding on to it. Hydrogen provides that means of capture, preventing waste in some circumstances.

10-24-2014 **Final Greenwashing.** The last desperate attempts to revive the hype for Volt are now being made. Watching the end draw near over the last few months has been quite vindicating. A struggling approach with no alternative can only survive so long before reality sets in. To be successful, the price of gas had to stay high and the cost of lithium batteries come down some. If the battery cost came down too much, Volt would lose its advantage to the EV. If gas prices dropped, Volt would lose its advantage to traditional vehicles. The position of Prius PHV irritated those enthusiasts to no end. It required less of a premium and gas & lithium didn't have as big of an impact. It also had a popular hybrid counterpart, one without a plug keeping the platform affordable. Needless to say, no growth for Volt made the story worse. With each month pounding another nail into the coffin, they knew the next-gen would have to be quite different to attract sales. But in spirit of true denial, we got this today on that daily blog: *"It would also be interesting to compare the amount of EV miles of the top 15 plug-in sales."* My response didn't make him happy. I made me though. There's no excuse for greenwashing like. Pointing out his attempt is totally appropriate. So, I did: That would be misrepresentative, since it wouldn't depict all the electricity actually utilized. Blending is when plug-supplied electricity is taken advantage of to reduce gas consumption by the engine. The result is significantly boosted MPG, a value not represented by EV miles. They are counted as HV miles instead. When purpose is to reduce gas consumption, electricity consumption is very important to know.

10-24-2014 **EV Sales.** These were the numbers that provoked the greenwash attempt: (10) Renault Zoe: 15,063. (9) Renault Kangoo: 15,369. (8) Ford Fusion Energi: 15,611. (7) Ford C-Max Energi: 16,377. (6) Mitsubishi i-MiEV Family: 30,501. (5) Mitsubishi Outlander PHEV: 35,188. (4) Tesla Model S: 47,000. (3) Toyota Prius PHV: 65,300. (2) Chevy/Holden Volt & Opel/Vauxhall Ampera: 83,687. (1) Nissan Leaf: 142,000. They are worldwide sales totals. I'm wasn't certain which irritated that Volt enthusiast more, the count for Leaf or Prius PHV, at first. Knowing his reputation for being disregarding data he didn't like and being a Prius antagonist, the response of attempting to belittle PHV was a safer bet. But then again, the numbers are a little too close for comfort when you consider the reality of PHV availability still being limited to the initial 15 rollout states. That sets a very interesting stage for next-gen competition. The lack of inventory reminds me of the Classic rollout more and more. The Iconic model which followed made the supposed lack-of-demand for the prior a trivial matter. People really like the new offering and couldn't care less what led up to it. That's why burning bridges with Volt doesn't make any sense. Why set a precedent for greenwash when the future could be so different anyway? After all, what does an antagonist really hope to accomplish by fighting both plug-in hybrids and electric-only vehicle when they are leading the way toward a market with fading interest in traditional vehicles?

10-24-2014 **Volt Summary.** This chapter in history is clearly coming to an end soon. The following wrapped up the situation well: *"Not to take anything away from Volt. It is a fine car that has been ride and handling and cleaner than a regular gas cars. If you look at it from a wider angle, it is not an effective solution. Costs too much for too little gain with many side-effects introduced, especially with the emission level in current grid."* Looking at goals, rather than just the vehicle itself, Volt fell way short. It was terrible from a profit & risk perspective, proved to be an unwise business choice. For the market as a whole, what did it actually accomplish? It certainly wasn't the game-changer it was hyped to be. In fact, it turned out to be a promotional disaster. Looking back, it closely resembles Two-Mode. The enthusiasts hated that prediction. Supporters had a feeling it would be true. Owners confirmed it was. So, the only thing to do at this point is look forward: Excellent summary. Having driven Volt several times on a closed track, I can attest to the ride & handling. That view fails to consider the unfulfilled goals though. The "saving gas" campaign further illustrates how need hadn't been fully addressed. Fortunately, many of the enthusiasts have come to terms with that reality and are placing their bets on the next-gen offering. They had thought we were being unfair by forcing the big-picture perspective, not giving Volt a chance. They now realize the importance of that cost-reduction, how it brings about vital improvements. Look at what shedding weight delivers; using fewer materials for the build also provides an efficiency gain. With subsidies expiring within the next-gen production cycle and the necessity to seriously increase sales volume, being an effective solution cannot be emphasized enough.

10-28-2014 **Grille Blocked.** The cold weather is quickly settling in. Fall seemed unusually brief this year. Freezing temperatures for the night low are already a reality. Ugh. The seasonal ritual of blocking the grille took place today. I simply squeeze foam-insulation for 1/2" pipes between each slot. It takes about 20 minutes to entirely cover the bottom grille on the Prius. The pressure alone keeps the stuff in place all Winter long, even with repeated trips through the carwash. It looks surprisingly nice that way too. When Spring arrives, the removal is just a matter of giving each a firm tug. In the meantime, it there to help retain heat. Why let so much cold air flow through the engine compartment when not that much is needed? That reduction keeps the engine from having to start up as often to for warming. Both the interior of the vehicle and the emissions system require heat. Blocking is the solution to consume less gas for that. It also helps the system warm up faster too. With a price of just \$2.35 for the foam, why not?

- 10-29-2014** **Product-Gap.** Remember how concern has been about the product-gap? That fact continues to get overlooked. Either you purchase a traditional vehicle or a Volt. Offering nothing in between doesn't position GM well for business sustaining profit in a highly competitive market selling to the masses. Yet, that's what we found how they will be doing. Whether or not the next-gen Volt is a refinement for the niche they carved out is besides the point. Too bad today's online conference didn't see that as a problem. We were told Volt would be without any variant model. It's the one-size-fits-all strategy reboot. Rather than reaching out to a wider audience by offering a choice, the decision has been made to rollout just one. Either you buy an affordable traditional vehicle delivering MPG in the 30's or you buy an expensive plug-in with a battery-pack delivering roughly 50 miles. Nothing between doesn't seem to worry anyone. Ugh. This upgrade was supposed to overcome shortcoming of the original. That's not going to happen... based on what we learned today. What could the details to be revealed in January do to change that?
- 10-30-2014** **That Question.** Yesterday's new information from GM was interesting. Everyone, including Toyota, is waiting to see what happens with Volt before making the next move. After all, gas prices are falling and high was necessary for sales growth. So, there isn't much to do in the meantime except wonder. Sadly, the market is loaded with examples of weak sales for high-efficiency offerings. The reason GM stands out is due to their magnitude of goals having been missed. Two-Mode, BAS/eAssist, and Voltec were all heavily hyped and were all a struggle to sell. Achieving that mainstream minimum (5,000 sales per month) simply won't happen if you don't appeal to a wide audience. So, it continues: Who is the market for Volt? That was the question asked prior to and following the rollout. Focus on the nice performance & handling seemed to indicate potential buyers were those who desired more from a vehicle than the typical consumer who would otherwise purchase a Malibu, Impala, or Cruze. It was instead targeted at those wanting more from a vehicle than affordable & reliable transport. In the end, GM did indeed confirm the market was for those seeking something special. Know that, now we ask a different question. For the next Volt to be offered to a wider audience, we know cost (the amount the automaker pays to produce the vehicle) much be significantly reduced. What other improvements are necessary?
- 10-30-2014** **Nailed.** The hype leading to the recent announcement was a large build up for a non-event. It fizzled. You could sense the "Is that it?" disappointment to such a degree, no one had to say anything. The lack of excitement following spoke for itself. Thud. So, the spin that emerged today had an attentive audience yearning for something to fulfill the emptiness. I could only shake my head in dismay. I really didn't expect it to die so quickly. But witnessing it firsthand, all I could do was pass on the spin, looking for feedback. This is what I took from the Volt daily blog and shared on the big Prius forum: Here's what one of the die-hard enthusiasts had to say in response to the recent info from GM about the next-gen Volt: *"GM has made the right decision in emphasizing more EV range, more responsiveness, and a more refined ride in CS Mode. They completely nailed what is important, thankfully tuning out the demand for higher but inconsequential MPG in CS Mode."* Interesting, you bet. We were told to expect much, for the next-gen design to leap-frog the competition... which would be great, considering what was needed. Instead, we're finding out the improvements are incremental and are already seeing downplay.

- 11-02-2014** **57 MPG.** The long drive home from my future in-laws place was a pleasant one. It was a nice Fall day. The temperature was just above 50°F. There weren't bikes on the back this time, since we went there to participate in a haunted house for Halloween. The grille on the Prius was blocked. That probably provided a small aero-dynamic improvement. MPG was outstanding as a result, even without plugging in. That's so nice on weekend get-aways. Being able to escape without consuming lots of gas rather empowering. You don't feel trapped or obligated. That's especially important when the opportunities to do that are so rare. Summer is far too short. But living in Minnesota, you take advantage when you can. It will be April before I can even consider any type of favorable weather trip. Almost 6 months. Ugh. It's a good thing I can plug in around here. That makes the cold season easier to endure. Snow is nice. But temperatures well below freezing for weeks at a time get annoying... winter coat... thick gloves... heavy boots... ugly sweaters.
- 11-03-2014** **No One.** It doesn't surprise me to see this so quickly: *"Of course the Toyota big wigs will look at it and say: See, no one wants plug-ins!"* It won't take long before people have no idea what was actually said. The quote isn't included in full anymore. The context is already lost. That's a recipe for trouble. We'll end up with a generalization which will be very difficult to shake. Sad, but true, is our reality. The best I could do about it was: The statement was actually about electric-only vehicles in the current market. It doesn't surprise me at all that has already mutated into a misunderstanding being spread around. Trying to point out to others last week that would happen fell on deaf ears... even though we've seen it happen before. I clearly remember a presentation Toyota made about lithium batteries a number of years ago. Cost was sighted as the reason for not embracing them. Almost immediately afterward, some started claiming the reason was fire concern. Even though that clearly wasn't what had actually been said, many people believed it. And still all these years later, the reason of cost still doesn't get recognized by some. It's greenwashing at its best. When incorrect information is innocently shared without anyone taking the time to verify that it is accurate. Eventually most people will end up seeing the difference. Sadly though, some will believe the change they see was the result of a decision change, having no idea they had incorrect information all along. Oh well.

- 11-03-2014 *The Other Perspective.*** It irritates me to no end how Toyota will get accused of a variety of different problems. But when GM does the same thing, there's no acknowledgement of it. Realistically, it doesn't matter anyway. One automaker is striving to deliver a product for the masses, pursuing the difficult consumers. Not going after the low-hanging fruit doesn't get much attention though. No one really cares about that other perspective. It's not exciting. It's just normal, what everyone buys. Not standing out in a crowd doesn't stir interest. Hype thrives on the unusual, not the ordinary. That's why there was always so much pushback from the idea of getting a second model of Volt, one with scaled-back features to bring cost down to a competitive level. Long story short, we found out recently from GM that won't happen. They will continue with the more expensive and higher risk one-size-fits-all approach for Volt. This is how I pointed that out, including the quotes made during the LA detail release for the upcoming next-gen model: Ironically, GM just conveyed a similar message, yet none have made a big deal about that: *"We will not offer varying battery sizes for the next-generation Volt but we will provide more EV range. Specifics will be released in January."* [Does Chevrolet have any plans to offer variations (aka models) within the Volt lineup?] *"No plans at this time."* [Is there gonna be 2 kind of volt? one will more Electric miles that the other?] *"We have only plans for one Volt."* In other words, no one is asking for a high-efficiency vehicle from them without a plug or a model choice that's more affordable.
- 11-04-2014 *Battery Speculation.*** There's lots of it and many of those speculated haven't actually studied the market or even Toyota history. That allows for a very distorted view, an incomplete perspective... prime with the opportunity for assumption. Some of the guessing is reasonable. Others can be without any basis on reality. We see it all. So, I join in from time to time, giving them something else to speculate about as well as interject some history. It's a counter-intuitive way of keeping hype from emerging. This was today's contribution: We already know that the design was intended to be verification for next-gen. Toyota has been taking that approach all along. Remember how Camry-hybrid got the two-speed upgrade before Prius? Engineering can be worked out in great detail. But market response and political/competitor spin is quite unpredictable. Being able to observe a wide variety of real-world data & reaction before going all-out can payoff big-time later on. Think about this. The small pack currently being used can be squeezed even smaller as battery energy-density increases. Cost will hopefully drop quite a bit too. Eventually, it would be realistic to use in a Prius C. That's a major potential benefit of starting small.

- 11-05-2014 EV Button, why?** It's existence really stirs the under-informed. We do what we can each time a new thread about it is created on the big Prius forum, like: There is an aspect of education & confirmation from the EV button. Many have attempted to greenwash by claiming Toyota didn't ever take adding a plug into consideration. That mode demonstrates there actually is more power potential available from the electric-motor already in the vehicle. It comes down to having a larger battery to deliver the higher kW required. It's understandable how that long-term view of the design can be easily overlooked. But then again, the regular model of Prius has already taken a next step. Maximum draw from the larger battery was increased in with the plug-in from 27 to 38 kW. That resulting power increase is easy to recognize behind the wheel. On paper, it gets even better. The electric-motor still offers greater potential. It is rated for 60 kW. Someday, battery cost and physical size could shrink enough to make that EV power increase a realistic option for the smaller model Prius too.
- 11-05-2014 Generations, part 0.** The reality of what generation actually mean doesn't sit well with some people... you know, those who see the world as an either/or situation with nothing between. So, building in flexibility, the ability to adapt along the way, doesn't sit well with them. We've seen that with Volt, we it was going to game everything, rather than being a contributing factor. Anywho, I posted this... know it was a topic which had been met with fierce resistance in the past: Prius PHV was designed without dependency on subsidies. It has a lucrative non-plug model to sustain high-volume production, reducing both cost & risk. That's proving to be worthwhile already too. With the price of gas dropping below \$3 per gallon and the cost of oil expected to remain low for years to come, it makes you wonder how the one-size-fits-all offerings will be promoted. Flexibility like that is very important, yet it continues to be dismissed as unnecessary. A basic principle of good business is having product diversity. Sadly, the gamble was made by some automakers that gas would remain expensive. It didn't. This is why we must take entire market into consideration. Looking at just plug-in offerings is a form of denial. Like it or not, plugging in will continue to be a tough sell. Election results from yesterday reinforce the support for increasing domestic fuel efforts, consequently keeping gas prices down. There is very little, sadly almost non-existent, support for the rollout of public chargers. The challenge to even stir effort in interest in efficiency will remain daunting. Blah.
- 11-06-2014 Generations, part 1.** That particular individual who thrives on debate wasn't too thrilled today when I called him out on what he had done to stir participation. He had been a source of irritation for awhile, contradicting posts just for the sake of keeping that topic alive. My attempt to look forward and advance the discussion required some context. He spun it to imply that context reference was actually focus on the past. Ugh. He was quite angry too for me having pointed out his activity. Normally, most people don't notice the pattern, since many are newer to the topic. Anywho, rather than fighting back and making it personal, I simply pointed out some perspective: It was well known right from the start the tax-credits would not expire until sometime in the middle of the next-generation. We all know design won't fundamentally change when a next-generation is rolled out. It cannot, since that would make it a new design rather than the incremental improvement the term "*generation*" represents. That means it must already carry those flexibility characteristics for the next to take advantage of them.

- 11-06-2014 Generations, part 2.** The attitude comes from having discovered how anti-climatic the next generation of Volt will be. Many of the high expectations have already been confirmed as not-going-to-happen. The biggest was hope that MPG would be competitive with Prius. But instead of getting a major efficiency increased as hoped, it will only be incremental. Some have figured the rough percentage stated will translate to giving Volt a rating of roughly 42 MPG. That keeps it in the traditional category, since we frequently see advertisements touting that highway value for some. The new Prius will obviously push beyond the 50 MPG it currently delivers, from the upcoming thermal efficiency and the software controller advances. Finding out there will not be a cost-competitive second model was obviously a let down too. Appealing to a wider market was really important... and the one-size-fits-all argument was something enthusiasts were hoping to finally rid themselves of. Not understanding what incremental improvement means has obviously become a problem. That hope of "*game changer*" still lingers. The idea of "*game player*" is not appealing... when your mindset has been focused on trophies, rather than becoming ubiquitous.
- 11-07-2014 Purchase Decisions.** The market for plug-in hybrids is obviously quite a mess. Ford's major space compromise and the MPG rating has kept it from getting much sales attention. They remain flat, which is nice for collecting long-term data, but not competitive when the sales of the non-plug model continue to drop. The situation is different for GM & Toyota. That odd association persists. Fortunately, discussions are surprisingly constructive and diverse... drawing in participation from both Prius PHV and Volt owners. This was my post on that decision thread today: In the early days of Volt, there were intense comparisons to Leaf. Remember the "*range anxiety*" campaign? That feel apart when Leaf sales ended up doing far better than GM supporters expected. So, comparisons refocused on Prius instead. It was an easy target, having a much smaller battery-pack. Keeping attention off the much better efficiency following depletion and the much larger seating area in back was fairly effective. But it didn't matter in the end. Volt would ultimately be compared to other GM vehicles. So, if you ask a dealer, they'll know far more about their traditional offerings than their plug-in selling at a rate of less than 1 per dealer per month. Those interesting in purchasing a Volt should shop carefully. Leases can be a great deal still. I know a number of people who took advantage of that opportunity to drive one without being obligated to keep it after a few years. Resale value, long-term reliability, or how much GM ends up altering Volt to make it a profitable high-volume vehicle is of no concern. You just enjoy the EV driving short-term. With the plug-in Prius, its a very close match to the non-plug model. You simply have a larger battery, offering much more electric power and delivering much more engine-off driving. There is no sacrifice of the cargo-area for carrying large objects inside. You get MPG just a little bit better than the regular model when not having plugged in. It should retain a decent resale value long-term. Just look at what happened with the gen-2 after gen-3 was introduced. Value remained high, despite the next-gen being available. Look at it this way, sales of plug-in vehicles will remain soft for the next few years. The price of gas is so low, stirring up demand is a major challenge. Infrastructure continues to present resistance too. You have to fight landlords to consider allowing you to plug in, employers are very reluctant to install chargers, and there is still some animosity among owners when space is limited. So, really study the market before making a decision.

- 11-07-2014** **There's No Way.** Several people jumped into that discussion about the EV button. A newbie absolutely insisted it wasn't possible to actually know what the system was doing and why... enough though I had pointed our aftermarket gauges which would enable him to see the same behind-the-scenes detail we do. Knowing what criteria triggers what response isn't rocket science, especially with so many years of so many people do the research and sharing their findings. He got really angry... never bothering to actually consider the suggestion learning more about those gauges. It's sad when people don't understand that they really do have more resources available at their disposal. They just assume incorrectly. Oh well. We try. It's their opportunity lost.
- 11-07-2014** **Cold Temperatures.** They have arrived... and wow, that certainly has presented interesting new data to collect & share. We're just above the freezing mark, currently. I can't wait to see what happens when outside conditions take a drop quite a bit further. Having the recharge end shortly before you drive most definitely influences the battery-pack. We know that electrical resistance increases considerably when dealing with frozen roads. So for those of you who get real winters, keep an eye on this thread over the next few months. Degradation from heat clearly isn't an issue in any respect. Yesterday's drive from work to my fiancée's home certainly confirmed that. The outside temperature was 37°F. The battery started at 46°F. I was determined to push the battery. The 10-mile drive started with a stretch at 50 mph, then increased to 60 mph. That flat highway then turned into a very, very long (about 3 miles) steep climb up at 45 mph. I arrived at the top with just 0.5 EV left. The battery had warmed to 72°F. Starting the engine at that point pushed the EV to 1.0 mile estimate. I got to her house just as the EV ran out and it switched to stealth mode. The battery reached its maximum of just 79°F. That's lower than starting temperatures in the summer, and I was really pushing it. That was quite an experience to witness. It's intriguing to observe rare data like that first hand, especially when the resulting efficiency was 225 MPG. Stay tuned for updates and eventually some cold-weather videos with temperature data.

11-08-2014 **Balance.** This speaks for itself: It's interesting reading the posts on recent threads. Prior to any info about the next-gen offerings, having any type of constructive discussion was quite a challenge. True, the ultimate goal of getting the plug-in vehicles to compete against the true competition rather than each other is still not close, but progress is being made. With that said... I have driven a Volt out on a closed track. In fact, I once chased a Tesla with it there. You'll notice the handling difference doing that. With ordinary driving condition, not so much. That's why the question of WHO? is so important. If you're not going to push it, there's no benefit. It's like owning a car capable of 120 mph but never going faster than 75 mph. The same goes for 0-60 times. Unless you press the pedal hard, you'll never use that faster acceleration available. Know your audience. The same goes for the cargo area. The flat nature of the Prius makes it much more convenient for hauling very large and very heavy cargo. The drop down into Volt's rear behind the seats is less accommodating. Simply pushing & pulling cargo in & out is much easier, since the entire surface is level. I roll in mom's 3-wheel recumbent bike into the Prius with very little effort. In Volt, that wouldn't be the case. I'd have to lower it in. The height of the seat folded down might cause the chain to rub on it too. Reality is that aspects such as those are what will be selling points of the plug-in vehicles, not a push for maximums. Just look at the computer industry for confirmation. There's no contest that the SSD (solid state drive) is superior. It's dramatically faster, uses much less power, and is far more robust. But to get a competitive capacity, it is very very expensive. That's why most people still purchase traditional hard-drives instead. For those willing to pay a modest premium, they chose a SSD with small capacity. It's a balance of priorities.

11-08-2014 **Balance (more).** It was pointed out that I forgot to mention the ability to sit on the back. I have done that quite a number of times. Simple things like using that flat surface while switching from shoes to rollerblades is easy to overlook. It's so convenient, you just don't think about it. What's even less obvious is the ability to host a tail-gate party. That large area works out great, especially being able to so easily access it from 3 different doors. There's no chance of anything falling into a lower section, since it's all at the same level. I've taken advantage of that storage usefulness on road trips too. You can shove bags & boxes anywhere, just pushing them over when needed. A height difference doesn't allow for that kind of flexibility.

- 11-09-2014 Business.** It's interesting to watch history play out. Decisions made in the present seem so wrong sometimes. Some people are so hung up on the fuel-cell product diversification, they feel Toyota's current efforts are being abandoned. The next-gen Prius is a great example; we already know of a few of the improvements on the way. They actually think not investing heavily in EV offerings right now will doom them to a future without anything electric-only to sell. The short-sightedness and quick-to-forget nature of consumers in this market is completely overlooked. I chimed into the on-going discussion with: I got a "*literal*" comment from a person the other day who does that on a regular basis. There was no point in even bothering to mention that though. The point is the business. That reference to "*door*" and "*knock*" was the larger market, not the literal. Cost is a major factor. It's easy to see Toyota embracing lithium when it becomes competitive. In the meantime, we have the NiMH patents expiring. I see that as a golden opportunity to push traditional vehicles out of the spotlight with regular hybrids. That will open the door for plug-in vehicles. Think about the misconceptions that still persist. The plug-ins have all of those for hybrids, plus quite a number of their own. I still hear the "*didn't know it could go that fast*" and "*when you have to replace the battery*" comments on a regular basis. Fortunately, those are far easier to deal with than in the past and the audience is much wider, but the real-world exposure for plug-in vehicles is quite lacking. We want more than just automaker offerings. We want them to be affordable and produced in high-volume too. People tend to forget about that part. That's the bigger challenge.
- 11-10-2014 EV Button, more power.** Turns out, the secondary aspect of the EV button was not apparent. People were making the assumption its only purpose was to prevent the engine from starting. Since the power tradeoff is often mentioned for the regular model, since the screen clearly shows the difference (for those paying attention), pointing it out for the C model hadn't occurred to anyone. So, I brought that to their attention. Exchanging speed for power hadn't been discussed... or even considered. That drew a conclusion to the thread in a hurry. It simply hadn't been taken into consideration that requesting EV would do more than simply switch from hybrid to electric-only. That's often the case. You can't blame those who get all worked up about a belief either... since it can sometimes be the case that they are under-informed. Just because they lashed out with emotion doesn't mean you should as well. After all, they did purchase a Prius and are making an effort to understand it better. Finding out you were incorrect can be an uncomfortable situation too. If they feel they can say "*oops!*" without feeling ridiculed, you did well.
- 11-10-2014 Last Week.** That terrible attitude is gone. The blogs and the old forum posts are now records of hostility, serving as a reminder of what we no longer have to deal with. I'm thrilled by how much things have settled down. Volt enthusiasts have grown silent. Volt supporters have been quietly waiting. Volt antagonists have run out of ammunition. It's over. Hooray! Confirmation of that came from all the likes I got from this: Volt is a nice car, rough around the edges currently and a terrible business approach, but owners themselves have been quite happy with their lease/purchase. Prius PHV owner satisfaction has been lower simply out of not having proper expectations. If you're hoping for an EV that switches over to gas after depletion, you will be disappointed. If you're hoping for an augmented Prius, delivering much higher MPG with EV driving at times, then you'll be quite pleased.

- 11-11-2014** **Winter.** It has arrived. We got some ice and a few inches of snow here. 100 miles north, they got over a foot. That had been forecast for here. Fortunately, the storm altered course. We still have the other effects though. The temperature is now in the 20's for daytime highs. We aren't expected to see temperatures climb for awhile. In fact, we may dip into the teens for a few days. I blocked the grille 2 weeks ago, which is the only thing I do to prepare. It helps with heat-retention. That's especially useful when driving a plug-in hybrid, since you want to hold on to as much warmth for as long as possible to run the heater. It delays the engine from having to restart. Anywho, the season called Fall is gone already. It seemed so short this year.
- 11-12-2014** **Still Good, uncertain.** A newbie from the forum dedicated to Volt recently joined the big forum for Prius included this in his comment about Prius PHV: "*...it may not use much EV mode at all...*". I took him at his word about being uncertain if that was correct. It was in reference to how the system operated below freezing. Knowing the source, I was well aware of how much effort has been expended there to misrepresent & mislead. Nonetheless, giving the benefit of doubt was still a wise choice. So, I did: That's called blending, not counted as EV even though it is still using lots of plug-supplied electricity. You picked up on a greenwashing effort, more information intended to undermine being spread. Always verify source. Here in Minnesota, I have lots of freezing data. And EV is most definitely still available. I have video clearly showing my usual commute with temperatures in the negatives, below 0°F.
- 11-12-2014** **Still Good, sincere.** Turns out, he was indeed being sincere. His objective stance welcomed the input, as well as the insight. That was very reassuring. In the past, that would have been an invitation for attack. Certain individuals were naive to the greenwashing, not willing to believe such effort would be made to make Volt look better. The thought of spreading incorrect information about Prius intentionally is difficult to accept. Why would someone stoop to the level of being dishonest? Well, it happened... a lot. That's rare now. We aren't totally certain why either. But with so much real-world data available now and such easy access to it, squashing bad intent doesn't take much effort. Thankfully, we don't even see the need for that anymore. It's remarkable how things have changed.

- 11-13-2014 Public Chargers.** Want to know how well the vehicles with larger battery-packs will sell? Look no further than your closest public charger. How far away is it? Who is allowed to use it? How much does it cost? Those basic questions get people thinking. The harder ones follow, like which vehicle gets precedence when spots are limited? If you only have a small battery-pack, but you drove to that location using only electricity, isn't that the point? What would allow the larger to recharge instead, especially if there's enough capacity available to get home anyway? What about the vehicles with engines too? Is it acceptable to unplug another vehicle after it has finished recharging? Who do you contact if a non-plug vehicle is parked in the spot? Needless to say, the situation is a mess. There is no clarity, no direction, no consistency. Faster chargers could be a possible solution. But then again, how many spots will a business choose to offer? What about landlords? How is pricing even determined? Will there eventually be a wireless (no plug, induction) standard? Heck, there isn't even a standard for indicating charge-status on the vehicles. It's a confusing market, even for the well informed. When the next-gen vehicles rollout and the tax-credits expire, it's going to become even more chaotic. Realistically, you cannot even expect anything beyond a common approach. After all, look at the way people connect to the internet. There's a wide variety of choices. Roadways are already filled with variety anyway. With increased pressure from competition, seeing some type of agreement at least among plug chargers represents a major step forward. Watch for that. It's a milestone for progress. In the meantime, good luck. I'm very happy with the plug-in Prius. It strives to offer the best of both worlds, demonstrating flexibility & balance in uncertain times.
- 11-14-2014 Cheap Gas.** It's becoming a problem. With the price of a barrel of oil now down to \$75, it's taking away the pain of refilling gas tanks. That's actually good for the economy. People will spend their money elsewhere instead. Retailers are excited about the possibilities that presents for holiday shopping. Automakers are excited about the potential that means for selling their high-profit vehicles... which unfortunately, are guzzlers. That's not good. MPG averages will go the wrong way and high-efficiency vehicles will be even harder to sell. I get the impression people are jumping on the chance to drive a large vehicle again and just figure they'll sell it later if the price of gas gets out of hand again. Sadly though, the forecast is for prices staying low. In fact, the House just passed a bill to allow the pipeline to be built. That will add oil from Canada into in the world market. Increasing supply certainly won't raise prices. That means the struggle will continue.

11-15-2014 Flawed Predictions. I just read an article predicting a huge sales increase for Volt when the second-generation is released. Needless to say, it caught my attention. The reasoning behind that prediction was based on Prius history. Problem was, the data used was flawed. So even if the logic was sound, there's no way the predictions could be accurate. The first problem was the writer's assumption that the first year of sales was an entire year. In reality, it wasn't even an entire month. Sales began mid-December back in 1997. Then, the writer went on to call the Classic sales here 4 years long. From late August 2000 to early September 2003 is only 3 years. Ugh. Following that came a complete lack of supply information. The Classic model wasn't even available on dealer's lots until May 2002. For the first 1.5 years, you had to order a Prius and wait several months for delivery. How could that possibly represent actual demand? Heck, most people didn't even have a clue what a hybrid was back then. When Prius was finally available for immediate purchase, supply was limited to a strict quota. It started at 15,000 annual, then increased to 20,000. So again, there was no way to gauge demand. What irritated me more than anything though was this particular point: "*Gas prices rose suddenly and sharply in 2004, right as the 2004 Prius hit the market as a new model with record-breaking fuel-economy ratings.*" That's just plain not true. The new model was rolled out in October 2003 and the spike in gas prices didn't come until September 2005. How such blatantly incorrect information can be published like that is beyond me. My guess is that there's nothing to write about anymore. Lack of new material contributes to such behavior.

11-15-2014 Battery in Cold. Yesterday provided new & unexpected data. Clearly, Toyota has a well thought out system. I went out to plug the Prius, late in the afternoon after having sat outside all day while I was working. The temperature was 19°F outside. I had expected the temperature of the battery-pack to have fallen to below freezing. After all, it showed itself to warm up from outside influence during the Summer. Turns out though, cold apparently has less of an effect. The temperature of the battery-pack was actually 51°F. That's great news for Winter operation. It also explains why EV is so easy, even when very cold out. That made me quite curious what it would be when I left work 2 hours later, after having fully recharged. To my surprise, it had only risen to 54°F. Though the outside temperature had dropped to 14°F, I still expected the act of drawing electricity to result in more heat. Later, when cold season eventually takes an icy grip on us and highs stay below 0°F, that should be especially intriguing.

- 11-16-2014 Battery Life.** People ask about it a lot. In fact, it's probably the most frequently questioned aspect of hybrid. Not having a plug confuses matters quite a bit. Fortunately, having a plug now is making the understanding of how the system works much easier. Phew! The biggest problem is not even knowing what to ask. People just plain never paid attention. They'd use a rechargeable device until it stopped working, then plugged it in. That's the worse possible thing you could do to a battery. Yet, it was very very common behavior. Sadly, we even see that with gas tanks in cars. A surprising number of people will often drive until the low-fuel warning illuminates before even thinking about refilling the tank. Squeezing out as much as possible is in their nature. It's that "*more is better*" mentality. Anywho, we try to remain constructive. I posted this today on the big Prius forum and got a few likes from it by none other than some Volt owners: 85% is what Toyota deems "*full*", stopping there rather than going to 100% for the sake of prolonging the life of the battery. 23.5% is cutoff for EV. Below that, high draw is prevented for the sake of longevity. 18% is the limitation for HV, for the sake of the battery preservation too. It's well thought out approach, avoiding stress from charge-level extremes. There's also a timer to allow "*cold soak*" time for the battery (letting it rest before recharging).
- 11-18-2014 Toyota Attacks.** I stopped participating on the daily blog for Volt. It just turned into a venue for hate. The source of ideas, material to confirm Prius was a wise approach for the masses, dried up. No more accidental reveals of important information. Detail exposing a shortcoming on GM's part really angered certain individuals. That's how those few enthusiasts who became antagonists emerged. Finding out the approach you heavily endorsed didn't deliver is a bitter pill to swallow. Reality on that scale is difficult to accept... hence the recent growing attacks on Toyota. They lash out, hoping it will make them feel better. It's why I became such a target. My stance was vindicated. They couldn't stand that. Those not obsessed with vengeance are often innocent bystanders. They aren't familiar with the history or simply weren't involved to that level. It's how we get commented like this intermixed in the discussion: "*The more I think about it, the more I see this car being a sacrificial lamb for Toyota. Its presence is totally for the sake of image. Its mission is to keep the spotlight shining on Toyota, and distract it away from GM, BMW, Nissan, Kia, Ford, and everybody else jumping onto the electrical bandwagon...*" Unfortunately, posts like that are enabling, especially when that quote ended with: "*...they see it as a promotional item to help keep the Toyota image front and center.*" The difference between Toyota's decision to follow-thru and actually offer fuel-cell vehicles to consumers is the quantity. GM was touting mainstream volume with Volt, hoping to achieve sustained sales of 5,000 per month by the end of their second year of sales and repeatedly stated production-capacity would be up to 10,000 per month by the end of the third year. Needless to say, that didn't happen... not even close. Toyota isn't saying that. In fact, all we get here is just 200 the first year. In their domestic market, 300 will be offered. The rest of the world gets 200. That's a total of just 700. Will that boost their image? Yes, of course. But they aren't in any way promoting a "*game changer*" as GM did. In fact, the production plans for the second & third year combined only a total of 3,000 worldwide. The true purpose is to prove the technology is robust, while at the same time help establish a hydrogen refueling standard.

- 11-19-2014** **More Hate.** It got really nasty today. I sure am glad my role is nothing but silent observer now. The attacks degenerated into: "*Government subsidies for new technology are BAD! (except for Toyota). Losing money on a new car is BAD! (except for Toyota).*" That was the result of so much hate having grown from Volt's \$7,500 tax-credit dependency. We all know the low sales would be quite a bit lower without that assistance. But rather than point that out, the rebuttal was rather clever. It came in the form of a reminder about PNGV. Remember that government funded program started in 1993 with the purpose of delivering 80 MPG family vehicles by 2003? Our government only providing money for the automakers in Detroit is how Prius was born. Toyota being left out had a profound unforeseen consequence. They delivered a hybrid by the end of 1997. Toyota began selling Prius before GM, Ford, or Chrysler even had viable prototypes. It was a devastating blow, shocking to the industry, and incredibly embarrassing. None of those Detroit automakers ever delivered a final product either. That was money wasted... which explains the resentment.
- 11-20-2014** **Disgust.** Remember the end of Two-Mode? That wasn't pretty either. The antagonists are well aware that the only way Volt can survive is for it to lose some of its niche qualities. Increasing sales requires appealing to a wider audience. That's a reality they just plain didn't want to accept. They were sincerely hoping market preference would instead change, rather than GM having to adapt to consumer need. What a concept! It's that "*want verses need*" problem all over again. That's what killed Two-Mode. That's what is killing Volt now. They see the announcements coming January 12 as the end, having to compromise rather than conquer. Admitting that balance was necessary is very difficult for some to accept. Going down fighting in the final battle is how they'll retain some pride. So, expect another 7.5 weeks of rhetoric. We'll still hold some disgust for such attitude, but at least it will come to a conclusion... and an abrupt one at that. As we've seen throughout hybrid history, they'll pretend those changes announced were part of the plan all along, that we had misinterpreted intent. Again, that's for pride, to protect reputation. Why must we have to deal with such obvious desperation? Everyone knew the purchase-priorities of middle-market right from the start. Hoping for a sudden paradigm-shift wasn't constructive.

11-22-2014 **Disappointment.** The push for goals ended up causing "5/50/50" to emerge. It's been repeated over and over again over the past 14 months as a result. The consequence of that was not getting any attention to the topic anymore. It's the reason why I persisted with the "Who?" question. That "5/50/50" from Volt enthusiasts represented: 5 seats, 50 mpg, 50 miles. Knowing the problems with that, it wasn't worth pursuing. Why bother? The design was not going to be fundamentally changed to add space for a 5th person to sit in back. It was a compact car with a battery-pack running through the middle. Why they somehow believed such a goal could be realistic was beyond me. And of course, we found out today that seating count for adults wouldn't change. It will remain 4 for the next-gen Volt. That goal of 50 mpg blew my mind. With such a heavy vehicle and Ford struggling to just deliver 42, how could so much more possibly be achieved? Supposedly, the efficiency of CS (Charge Sustaining mode) isn't important, since most driving is promoted to be electric-only anyway. As for hoping for 50 miles of EV range, that supports the lack of importance for engine efficiency. But with cost-reduction a major priority, that hope is a very real problem. To make matters worse, if battery cost drops that much, it makes electric-only vehicles even more appealing. That's why keeping the pack size fairly small makes it an appealing package option for Prius. The plug-in model becomes competitively affordable. Being in the middle equates to the worst of both worlds, paying extra for features you won't fully take advantage of. Anywho, that's what enthusiasts are beginning to understand now. As GM continues to release more information, we hear more grumbles of disappointment. What they hoped would raise appeal of the next-gen for the masses isn't going to be delivered.

11-22-2014 **Online Distortion.** It happens frequently. People assume what they read online is an accurate representation of what the market feels as a whole. The "*silent satisfied*" get completely ignored, not taken into account since they are never heard from. That causes a distortion. Yet, some refuse to accept that. It fit it frustrating. This comment today emphasized that point: "*Most of us, based on the comments in this forum, just want a really fuel-efficient car while satisfying most of the normal human appetites for power, cargo room, ride comfort and reliability. I think ads like this only alienate those of us who resent the image it paints of a Prius-owner. No wonder we get the finger so often.*" It was the type of over-generalization we've seen again and again. It's quite vague too. Needless to say, I pushed for more information... knowing getting any was highly unlikely: Who? Those of us on the forum represent at the very most just 4% of the entire Prius population in the United States. We all share a bias of being outspoken too, since we are online participants, which is not an ordinary trait. Try getting feedback from an ordinary consumer who simply just went to a dealer and purchased a Prius after having a pleasing test-drive experience. You'll find they have little in common with us here. Also, who's giving the finger (which I assume you mean figuratively). The many offline people I get feedback from about Prius simply aren't interested, they're indifferent toward owners. With so many more hybrids available and plug-in vehicles starting to get attention, what image do you think still exists? The new advertisement campaign continues with the effort to point out the variety of choices available, going out of its way to distance itself from the promotion of overkill features of the past. Remember that nonsense? Watching commercials of cars & trucks doing things you would never, ever dream of doing with your own vehicle was pointless. Yet, people came to expect that anyway... and ultimately would succumb to the hype. I'm glad Toyota is adhering to principle by not giving in to the pressure to push what consumers don't actually need. What do you think they should do instead?

- 11-24-2014 60 MPH Climb.** Yesterday's commute home was at 19°F. But rather than fire up the heater, I put both seats on high. My friend was intrigued by having started in EV and wanted to know how hard I could push the system under those conditions without the engine running. Since 2 miles away was a long, steep climb out of the river valley, it was the ideal opportunity to show off. This was the on the east side of the cities, the more intense road, complete with an extra lane for slower traffic. Normally taking the west side, which isn't as demanding, I was rather curious myself. So, we set out to observe it firsthand. I handed him my phone, so he could observe the many gauges available through the OBD-II reader. I pulled out into traffic and started the climb. To stress the point of the system being capable of keeping up with traffic in EV mode, I keep the distance between my Prius and the vehicle in front only a few car lengths. I made it up two-thirds of the way without any struggle whatsoever, going 60 mph using only electricity. That opened up the opportunity to really show off. I said "*watch this*", then pulled out into the left lane and started up the engine. It was a remarkably smooth transition to EV-BOOST mode, despite the continued climb and the engine being ice cold. That was great! I'll have to film that sometime. You can see how well the design is thought out by watching the electricity being taken advantage in that situation. It's quite informative. He certainly was impressed.
- 11-25-2014 \$2.59 Gas. \$3.93 Diesel.** The per-gallon price difference between the types of fuel has become rather extreme. It was really surprising to see those values on a sign today. I can't imagine what people who purchased diesel passenger-vehicles are thinking now. Of course, not many ever expected to see the cost of oil to drop so low. But then again, the "*drill baby drill*" chatting never died. We have continued to hear that on a regular basis. Keeping the price of gas at the guzzler level has been a major priority for some people of power. That wouldn't be so bad if that was balanced with a push for improved efficiency technology. But with such weak support of things like installing charge-stations, it's hard to see how plugging in will catch on. It makes me sad to say there's a "*Why bother?*" attitude. But then again, that's what makes Prius PHV so well positioned. It's the only plug-in hybrid approach targeted at ordinary consumers. The next-gen needs to be positioned to compete directly with traditional vehicles. Thankfully, that looks realistic. How else will reaching middle-market be possible with the price of gas that cheap? Offering the plug as a package option still looks a very sensible approach.

11-25-2014 Fuel-Cell Spin. There's been a lot of it lately. Much originates from the belief the Toyota's effort to deliver a fuel-cell vehicle represents an abandonment of plug-in choices. That mindset of "one" is really a problem. The concept of diversifying products simply doesn't register. They refuse to accept the idea of multiple offerings. Growing up in a society with an expectation of the market selecting a single technology as the "winner" has made that a fundamental part of who they are. You watch a standard be selected and everything else be abandoned. They cannot deal with a co-existence market. Yet, that's exactly what Toyota is pursuing. Some consumers won't have access to a plug. Some consumers will need to refuel within just a few minutes. That alone should be a clue that diversity is a good idea. The reality of the grid not being able to store large quantities of electricity is beyond their grasp. Turns out, hydrogen is a solution for many of those particular needs. Embracing that reality is too much... for some. For me, I understand it. That's why I pointed out today the huge improvement Toyota has made over the past 8 years or so. They've made a huge effort to reduce cost and now are reaching out to consumers for real-world data. To my amusement, that antagonist on the big Prius forum provided a link to an article with the claim that Toyota hasn't made any progress at all over the years, that in fact their MPGe (mpg equivalency) has actually dropped. Taking into account the cost difference was either completely overlooked or intentionally dismissed. Whatever the case, it's clear he doesn't like fuel-cell progress. I do. I see it as a complementary technology, existing side-by-side with plug-in hybrids many years from now. Not all consumers have the same need. Expecting a single technology to serve everyone is not reasonable. For that matter, it's not practical either. Just look at how diverse the market for mobile devices has become.

11-26-2014 Rewriting History. In the past, spreading incorrect information was the big problem for those of us participating on non-Prius forums routinely had to deal with. Now, we are seeing lots of incorrect history being spread. It's really difficult to know the intent of some individuals. Whatever the case, the outcome is a rewrite, conveying a story of events which never happened that way: For example: *"Even Toyota didn't branch out the Prius family until generation 4."* How would you respond to that? Knowing that generation 4 hasn't even been rolled out yet, there's reason to believe the person doesn't have a clue. It's probably safe to assume he actually meant 3 instead. But even so, that is very very wrong regardless. Sales of wagon model began the last month of 2011. That's an error of 6.5 years. So, he certainly wasn't close. Of course, it could have been deliberate greenwashing. Pretending that only hybrids labeled "Prius" count as branch is quite misleading, but we know certain individuals will spin words like that. I broke my silence on that daily blog for Volt and posted this in response: Highlander was rolled out as a hybrid way back in July 2005. It was a SUV, using an advanced version of the system in Prius, offering AWD. The following year, another version of the system rolled out. It was the hybrid Camry. GM should have similar plans to branch out in the next few years.

- 11-26-2014 Evidence of Change.** Switching over to the big GM forum, I was delighted to have stumbled across this: *"GM is absurdly lacking in hybrids. The Prius starts at \$25K and gets 51/48mpg. The Prius C starts under \$20k and gets 53/46. The Prius V starts at \$27K and gets 44/40. The Volt starts at \$15K MORE than the cheap Prius, \$10k more than the regular one. And if you live in a city you can't plug it in b/c you live in an apartment and don't have a garage. They should offer the Volt as a "regular" hybrid at a price competitive with the Prius. Chevy should also sell a hybrid Equinox. Buick should sell a hybrid Encore. It's ridiculous that they think they can get by with a two electric cars that barely sell."* It was a great summary pointing out the continuing product-gap GM faces. Ironically, it was in a thread about the future of ELR. With sales of that Cadillac version of Volt so poor, it does make you wonder what next steps will be taken. What is the overall plan? We still have no idea. Not being able to achieve the low sales goal set of just 200 per month, how can it be improved for growth? As much as they hate Prius, reality is that it sustains itself. Profit is being made. The platform is proving to worthwhile to build upon the plug offering too... as a package option, rather than requiring the business risk of needing an entirely separate design. It's good to see some understanding of the market sinking in. That engineer-only perspective was doomed from the start; yet, some hoped for a miracle anyway. Now, priorities are changing. Evidence of that is becoming easier and easier to find.
- 11-28-2014 Diversification.** Having to point out the importance of long-term and business-need over and over again gets old. But knowing how the market operates is the only way to overcome barriers. You cannot just hope for the best. Certain enthusiasts have overwhelmingly proven that's a dreadful idea. We're watching the earliest days of hydrogen play out, which serves as a nice example. It's an effort to reach those with needs a plug-in cannot serve. You wouldn't think that would be an issue. But coming from the mindset where only a single solution is acceptable... because that's all they've ever known... it's basically wasted effort. I find the unwillingness to consider a world with options quite frustrating, but understanding. Many desire simplicity. The idea of diversity is too much. So, they attempt to dance around reason and only accept the basics. That presents lots of problem; however, you can sometimes actually reach a few. Here's an attempt: Advanced Economics points out that market penetration cannot progress beyond a plateau if only a single manufacturer offers a fundamentally new product. The reason why is simple; there will be strong competition favoring the older choice instead. In this case, without the cooperation of other automakers, it isn't possible. They are necessary to increase sales for the original manufacturer. That means the others have to finally get in the game. It doesn't matter what they offer either, just as long as they aren't supporting only the old product anymore. It's that embracement of diversity, the act of joining with a new product of their own, is what allows the progress to occur.

11-29-2014 **Careful Reading.** It became quite clear many years ago that certain individuals outside of the big Prius forum responding to my posts weren't actually reading them. They'd just spin rhetoric for self-validation and their own entertainment. After all, when you're supporting a design struggling to achieve sales, lashing out at the person who was correct about some predictions right from the start is to be expected. What I didn't expect was to recently discover that some simply don't bother reading for detail from any source. On that daily blog, which rarely ever has anything about Volt anymore, there was a first-encounter report of the upcoming Toyota fuel-cell vehicle called Mirai. Even though the article clearly listed a driving-range of 300 miles and a price set at \$57,400 for this market, those were posted about incorrectly. One person complained about it only delivering 150 miles of range. Where the heck did that come from? One person said he had to hunt and finally just quoted \$60,000 as the assumed price. They were never corrected by their peers either. Everyone just silently agrees. Ugh. What gets me though is when it happens on the big Prius forum. Some people clearly don't read the posts there either. Even though you clearly & repeatedly mention the words "*competitive*" and "*choice*", there are complaints about you not having said that. I can understand a misread, where the word was overlooked. But when the same message is posted over and over again each time the topic comes up and the same people are participating in those discussions, there's no possible way to miss it. What excuse is there? Needless to say, it's annoying and obvious evidence of not making an effort to be constructive.

11-30-2014 **Why Bother?** That's a perspective we never encounter from an actual owner. Naturally, this made me quite curious: "*When I purchased my PiP, I calculated my costs and it was some \$0.33 per kWh. This is like paying >\$4 gallon gas. Might as well not plug it in.*" Whether or not I get a constructive reply is a mystery. Owners who made comments of that nature about the regular Prius already had made up their mind. So, it was pointless trying to present aspects of ownership they had probably overlooked. I gave it a try anyway: Fortunately, that isn't how our PLUG-IN HYBRID actually operates. Unfortunately, that is a very common assumption to think the benefit only comes from EV miles. Sadly, we unknowingly contribute to it too. In reality, you get a gain from the plug-supplied electricity that is very difficult to quantify... and for that matter, even to explain. For example, being able to take advantage of engine coolant heat while driving in EV is something many researching PiP don't think of or have any idea how to calculate the value of. Another example is simply not being aware of how quickly the engine shuts off after using it for a hard acceleration. It's too easy to assume it runs more than just a few seconds after warmed up. It's too difficult to determine how much gain you get from allowing the engine to join in to provide that extra power too.

- 12-01-2014** **Not Liking Answers.** Those certain individuals I keep mentioning share a trait. They don't like the answers. So, they keep asking the question over and over again. Sadly, that behavior rubs off on those who really are making an effort to be constructive. This particular comment today feel into that category: "*Clean air aside, what is the benefit of a hydrogen car to Joe Public? None.*" That meant it was worth the effort on my part to contribute something, hopefully, helpful to the discussion: Directly for Joe is the ability to rapidly refuel. Indirectly for Joe is the ability to store electricity. Remember that the grid doesn't actually have any batteries. That means renewable energy generated during the day from solar & wind needs to be held by some means. Think about how important that is over in Japan, where nuclear (their primary source of electricity) has become a very real concern. It's too bad here we aren't taking renewables as serious.
- 12-02-2014** **Needs & Goals.** More of the not liking answers. It's annoying. Oh well. The discussion continues: "*Letting other automakers expand the PHV market is part of the reason that the majority don't understand what Toyota's idea of plug in hybrid is.*" At least the active dialog is civil and somewhat thoughtful. Too bad some don't what to accept the reality of the situation. Like I said, oh well. I'll just keep asking: The true situation is not competition among other plug-in vehicles. As much as many hope that will be, it simply isn't. Traditional vehicles will continue to put intense pressure on the plug-in market. No matter how impressive those vehicles taking advantage of batteries and plug-supplied electricity are, the reality is that gas is dirt cheap. So, the majority just plain aren't interested. Reality bites. Dealing with it first requires acknowledgement of the actual problem. Start by identifying needs & goals. What are we trying to accomplish?
- 12-02-2014** **Acknowledging Facts.** Some people just plain don't like them. I kept my added contribution to the on-going discussion brief: What's comforting is FCV use the same propulsion system (motor & controllers) as EV. So offering a battery-pack instead of a fuel-stack isn't a big deal.
- 12-03-2014** **November Sales.** There's not much to say. They were pretty much all flat. Virtually no growth with gas prices so low was the expectation. Nissan stood out with Leaf though. But being the only competitive EV available, that was expected too. Even so, the amount was modest. That was enough to infuriate certain enthusiasts though. Leaf sales (2,687) were not supposed to be double that of Volt (1,336). Remember all that "*range anxiety*" nonsense? That marketing strategy completely fell apart. Seeing how uncertain the market can be is good reason for Toyota to wait. It's too bad antagonists love to spin the delay as a failure. That's quite hypocritical considering Volt enthusiasts said the very same thing. However, the difference is Toyota still has something competitive to sell in the meantime. They're fairly respectable too. 2,493 for Prius V and 2,975 for Prius C last month. The 8,038 for the regular model is well above the mainstream minimum of 5,000 per month, but we've obviously seen higher in the past. But then again, gas has dropped below \$3 per gallon and continue to fall. There isn't any tax-credit assistance for regular hybrids either. Anywho, weren't in a time of no little to no growth. That fear of the "Osborne" effect is a very real concern too. So, we continue to limp along with the current situation for now.

12-04-2014 Semantics & Quotes. When nothing constructive is left to say, the enthusiasts become antagonists. For example, last week I made an "*infrastructure*" comment. He knew my reference was to the market as a whole, not just the literal hardware-only perspective. I even pointed that out with a follow-up post. Yet, he went on and on about it anyway. Finally I had it and told him off about by saying to actually read what I post rather than fixate on literal. Those particular individuals like to dominate discussions without actually providing anything useful. The same thing has been happening with the comment from a Toyota executive about EV offerings. The people all worked up, believing Toyota is abandoning them in favor of fuel-cell vehicles haven't been listening to the comments about cost. Heck, they haven't even acknowledged the reality that a FCV uses the very same propulsion & comfort systems as EV. The difference being just a fuel-cell stack for power rather than a battery-pack is totally disregarded. It's a dead giveaway that they are responding due to emotion rather than actually thinking through the situation. Nonetheless, it is still frustrating. Toyota is responding appropriately to the market. They had flexibility built into their design. No one expected gas to actually drop to \$2.54 per gallon like it is now, but at least that isn't harming Toyota's profitability. They held back on further rollout of PHV and delayed the next-gen upgrade. Like it or not, it's proving to be a wise business decision... which is what the arguing of semantics and quibbles over quotes don't address. Find what was actually meant. Terms & Phrases are so easy to misinterpret without context, especially when there are some who don't want mainstream success. It's much more satisfying to have a standout vehicle rather than one that everyone else has. Change brings out the worse in some people.

12-05-2014 Repeating History, taunt. Watching the big GM forum distance itself from Volt certainly was an interesting chapter in its history. Two-Mode had become a hype nightmare. Allowing that to happen again was a terrible embarrassment. So, those most troubled by having made the same mistake twice lashed out, doing all they could to assign blame rather than accept what happened. Toyota & Prius were the obvious targets. Bait would be dropped. Sometimes that worked. But attracted little known contributors wasn't satisfying. That led to outright taunting, desperate attempts to provoke. Eventually, they satisfied their need and moved on. Now, Volt rarely ever gets mentioned there anymore. What was intended to be GM's premiere vehicle turned into a disaster. Knowing that history, it was only a matter of time the same sequence of events would play out on the daily blog for Volt too... especially since there were so few blogs actually about Volt anymore. On a regular basis, something about Toyota would be featured. After all, those articles are just republishes from the parent website... which has a very different audience. Anywho, with the exception of that solitary post at the very end of the thread at the end of the day, I haven't participated on the blog in weeks. Today's topic was too good to resist. I got called out by name... just like on the forum, it was a taunt to get me to sound off.

- 12-05-2014 Repeating History, comeback.** I posted a reply. It was immediately followed by insults, some outright lies, and confirmation of the very refusal response I had pointed out. Having read their posts over the past few weeks without participation, their hate for the situation Volt was now in had become obvious. That meant their reaction to my post was very much expected. No surprises there. Back in January, they had very high hopes for Cadillac ELR, anticipating a mid-cycle upgrade that would propel Volt into the mainstream. That fell apart. The technology didn't advance and sales were disappointing. Recent reveals about the next-gen upgrade to Volt have made that bad situation worse. With only a modest increase in engine efficiency and the much hoped for fifth seat not being delivered, there's been a subdued feeling. The improvements will be incremental... exactly what the word "generation" indicates. Cost will be reduced, performance will be refined, appeal will grow. Unfortunately, that also means having to deal with put-down comments about the model they currently own and constant questioning about the spreading of the technology. In other words, it puts them at a distinct disadvantage and they face having to post comebacks of their own.
- 12-05-2014 Repeating History, reply.** This is what I actually posted on that thread today: There are 2 realities some people continue to refuse to acknowledge. One is that a FCV is really just an EV with a fuel-cell instead of a battery-pack. So by taking on FCV so seriously, they're delivering technology for both. The propulsion system is totally electric, sharing the same traction-motor and controllers. The comfort system is totally electric, delivering both heating & cooling for the vehicle interior. There's a fuel-cell stack instead of a battery-pack. The other is that there is no way to actually store electricity on the grid. That means solar & wind, both of which are daytime intensive, cannot be used for overnight recharging. Being able to store that electricity in the form of hydrogen is a effective mean of taking advantage of renewable energy. Those are attempts to reach wide audiences, delivering a variety of solutions. Remember, they're still actively developing improved batteries too. They just aren't rolling them out yet.
- 12-05-2014 Repeating History, thoughts.** They didn't have any. The usual hungry until the message was suppressed happened. Again, it was refusal to acknowledge. The fact that a fuel-cell vehicle is really an enhanced battery-pack vehicle absolutely infuriates them. By focusing on FCV, they are also delivering a viable EV platform at the same time. Refinements in design, production, and cost to the electrical system will benefit both. As for the storage of electricity, that angers some to such a degree, I don't expect that to be taken seriously for years. We keep hearing that the plug infrastructure is already well established. That just plain is not true. Apartment renters and condo owners have major obstacles to overcome still. Those who actually own their garage don't necessarily have the electrical capacity to plug in. How many garages are you aware of that can handle two 12-amp draws at the same time? If you've got 2 cars you want to recharge overnight, how will you accomplish that? There's the obvious problem of speed too. Countless vehicles require refueling in 5 minutes or less. How the electricity is going to be delivered is a big deal. That's why EV alone isn't enough. We require a variety of solutions. Since GM abandoned fuel-cell efforts, it only makes sense that their supporters lash out at anyone endorsing a portfolio of choices which includes fuel-cells.

12-06-2014 **Repeating History, cheap gas.** Talking about repeating history. The price of gas here has dropped to \$2.49 per gallon. Plans for production numbers are getting revised. We expect interest in hybrids to drop. People will turn back to guzzling. It's a sad reality. That causes problems for plug-in advancement. Attention will be lost. It's a simple matter of priorities. Efficiency falls off the list. That "*good enough*" mindset is a barrier we'll have to overcome, yet again. The cycle is maddening... especially for those who gambled everything on the hope that gas prices would remain high. We saw \$4 gas. The missed opportunity Volt had to capitalize on that now burns more than ever... which why those enthusiasts get so angry at people like me... who endorsed a flexible platform instead. They sincerely believed it was unnecessary, that the ability to cope with a changing market was a waste. They were clearly wrong. The market is unpredictable & unforgiving. Being told that before is made no difference. Hearing it now won't either. They're lost & desperate... just like we saw happen with the forum. People will just move on. Leaf is obvious evidence of that. Sales are stronger and growing. The lesson to be learned is a plug-in hybrid much be have both competitive production-cost and competitive depleted-efficiency is a painful one. You'd think the first time with Two-Mode would have been enough. This second with Volt should make it obvious. Not being competitive means major challenges.

12-07-2014 **MPGe Issues.** It's not with this method of quantifying efficiency. That works fine. The issue is that it doesn't fit into the perception of green verses its reality. More EV miles is thought of as better, period. How much electricity is actually consumed is disregarded; instead, there is a stigma made from an engine running. It's basic greenwashing. Disregard true performance in favor of large numbers. Needless to say, that comes up a lot when discussing Volt. Today, it was a woman getting attacked for pointing out the first one to reach 200,000 miles only delivered 49.64 MPGe. That's a devastating blow for a vehicle a rating of 94 MPGe. Right away, the enthusiasts pounced, attempting to discredit any value in that equivalency measure. Fortunately, the responses on the big Prius forum were more constructive than that on the EV website. I do wonder what my post will stir in response to this comment though: *"I don't like to confuse things with that horrible MPGe garbage. It's more accurate to calculate actual costs using the current prices for electricity and gasoline. So as you can see the actual economics are very dependent on the specific owner. Some people pay for all of their electricity, some pay for none and others pay for only some."* It started as a constructive discussion. But leaving out detail is rather frustrating for me, hence: LOCATION does far more to spread "*garbage*" in reality. At least with MPGe, there's a clear understanding that it is just a standardized measurement taking all fuel energies into account. When a tread like this is starting, it provides a great source of real-world data for readers to analyze and comment about, but it is so far off from reality for those living in the north, there's no benefit from it. In fact, without a disclaimer of it only be representative of mild-climate driving, the data can be very misleading. That's why comparisons being the regular model Prius and the plug-in still don't have any generalizations associated with them. You just plain cannot. It doesn't set an appropriate expectation. The fluctuations in temperature make are far too much of an influence. So comparing to a totally different approach, like Volt, skews outcome even more. Sorry, but that's the reality of the situation.

12-07-2014 New Technology. The mentality of "*ready*" is an interesting one these days. I remember my neighbor about 12 years ago making comments about not wanting to purchase a hybrid until they were "*ready*" for everyone. He had absolutely no idea what that actually meant though. He couldn't quantify any measure to confirm when that milestone had been reached or even describe how it would be accomplished and by who. It was the classic "*not me*" perspective. People simply didn't care about something until it affected. But nowadays with the internet such a part of our lives, we hear about those things far in advance. Notice how virtually no one cared about E85 until that craziness in 2006. Back in the late 90's, that was a normal part of our lives here. 100% of the Ford Rangers, which were produced just miles up the road from where I live, were flex-fuel. It was no big deal. We already saw it as ready... even though the future of ethanol wasn't clear. So, this comment today stirred me: "*Totally new technology should be adopted when it is clearly a winner. Hydrogen fuel cells for everyday passenger cars (or as range extenders in ordinary plug-in hybrids) just don't have a compelling case that makes it worth the effort to adopt them.*" What was the purpose of that? For that matter, who will be adopting? Why does he even care? I remember the generation-zero data-collection here for Prius back in 1999, prior to the rollout of "*first*" generation. How is this any different? Anywho, the response was: Drawing a conclusion about new technology shouldn't be made until it is ready for that stage either. Hydrogen fuel-cells are still only at the "*try it in real-world conditions*" stage. There is no effort whatsoever being made to reach anything representing the everyday market yet, not even remotely close. 200 of them will be offered for purchase here the first year. That's not even enough to qualify as a compliance quantity. It's nothing but a "*collect data from random people*" step. That's what you do to progress forward with development. Long story short, the "*compelling case*" consideration is many years away still.

12-07-2014 That Petition. The number of people who have signed it is close to reaching the goal of 100,000; yet, its purpose still remains unclear. Remember all the signatures for Volt? They got 50,000 and that was loaded with uncertainty. It didn't end up accomplishing anything either. So, with this one, I had to say: I keep wondering what the petition is actually for. We know they are still working to improve batteries. We know that motor & controller improvements for the fuel-cell will be a direct benefit to future battery-powered vehicles. We also know that Toyota doesn't bet the farm on any single technology. Who else has had success in the EV market so far? Sustainable quantities have only been achieved by Nissan & Tesla. Both of which depend upon tax-credits and have uncertain targets though. The long-term potential is fantastic. But looking at the other automakers (Ford, GM, VW, Honda, Mitsubishi, Smart, Kia, Fiat) all struggling right now, it seems odds to push for rollout from Toyota. Changing the way the EV is promoted makes far more sense. I can see that as a worthwhile effort. We already know any low-volume attempt will just be spun as a compliance move anyway. What will adding another choice accomplish? I see the real gain coming from greater market penetration of hybrids. Finally letting go of traditional vehicles is an extraordinarily difficult bridge to cross. So many pressures pushing back make it a daunting challenge to try to achieve a paradigm shift quickly... hence striving to diversify instead. We'll see the fuel-cell & hydrogen progress slowly in the meantime. We'll also see uncertainty faced by the other automakers. What will their next move be? The next-gen plug for Prius will tell us much about what true change is coming. It will be the major influence as to what degree other plug-in offerings from Toyota will be, not a vague petition without any clear message on what's actually wanted.

- 12-07-2014 Repeat Purchase Survey.** What do they tell us under normal circumstances for major purchases? Heck, how much it cost for a gallon of gas has much more of a impact than anything even the most resourceful of us can do to influence a hybrid purchase. So when it comes to plugging in, what can we learn about first-generation offerings? Know the second will be quite different anyway, what's the point? There probably isn't one, but at least there's an effort to see if any type of pattern or majority emerges. That's at least better than nothing... or is it? At what point is it better to start fresh? After all, when most owners of a Prius PHV made their purchase, how many plug-in vehicles were even offered then? Did then even know what it meant to be a plug-in hybrid? How accurate were their assumptions? After all, the availability of real-world data is still rather scarce. Anywho, this is what I contributed to the thread about this topic on the big Prius forum today: Expectations for the plug-in were all over the place. There was a major greenwashing effort underway in the early days too, taking advantage of people's lack of understanding of what batteries can and cannot deliver. Combine with the assumptions people are now making about what the next may or may not deliver, how could anyone get an accurate depiction of what future purchase choices may be? Heck, just price alone has a major influence... and we have no idea what it will be.
- 12-08-2014 Conspiracy.** Wanting some level of closure prior to the gen-2 reveal of Volt, the topic of fuel-cell advancement has been helpful. It's a flushing out those who aren't constructive, those who just like to debate or have some type of vendetta... or this case, wish to stir up trouble. I start by addressing there posts indirectly. If they still lash out and don't even try to meet in the middle, they'll end up getting ignored. That forum feature is very handy. This was one such flush: How is fuel-cell advancement any different from other "*alternates*" with the same long-term ambitions of eventually becoming a common choice? It takes decades and there are very real barriers to overcome. One big one everyone seems to overlook is the reality of patents. If you're first to pounce, you stand a greater chance of capitalizing on the opportunity. It's a simple formula to success we've seen play out many times. The costs & risks are traded off with that leadership potential. There's obvious upset from the EV crowd for Toyota not delivering something competitive in the electric-only arena, but there aren't any bridges actually being burned. Look at all the "anti" advertising of the past for proof. We all know that battery advancement can & will change automaker stance on their offerings. We also know that reputation is not built upon offerings alone. I personally get annoyed by the effort to push a conspiracy belief, especially what all the history we've witnessed with hybrids. Remember all the anti-hybrid nonsense from GM, followed by an intense anti-EV campaign? All that effort resulted in a vehicle which didn't take the market by storm as promised. Heck, sales are just barely squeaking along, even with a generous tax-credit. Take a close look at Ford, who really did try to deliver something competitive. Sales have been adequate, but next steps are a bit of a mystery. Is keeping silent on plans better? The double-standards and lack of big-picture consideration is frustrating. Not taking into account history adds to it. But what I find most interesting is the complete disregard for the existing energy distribution system. It seems as though there are some so naïve that they think the oil, gas, transport, and reseller network will just abandon their business? Hydrogen will become the take-over product. They can continue their business as usual, but with that instead. We'll be able to produce locally too, without having to drill or frack. Somehow, all the players involved must find a way to get along. Without a major effort to cooperate, how much change do we actually think we can achieve?

12-08-2014 **Hypocritical.** The look-back afterward is absolutely fascinating. Some people say the outcome was so obvious, it was ridiculous to assume any other choice would have been supported. Yet, when in the mist of that choice, they cannot see it. That's playing out again. Certain people believe the long-term effort to offer hydrogen as a fuel option is really an effort to not deliver EV instead. It's not taking all the factors at play into account which often causes that, another is the mindset of only a single type winning. The thought of a world with multiple choices is beyond their grasp or desire. The reality of both using electricity for propulsion and not everyone being able to plug in to recharge is too much. Ugh. Oh well, they'll just fade away like all the others we've had to deal with in the past. They'll look back and finally see what we had been saying all along. I put it this way: Reality is, batteries still cost too much... hence the current stance. Spreading of the belief that electric-only vehicles are actually competitive isn't helpful. Traditional vehicles are absolutely crushing the high-efficiency market still. Why is that so difficult to accept? I'm amazed by the continued double-standard. I could just as well call it hypocritical. My blogs are loaded with quotes about how absurd it was to believe Volt hype years ago, that the posts of enthusiasts and articles from media shouldn't have been taken seriously. Yet, that's exactly what's happening now with FCV. Looking at attempts to diversify for long-term well-being as an anti-plug-in war is rather amusing. We all know how easy it is to spin comments, take them out of context, and blow them out of proportion. No amount of replies will change the minds of some though.

12-09-2014 **\$2.44 Per Gallon.** The price of gas is remarkable. It's the result of oil barrels dropping to the low 60's. With prices cut that significant, the outlook is rather grim. What incentive is there anymore? Cost is a very real problem. Not much can be done due to the over-supply though. We'll end up watching the fuel-economy average revert. Going in the wrong direction like that is the very thing those watching MPG feared. Remember the "*boil a frog*" analogy? Interestingly, the upswing will likely happen around the time the next-gen Prius is rolled out. In the meantime, our lowered standards will continue to cause harm. That's sad. Maybe this is a good thing, an opportunity to automakers to discreetly catch up... or at least try to develop something actually competitive. We've seen the emphasis on speed & power result in efficiency sacrifice. Maybe this time that tradeoff won't be as severe. After all, that excess speed & power increased cost. Making the vehicle affordable was the lesson learned. Perhaps they'd finally acknowledge the importance of what's actually needed rather than catering to want. But then again, perhaps not.

- 12-10-2014** **Misrepresentation.** This is quite common: *"We are continuously contrasting and projecting the sales performance of the Prius with the Volt on this site. Especially those who shall remain nameless. The Prius is a fourth generation product with 17 years incubation in the product pipeline, the volt barely has 4 years on generation one."* On that big GM forum, I become the lightning-rod. Everyone upset with Volt's struggle associated comments made in favor of Prius or Toyota as things I said. It got pretty bad too. There were quotes used in retaliation to mine that I just plain didn't say, not even close. Posting nameless messages like this contributed to the false belief. They'd refuse to link back to the source too. Also, note the intentional misspelling of Prius. That daily blog is trouble; thankful, it is far from representative of most Volt owners. These are just enthusiasts attempting to rekindle lost hope by keeping focus off the actual problem. Having someone else to blame can be healing. I find the blatant misrepresentation annoying. But then again, there are interesting ways to respond: Would you like me to provide the topic link from this website explaining in great detail how Volt inherited experience & expertise from GM's prior high-efficiency offerings? Note how both EV1 and Two-Mode played major roles and contributed a great deal to what's in Volt now. As for the comparisons to Prius, I too wonder why some people still do that. In fact, they often don't even refer to the plug-in model. How does that make sense? Anywho, my compares have been in reference to GM's other offerings, since that's the true competition. Cars like Malibu, Impala, and Cruze continue to draw GM customers away from Volt. Also, the precedent of 5,000 sales per month, was established well over a decade ago by the industry and was embraced by GM as the target they too would strive for with Volt. So, there's no need to compare to Prius anyway. Whatever the case, Volt must become sustainably profitable without tax-credit help. Seeing how much the plug-in category is both growing & diversifying, that's a tall order. With the price of gas so low now and *"range anxiety"* proving not to be a major concern, the challenge is even more difficult. GM must find a way to increase sales of the platform within the next few years for it to continue.
- 12-11-2014** **Desperation Growing.** The article published today was so reminiscent of 10 years ago, I was beside myself. It was an outright attack on owners titled: *"With \$2 Gas, the Toyota Prius Is for Drivers Who Stink at Math"*. It was stunning to see such blatant greenwashing. This was caught my attention, resulting in anger I wasn't sure where to direct: *"The Cruze gets a respectable 30 miles per gallon of combined highway and city driving, but its real strength is relative affordability. Without a second engine and a massive battery, the average Cruze had a \$21,322 sticker price last month, compared with almost \$31,973 for a Prius..."* Having lowered our standards to the point where a compact car delivering a combined efficiency of 30 MPG is considered acceptable is embarrassing. But to mislead on price to that extreme is terrible. The base price for the Prius larger than Cruze is \$25,025 (msrp + dest). The base price for the Prius the same size as Cruze is \$19,905 (msrp + dest). The decided to use fully loaded models for comparing instead, but without disclosing that or pointing out the features Prius delivers which Cruze does not. Leaving out detail to make people assume incorrectly is desperation... definitely not anything we'd consider journalism.

12-12-2014 **Bigger Big Picture.** That was the spin today. You guessed it, those Volt enthusiasts are in a state of panic at this point. Gas is down to \$2.34 per gallon here (even lower in some places) and the news is filled with expectations of prices continuing to drop. The problem comes from supply. It's cheap to continue pumping oil. Stopping costs money, even with oil having fallen below \$60 per barrel. The system is getting flooded with excess. That will be a boost to the economy, so there isn't much concern about stopping the events now playing out. In other words, we're seeing signs of consumption encouragement emerge. That's troubling in the long run. Small SUVs will likely see a rise in popularity. Imagine the kind of pressure that puts on the forthcoming next-gen rollout for Volt. Some areas of the country will be selling \$2 gas. How will it stir demand? Needless to say, when I pointed out the true competition, the reaction was extreme. They want someone to take their frustration out on. Knowing a hybrid like the next-gen Prius stands a much better chance of competing in a market with cheap gas, that was to be expected. I'd love to hear what Leaf supporters have to say about the situation. For that matter, even Volt supporters will have my interest. Their comments are usually quite constructive. The childish insults, name calling, and dismissals as "*stupid*" from enthusiasts certainly isn't worth wasting time on. I still can't believe we're witnessing that type of behavior still, but it does explain why the supporters don't want any part of the nonsense they stir. Long story short, this lead into the new year sure is building up. 2015 will be a pivotal time in high-efficiency, clean-emission vehicle history.

12-13-2014 **4.5 Years Ago.** There was an interesting outlook on the potential for plugging in back then. Volt enthusiasts who had been pushing the "*vastly superior*" hype were beginning to learn that something was wrong. Details being revealed prior to rollout weren't meeting expectations. That left those of us hoping for the potential from Nissan, Toyota, and Ford to not reveal similar concerns. That seemed unlikely, since they didn't leave fundamental questions unanswered. GM was touting "*transparency*" but leaving some of us scratching our heads. That meant asking the questions again ourselves would inevitably result in explosive reaction. That same hostility is alive & well again now. They focus on engineering, claiming that was the better approach, but not wanting to look at all the data to confirm it. Getting caught cherry-picking obviously stirs post activity. They're well aware they're being selective, but just plain don't care... hence the difference between an enthusiast and a supporter. Even at the minimum mainstream sales volume of 60,000 annually, making a real difference will be a challenge. The quantity of guzzlers (traditional vehicles) will easily overwhelm. That's not enough to offset the wasted consumption... and they know it. That's why there is so much resentment for Toyota. Selling 1 million hybrids worldwide within just the first 9 months of 2014 is what's really making an impact to oil-dependency reduction, as well as both less carbon-dioxide and smog-related emissions. The approach of offering a larger capacity battery as cost & density improve is clearly proving to be the better choice. The hope for cheap-batteries & expensive-gas approach clearly didn't work out well. There's still that matter of tax-credit dependency too. Now, 4.5 years later, what are consumers purchasing?

- 12-13-2014 Automaker Production.** That's been at the heart of the issues with high-efficiency, low-emission vehicles all along. The reveal 2 months ago that Volt would remain a single model obviously stirred the market-growth issue. That made the issue of traditional-vehicle sales sting even more. What I didn't realize though was to what degree. I was unaware that GM had just announced another \$3.6 Billion investment for production increases in Mexico. That brings expectation of job generation up to 5,600. Knowing there have been plant closures here and that the federal government lost over \$10 Billion in the stock purchase, the abrupt increase in terse posting makes sense. Supporters aren't happy either. It's unfortunate that newer technologies get dragged into political & economic strife, but that's reality. Those issues will always exist. Either face them to overcome or pretend they aren't a problem. Which seems the sensible tactic?
- 12-13-2014 One Month From Now.** We'll have the long-awaited details for the next-gen Volt then. That's been holding up the rest of industry mainstream rollout announcements. Other automakers are delaying until GM takes the stage, though we have been getting hints from Nissan. Nothing has come from Ford. Their heavy anti-Prius campaign claiming C-Max efficiency was better than Prius-V has turned into a major setback. There's a lot of disappointment from having discovered it wasn't. Fortunately, they still have the plug-in models to draw upon. Toyota has done as the usually do, waiting until the fallout before making announcements of their own. Expectations for GM have already been lowered from colossal to incremental. Hope of major engine MPG improvement is gone, as is the hope for a fifth seat. No word on legroom in back already has some worried too. Capacity from the battery is expected to fulfill the hope of many; however, that is presenting concern about vehicle cost remaining high as a result. That's a very big deal for a vehicle needing to sustain high-volume sales without subsidies. There's wonder who the audience will be as well. With gas prices continuing to drop, it's very reasonable to see the spotlight cast on small SUVs and Pickups instead.
- 12-14-2014 Avoiding Detail.** This is a favorite recent greenwashing quote I had to deal with: "*To rebut such statements unfortunately gives them some measurable status and so I don't even feel it otherwise needs to be rebutted, as it should be evident as meaningless to most everyone here following this greater discussion.*" When they don't like what you have to say, the typical response is to shot the messenger. They do everything they can to discredit the person, rather than actually address whatever statement had been made. That's typical it though. Rarely ever is there any type of acknowledgement of claim itself. That's why I liked that one so much. The matter would have been over with a simple provision of detail. But it wasn't. The greenwashing comes about from the effort to avoid detail. Even with trolling, at response with detail is what brings that to an end. He didn't, since he'd knew it would reveal his true intentions. Aren't these online games fun? What a pain. I found it amusing how lengthy his response was. That in itself served to provide some measurable status. Ironic, eh?

12-14-2014 **Old Arguments.** We've heard the same old nonsense over and over and over again. Each ends with a statement similar to this one yesterday: "*Yet, plugins are being adopted at a much faster rate than hybrid ICE's were.*" Back then, each automaker wasn't striving to deliver a hybrid of some sort as we see with the plug-in choices now. That sense of collaboration simply didn't exist, in any fashion. The market was very anti-efficiency. Remember the wide variety of SUVs being offered and the push to consume cheap gas for the betterment of our economy? That in itself makes such statements disingenuous. The fact that there was only a \$2,000 tax DEDUCTION available back then (which amounted to between \$300 to \$400 back on your taxes) was nowhere near as generous as the \$7,500 tax CREDIT available now makes any claim of being the same a desperate effort to mislead. That's one of those bits of detail they very much try to avoid. It never ceases to amaze me how some people believe that deception is acceptable. Whatever the case, it's now an old argument. By the end of the 4th year of sales, which is what Volt enthusiasts are comparing to now, Prius was rapidly approaching the mainstream minimum of 5,000 sales per month. The total for the year was 53,991 here in North America... which is amazing considering Camry was at 426,990 and Corolla 331,161. Volt is only at 17,315 for the year, so far through November. Add in 27,098 for Leaf and 14,650 for Tesla Model S, you get a number not big enough to call "*much faster*". That's with a tax CREDIT and not taking into account that Prius was profitable at that point too. The fifth year really made things interesting. When the price of oil & gas shot up, so did the sales of Prius. The expected low prices for next year certainly won't boost plug-in sales.

12-14-2014 **Tax Credits.** With the count of Leaf sales now exceeding 70,000 and 200,000 being the expiration trigger for the credit, talk of the "*imperfect*" nature of how the money was allocated is becoming a popular topic. Each of the next-gen offerings will have to deal with that loss of incentives. Without that subsidy available, competing will be quite a challenge. Just imagine how Nissan will have to deal with that when GM still has a large amount still. That imbalance will be a very real problem. There's always been the complaint about the amount itself too. Setting the value based on capacity disincentive a push to reach more consumers. There was no choice about how the money could be allocated. The big issue I've been focused on though is the lack of any time duration limit. When assigning homework, there's always a due date. Why wasn't there one with this? After all, there was a quantity goal of 1,000,000 by the end of 2015 set for the country as a whole. Why didn't the credit coincide with that? I find it quite reasonable to specify a time-period, allowing it to expire for everyone on the same day. After all, the other incentives (like home charging-stations) had a specific ending. Otherwise, automakers will just drag on for years and years, milking their niche offering for sake of a green image without actually needing to sell many. There's less to encourage competition otherwise. Having set an across-the-board expiration would achieve that.

- 12-14-2014 Long-Term.** My issue with Volt, besides the obvious cost problem, has always been the self-deprecating nature of its approach. There was a huge campaign promoting the importance of offering a "40-mile" range. Now, 4 years after rollout, absolutely everyone has abandoned that. Even the enthusiasts are clamoring for more. But as the increase becomes affordable, the point of also including an engine drops. That's why Toyota's modest approach still worked. It was small enough to augment the hybrid without requiring a huge premium. That's great for short-term and reaching the masses. Long-Term, we're looking at EV and FCV offerings as the solution. Both work for the age when oil is extremely expensive and when smog-related emissions are terrible. Ever notice how the only shortcoming fuel-cell opponents can come up with is carbon-emissions and cost? The reduction of cost seems realistic, especially since we are well over a decade away still before any significant infrastructure will be in place for distribution anyway. As for carbon, that's where the renewable sources for electricity come into play. They also contribute heavily to no longer needing centralized production. All that is a big deal for Japan too, a country without any natural resources. Sadly, we feel it isn't an priority due to the abundance of oil & natural-gas. The dual benefit from pursuing fuel-cell advancement is a win as well, but share propulsion & comfort components.
- 12-14-2014 Air Quality Advisory.** It's been unusually warm here lately. The result has been thick fog overnight and dense wet air during the day. As a result, we've been seeing air quality advisory notices on the flexible-text highway signs. While driving home today, I saw "Reduce Trips" and "Avoid Idling" notices. It makes you wonder how effective advice like that really is. For me, driving a plug-in hybrid, it made no difference at all... since my contributions to emissions are much, much lower than just about everyone I see on the roads everyday. The idling aspect brings up an interesting thought. Hybrids like Prius keep that to a minimum, especially in stop & slow conditions. What to people do when in a drive-thru with a traditional vehicle on a day like today? Do they shut off there engine manually in the meantime? Do they go inside instead? Do they even give a thought about their emissions?
- 12-15-2014 Mirai Sales.** They began today. That's why there was so much of an outcry. Rather than hype for years and years, Toyota simply showed the world and said they'd begin offering it for sales shortly. That's exactly what happened with Prius many years ago too. Of course, back then (in 1997), the Big 3 were scrambling to deliver high-efficiency vehicles of their own. In this case, there is no race. However, there are 16 other hydrogen vehicle which have all be revealed in some fashion by the others over the years. It's just that this is a more ambitious plan than just limited quantity leases. An interesting point though is that the "anti" crowd made such big deal out of the situation, attempting to amply expectations to such an extreme, the outcome has been attention which otherwise wouldn't have happened. Negative publicity having a positive effect is nothing new. The worse that can happen with a rollout is no one caring. To go completely unnoticed is worse than backlash. Of course, there won't be much backlash anyway. Toyota clearly stated this is a long-term effort with very limited quantities for the next few years. It's been a multi-generation effort, where major improvements are delivered along the way. They made major progress since the previous generation in 2008. Refinement will continue. The next will bring more improvements. Point being, this isn't one isn't targeted for mainstream consumers. It is for the niche buyers though, those who are willing to pay for premiere technology.

- 12-16-2014 Know Your Audience.** Invited to participate, I went back to that blog to post this: 4 years ago, GM rolled out Volt. The design focused on want, following the "*if you build it, they will buy it*" approach. Consumers were purchasing cars based on need though. The result was far fewer sales than planned. That's why asking the "*who?*" question about gen-2 stirs such responses now. There's concern that the same priority mismatch could happen again. In one month, we'll get the answer, we'll find out about the audience. Will out be ordinary mainstream consumers, those set a high priority on vehicle price and interior space? Or will there be an emphasis on performance instead?
- 12-16-2014 Engine-Braking On Ice.** Talk to someone who's driven a vehicle with a manual transmission. Down-Shifting when you have the need to slow down but don't want to use the brakes for risk of them slipping from pressing the pedal too hard. It's what they naturally do. It's no big deal. Mention doing that same thing with a Prius, some owners go nuts. They're passionate expressions of how terrible of a choice that is makes you wonder if they've ever had any training on how to drive on slippery roads. I still cannot figure out if they don't understand the concept or simply haven't ever actually tried it. Needless to say, with 14 Winters of driving a Prius in Minnesota, I have... and think it's a great idea. Today's experience provided a wonderful example of the behavior too. I was doing 65 mph in the left lane of a 3-lane highway. The temperature was just a little above freezing. There much have been a wind funneling through a tight area, since all of a sudden there was ice and brake-lights. Someone had an accident there too, so the backup was widespread. I pawed the dashboard. Toyota's well thought out design allows you to shift to "B" mode for engine-braking without having to look. All you have to do is make contact with the shifter in a downward motion. It's position makes that simple. The Prius quickly slowed... without ever having to touch the brake pedal. That was great! It's a smoooooth deceleration, not harsh like hard braking, especially if you overdo and the anti-locks having to compensate after slip has been detected. Remember, you don't want to contribute to panic in the vehicle behind you. Being able to prevent potential slipping helps. It's as simple as using the hybrid version of down-shifting.
- 12-17-2014 \$2.25 Per Gallon.** I remember how traumatic that was over 9 years ago, when it first climbed to that height. No one ever imagined it would drop back down to that level once we hit the end-of-the-world price of \$4 per gallon. That's where we find ourselves now though. What a bizarre situation. The growing expectation is a big step backward in terms of vehicle efficiency. There will undoubtedly be lots of great year-end sales to dump guzzlers. I can't imagine what that will mean for hybrid & plug-in vehicles. We'll likely find out within just a month. The debut of ELR back in January hit the market with a thud. The disappointment was so obvious, it faded away from interest almost overnight. Price was the major deterrent. With gas being at such a low price now, how will the next-gen Volt fair? If the "*who*" is ordinary consumers, what would compel them to purchase? There will be obvious cost-reductions helping out, but that appeal factor is a tough one even when gas is expensive. At least with Toyota, there hasn't been a dependency on tax-credits to sell Prius. There hasn't been as lofty of a cost-reduction goal either. Think about all those EV supporters who anxiously awaited rollout, now faced successful technology not stirring much interest. Needless to say, this is an interesting time in automotive history. No one knows how the market will actually react as the next year progresses.

12-17-2014 **Often Overlooked.** People tend to forget about charging-loss. They often convey the message that capacity of the battery-pack is only electricity used to replenish the charge-level to full. The extra electricity consumed as part of the conversion process isn't mentioned. For the lithium batteries currently being used, that comes to roughly 15% additional. To make matters worse, there's also a self-discharge loss. When discussed, it is referred to as "*vampire drain*". With Tesla, that can be as high as 4 kWh per day... which is well over the entire recharge usage (2.75 kWh) for Prius PHV. Now that fuel-cell energy consumption has become a hot topic, things like that are important bits of information. Knowing that the compression energy required to refill the 10,000 psi tanks takes less than 5% and there is virtually no drain afterward is a big deal. How often do you think that will actually be brought up in discussions though? Sadly, it will likely be quite infrequent. It's just another fact often overlooked.

12-18-2014 **Fuel Saved, part 1.** Tired of the continuing nonsense, I let them have it tonight: When will the misleading finally end? The fact that the "*fuel saved*" value is so vague tells the story in itself. Rather than stand up to the true competition... similar size & shape vehicles... it resorts to an overall average. Following that same percent, overall sales for GM should be used for compares then. How do the 17,315 Volts and 1,192 ELRs measure up against the other 2,642,018 GM vehicles sold here so far this year? Making excuses. Placing blame. Criticizing automakers. None of that will change those sales results. Reality hurts. Want some perspective? Take the claimed 36,367,716 gallons of fuel saved (total for all 4 years) and compare it to those others. If each new GM drove the industry standard of 15,000 miles per year, for just 1 year using that 19.2 MPG average, would come to 2,064,076,562 gallons. That reveals Volt's portion is tiny compared to how much is actually consumed. In short, 36 million sounds impressive. But in reality, it's a small amount. Using a single-year approach for Toyota, we see that their 1,965,756 non-Prius sales would come to 1,535,746,875 gallons consumed. The 192,958 Prius (using a weighted-average of 48 MPG for the Liftback, Plug-In, V, and C combined) would have saved 100,498,958. Still, not that much. However, that 6.5% is quite a bit more than the 1.8%. And if the goal is indeed to have a greater impact on consumption, the winner is clear to see. It's too bad the "*fuel saved*" promotion doesn't inform people about what really makes a difference. EV purity sounds better. But a combination of battery & engine is what truly saves more.

- 12-18-2014 Fuel Saved, part 2.** Between the hypocrisy and the superiority, I had it. With all those years of comparing Prius to Corolla, not doing the equivalent for Volt was maddening. GM continues to use greenwashing value. How is 19.2 MPG representative of anything even remotely comparable? It's not even as high as the industry average back when Volt was first rolled out and certainly not as high as the 23.9 MPG average now. Shouldn't it at least be 30 MPG, like the Cruze delivers? After all, that is the same size-class as Volt. With Prius, compares to Corolla were never appropriate, since Prius was larger. As for the superiority, that group of enthusiasts keep hanging on to GM's promotion of EV miles, not giving any care whatsoever to blended miles... since then, they can simply dismiss all the other plug-in hybrids. Well, no matter. Even without a plug, we know that the regular Prius saves more fuel. The math to verify that is easy. All you have to do is look at how many are sold. As a whole, even being less efficiency, the fleet average is improved overall... way higher than 19.2 MPG. I could have added in the Camry & Highlander hybrids along with the ones from Lexus, to stress the point even further. But what would that have accomplished? The problem with their trophy-mentally has not been overcome after all these years... which means my post only served to upset... if it wasn't for the sake of doing the calculations myself to confirm true impact. They don't like the reality that a smaller battery can actually make a larger difference. They don't like that EV purity isn't necessary. They just plain don't like anyone who points that out.
- 12-19-2014 Fuel Saved, part 3.** I posted this as follow up: Some people still haven't learned that personal attacks aren't effective. Ugh. What I find telling is how posts get voted down to hide them. If there was incorrect info, someone would simply provide debunk detail and we'd move on. Ignoring it instead is confirmation of that being a fact. Ironically, the vote provides acknowledgement, which serves as a confirm. The idea of Voltec becoming a platform and diversifying throughout the fleet continues to be a topic of disinterest. Why? I find that truly amazing. This very thread shows the resulting increase in sales would increase the amount of fuel saved. The announcement last month which included this quote, "*We have only plans for one Volt.*", ended hope of a second more affordable model targeted at mainstream consumers. So, it is understandable that the position of supporters is a difficult one now. But unconstructive behavior like we've been seeing certainly isn't helping the situation. Volt alone has not been able to achieve its own goal of "*leap frogging*" the competition. Whether you call the competition other battery/engine choices or GM's own traditional inventory, the numbers clearly confirm that outcome. Something needs to be done. What will it be?

12-20-2014 Explosive Topic. I don't participate on the big GM forum anymore, but do drop in from time to time to see what the new threads are discussing. Today, it was a topic about an Impala owner being excited about his decision to purchase a Volt soon. The reaction was truly astonishing. Within a few posts, this was added: *"Amazing what infinite taxpayer money can build."* That certainly caught my attention. Then came: *"That's a pretty irrelevant statement, considering the car was mostly baked before the bankruptcy was completed."* I took that as blatant denial. That's like saying all the holiday shopping is done and showing no care whatsoever about how to pay for all those gifts when the bill is due. It went downhill in response: *"That's a pretty short sighted statement. The car had most of its engineering and design completed before bankruptcy."* They just piled on the group-think, without any care: *"The Volt took years to develop, the bankruptcy was something like 43 days in 2009."* True, the legal proceedings took only 43 days, but the cause of it took years. We watched GM make poor decision after poor decision. Just in the efficiency category alone, they had both Two-Mode and BAS to confirm money had been poorly spent. From there, it got nasty: *"It was smart of GM to invest all that capital into the Volt and then go bankrupt and need us to bail them out."* I was surprised by the attitude. I never posted anything even close to that level of cynicism. Oddly, it was rather effective: *"I must admit as the price of gasoline quickly drops it is much more fun & rewarding to drive my V8's as the mileage penalty now seems moot."* The concern about tank-filling expense is gone. So, even when there is a constructive observation, it falls on deaf ears: *"GM needs a couple really good hybrids, but I think they are afraid it'll eat into the very, very small niche that the Volt has carved out."* This is the market GM is about to reveal the next-gen Volt to. This is why I'm spending so much effort to document the moment. Looking back afterward, the perspective will be lost. We'll see both defensive & offensive statements emerge immediately following. Then, we'll get the spin & parroting. This is the very reason I push for goal ahead of time. Knowing what the expectations were before is how you know if they were truly met after. Falling short, way short, was the outcome 4 years ago. Enthusiasts moved the goal posts back as a result; they lowered expectations. Supporters grew silent with disappointment. What will happen this time? What does that mean for Nissan & Toyota, who are both striving for deep penetration into the mainstream. What about Tesla & Ford with the opportunity they hope to capitalize on? This moment we're approaching marks a pivotal time.

12-21-2014 Peak Oil. It's fascinating how people don't recognize the very time they are in. That often comes from definition shift due to lack of understanding. Well over a decade ago, especially among Prius owners, the view of *"peak oil"* was the time when it became very expensive. Most people simply took that to mean the price of gas alone, without taking any other factors into account. It was unfortunate they didn't consider impact to the environment or political shake-up. Look at the mess tar-sands and fracking have contributed. Combined with the volatile drilling regimes, the result is an oil market turned upside-down. There's also the reality of climate-change. Needless to say, we're dealing with new circumstances and greater pressure. That's peak oil. It has nothing to do with how much is actually still available underground. We've reached the summit, when no more stable growth is expected. It will be a mix of solutions and compromise on a variety of levels. That's a paradigm shift... the result of a pinnacle having been reached.

- 12-24-2014** **\$2.09 Per Gallon.** That's the price I saw here this evening. In a few other parts of the country, it's even lower. How does that position the high-efficiency market? What will be done to draw attention to those vehicles? We have a bizarre situation with oil-supply. The economy is seeing record highs with the stock-market and reaching normal lows for employment. It's an interesting & unexpected set of circumstances. Overall, this can be good, but it certainly feels like a big step backward. Seeing MPG standards fall shows how volatile the market actually is. That huge risk GM took with the hope gas prices would remain high and technology costs drop quickly didn't payoff. It's really a problem promoting "saves gas" when the price of gas is so low. At least with Prius, you still have the comfort & convenience of it being a midsize vehicle. The appeal of "*fun to drive*" falls apart with "*cheap to fill*" prices, since that's what contributes heavily to small SUV purchases... and large pickups. Ugh. That market is booming now. Of course, it does reinforce what I've been saying all along about what we need. We're back to the days when Volt was first revealed. Remember late 2006? The circumstances feel quite similar. The upcoming next-gen reveal of Volt certainly will be noteworthy.
- 12-26-2014** **Uncertain Goals.** Remember what happened last time? Some people do: "*As a long time GM fan, I'm like others when I say: 'Hoping for great things, but bracing myself for disappointment.'*" We know what Toyota plans with Prius. It will take on a competitive look as well as deliver higher MPG and without a cost increase. We have been told about the effort being made to improve thermal-efficiency of the engine. We've been told the PHV model will stand out from the regular too. There's also the expectation of PHV an increase in battery capacity and more power. There aren't solid numbers, but that isn't really necessary for generational upgrades. It's an incremental process. We already know what the purpose is. The next simply delivers improvements. But with Volt, purpose is uncertain. What are the goals? Even though there have been droves of supporters pointing out the importance of greatly improved engine efficiency, the feeling now is that it will only be modest. Although being quite vague, the impression is focus has been put on battery improvement instead. Problem is, the purpose of a EREV was supposedly to deliver only what was truly needed for capacity: 40 miles. More exceeds that, which aims the target away from mainstream consumers. Remember how cost was the biggest concern? That increase represents a step in the wrong direction... and they know it. So, hope is fading. GM's desire to produce a stand out vehicle instead is getting confirmed in bits from comments about speed & performance, rather than any talk of something competitive with mainstream vehicles.

- 12-27-2014** **Anti-EV Sentiment.** The frustration is growing and the want for Toyota to become a major participant right away is contributing to that. Focusing on long-term makes it worse. But with the challenges fourth-generation Prius rollout presents and trying to establish some type of approach for fuel-cell choices, it's easy to feel that way. I understand, but don't appreciate the lack of acknowledgement. So, today it was: It's telling how the short-sighted statements are selective. Notice how Ford's actions & claims aren't getting attention? What about GM not targeting mainstream consumers? There aren't even any expectations from Chrysler anymore. And what happened to Honda? Toyota carefully studied the market and prepared by focusing on long-term. Yet, even in the face of \$2 gas, they get grief for some delay. It's not like they don't have other high-efficiency choices available in the meantime. That's good business. They continue to sustain profit, even though the market isn't favorable. As much as we'd all like to see more offerings like Leaf, that just plain isn't realistic. The other EV choices have come even remotely close to its success. Not rushing to market and delivering something for the masses is what Toyota strives for with Prius. That's a big reason why PHV wasn't rolled out to the other states. They're well aware of the tradeoffs involved and the opportunities available. The short-sightedness is a matter of patience. Don't fall into the group-think trap. Focus on goals. Prius became a success by being attentive to mainstream priorities and not giving into pressure from enthusiasts.
- 12-27-2014** **Incentives.** I couldn't resist responding to this: "*However. Hybrids were originally incentivized also.*" That concluding note to a summary of the market situation now with plug-ins certainly got my attention. I posted: I take issue with that comment and see this as an opportunity to clarify assumptions. (So, thanks!) The tax deduction working out to \$300 to \$400 on your return hardly qualified as an incentive. It was basically a nice "thank you" for purchasing. Prius exceeded mainstream minimum (60,000 annual) prior to any credit being offered and it certainly wasn't comparable. The quantity limit back then was 60,000 tax-credits per automaker before phaseout began. That's a far cry from the 200,000 available now and even smaller when you can consider the market sold 17 Million new vehicle purchased per year in this country. That has since fallen to around 12 Million. The maximum amount was \$3,150 per purchase, starting in 2006, well after Prius had already become well established. The purpose was to push hybrids deeper into the mainstream. The \$7,500 available now is more than double and with the intent of introduction instead. It's unfortunate that history isn't clear. But finding out explains why there are so many misunderstandings about automaker decisions. The economic factors are quite complex. Not having the whole story and dealing with audiences expecting to-the-point responses miss out on important detail... then spread that vague to others. Hopefully, this post was helpful.

12-27-2014 **Frustrated.** This comment today was quite understandable: *"I am just frustrated with the absence of information. To me, the reading, studying, and analyzing, must precede the purchasing. Toyota has thus far, denied me of that pleasure."* But at the same time, not reasonable. It all comes down to the "Who?" question. That's absolutely vital. I responded with: Know your audience! That point cannot be stressed enough. You want Toyota to provide information now, well ahead of rollout. That's what enthusiasts want, not mainstream consumers. The audience they're targeting Prius at is those who research shortly before purchasing, sometimes at the dealer itself. Those are ordinary people who would otherwise purchase a Camry or Corolla. The masses who buy high-volume profitable vehicles are the audience, those who often simply aren't paying attention to the automotive market until they are ready to replace their current vehicle. It presents many challenges for sustainable sales. That's an extremely fickle group to deal with. They do little online. Just look at Prius owners for perspective. There are over 3 Million here, yet membership of this forum is just 112,567 right now... and not all of them even own a Prius. That's about 3.5% representation, hardly any sort of majority. And how many of them joined the forum to learn more about their purchase, after the fact? As much as we'd like more, it's just plain not realistic. The competition, both within and from others, is too great. There is much at risk. The very fact that Toyota has been willing to alter plans along the way is something we should be thankful for. Having that flexibility and the willingness to acknowledge change is very important. Want some more perspective? Just look at GM. Enthusiasts still have very little detail about the next Volt, even though the rollout is about 6 months away. For that matter, they don't even know who the audience will be.

12-27-2014 **Power Steering.** I've kept quiet about the special coverage adjustment for Volt, campaign #14232. There's no benefit in focusing on a mechanical issue, since those can be resolved. After all, Prius wasn't perfect. Though with the way GM people reacted to Prius, telling us that owners and those nearby were at great risk, it is reasonable to at least say something. It was a *"we're all going to die"* campaign that proved to be an intentional effort to undermine, but I really don't want to stir that pot. My purpose, as stated on my website for a decade, has been: *"To significantly reduce emissions & consumption in a reliable & cost-effective manner."* That means providing support to vehicles which are actually affordable and targeted at the masses. Anywho, this changes the situation a bit. Rather than just expanding the update campaign (it's listed as a reprogramming of the power-steering-control module, though there have been reports of rack & gear replacement too), there's been a proposal for a class-action lawsuit. A claim has been filed stating 100 plaintiffs requesting \$5 Million for an: *"alleged defect in the steering system of its Chevrolet Volts which causes the steering wheel to freeze intermittently while driving"*. What should the reaction to that be? Reading this makes you wonder: *"Complaints that consumers filed with National Highway Traffic Safety Administration and posted in discussion forums demonstrate that the defect is widespread and dangerous and that it manifests without warning."* Is this another circumstance where the situation is just being blown way out of proportion? And what about the timing? I'm hoping focus will be on the fix. Get it done for owners quickly, then it's over. No need to drag this out.

- 12-29-2014 IIHS Award.** It was nice to here that the V model of Prius earned such high praise today. The award gives it a top safety rating. Being the larger wagon version makes it appealing to families already. Seeing that Toyota worked to improve it will help sales grow. Of course, the reality that Ford's advertising of C-Max drew so much attention to the V model has becomes an interesting twist... as people discover Toyota's hybrid was actually more efficient than the television commercials claimed. Ford really blew it with that campaign. Safety is obviously unrelated to fuel-efficiency too. Adding safety to the primary draws is a big win. For far too long, many assumed hybrids made many sacrifices for the sake of saving gas. This highlights how that isn't actually the case. Remember all that nonsense from certain automakers a decade back who claimed we'd all have to give up being safe? Thank goodness we're finally able to move beyond that. Even the most desperate will have trouble raising doubt now.
- 12-31-2014 \$1.99 Per Gallon.** Finding out how consumers have been reacting to the low gas prices will be interesting. December sales results will be the big clue as to what 2015 holds. The expectation is oil cost will remain low for quite some time to come. That makes marketing high-efficiency vehicles extremely difficult. In the meantime, it is nice for those of us who already own them. I myself took full advantage yesterday evening. It was my final opportunity to take photos of Christmas Lights. With the temperature at -2°F and a steady breeze, it was far from ideal conditions. But we finally got snow to cover up the dormant grass. So, I bundled up and headed out. Knowing my hands would be entirely exposed to the extreme cold meant running the engine at times just for the sake of generating heat. After 2 hours of that on & off, along with a commute back and forth for work and recharging 3 times (morning, afternoon, evening), results were surprisingly good. The 57 miles ended up averaging 64 MPG. That was totally worth it. I got great photos. It sure was cold though, especially when grabbing the frozen tripod with bare hands. Of course, with gas so cheap...
- 12-31-2014 Game Changer, part 1.** It wasn't. Knowing the potential of the next means understanding audience. Clearly, some still don't: *"May 2015 be the year that GM kicks it's old advertising agency handling the Volt account the door and learns that it's target for Volt are current Prius owners and people who are open and interested in shopping Prius against it's rivals."* I was beside myself reading that from such an active supporter who really works to be constructive. I tried: Who is the market for Volt? That targeting would mean nothing was learned still. The true competition is GM own vehicles, the traditional offering their own customers continue to buy in very high volume. Malibu, Impala, Cruze, Equinox, and even Sonic are all absolutely crushing Volt. What difference do the other automakers make? Of course, if GM did choose to disregard losing Volt sales internally, they should be targeting Leaf not Prius. Notice how much less Nissan advertised and how many more sales they achieved? If the goal of Volt is to become a mainstream vehicle, it needs to achieve minimum sustainable sales. That's 5,000 per month... which means focus on the big picture, acknowledging the true issues. Reality is, the generous tax-credit help will expire and gas prices will remain unsupportive of high-efficiency vehicles.

- 1-01-2015 Game Changer, part 2.** Just 11 days from now, the second-generation Volt will be revealed. Some long-awaited details will be provided. Reading online speculation, it's still a mystery what GM is trying to achieve. Years back when the first-generation began to fall well short of goals, the response was delay. They told us to be patience, that the game-changer will come from the next instead. Now, that's less than 2 weeks away. Will it? Should we really be expecting those same goals to now be delivered? The answer is an overwhelming no. The huge success of EV offerings ended up changing the game. So now we again ask, who? Knowing what consumers the new Volt is attempting to lure is absolutely vital. Will it focus on the priorities of family transportation? Or will it appeal wanting to tradeoff that balance in favor of performance? Recently, it's all been extremely vague. Obviously, the rest of the industry is waiting for the reaction before taking a step forward themselves. It's simply made no sense not knowing what GM deemed important... know what their goals are now... knowing what they think the game is.
- 1-02-2015 Questions Remain.** The topic of the day on that daily blog was about a Forbes article asking the very same questions I have all along. Some comments right away reflected a not-so-happy outlook. This is the one which stated an expectation I wouldn't have ever been able to post myself: *"If you are like me, and wanted the Volt to be less expensive and go mainstream, then I predict we will be disappointed."* But now, others are chiming in with similar sentiment. I posted: Yes, questions remain. The biggest one continues to be: Who is the market for Volt? The most influential is still: When with the *"nicely under \$30,000"* be achieved? Having not reached the goal of 5,000 sales per month yet and now having to deal with gas that's only \$2 per gallon makes the upcoming reveal in less than 2 weeks a very big deal. Specifically, answers need to be provided. Investors, both business and consumer, are looking for direction from GM about what the plan is for Volt. Is this next step a clear effort to break into the mainstream and make the technology a high-volume profitable seller?

1-02-2015 **It's Happening Already.** The lack of any clear message with the first-generation Volt turned it into a mess. Then when rollout began, chaos. A complete lack of any particular goal is dooming the second-generation to the same fate. I had no idea what started out as a constructive discussion this morning would degenerate into a Prius bashing session like that. Not mentioning it or Toyota was what other attempted. But when the posts become more and more worrisome, they revert to attacking a scapegoat rather than actually addressing the issue. I was astonished that they'd turn to loyalty attacks and spinning history like that. When that group of enthusiasts recognizes the significance of cost-reduction and the importance of high-volume sales, it's a good sign. Falling apart so quickly is a sign of trouble ahead though. That most devoted group doesn't see that being realistic. What does that mean? Can we finally move on? Having Volt constantly clamoring for attention and not delivering was hard enough to deal with. But now that specific need has not been met, how will the fallout affect the rest of the industry? That's been the concern all along. If GM wants to focus on want instead, is that going to be a problem for the other automakers who are actually targeting middle-market? Remember how Volt was promoted as a mainstream solution even though it didn't satisfy purchase priorities of ordinary buyers of high-volume cars? Are customers who consider the purchase of a traditional car really going to be disregarded again? We're certainly seeing an indication of that happening already. I sure hope Nissan, Ford, Toyota, and the other automakers who are striving to breakout beyond niche aren't pulled into the mess. It's really unfortunate to witness this. It's sad that talented engineers will deliver technology advance that won't reach the masses. This is why adhering to those original goals has been so important. Who? When?

1-03-2015 **Enablers, part 1.** Remember why I joined discussions on that daily-blog for Volt all those years ago? It came from the hope of building an ally. The first step was getting cooperation from correcting posts with incorrect information. Much of that started from misconceptions which originate from assumptions. The process should be simple. You provide detail explaining how the system actually operates, they acknowledge the misunderstanding, then we move on as partners. Instead, there was outright hostility from the belief that no partnership could ever exist across automakers. Those enthusiasts sincerely believed a joined effort to promote plug-in would ever be possible... hence the "*vastly superior*" exclamations. They took advantage of those misconceptions for the sake of greenwashing. That ended up becoming a disastrous choice, creating chaos among supporters. First-Generation Volt fell apart from mixed messages and lots of uncertainty. Will the second suffer the same self-deprecation? Who knows. At least the rest of us are looking at the big picture. Today, it was specifically the enablers on the forum dedicated to Leaf. Someone on the big Prius forum pointed out an active thread there which was disparaging to Prius PHV owners. That didn't upset me. Behavior like that is to be expected. In fact, friendly rivalries can sometimes emerge. We'd like that. The problem was seeing a few high-posting participants on the big Prius forum also participating there very often but not making any effort to counter the greenwashing. They are enabling that activity with intent to undermine by not speaking up and providing corrections. Irritated, I called them out on it.

1-03-2015 **Enablers, part 2.** Here's what I posted on the big Prius forum after reading that long thread on the Leaf forum: What gets me is how they make blanket statements about minimum capacity without taking into account how far the person actually drives. If you have a 12-mile capacity and only drive 12 miles to the destination, that's an excellent use of capacity. Recharging before driving back makes perfect sense. Why in the world should you be required to have more in that case? For that matter, why would you plug in if you already have the capacity to return without? What really gets me though is how members here who participate there serve as enablers. For example: *"Yes, slower, because any faster than 61 MPH and they're blowing through gas at the rate of 1 gallon for every 50 miles, lol. But seriously, the first 5-6 miles of my freeway commute leaving downtown is always behind a PiP doing 60 MPH. After that 6 miles or so at freeway speeds they are out of battery and the gas engine fires up, then I think they finally speed up."* Failing to respond with the correction information not only allows the misconception to continue to be spread, it also provides a bit of legitimacy to it. The belief that benefit from plug-supplied electricity is lost entirely at speeds faster than 61 mph is successful greenwashing, where certain individuals intentionally misled about how the system actually works. The reality that it is allowed to continue is just plain wrong. Same goes with the "6 mile" range. Here, we know that is an exploited misunderstanding of the EPA rating. But the effort to make people assume that is the entire capacity available has been very successful. It's quite irritating to read misleading statements. It's even more so when you know there are those who can stop them. How much effort would it take to point out the system delivers +100 MPG at 65 mph? Come on! Someone needs to make an effort. The same goes for pointing out the EV capacity. We all know here that the charge is far from used up entirely at just 6 miles.

1-04-2015 **Aggressive Look.** A factor contributing to the delay of the next-generation Prius which didn't get much attention at first but now is has been stirring new discussions. I was annoyed that the obvious stay-away and expiring-patent factors weren't acknowledged. People mostly focused on fabricated conspiracy theories, rather than actually looking at the detail presented and studying past history. A big part of it is likely not actually having paid attention until recently and even now only looking at Prius. Stepping back though, we see Toyota is taking on quite an effort to add visual excitement to their product-line. Camry & Corolla very recently just went through significant aesthetic changes, really big ones. You can see that with the newest Lexus rollouts as well. Long story short, the body design for Prius was rejected. Having achieved a unique look, which competitors attempted to stigmatize over the years, brought about the late decision. Back when it was introduced in 2003, Prius was the only midsize hatchback offered in this market. That made it an easy target for greenwashing. Underminers would claim the visual aspect was the reason for strong sales, claiming it made a green statement only with no other appeal. The fact that the shape also offered an extremely practical cargo-area was outright dismissed. Well, all these years later, other automakers have caught up. They too offer larger hatchbacks and even wagons. So in the spirit of self-fulfilling fantasies, the ultimate backfire is for Toyota to take advantage of the supposed green appeal. Why not? After all, it was the competition who set that precedent. So, Toyota has set out to make the next Prius take on an aggressive look.

1-04-2015 **Showing Votes.** That daily-blog for Volt is like that old forum with the obtuse "*up to the chore*" discussion all those years ago. The structure of the forum contributed profoundly to the unending nature of that thread, which ironically was what contributed to the ultimate end of the forum itself. Elsewhere on the internet where hybrid & plug-in discussions take place, the likes are displayed with the names of who submitted those votes. On this one though, you don't even have to log on. In other words, there's no accountability. That prevents constructive discussions from ever really taking hold. If someone doesn't like what was posted, they just keep voting until the post disappears. Of course, we know one of the people responsible for that. His posts are nothing but personal attacks, never responding to any of the actual content. It's such blatant bad behavior, I'm amazed the moderator hasn't done anything to stop it. After all, the moderators of the big GM forum eventually ended up needing to do that to restore the credibility lost as a result of that enabling. Of course, the daily-blog wouldn't attract much participation then. After all, many of the same topics are also published on the parent-site before there and very few comments are posted... yet another indicator of what's to come for Volt. Allowing that behavior shouldn't be necessary to get people to post. Needless to say, I'm thrilled by the progress elsewhere on other forums.

1-04-2015 **Structurally Deficient.** Of the 20,000 bridges in Minnesota, there are 1,200 of them which are structurally deficient. In other words, we are still struggling with the same problem as when the one fell here 7 years ago. How many other states do you think are in similar situations? Having to closely monitor the safety of those bridges shouldn't be necessary. We should have been replacing them over time, budgeting to cover the cost along the way. Instead, the resistance to using tax money for that continues. To make matters worse, that disregard for the future is reflected by the roads too. There's 12,000 miles of state highways alone. Funding for infrastructure still isn't getting the attention it should. With gas prices so low now, it's hard to believe raising funds how would be a problem. Yet, we know it will. Currently, the tax-rate is 28.5 cent-per-gallon. Trouble is coming and many people are strongly opposed to actually paying for what's needed. It's really sad. Notice how there's still a heavy dependence on tax-credit money for plug-in vehicles, yet none of those in favor of that want to address funding? How things are paid for is really nasty. Reading the online-comments from today's article published in the Sunday newspaper on this topic make that overwhelmingly clear. I find it so hypocritical how the "*no free lunch*" argument is often used, but the cost part not addressed. It's quite frustrating.

1-05-2015 **Not Knowing Yet.** We won't have details about the next-gen Volt until a week from now; however, we did get more of a look at the vehicle exterior. GM revealed all but the back end of the upcoming model. These were some of the comments which caught my attention: *"I'll reserve judgment until I see better pics of the whole car, but so far, it appears that Volt 2.0 has taken a step towards being more ordinary."* and *"They are trying to go mainstream with the looks and I think that's a mistake."* and *"I'm disappointed, looks pretty boring!"* There's an obvious effort to make the new Volt stand out less, to make it blend into the crowd now. I see it more as GM recognizing how futile it was to concentrate effort on conquest sales. They and enthusiasts worked that angle to death, neglecting their own customers in the meantime. The showroom floor experience was totally disregarded. That's where Volt varied dramatically from Prius. Toyota made sure that Prius was presented along with their other vehicles, making it seemingly ordinary from observing it up close at the time of first-hand research. People know the Prius name, but for many, it wasn't until being at the dealer that they ever actually considered one. They wanted to capitalize on the opportunity of someone interested in purchasing a Toyota vehicle but never having considered a Prius. Many, many, many owners were captured that way. In the past 4 years, I haven't heard a single story of a Volt owner having discovered Volt on the showroom floor like that. Now we know, GM is shifting over to the same type of buyer. Yeah! Of course, the "not knowing yet" part of the equation is making both enthusiast & support quite crazy at the moment. They want to know detail about how this more ordinary looking version of Volt will actually perform.

1-06-2015 **Doing The Math.** One of the supporters of Volt tried to help out the enthusiasts with: *"If sales go up to 50,000 Volts sold per year, that would still be 2.5 years of Gen II sales to exhaust the credit. The full credit wouldn't expire until the beginning of 2018, which is a long time from now. Plus, then there would be 6 months of sales with a \$3,750 credit, and after that 6 months of sales with a credit of \$1,875."* My dose of reality was obviously not going to make him happy. But all the poking now for goals is to make sure expectations are properly set. If you don't, the spin afterward will get out of control. Fallout happens from not preventing. We should have a clear understanding prior to the reveal of Volt next week of what GM is truly attempting to deliver. And yes, that includes knowing who the audience is. Do they expect to produce a lot of them? Will it be profitable enough to compel dealers to stock many and for salespeople to take the time to sell them? Are they intended to diversify offerings in the few years? What the heck are they trying to accomplish? With the limitations of the tax-credit money, that's important to know. Needless to say, there are many questions. I responded to that post with: Gen-2 won't be mainstream either, despite all the hype telling us it would easily hit that mainstream minimum of 60,000 annual? It is good to be realistic. Since Nissan will run out of tax-credits earlier, it is quite reasonable to expect them to ramp up competition pressure prior to that happening. Already, we know that's happening with Tesla. We can see that plan clearly being formed by both Ford & Toyota too. Then of course, there's the bitter reality of growing GM sales among their traditional fleet. Notice the December sales of 16,817 Malibu, 17,800 Cruze, 13,088 Impala, and 21,298 Equinox? Heck, even the 5,456 Sonic clearly shows that. The competition will be from all directions. It's essential that Volt achieve the 5,000 per month prior to tax-credit money being reduced. Because when that reduction starts, sales will become even more of a challenge.

1-07-2015 **5,000 Per Month.** Certain individuals really get riled up when sales are discussed. Well, too bad. That's the reality of business. As much as they like to show off trophies, the bills still need to be paid and supposedly, this was to be a high-volume profitable vehicles. It's a simple equation. Many need to be produced & sold. Anywho, I sounded off about that this way: Notice how the original goal of Volt becoming a top-seller among GM's popular car offerings still isn't being discussed, despite being on the verge of next-gen reveal? We've been told for years that patiently waiting for this upgraded design would get Volt back on track to becoming the game-changer which had been promised. Fine. The delay was an admission of not having understood all the market needs & pressures, that the next would address them. That standard industry sales watermark of 60,000 annual has been in place for well over a decade. It helps to identify the profit-earners in this time of increased competition. Big automakers require those high-volume self-sustaining vehicles to survive. We've been expecting Volt to join in, to fulfill that role. The purpose of the tax-credit is to accelerate the acceptance process. So by the time it begins the phase-out process, monthly sales would have reached a rate where less assistance wouldn't have any impact. In other words, sales would be comparable with the other profit-earners. Not even having reached the watermark at that point of phase-out means struggle ahead. This is why that "*Who?*" question continues to be asked. Lots of buyers are needed to achieve the goal. Like it or not, gas is cheap and the clock is ticking. The reveal coming up in just a few days is a really big deal. There's much at stake. Ask yourself what's truly necessary for sales to increase significantly, to a minimum of 5,000 per month.

1-07-2015 **Mission Accomplished.** When goals aren't actually met, but you want to call it good enough and move on, you make the declaration of "*mission accomplished*". That's the ironic expectation nowadays... which is what the fans of the first-gen Volt have been doing. Unfortunately, GM's executive chief engineer of electrified vehicles, said the Volt in 2010 had two goals: 40 miles all-electric range and 300 miles in charge sustaining mode. I wasn't surprised to see it. Pretending other goals weren't set is nothing new. Lowering the bar for the upgrade isn't either. It sets up an environment for mixed expectations, the very thing that caused the original fallout. Next week's debut certainly will be interesting. In the meantime, this is what I ended up posting in response to the mission accomplished discussion: We know there were other goals. The big ones were getting MSRP below \$30,000 and hitting that 60,000 annual milestone. Neither was achieved with the first-gen Volt. They choose to say "*mission accomplished*" and move on. That's fine. The question now is: Will those same goals apply to the second-gen Volt? If not, what is the mission? Watching sales numbers like we saw for December (16,817 Malibu, 17,800 Cruze, 13,088 Impala, 21,298 Equinox, and even Sonic at 5,456) leaves you wondering. Shouldn't a goal be to attract those customers to Volt? Shouldn't we have an expectation of seeing Volt included in the list of GM top-sellers?

- 1-07-2015** **Major Concern.** The response to that mission accomplish was explosive. I sat back and watched the posts & voting go wild throughout the day. Eventually, I ended up posting this later in the evening: "*The extreme reaction to asking that is confirmation of having identified a major concern. Only a few more days until we finally have some answers.*" That was it. Nothing more needed to be said. I clearly had identified a major concern. They're so hypocritical, I don't know where to begin. For years, those enthusiasts were telling us how sales would dramatically increase when the next-generation model was rolled out. Now, there's a message being sent that it will remain a niche, that the fiercely defending mainstream delay really never was a goal, that the market will experience only minimal growth. There's no expectation for fuel-efficiency leadership anymore. Sales of the traditional vehicles will continue to grossly overwhelm Volt. Wow! While Toyota strives to deliver a choice that's competitive, GM continue to focus on want instead. Ugh.
- 1-09-2015** **Engineering Triumph.** Based on the information people have been able to glean so far, it appears as though GM did some rather major redesigning to the second-generation system for Volt. Looking back at Toyota, that really didn't happen for Prius. The approach was already well thought out for the wide variety of operational conditions the vehicle would have to deal with. We saw an increase in voltage and an increase in both teeth & carrier count for the PSD. There was the replacement of the reduction-gear with a second PSD. The motors could run at a higher RPM than previously too. It sounds like Volt underwent more significant changes... which begs the question of cost. The word is that the new system will deliver quite a bit more power. Why? Enthusiasts have been gloating for years about how "*vastly superior*" the performance actually was. What is the point of adding to that? It's an engineering triumph we'll hear about to no end, but there wasn't a need for it in the first place. The system already fulfilled power requires. Perhaps if that was a side-benefit of the improved depleted efficiency, then it would make sense. But since that CS-mode expectation isn't anticipated to be a major improvement, there is good reason to question intent. For that matter, we have to wonder about overall purpose. Mainstream consumers couldn't care less. As long as the technology is efficient, reliable, and affordable, details of the engineering are meaningless to them. Even when it comes to generalized goals, there's no point. Notice how the enthusiasts changed the goal from delivering a "*game changer*" to just "*proving it could be done*"? We already knew it was possible. The question was whether or not the cost could be realistic for profitable sales. The answer to that is an overwhelming no; yet, that aspect of engineering isn't given much... if any... attention. That's a lose-lose situation. Both business & consumer losing isn't a triumph.

- 1-10-2015** **Cheap Gas.** It's really strange watching it drop. We never imagined prices ever being so low again. True, it's only temporary and it does put a new twist on boiling the frog. But even so, this is uncharted territory. Seeing \$2 per gallon along with plug-in vehicles adds an element of the surreal. The situation makes you wonder what comes next. How will the EV be marketed? Getting it thought of as anything but a niche was already challenging. We cannot talk about the new "normal" when we are back to cheap gas. This is definitely a head-scratcher. With the market for trucks already ramping up competitiveness, how will the lower price of gas influence purchase decisions? For those who actually use their trucks as trucks, it's nice. For those who want a truck but clearly don't need one, will they jump on the opportunity anyway? That is how the SUV market got so crazy. In fact, that's why the small ones are so popular now. Let's not forget the underlying reason the big ones became so popular in the first place: Profit. Rather than invest in the future, there was the quest for quarterly-returns for stockholders instead. That's sad. Trucks continue to be high-profitable. Cheap gas will likely help them a lot.
- 1-11-2015** **New Location.** My data, ever since my first Prius 14 years and 4 months ago, has been consistent. Having the same driver and same routes made endorsing the technology easy. It was very clear to see the influences of factors like temperature & traffic. That's about to change. In roughly 6 weeks, if all goes well, I'll be moving. We found a home to settle down in. The location is fantastic. There's no need to drive to either of my favorite small lakes to rollerblade around. All 3 are just a few blocks away, rather than miles. The one is our favorite to kayak on too. So, the journey with the Prius to bring them over will be a very short one, perfect for the plug-in. The location is scenic as well. Sunsets during this time of year can be spectacular. It will be quite convenient being able to just back the Prius out of the driveway to capture it with the colors. I may be able to do the same across the street with sunrises. In other words, we got really lucky with that particular house. Being in the right place at the right time has to happen to someone. Why not us? Making the situation even more exciting is the fact that this garage should make the installation of a 240-volt charger really easy. Everything is right there and I believe the input is enough to offer a dedicated high-amp line. However it plays out, this is a great opportunity. We have a lot to look forward to. I feel quite fortunate.

1-12-2015 **OMG!** The reveal happened. The following details stirred far more than even I imagined: *"The front-wheel-drive compact hatchback's new 1.5-liter Ecotec generator now runs on regular gas instead of needing premium, and combined fuel efficiency on gas is expected to be 41 mpg – up from 37 mpg for the present Volt."* and *"...with rear legroom increased by 0.6 inches and rear headroom decreased by 0.2 inches."* and *"Its new top speed is 98 mph and while the battery is charged the gas engine does not come on even if the accelerator is pressed to the floor. This differentiates it from every other plug-in hybrid and makes it its own unique type of vehicle."* and *"Its new 0-60 time is quicker by a half second at 8.4 seconds estimated, and the 0-30 time has been cut by 30 percent to 2.6 seconds."* I posted the following on the big Prius forum in response to such revelations: Even without knowing MSRP yet, it's clear that the audience didn't shift. Offering 1.3 inches less legroom in back is a big letdown. We saw lots of posts just last week saying people were hoping the headroom in back would increase; instead, it shrunk a tiny bit. As for the performance increase, why? We certainly weren't hearing anything related to the current model under-performing. In fact, we've had to deal with quite a bit of gloating over the years about how quick & powerful the system already was. What do those same people have to say about the new one? With what was just revealed, it's going to be a difficult argument claiming the next-generation was designed to appeal to ordinary consumers, those who would have just purchased some other GM car.

1-12-2015 **Niche.** Now we know. I got a kick out of reading this particular comment: *"This can still be an excellent commuter car & occasional small family car for many people. It occupies a unique and important niche for a 50 mile EV roundtrip commuter car (plus range extender) that only requires overnight charging or a 100 mile EV roundtrip commuter (plus range extender) with workplace charging. That's a very large niche."* It's among the very first damage-control posts on the big Prius forum about the new Volt. When expectations aren't met, posts like that are what happens. Hey, at least they are being sincere. That's a huge improvement over some of the nonsense we had to deal with in the past. This was my remark to that: The hope was this generation would become the one to take on ordinary competition, winning people over on showroom floors and dealer lots. Watching traditional vehicle sales absolutely crush the plug-in segment is obviously unappealing for everyone involved. A win anywhere from any automaker is what's needed. We need something for the masses. I'm glad Toyota has always remained true to their pursuit of affordability. The Original Prius strived to keep costs in check, rolled out with an attractive sticker-price right from the start. When the Classic, Iconic, and +2010 all rolled out, the temptation to shift priority was avoided. The power & capacity increases were modest as a tradeoff to keeping it affordable. Toyota obviously could have delivered more. The hybrid Camry clearly demonstrated more power was easily available. So, we've been led to believe GM would keep performance (speed, power, capacity) as is and instead focus heavily on cost-reduction instead. True, everyone likes more EV range, but we've seen how effective blending can be. Why not taken advantage of the hybrid system? That way, a competitive model with more leg & head room in back could also be offered. This design approach doesn't address the reality of traditional vehicle sales. What do you think the MSRP will actually be?

1-12-2015 Underwhelming. That's the best way to describe the overall response. Of course, with a generation improvement, that would be the anticipated outcome... since incremental is the proper expectation. The problem was, both enthusiast & supporter were hoping for a major redesign. They essentially wanted a complete redesign. Since the first-generation of Volt was written off as an "*early adopter*" rollout, rather than the "*game changer*" it had been promoted, that made sense. In other words, they had convinced themselves this wouldn't happen. Well, it did. The second-generation will likely be trapped as a vehicle not for the masses. With the long-term future hope of \$275 per kWh for the battery, cost will still be uncompetitive. Nissan will continue to push for a less expensive platform... no engine, no liquid cooling. And with Leaf using up tax-credit money at a faster rate, there's obviously going to be pressure building on Volt. In the meantime, Toyota hasn't played its hand yet. Those cards they are holding continue to remain unknown. What we do know though is the audience for Prius. It's the masses. That's why keeping battery-capacity small and battery-cooling air is what PHV has pursued. It's how to keep competitive, without dependency on tax-credit money. We know that the typical consumer will be thrilled with modest EV. That's just basic automotive study. You can see examples of the trickle-down effect from a wide variety of vehicle technologies of the decades. This isn't anything new. Don't let the enthusiasts convince you of that. Do your own homework. See how components now considered ordinary had their start. Look at what happened to those technologies as they were adopted by the masses. Then, think about this particular instance of being underwhelmed. What should they have expected?

1-12-2015 Distraction. In the very predictable style of GM, when an "*over promise, under deliver*" situation occurs, they make an announcement to distract. Well, sure enough. Exactly as anticipated, Volt's reveal was preceded by that very thing. GM introduced us to Bolt. It's nothing but a concept vehicle with a bold promise. They presented it as a 200-mile range EV with a price of \$30,000. Right away, there were those of us seeking out detail. The first big undercover was the fact that the price included a \$7,500 tax-credit. The second was that the vehicle wouldn't be available until at least 2017. That meant it was really more expensive and that the expectation of Volt sales will continue to be so low that the tax-credit wouldn't have been used up by then. GM is obviously desperate to compete directly with Tesla & Nissan; they've clearly given up trying to compete with Toyota... who continues to seek out solutions to replace traditional vehicles. We hope, of course, that Model X and Leaf really do attract ordinary consumers. But not everyone has the same need. The masses aren't ready for exclusive electric-only choices yet... which is why GM started with Volt in the first place. Oh well. It's not like we haven't pointed out the mixed messages. Perhaps this will ultimately turn into a diversity outcome. That would be great. Right now though, it is clearly a distraction.

1-13-2015 **How?** I waited 2 days before posting anything on that daily blog for Volt. It was a large thread that went no where. The title was: "*2016 Volt seats five, promises 50 miles electric range.*" Discussion points were all over the place. It was a chaotic mess. Opinions were all over the place. Not knowing price for at least another 5 months means the posts will likely fizzle to almost nothing, since that's such a massive factor and no other detail is expected in the meantime. I climbed up on the soapbox for a quick sound-off: 5 seats? Not if you have legs! Any child old enough to not need a booster-seat won't fit. No one older will fit either. Last week, there were many posts stating the hope of having a headroom increase in back. Instead, there was a minor decrease. Also, the modest increase in legroom wasn't enough to reach midsize class. Strangely, the rear window still lacks a wiper. And whether you feel MPG in CS-mode is important or not, that depleted efficiency being much higher is an expectation not fulfilled. Appealing to mainstream consumers didn't happen. Fine. Appealing to the car enthusiast is the focus of this newly revealed generation. Having that clarity of purpose early on is great! However, the fact that high-speed charging won't be offered does leave you wondering... especially with GM now embracing the EV, something they heavily campaigned against in the past with their "*range anxiety*" promotion. Whatever the case, we move on. It feels good knowing clashes of the past are over. We finally have an answer to the "*Who?*" question. Low gas prices and the growing demand for trucks and small SUVs will continue to increase pressure though. That reality cannot be avoided. It changes the question now to "*How?*"

- 1-14-2015** **Different Animals.** It has been fascinating to witness the reaction to the Volt reveal. There was no "*over promise, under deliver*" this time. It was simply hoping for the best... which clearly didn't happen. Instead, there was a change in direction. Last time, Volt enthusiasts became Prius antagonists with "*vastly superior*" taunts. It's a chapter in their history they attempted to distance themselves from by shifting focus over to Leaf instead. Ironically, that was what Volt was intended to compete with. Remember all the "*range anxiety*" campaigning? Well, when people started purchasing more Leaf that Volt anyway, enthusiasts changed goals. It was an act of desperation... making the purpose of Volt questionable. Things went downhill from there. The situation was a mess. GM made choices with the next-gen Volt to get them back on track. The decision was to compete with EV offerings. Prius PHV, Fusion, Energi, and C-Max Energi would now be recognized as plug-in hybrids without the contradictory EREV definition confusing matters. GM made Volt more of a EV, even though it still would be forced to run the engine in extreme cold conditions (what we call a normal Winter here in Minnesota) and would use direct-drive more following depletion. The next Leaf is expected to deliver quite a bit more of a range increase from the current 84-mile rating. That makes the new Volt's expected 50-mile rating a head-scratcher. True, it should do a better job of covering EV travel needs. But at the same time sours the engine-running experience even more. Whatever the case, it is GM who will have to deal with that. Toyota, Ford, Honda, and Hyundai will all be trying to deliver a well-balanced solution for the masses. That means a small enough battery to keep it affordable and not impair passenger/cargo space, yet still deliver much improved emissions & consumption over traditional vehicles. It summed the comparison outlook on the very active thread about it with: Yup, the business purposes of Volt and Prius PHV are simply far too different. The consumer audiences are not the same either, which GM clearly just confirmed. Toyota's quest to keep it affordable (traditionally competitive without tax-credits) means expectations for the Gen-4 are no cross-shopping. There will be plug-ins offering speed, power, and distance, then there will be Prius offering a balance of traits with the intent to appeal to a wide array of potential buyers. You calling them "*different animals*" is an excellent way of stating it.
- 1-15-2015** **Didn't Happen.** Curious as ever how that daily blog for Volt will change, I've been refraining from saying much. Posting thoughts isn't needed anyway. There are many others already doing that, making the very same observations I have. It's no secret what had been hoped for verses what was actually unveiled differed quite a bit. That leaves the past vulnerable to spin. A lot of misleading has come about as a result. It's not a big deal. Lack of substance causes most of the rhetoric to pass quickly. I did take issue with misrepresentation of goals though. So, I did end up chimed into a discussion with: The vaporware comments were based upon GM's claim of delivering a 40-mile all-condition range plug-in hybrid for "*nicely under \$30,000*". It didn't end up happening. MSRP was well above that price and range was well below. People assumed, without taking the time to consider detail, like production-cost or heater-impact. They also believed the "*leap-frogging*" Prius meant a vehicle of equal size with similar efficiency following depletion. That didn't happen either.

- 1-15-2015** **Advice.** Now that Volt has vanished from the picture, no longer undermining Prius with bold promises it couldn't keep, we are seeing a shift in posting activity. We are seeing more of the new owner posts. Yeah! Getting drown out by rhetoric was horrible. I'm sure glad that's over. That nonsense of the past was very frustrating. I enjoy sharing advice. Of course, it's even more rewarding seeing others share the same wisdom without me. But today, I did some by answering a series of commutes about Winter cabin heating: If you want to warm-up the system for heat, turn on the heater. If you want it to warm-up faster, turn on the defrost (since it increases engine RPM, on the plug-in model anyway, not sure about the C model). Low blower and low temperature (like 65) will keep you from feeling much for cold air in the meantime. You need that to keep the window clear anyway. If there's no concern about humidity, you can change the vent to recirculate. Having an aftermarket gauge will allow you to know exactly when the air goes from warmish to hot, by monitoring the coolant temp. Blocking the grille to increase heat-retention and reduce cold air-flow is helpful too.
- 1-15-2015** **Normal?** Some operational aspects of the hybrid system are counter-intuitive. New owners often ask what the heck is happening. They sometimes even wonder if something wrong. Active members of the big Prius forum help out by responding with detail. Today, it was my turn: That's quite normal. Since your Prius doesn't have a plug, it seeks out the most efficient opportunities to recharge the pack. It will start the engine when the power load is at a balance, where some of the resulting output can be used to generate electricity. Note the at the plug-in model does the very same thing when in HV mode. It takes advantage of the engine. Also, keep in mind that some of the generated electricity will be consumed immediately and the fact that the energy-flow from the system will change rapidly & often. Watching the screen, you can see it happening anywhere from 10 to 20 times per minute. That's the result of having a PSD (Power-Split Device) connecting a gas-engine with 2 electric-motors. The dynamic nature of that design is often not realized by new owners... who question why the heck the engine started. You're not alone. That is indeed what's suppose to happen. If that makes sense, now consider the other goal of reducing emissions. It seems counter-intuitive to run the engine without having first exhausted the battery. Keeping the emissions from engine exhaust low requires heat. That heat is used by the catalytic-converter to cleanse the exhaust. When the engine runs, its own heat that it creates is used for the cleansing. The heat is retained by the coolant. It's an interesting cycle of one feature taking advantage of another.

- 1-15-2015** **\$1.85 to \$2.09 per Gallon.** What a strange thing to be writing about. But when the President makes a statement about trying to be realistic, to properly set expectations about the price of gas, and it results in hostile rhetoric, you have to respond. I was dumbfounded by how un-understanding some people were. The posted comments on the article I read were amazing. People were blaming him for not allowing them to "*catch a break*". It was very clear that many has absolutely no clue why the price was so low. For the first time in over 30 years, the United States is actually exporting more oil than it is importing. That's a bizarre switch. The surplus from the increase interferes with the delicate balance of cost. Normally, the oil-producing nations would reduce their pumping rate to balance out supply. But this isn't a temporary situation, as in the past with surplus issues. The volume change is permanent. The United States is drilling more. They continued as usual anyway. It pushed price down. Obviously, that cannot continue for too long... hence the warning not to rush out and purchase a guzzler. Being realistic means recognition of the problem. The market simply cannot be flooded with excess inventory like that. Those oil-producing nations depend upon money from the sales of their oil. Low prices hurts them significantly. We're seeing the price increase begin already. Where it will stop is anyone's guess.
- 1-16-2015** **Semantics.** Having been pulled deep into those arguments years ago, there is now a strong effort to avoid dealing with that again. It's a waste of time. Nothing is accomplished anymore from any type of labeling. In the past, the point was to simply point out that the systems were not the same. That goal has been achieved, so no need to dwell. Unfortunately, there are a few antagonists who thrive on debate exchanges. One such attempt to stir was: "*It is a full or strong hybrid for being able to propel the car at 75mph on electric alone.*" He's well know for getting into intense pointless points. Being constructive means working toward a goal. The quote certainly didn't pursue that. I choose my words carefully, responding with this hoping to direct the thread off the obvious tangent: The definition of FULL has always (for 15 years now) been any system with the flexibility to deliver propulsion & generating both with the engine and without, as well as blending & separating through the use of some sort of power-split device. That's why IMA was always identified as a different type. Since it only had a single electric-motor and it was connected directly to the engine, it lacked some of those abilities... hence it being just an ASSIST hybrid. At no time has there ever been any MPH or even KW criteria. And without the flexibility, is not a FULL hybrid. That's why we are trying to get away from labels... especially since they are so much less clear now with the variety. People will looks at whatever claims are made and validate. No more taking things at face value. Yeah!

1-16-2015 Quick & Painful. It's late Friday evening. Details of the new Volt were revealed very early Monday morning. Discussions have died already. The big GM forum had literally nothing. I'm amazed at how quickly the disappointment spread. Expectations were much higher... and clearly were not met. It was a painful outcome. Too bad. The PEV Owners meeting was yesterday. I got to chat with a number of Volt & Leaf owners... as well as Tesla and even a Mercedes B-Class. We had a blast getting to share stories and discuss the future. There, we were told 7 high-speed DC chargers had just been made available throughout the metro area. That puts Minnesota on the map for super-fast charging opportunities. It's great for traveling further with your EV. What a fantastic debut! Minnesota is already the #10 state in the country for EV ownership per-capita in the United States. Anywho, the point is GM's choice to focus on more EV competition and abandon traditional competition puts Volt in an awkward category instead. With ranges & capacities increasing and more & faster chargers becoming available, that's going to be a tough sale. Look at how well Leaf is already doing. Speaking with those owners last night, range-anxiety is non-existent for some. Nissan knows that and is targetting those consumers now. In 2 or 3 years, we'll see the big improvements several automakers are striving to offer. How Volt will compete with that, especially without a tax-credit, remains a serious concern. Whatever the case, I'm glad Toyota's focus is the masses who would otherwise just buy a traditional vehicle. It's an odd sense of balance having market diversity in that fashion. It comes with quite a bit of risk too. Screwed gas prices and fickle consumers are a challenge to plan business around. If this week's discussions are any indication of Volt interest, GM is in trouble. Remember what happened when final production details of the first-generation Volt were revealed?

1-16-2015 Argument Sparring. I got a big kick out of reading this series of posts. It started with: *"GM is still by far the leader in Hydrogen Technology... They forced Toyota's hand since the Volt has virtually spelled the death knell for the Prius as a hybrid technology."* That was on the big GM forum. So naturally, I was quite intrigued what kind of response that would generate, especially since the thread was about a Toyota Mirai driving report. (That's the new fuel-cell vehicle which recently sales recently began in Japan.) The respond post started with: *"What do you mean by leader? Better technology? Where are they keeping it? Did they forget it under a table somewhere?"* Rather than something actually constructive, the thread got lively with this: *"I really like the Volt, but it is in no way a threat to Toyota hybrids yet."* I was obviously captivated at that point, very interested in what would be posted next. It was: *"A 50 electric mile volt, plus 41 mpg on generator with over 400 miles total range that can sit 5 is and costs around the current volt is not going to affect prius sales?"* That deserved a LOL reply. Prius is currently aimed at buyers looking for something not requiring a plug. Volt isn't even in the same category. Talking about not understanding audience! Of course, what I found hysterical wasn't that blatant disregard for who. It was the claim of being able to sit 5. That fifth seat is a joke. There's no legroom whatsoever. It's a battery-pack mound covered by 2 cupholders. Nothing but a small child could actually be seated there. Ugh. Thankfully, that nonsense same to a sensible end: *"I really love Voltec, and a Volt would suit me just fine, but it made nowhere near the splash it could have. I was expecting it to be a rival for HSD right out of the gate, but somehow GM sold fewer this year than last."*

1-17-2015 **Too Little, Too Slowly.** Remember that concern? Remember why it came about? There's a massive need to deliver clean & efficient choices for the masses. Ordinary people have to purchase something. Business profit must come from something. Remember how the second-generation Volt was to fulfill the need? It's an uncomfortable position not having any particular goal to look forward to. There are even any mixed messages this time. The outlook is grim. Oddly, you'd think there would be cries for patience to wait for the price reveal. But then again, having learned the lesson of silence is possible. Who knows? What we are certain of is that depleted efficiency was only modestly improved, that the legroom & headroom in back is still cramped, and that there is no fifth seat. That makes us all wonder what comes next. GM's focus away from mainstream consumers is a welcome sign for Ford & Toyota, the automakers who wish to target the high-volume profitable audience. I had really hoped the next Volt would somehow change to address the same goals... instead of remaining in the niche category. Oh well. There isn't much that can be done anymore. Buyers will be pleased. The vehicle itself should perform well. In fact, I suspect we'll get lots of excited reports from new owners. Unfortunately, the problem will remain. GM customers will continue to purchase traditional vehicles in large numbers. We will be left waiting, again. Wouldn't it be amazing though if cost could have somehow been reduced to such an extreme that the new Volt could be delivered in massive quantity? Sadly, that doesn't look realistic yet.

1-18-2015 **Engineering Choices.** The big ones are made by management executives, not the actual engineers. Their choices dictate what happens with the engineering. This is why the next-gen Volt and its tie to Prius have been getting so much attention. Would GM stand true to their original goal of delivering a 40-mile range? If so, the cost of the vehicle would be reduced simply through their advancements related to battery energy-density. The side-benefit of that would be reduced size, resulting in increased cabin-area... as well as reduced weight and reduced support hardware. It was an opportunity we didn't know if GM actually would take, but hoped they would. GM didn't. Instead, the choice was to increase range and increase performance. The executive decision was to compete with EV offerings, rather than go after ordinary consumers interested in a high-efficiency hybrid. In other words, the answer to whether or not the new Volt would compete with Toyota PHV and Ford Energi is clear. It wouldn't. We went from a flurry of mixed messages over the years to extreme clarity. At the same time, we just got a unveiling from Hyundai. The upcoming next-gen hybrid system for Sonata would deliver increased passenger space and an estimate 39 MPG city / 44 MPG highway rating. That will likely work out to a combined rating of 42 MPG. The smaller Volt is expected to deliver 41 MPG following depletion. That seems close enough for competing... until a Volt supporter points this out: *"I am pretty disappointed with the 2016 gas mileage given that the less aerodynamic Accord Hybrid which weighs a similar amount and largely copied the Volt's drivetrain gets 50 city and 45 highway."* Then when you consider the improvement the next-gen Prius is expected to deliver, it becomes more and more clear why GM gave up mainstream aspirations. That hoped for high-volume sales soon has been abandoned. Hey, at least we know now. Makes you wonder what next step Honda will take with the plug-in Accord-Hybrid, eh?

1-18-2015 **PHV Heating.** It's so refreshing getting back to questions about Prius operation, providing answers to ordinary consumers trying to figure out how the system works. Hearing from those asking, without any engineering background, is great. It's reward to provide responses too. Today, it was about what happens when you request heat. That knowledge of how heating occurs isn't easy to undercover and it often ends with assumptions based on anecdotal evidence. So, I posted: The influence of the fan on the EV range is nothing but a reminder that the heater will cause the engine to run more often. That's it. The battery-charge level doesn't change. Confirming that is just a simple matter of watching SOC (battery charge-level) on an aftermarket gauge, like Torque or ScanGauge. PiP does offer an advantage over the regular Prius as to when the engine starts back up. The tolerance based on coolant temperature is variable rather than fixed. That means a lower setting on the heater will keep the engine off longer. You can clearly confirm that using an aftermarket gauge. And yes, the A/C does indeed come on while the heater is running. That's how dehumidifying is achieved when you press the DEFROST button for the front windshield. It's a normal operation on vehicles most people aren't aware of until they wonder why MPG drops as the temperature drops. For those who experience true Winter (that's when daily high temperatures remain below freezing), you can get the most out of the heater by monitoring coolant temperature. There's no reason at all not to run the heater if the coolant is has been warmed. Taking advantage of that waste engine heat is as simple as looking at a number on a gauge. You'll know exactly when the engine is about to restart too. In the meantime, you can cruise along in EV without freezing.

1-18-2015 **Media Substance.** We get a lot of hype articles. It's annoying. Today's was especially bad. I kept hoping for substance of some sort. The writer went on and on about how battery costs have been dropping, but never actually stated a cost. There were only vague references to percent changes. Upon re-reading the article, I noticed there was nothing about capacities or expected market penetration. It was nothing but a fluff piece written to tell us that someday we'll be driving without oil. It's amazing how you get the impression of journalism, but then later discover you didn't actually learn anything. It was just a waste of time. What I especially like though was the picture it painted at the ending: *"But ground transportation still makes up the bulk of our oil use. So when batteries advance to the point where oil is no longer used for cars and trucks, the Saudis, Russians and Iranians will find themselves selling what is suddenly a niche product. And simultaneously, the U.S., Japan, Europe and other energy importers will find themselves free from the yo-yo of global oil prices. In other words, it's less than two decades until we are free from the yoke of the petrostates and their nasty, backward regimes."* I couldn't resist posting that entire quotes. The average vehicle remains in service for 11 years now. That means just 9 years from now we'll be replacing all new vehicle production with electric-only vehicles. That's amazing... and a crock! It isn't even the slightest bit realistic for that to happen. Want to know more? I certainly did. Notice how the *"when batteries advance"* point isn't actually defined? That complete lack of criteria is what angers me. That's why I got on the Volt enthusiasts so hard about stating goals. They didn't. Expectations were always horribly vague, yet outcome would somehow be a miraculous success. No detail is reason for concern. Popular media often isn't interested. They just want your attention for a few minutes. Sadly, I got sucked into that with this particular article.

- 1-20-2015** **Unprofitable.** The disappointment from the reveal of the 2016 Volt was made undeniably clear. We went from great anticipation to silence in just a week. Since there's nothing else to discuss with respect to operational/configuration hope, the focus has shifted to production cost. Yesterday, it was this rhetoric: *"Although GM has added value to the 2016 Volt (more AER, improved interior, smoother transmission), almost every effort I see has been focused on reducing cost."* That was followed by a detail list of improvements. I couldn't get past the blatant contradiction/disregard though. That *"almost"* reference is a problem. If GM had really been attempting to make a car for the masses and wanted to keep cost-reduction the top priority, that AER (All Electric Range) wouldn't have increased. Keeping it fixed at the current 38-mile estimate would have allowed for a battery-pack savings. How is adding 12 miles a way of cutting cost? Supposedly, making Volt profitable was key. What justified the increase then? Of course, these recent executive words are a hint of what's to come for the MSRP: *"in line with the current generation Volt"*. Each new bit of evidence shows us intent with the next-gen is quite different from that of Prius. GM will offer a vehicle for the enthusiast. Toyota will offer a vehicle for the masses. The price will make that obvious. Taking on the true competition... traditional vehicles... requires a similar MSRP. The hope that tax-credit dependency wouldn't be an issue for the second-generation has faded, leaving it higher priced. It would be unprofitable otherwise. That's sad.
- 1-21-2015** **Uncompetitive.** The nightmare of the past is over. Yeah! These personal logs are filled with quotes of absolutely desperate Volt enthusiasts attempting to undermine Prius. By misrepresenting it, the hope was their vehicle would attract more sales. That's back when leap-frogging and vastly-superior and game-changing nonsense was chanted on the regular basis. Not anymore. Some were rather clever with their greenwashing, others would outright lie. It was unbelievable... which is why I documented so much of that while it was happening. Thankfully, it's an ugly chapter in automotive history now closed. Change rarely comes easy. That was a prime example. Looking forward, this apparently is what the future holds: *"As Chevrolet formulates marketing plans for the 2016 Volt launching the second half of this year, it has a head start over generation one, but if there ever were a vision of the Volt surpassing Toyota Prius sales, that's a premise Chevrolet doesn't even want to entertain."* It was the opening line to today's daily blog. Coming up with topics now is a challenge. That blog has become more of a curiosity than anything constructive. Reading through today's topic on pricing was pointless. There's such a heavy dependence on the tax-credit still, it's quite obvious the next-gen offering is uncompetitive. Cost is still too high. GM chose to deliver what they want to see, not what they need. It happened again. Third time is a charm, eh? First was Two-Mode. Second came Volt. Now this. Ugh. What in the world are they going to sell that actually is competitive? Are they really going to ignore the mainstream for another generation?

- 1-22-2015** **Unsuccessful.** Isn't the point of any new technology to reduce emissions & consumption to sell lots of it? Watching the second-generation remain low-volume and be dependent upon tax-credit for sales was the concern right from the very start. Remember what came about in the bankruptcy recovery plan? Concern was explicitly expressed about the process taking a long time. Remember "*too little, too slowly*" and the harsh response to that reality? That group of enthusiasts just plain didn't care. They saw Volt as a great technological achievement, based on engineering accomplishment alone. Whether or not it was even remotely capable of surviving on its own as a viable business product to generate profit-sustaining sales was meaningless to them. Anyone who expressed that need for well-being or pointed out the rest of the GM product-line was attacked. It was a great example of group-think, where they completely lost sight of the true goal and just lashed out at those attempting to get things back on track. That level of disregard was quite astonishing... which is why I was so compelled to observe the outcome firsthand, rather than watching the group from a distance. It's over now. The next-gen design has been revealed. Just 10 days later and it is already quite clear their are major shortcomings with respect to being able to compete on its own. No leap-frog. No vastly-superior. No game-changing. Traditional vehicles will continue to dominate. Aspirations of mainstream penetration have been abandoned. It will be sad to see the guzzlers sold in such great numbers without a low-emission, high-efficiency choice that's competitive.
- 1-23-2015** **Not Plugging In.** It's a good sign when owners ask questions about non-issues. That means the technology is attracting newbies who simply don't the background to figure out the answers, but are aware that battery-pack is equivalent to the power-supply found in other plug-in devices. This is what I posted to one such question about Prius PHV: The system in the plug-in Prius protects itself. It won't allow you to exceed the charge limits, since a primary benefit of the gas engine is to ensure longevity of the battery-pack. So, even if you aren't able to recharge for a very long time, there's no harm done. It will continue to age, since all chemical-based batteries will anyway, just not as fast as when you charge & discharge the usable capacity on a regular basis. When you do find yourself in the position of not being able to recharge, it's best to allow the system to deplete all the EV range and just drive around with only HV capacity. Don't attempt to preserve any of the plug-supplied electricity. Driving it around as a regular hybrid in the meantime is fine.

1-24-2015 For the Masses, sales. Now that the storm has passed, I unignored those who were clearly antagonists. Some simply like to debate. Others have something against Toyota. Whatever the case, the opportunity to be heard has been opened. The new outlook started with this: *"How come Toyota is selling only 400 something Prius Plugin per month in the US? I Thought PiP was supposed to compete with Volt. PiP is getting whupped."* That wasn't the most constructive approach. But it was a question worth addressing... yet again... hoping for a different response now: Both intent and purpose has always been very, very different. Long before PiP was rolled out, there was a major effort to determine what a sensible price would be, something actually competitive in the traditional market. That meant careful design consideration to keep cost low. Toyota worked hard to deliver an option complimentary to the Prius offerings. Rolling out a low-volume choice mid-cycle fit into that goal well. HSD would be getting an upgrade in a few years, delivering even higher HV efficiency along with new opportunity as a result of NiMH patents expiring. That left the door wide open for greater battery augmentation with the plug-in model, especially with the knowledge gained from initial PHV rollout. The business approach for Volt was entirely different. There was no plan for any type of second model. There wouldn't be one with a smaller battery-pack or one without a plug. It was always a vehicle with very high production-cost. GM was targeting an entirely different audience. As for the sales themselves, Volt gets triple the tax-credit and is offered in over triple the number of states. It certainly should sell better with such an advantage.

1-24-2015 For the Masses, leadership. Certain individuals have been blinded by engineering. They sincerely believe the only approach to change is by pushing the high-end, that somehow the masses will naturally just embrace change as a result. There are many business classes a person could take to learn that is an incomplete picture of what's actually needed. There's no arguing with the uninformed though. They've already made up their mind and will outright dismiss any evidence to the contrary. They've never really taken a look at what appeals to a consumer with a lower budget and little interest in performance or technology. It posted: It's sad how *"technical leadership"* continues to be represented only in terms of racing to market. Blatant disregard of the goal for profitable high-volume sales, competing on the showroom floor without tax-credit dependency, speaks volumes. As for the drawing of conclusions of *"hurt"* and *"damage control"*, that's called not understanding audience. The debates of the past are over. It's not worth posting unless there is clear acknowledgement of who the customer for Prius PHV will be. And now that gas prices are so low, it's more important than ever to finally address the sensible business choices Toyota has made. Whether they make those who want *"technical leadership"*, you have to admit the decision to not push has worked out well. You don't become the top-seller of vehicles in the world by not planning well.... which includes the flexibility to adjust as the market changes. Personally, it is no surprise to me that the trophy-mentality makes it difficult to be constructive about business approach. The accounting part of automotive sales rarely gets the attention it should. People don't find the high-volume cars exciting. Being common isn't what stirs discussion. But that ultimately is what pays the bills.

1-24-2015 **For the Masses, nonsensical.** When someone isn't following what you've been saying for months, they end up attempting to discredit. This was such an attempt today: "*You use the same vague, nonsensical terms such as "understanding audience".*" That type of denial is quite common, but rarely actually gets posted. Most online participants simply don't bother to say anything. But for a few, their frustration manifests itself. I find the lack of effort on their part to understand remarkable. Why post if you don't want to achieve some type of clarity? Perhaps he views my statements as the means to end the debate. After all, some thrive on the attention. Of course, some see non-EV choices as a threat. My endorsement of a choice for the masses presents a barrier for some, rather than support for change over the long-term. I wanted to make the message crystal clear, before returning him to ignore: We've been through this countless times already. The never ending repetition in each new thread is counter-productive. So, one last time, but in bold & caps with the hope it won't be forgotten and is easy to refer back to later: **THE AUDIENCE IS CONSUMERS SHOPPING FOR OTHER VEHICLES ON THE SAME SHOWROOM FLOOR. THAT MAINSTREAM MARKET IS WHAT EACH AUTOMAKER MUST OVERCOME TO ACHIEVE GROWTH. NO AMOUNT OF "WHAT OTHER AUTOMAKERS ARE DOING" BANTER WILL CHANGE THAT REALITY.** It's very clear that much of the nonsense we have to deal with comes from the unwillingness to see beyond enthusiast interest. The amount of time wasted not recognizing that is real problem. The disregard for economic well-being and the disconnect between want & need makes it worse. Not understanding "*who*" means being unsuccessful.

1-25-2015 **For the Masses, cost.** It's good to that some are thinking clearly: *"If Toyota could get their cost for a 10-15 mile range EV plug-in down to \$1-3K, they could make that standard on trim levels 4-5. Granted, some will not be able to plug-in routinely if they live in an apartment. A plug-in that can stay nearly all EV for in-town driving and commuting, then get the best mpg on road trips, is a significant market Toyota can lead in."* I was delighted by the constructive view. For far too long, the voices of a few who clearly only cared about engineering achievement dominated discussions. That's changing, especially now that the next-gen Volt reveal didn't meet expectations. Moving on to offerings for the masses is great! I responded to that with: \$3,000 has been the ultimate target for many, many years. Having that as a feature on the nicer packages makes sense. It emphasizes the simplicity of the approach too. Getting cost down low enough to earn a modest profit at that price would indeed make Toyota the leader. Ford is clearly attempting to offer a plug-in hybrid option for the masses too. It will happen. As was just revealed by GM with the re-categorization of Volt, the segment for higher-capacity dedicated plug-in hybrids is taking shape. That makes it far easier to convey the purpose of the hybrids with a plug option, like Prius, Fusion, and C-Max. No more mixed messages is great. The problem many haven't understood is purpose. Granted, some of that was intentional greenwashing, but there was quite a bit of simply not knowing too. The augmentation of the hybrid system with a plug and larger battery had been clear, prior to the chaotic rollouts a few years ago. The automotive market was in a mess to begin with. Now, the situation is different. There are enough choices to allow consumers to see how the various approaches differ and why. I'm thankful the effort to appeal to the masses continues, even if some have already given up hope. Penetrating the mainstream is a painfully slow process with very little excitement. It's easy to lose sight of what's really important. Introducing a product is much easier than getting people to move on beyond what they already feel comfortable with.

1-25-2015 **For the Masses, category.** The lack of any clarity of purpose & audience for Volt did quite a bit of harm to the market. It started as a *"range anxiety"* solution. A hybrid offering a plug would supposedly be far more appealing than an EV with a finite range. Leaf was far more successful than GM ever imagined though. But rather than accept that mistaken understanding of the market and refocus, the response was to attack Prius instead. It was brutal. There was greenwashing and outright lies. I was amazed how bad things got (which I documented heavily in these personal logs). The next-gen reveal of Volt 2 weeks ago by GM and detail which followed will help make up for the problems it caused. The rest of the industry can breath a sign of relief. We now know who. There is an emerging category of higher-capacity plug-in hybrids. Volt fell short offering only 38 miles. The increase to 50 is still low compared to the BMW i3 which delivers 81 miles. But at least the intent is easier to see. There will be a category for *"entire day"* capacity and another for *"mpg boosting"*. True, some will be able to run errands in Prius PHV entirely using electricity. Some will be able to commute that way too. But the purpose of significantly reducing emissions & consumptions in an reliable & cost-effective way won't be lost. That category remains. Some owners will have the package with a plug, others will not. The goal of reaching the masses will be achieved.

- 1-25-2015** **For the Masses, now.** That unwillingness or inability to wait is the norm. We heard about the *"hybrid premium"* from the very beginning. There will always be some degree of higher upfront cost. But with gas prices at \$4, that issue became a wash. It's much easier to finance purchase payments than to empty the wallet each time you fill the tank. But with cheap gas back, we must acknowledge this: *"Customers want the best for their money NOW, and most aren't into EVing, plugging in and such..."* I was quite pleased to have read that in a post today. I chimed in with: A great deal of the hate from Volt supporters came from that reality. Pointing out losses on the showroom floor resulted in hostile responses sometimes. The thought of GM customers choosing a traditional cars instead was too much to accept.
- 1-25-2015** **For the Masses, reality.** That same original post I originally responded to also had this: *"Prius needs to come down at least \$2k in price."* That was very clear recognition of who the audience actually is. Yeah! My references to showroom loss is getting the message through. So much attention had been placed on emerging plug-in choices, the ultimate goal of replacing traditional vehicles was lost. It's that not-seeing-the-forest problem. Some would get so fixated on just the tree in front of them, all else wasn't noticed. That was both naive and careless. So, I was happy to add this to what was becoming a very constructive discussion: Pointing out the same showroom issue existed with Toyota fell on deaf ears. Some refused to acknowledge just how strong sales of traditional cars continue to be. Leadership will come from being able to overcome those barriers. Cost reduction to compete directly with traditional cars is a very, very big deal. Fortunately, the patents on NiMH batteries just recently expired. The next-gen Prius could exploit the new found opportunity that presents.
- 1-25-2015** **For the Masses, pricing.** I wasn't sure exactly how to respond to this: *"Well, it appears GM has Toyota / PiP on the ropes with their newly unveiled Volt 2.0: It's good looking inside and out, improved range, now seats 5, runs on 87 octane and more. What about price though?"* I suspect it was just a matter of not having all the information now available. We'll see. Perhaps this will keep useful posts flowing: No. Even GM has stated they aren't competing with Prius anymore. Toyota is on a quest for affordability, attempting to take on the mainstream directly. Even supporters of Volt say that isn't the case for gen-2 of Volt. It will instead take on the EV competition, hoping it to be well positioned in that growing market. As for seating 5, take a look at recent photos. That spot is for nothing but a small child. There's no legroom whatsoever in the middle. Price will be interesting. GM's big worry will be Nissan, not Toyota. Leaf will burn through the tax-credit money much sooner than Volt. That means aggressive promotion after expiration to keep sales going. Is GM prepared to deal with ramping up of pressure like that?

1-27-2015

How It Happened. My participation on the big GM forum was a result of Prius misrepresentation combined with curiosity of the unrealistic expectations. I witnessed greenwashing & denial by many. It was fascinating. Two-Mode started it all. Even way back in that beginning time, there were the words of "*over promise, under deliver*" haunting GM supporters. And sure enough, that's exactly what happened. It was a remarkable process to witness... something you wouldn't expect to actually be repeated. The technology fell well short of the goals. Enthusiasm for it faded. Misplaced hope returned. Volt became the salvation. The same cycle would play out again. I was astonished by the parallels, especially when such obvious signs were so recklessly dismissed. It didn't end the same way though. That was an interesting twist. When Ford rolled out their first Energi vehicle (C-Max plug-in hybrid), that big forum turned hostile. Rather than a foreign automaker highlighting GM's shortcomings, it was a fellow automaker from Detroit. That ended discussions about Volt there. For the following 2 years, it was the daily blog which took over, becoming more and more desperate as time rolled on. Sales never improved, even with a drastic price-reduction. The enthusiasm there became ended up becoming hostile too. What had once been blind hope turned into looking for someone to blame. ELR presented a glimmer of change, a chance at redemption... which fell apart almost immediately after the reveal. The signs of that same thing happening with the next-gen Volt were there, in abundance. On a regular basis, they'd be pointed out... with terrible consequences. The resulting personal attacks were unbelievable. But it didn't matter. When things don't add up like that, simply sticking to facts and ignoring the rhetoric is a wise choice. The day finally arrived... 2 weeks ago... that long-awaited about the next-gen Volt was revealed. Disappointment was swift & painful; so bad, we aren't even witnessing any fallout. It's just an abrupt end. There's nothing to argue about. People are moving on to other offerings from other automakers. GM's lack of interest toward delivering a vehicle for the masses is so obvious, discussions have ceased. Even that daily blog is winding down. The silence is becoming very easy to notice... if that makes any sense. I'm writing summaries now to retain the feelings & views at this moment. Looking back years from later, reading this, thoughts about what actually happened will make some wonder how so many mistakes could be repeated. Lessons most certainly were not learned.

- 1-30-2015** **Really?** It has been extremely quiet now that the big reveal has passed. Most of the automakers had little to show, which is why GM got so much attention with Volt. That brings emphasis to what's happening at this point. The thought was that going forward there would only be attention on price, since basically everything else has been told at this point. Hype about it was to be expected, in fact. But this turn of events is rather astonishing. We're instead starting to see posts about the hope for conquest sales, going after Prius buyers with the new Volt. This demonstration of still not recognizing audience tells us much about what is to come. Apparently, little was learned. GM didn't increase size from compact to midsize to make it competitive. They also withheld an obvious convenience to make it look more like a sedan rather than a hatchback. Notice the lack of a wiper in back? The size and the hatch were major selling points for Prius. What will they do to entice customers on the showroom floor? The newest television commercial (available online already, expected be shown to the world during this weekend's Super Bowl) makes no reference whatsoever about plugging in. There is only a one-second glimpse of the battery-pack. That's it! With supporters disappointed about the leg & head room in the back seats, what will make this next-gen offering stand out? Who will the increased range and increased MPG appeal to? 50 miles is quite a bit less than what the EV competition offers. 41 MPG is quite a bit less than what the hybrid competition offers. Wasn't the point to appeal to their own customer base? Is that really what that audience wanted? Really?
- 2-01-2015** **Speculation & Rumor.** We encounter this from time to time: *"A fellow who works for Toyota told me last year that a bigger battery wasn't going to happen because it would change the classification of the plug-in due to the weight and size of a bigger battery and Toyota didn't want to do that."* Usually, that kind of vague-yet-definitive claim come from the GM enthusiasts. Reading that on the big Prius forum from a regular poster was a big odd. In fact, it gave the impression of trolling. Sure enough, a newer member took the supposed bait too: *"In that case, I've bought my last PiP."* I was somewhat perturbed at that point. Vague contributes to assumptions & misunderstandings. Detail should have been provided to prevent that. After all, we've seen lots of undermining over the years. Oh well. I tried to intercept with some insight right away: You're overlooking what should be obvious: No one wants size & weight to increase. Sacrificing cargo & seating capacity, as well as reducing HV efficiency, for the sake of farther EV range would be a step backward. The whole point of advancing lithium battery chemistry is to squeeze more out of less. In other words, more capacity is wanted... which is commonly referred to as increasing energy density. That's often achieved without cost increase too.
- 2-02-2015** **\$50 Per Barrel.** We never thought that price for oil would ever return. Sadly, even though it has, the fuel-surcharge many service-providers added when oil was much more expensive has not been removed. People are still seeing the charge on their bills. It has turned into an arbitrary increase without justification or clarity. That's become a concern for some, since it's an extra not part of the regularly advertised pricing for services. Lack for full disclosure can be a problem. Why shouldn't it be discontinued? We are seeing much lower expenses related to gas & diesel consumption now. Still having to pay as if that wasn't the case isn't right. Oil costs less now. In fact, some are now back to guzzling.

2-03-2015 **Climate Change - Acceptance.** Somehow, we abruptly went from denial to acceptance here... locally, anyway. The all of a sudden shift to "*what are we going to do?*" question is getting a lot of attention. Stepping back to look at what just happened in our country which could have influenced the attitude change, 2 things become abundantly clear. There's a rapidly growing interest in truck sales and the Republican party just took control of Congress. Both had been outspoken deniers of climate change. But with so much evidence now confirming things are different, denying it makes no sense. Instead, the posture of accepting it has been embraced. Unfortunately, rather than acknowledge contributing factors, talk is of how we are going to deal with the change. In other words, keep drilling & guzzling as usual, we'll just improve infrastructure to deal with the drought, snow, and floods. That's quite disturbing. Those who opposed improved emissions & efficiency found a new way to continue to hold back the technology. This is yet another reason why the "*too little, too slowly*" concern should have been taken seriously. It was opportunity lost, intentionally! That good enough stance has consequences. Here's a great example of that. Those wanting to undermine found a way to keep doing exactly what they want. Why bother when you can just come up with new ways to fight? Ugh.

2-04-2015 **Sales.** For the Prius family, there was a teeny tiny bit of growth. Remaining basically flat in a time of weak sales (Winter) and cheap gas (\$2 per gallon) that's a nice outcome. Seeing a little more than that is even better. Everyone was obviously focused on Volt though. Unlikely with Toyota who reveals then rolls out fairly quick (5 months for the current generation Prius), there's going to be a lag by GM. Originally we heard June. Now, it's sometime in the Fall. What does that mean for sales between now & then? Anywho, it dropped from the 1,600 per month we've seen for years to just 542. That obviously meant a rather moot discussion yesterday on the blog. I chose not to participate. There's nothing else to say. In the forum section, there was this summary: "*The Volt really is a hard sell! \$35-40K OTD for a compact car with cramped rear quarters and small cargo space is a deal-breaker for most. While tax incentives help to level the playing field, not everyone qualifies for the full amount and the benefits are not realized until the next tax year.*" That said it all. And coming from a Volt owner, there was little else to contribute. It makes you wonder how much will actually change with the next-gen. Needless to say, neither the enthusiasts nor the supporters wanted to address the big picture sales numbers... 18,693 Cruze... 11,878 Malibu... 9,214 Impala... 3,521 Sonic... 3,170 Spark. Each of those mainstream cars sharing the showroom floor with Volt are absolutely crushing it. Supposedly though, the next-gen will appeal more to the fun-to-drive buyers. But looking at the 4,991 Camaro and the 2,127 Corvette sales, that doesn't work either. It should be absolutely crystal-clear at this point why Toyota chose to delay the next-gen Prius. That true competition (traditional vehicles) presents a daunting challenge to overcome.

- 2-05-2015** **Apartment Plugging.** I took care of a friend's dog over the past 5 days, while they were out of town. That required stopping by the apartment several times per day to take the dog out for a walk (and other stuff). All those trips over there gave me a close firsthand look at the prospects of being able to plug in a car there. Put simply, the opportunity is pretty much non-existent. It just plan won't happen for many, many years to come. Sadly, that solidified the talks I've had with other apartment dwellers. You're extraordinarily lucky if you actually can. That means the odds of enough spots for multiple parking-spot to plug in at the same location are totally unrealistic. See why Toyota is choosing to offer fuel-cell vehicles as an alternative for those who need to "recharge" elsewhere or need to "recharge" within just a few minutes? The infrastructure simply isn't going to be able to accommodate a single "*recharge*" approach. Options will be necessary. Direct electricity for batteries will worked great for some. Indirect electricity from hydrogen for fuel-cells will work for others. Think about how expensive & complicated the request is for installing charging stations.
- 2-07-2015** **Looking Back.** It has been almost 4 weeks. The fuel-cell rhetoric has finally ended. Geez! No matter how much information is shared, there were a few individuals who absolutely insisted the technology was intended to replace that in Prius. Pointing out how it is mutually exclusive and designed to fulfill a different purpose feel on deaf ears. That's why the nonsense around Volt is now in a death spiral... spinning out of control now. The excitement about Bolt has squashed it. No one talks about "*range anxiety*" anymore. The next-gen batteries are looking to offer great potential. That makes a so-called EREV competing directly against an EV the type of clash to make you wonder. Why? In the meantime, talk of the refreshed look for GM's Equinox is stirring interest. Last month, that 19,555 of that small SUV was sold. It is clearly a threat to be taken seriously on the showroom floor. That puts Toyota in a position of independence. Yeah! No more senseless attacks. Phew! That chapter in history where the "*Who?*" question could be disregarded is over. The intent to deliver an affordable hybrid able to compete directly on the showroom floor cannot be denied. It's quite obvious to see that, as well as the need. We can actually look back at this point. Change is coming. The market will be filled with a wide variety of choices... which is great, since there is such a diverse consumer market. Expect new approaches. Heck, even the way plug-in "*range*" is measured will be getting a re-evaluation. Acknowledgement of traditional vehicle competition is finally happening.
- 2-10-2015** **176 MPG.** This morning's commute to work was one I really, really I would have filmed. My assumption was that with fresh snow falling, it would be difficult to keep the windshield clear. Turns out, it wasn't too bad. The part that made this commute special was only reaching a top speed of 48 mph. The slippery conditions prevented going any faster. That worked out nice though. The traffic was slow & steady as a result. The end result for the 17.4 mile drive was an overall average of 176 MPG. Bummer. That's absolutely incredible for Winter temperatures. That was my only chance to record it too. I'll be moving in less than 2 weeks. My commute will change. It will become 2 miles further and that river route will change to large rolling hills. It will be great for gathering mass quantities of different real-world data. But the memory of today's drive will never be relived. Oh well. It was nice to experience... especially knowing that just about everyone else on that same drive weren't getting anywhere near that level of efficiency.

2-11-2015 **Short Sighted.** When a cherry-picker, one who pushed very specific data for years while dismissing most else, it's good to pay close attention. This conclusion really irked me: *"I really believe super charging is a dead end. The mass market won't accept 30-minute charge times every couple hundred miles. That's not competitive with today's solution."* Lately, he's been making lots of generalizations is strongly outspoken against EVs. So, that comment wasn't much of a surprise. What got me though was the opportunity to point out how short-sighted that really was. Needless to say, there was no response afterward. Lack of any rebuttal whatsoever is a sign of acceptance. Normally, there's some type of denial or spin. The nothing was a nice change. Here's how I replied: You're overlooking a fundamental. The chargers are not just for those who travel long distances. They are for local travel too. One just installed here is among the first in the area to encourage retail purchases while you recharge. Think of it as the 21st gas station, but you don't necessarily need to refill the tank entirely. It makes lots of errand running around more practical. In other words, it's an alternative solution to *"range anxiety"*. Why carry around an engine when you rarely ever will need it and can just plug-in for a few minutes instead?

2-12-2015 **Crash Prevention.** Remember all the emphasis on crash tests? People obsessed over their favorite vehicle's ability to survive a crash with complete disregard for being able to prevent crashing in the first place. It was quite disturbing. Why in the world wouldn't you want to just avoid it instead? Sadly, the answer to that question was simple... the large powerful vehicles they preferred had terrible maneuverability. Crashing was the only option. Thankfully, technology is coming to the rescue. Unfortunately, those vehicles typically still lack the ability to stir clear of an accident, but they do offer something new... well, new for some. Prius has offered it for a number of years. With mine in particular, I've had it for 3 years. Telling Mr. Vastly Superior that though wouldn't have been constructive. So instead, I took the avoidance approach responding to this: *"I really do hope that GM at least offers adaptive cruise on the Volt 2.0. It's a perfect companion to a quiet smooth electric ride."* He was quite nasty with his superiority flaunting over the years, declaring Volt 1.0 to be so much better... even though it lacked some standard features... like midsize legroom in back and a rear wiper. Sadly, the next Volt still won't offer either. It may offer this though, as an upgrade feature like Prius already does, as I posted: It also doubles as a safety feature... which I'm seeing more advertisements for on television lately... crash prevention. Since adaptive-cruise requires radar for sensing vehicles in front and it has the ability to apply brakes, it will detect a collision and take action before you even have a chance to react. The first time I experienced it was when a turkey jumped out in front of the car. The system sounded an audio alarm, flashed a danger message on the screen, ratcheted the seatbelts tight, and hit the brakes incredibly quick. It was an impressive demonstration of new technology.

2-13-2015 Promises. Watching history repeat for a third time is remarkable. Two-Mode was a major endeavor, which never did result in many sales. Volt struggled along for 4 years, even with a \$5,000 price-reduction and a \$7,500 tax-credit. With years of hype prior to rollout and that undeniable failure to reach the masses, you'd think those following GM would have learned. Breaking out beyond niche takes far more than bold promises. The lack of substance should be a dead giveaway. But then again, it wasn't the first to times. What will make this third attempt to achieve mainstream sales work? Needless to say, we're hearing a lot about Bolt now. The North American President for GM is really feeding the hype. We have absolutely no clue what his "*shake up*" or "*status quo*" references actually mean. It's that same misleading expectation setting as in the past. Both Two-Mode and Volt started the very same way. Ugh. I asked: How is what we're now hearing about Bolt different from the past? GM hyped Two-Mode for years, attempting to avoid their "*over promise, under deliver*" reputation by being a little ambiguous. Each announcement was just vague enough to not be something which they could be held accountable for later. We watched the very same thing happen with Volt. Heck, even the term "*game changer*" is being used again. What does "*to completely shake up the status quo for electric vehicles*" mean anyway? Wasn't that the purpose of Volt? Who will Bolt be marketed to? What should we expect?

2-14-2015 Domestic Production. There is still a strong flag-waving presence in the market. Examples are common, but surprisingly easy to overlook. The latest is a television commercial for the new Chevy Colorado pickup. They super-impose a photo of the pickup onto a scenic background with a man standing in front. Then they exchange it with a photo of a car, asking something about which is more manly. Problem is, the car used was a Toyota, not a Chevy. Why? Unfortunately, that obvious act of bias is something most people likely wouldn't even notice. I could understand the comparison if a Cruze has been the car, but not a Corolla. Far too often we had Volt promoted as "*American*" as the highest factor of importance... even though it was made up of mostly Korean parts and powered by Canadian electricity for several northern states. That's sad, especially when you consider the fact that Corolla is looked upon as foreign... even though it is produced in Mississippi. Ugh. It does make sense, since over 40 million have been sold worldwide since its rollout back in 1968. Only a half million have come out of that plant here, the one which Prius was originally intended for. That's still a lot, but tiny overall quantity. Heck, when you consider the reality at 21 million Toyota vehicles have actually been produced in the United States over the decades, it really should be thought of as domestic. That level of production has generated 365,000 jobs here. Again, why... unless this commercial is actually a subtle way of finally acknowledging that. Of course, no objective analysis would ever intentionally include a factor which could so easily negate findings. Another Chevy should have been used for unbiased comparison.

- 2-15-2015** **Excuses.** I knew this would stir the pot. But it was my first ever post on a Bolt blog topic and figured it would also be my last. So, there was no reason to hold back. This is what caught my attention: *"If the perceptions are so bad, why are most Volt sales conquest sales?"* It was from a Volt owner who obviously hasn't considered the entire GM product-line yet. That selective vision makes constructive discussion quite a challenge. So, I included this other quote from a frustrated Volt enthusiast in my response: *"Your post reveals that GM may have part of the blame, but their dealers (who have a different mindset) are the real culprits for low EV sales."* It ultimately comes down to a series of excuses... every time. After over 4 years of struggling sales and an underwhelming next-gen reveal, you'd think that pattern would finally get noticed. Oh well. Bolt is their latest hype vehicle. As long as it doesn't undermine the market as both Two-Mode and Volt did, we'll probably be fine. After all, the resulting sales struggle speaks for itself. So, I posted: Conquest sales being a high percentage is because GM is unable to sell Volt to its own customers. You can't blame the dealers for people seeing Malibu, Cruze, Sonic, and Equinox as better choices. LOSING SALES ON THE SHOWROOM FLOOR is something GM only now is beginning to see as a major problem. That's a been a shortcoming some of us have been harping about even before the first Volt was rolled out. It's why the "Who?" question was asked over and over and over again. Those traditional vehicles offer a better balance of features, what the masses prefer. A vehicle optimized for efficiency that isn't cost-competitive won't sell well, which has overwhelmingly been confirmed. It is absolutely vital for GM to address the proper audience. This comment about Bolt should be reason for question: *"We are moving quickly because of its potential to completely shake up the status quo for electric vehicles."* Who will GM be attempting to attract? Will they really only go after the current EV market as a whole rather than actually going to appeal to those who are shopping on the showroom floor? Traditional vehicles will continue to absolutely crush sales as a result. That would be yet another opportunity to change mainstream purchases being missed. Remember the *"too little, too slowly"* concern?
- 2-17-2015** **Still Trying.** There are a select few who are still absolutely desperate to undermine Prius PHV. I find it truly remarkable such blatantly dishonest attempts continue to take place. But then again, it's a Volt enthusiast who got burned. He has a score to settle. The Volt owners I associate with are totally different, the opposite extreme just happy to share stories with other plug-in owners. Anywho, this was what he posted today: *"The next plug-in needs to quadruple it's all electric EPA 6 mile all electric range. Yes, you can drive 11 EPA electric miles but that's with using gas due to having to press the peddle during the EPA test."* After posting details as follow-ups many times already over the years, I really struggled how to respond this time. He simply doesn't care. And on a open green blog, he was hoping to mislead newbies. I ended up going with this: It only takes a moment to confirm that claim is misleading. EPA lists "29 kWh per 100 miles" on the sticker as the electric efficiency. So to travel 11 miles, you only need 3.19 kWh of electricity. We know that the total capacity of the battery is 4.4 kWh. The misleading about the EPA test the engine running is getting really old. At this point, pretty much everyone knows the engine shuts back off after that hard acceleration and you still have the remaining capacity available for EV travel. If you don't have a hard acceleration, which suburb driving typically doesn't, the engine won't start. For me in the summer, I have routinely seen 13 miles of consecutive EV driving.

2-22-2015 **Questions.** There are some who simply enjoy the discussions. They'll ask constructive questions... over and over and over again. These are the individuals who's time has come to be ignored. Repeating the question & answer exchange has proven a waste of time. If there were newbies participating, drawn into the thread, that would be different. But in the cases recently, it's become clear the outcome is undermining... holding back, rather than taking a step forward. It's too bad. Some of the questions were worthwhile. Providing the answers hasn't. It's the same old thing. Each new thread, they pretend that information has never been conveyed. I was stumped at first, wondering if somehow the detail hadn't been shared effected. After awhile though, it become obvious that wasn't the situation. Any of these sound familiar: *So the 5,000/month, is that an average over a year? What happened if 6,000 are sold eleven months, and 4,900 the twelfth? If you have spelled this out, either in an earlier post or your blog, perhaps a link would be easier? Again, is this U.S. Sales or worldwide? And again, why the mention of two years?*

2-22-2015 **Answers.** It's almost to the point of madness. Why in the world would a person keep asking the same questions over and over and over again if they were truly trying to understand & advance? Realistically, I'll never find out. There are motives we'll always wonder about. With this situation though, it's clear the effort to find out won't accomplish anything. We saw this years ago when expectations weren't met. Disenchantment makes people do illogical things. Actions surprisingly unexpected are part of the acceptance process. But it sure is annoying for those of us who only feel finding out answers should only happen once. As politely as I could, this was my final post to end that endless questioning: No more agains. Remember the all BOLD CAPITAL response a few weeks back that I told you to bookmark? It was because I was tired of having to re-answer those same questions in each new thread. You may thrive on repeating discussions, but the pattern shows that isn't productive.

2-23-2015 **Fallout.** It's so redeeming to encounter more and more posts like this: *"I guess that's good for city dwellers that only go on short trips, but can obviously go farther when the ice kicks in. I'm kinda ignorant to the whole plug in scene as I never considered one."* Everyone is relieved that the new chapter is being written so quickly. It's pretty easy to see the situation now. That's quite normal, after the fact. But in the mist of the hype, no. I joined in with: That's fallout from Volt, which is making itself more apparent as time goes on. Prior to its rollout, everyone clearly understood the purpose of a PLUG-IN HYBRID. The act of augmenting the system in Prius would result in more battery use. It was that simple. There was nothing discussed about EV range. It was always seen as plugging in would deliver higher MPG. Then came the hype. Volt would be an EV until the battery was depleted and the engine would never contribute any power directly to the wheels. Well, that obviously fell apart. Enthusiasts disregarded information about thermal limitations and efficiency considerations. They only cared about the purity of EV, even though it meant sacrifices. GM was happy to deliver their want. Toyota chose to focus on need instead, placing a very high-priority on cost-containment. They didn't want to compromise on seating or cargo space either. The result was a configuration capable of actually taking on the true competition: traditional vehicles. MPG is boosted significantly over the regular hybrid, regardless of how far you drive, without the need for a massive battery-pack. It's too bad so much emphasis on EV range has made that effort by Toyota so difficult to see. Think about the complications that causes for the other automakers attempting to offer plugs with their hybrids. People won't have a clue how it actually operates and will likely draw incorrect conclusions based solely on EV range. That's really unfortunate.

2-23-2015 **Unsupported.** Sorting through the mess to identify those who purposely misrepresent is a challenge. You have to patiently wait and carefully observe. Eventually, the pattern makes itself apparent. This individual continues to confirm his intent. Unfortunately, it's not good. Even when pointing out lack of detail, the vague persists. When pushed, he'll change the topic. That's how you know. The evade & switch behavior is difficult to deny and easy to verify. This time, it was: *"In a 2016 Volt, 50+ miles."* And sure enough, when I called him on that, the behavior continued. That means another addition to the ignore list. Why waste time on someone who simply doesn't care. There are many, many others on the big Prius forum who actually want to have productive discussions. I ended it with: Based on what supporting evidence? You may not remember the conjecture we had to deal with prior to the first Volt rollout, but some of us do. Unsupported claims would be posted. They'd end up becoming self-validating after being reposted enough. When those of us who did our homework questioned for detail, the response was anything but constructive. It was really sad watching false expectations rise. The inevitable disenchantment which followed could have been avoided... simply by providing the requested detail. Not having any doesn't mean comments cannot be posted; it only means they need to be identified as speculative and educated guesses rather than fact.

- 2-25-2015** **New Commute.** I moved into the new house last weekend. Yesterday, was the first commute from it. The location is 6.5 miles from the old house. That meant quite a few trips with the Prius to transport everything except the large furniture. It's amazing how much cargo the Prius can carry. Too bad the temperatures were averaging 30 degrees below the freezing point. The morning we closed, it was -13°F. That's nasty. Anywho, the temperature had warmed up to 12°F for this particular drive. I was quite curious how it would go. Rather than being just 2 blocks from the highway, I was now several miles but would enter it quite a bit closer with respect to work. It turned out to be a 15-minute drive to that point. With lots of stops and lots of hills, it was nice route for having a plug-in hybrid. And sure enough, the end efficiency reflected that. Overall distance was only 1 mile further, delivering a very respectable 85 MPG. Today was the next time to do the same commute. 96 MPG was the result, despite only being a few degrees warmer. I can't wait to see what happens when Spring finally arrives.
- 2-27-2015** **Progress.** It comes from learning what works and what doesn't, then applying that knowledge to take the next step. Interest in Bolt has grown so much, Volt has already faded away into memory. No one is talking about it anymore, even on that blog which was once-upon-a-time dedicated to Volt. Too small and too expensive makes Volt unable to compete. Why bother with an engine when you have battery-capacity in the 200-mile range coming to market? The 50-mile range simply isn't competitive. It's that simple. This is the very reason why Toyota chose to go with a much smaller plug-in capacity instead. By not sacrificing cost, seating/cargo space, or depleted efficiency, the plug-in Prius would stand a chance at being able to compete directly. That goal continues to demonstrate a winning balance for business & customer. We know the "Who?" answer. The showroom floor is absolutely vital. That is the battleground. Toyota is striving to make a choice able to draw interest from those customers... who are quite different from those seeking an EV... which supposedly Volt will attempt to entice. Knowing your audience is the lesson learned, which is playing out right before our eyes. We can clearly see the potential and the lost opportunity. Progress is tapping that potential. Failure is not being able to take that next step... which in this case, means market growth... increased sales from those who would otherwise just purchase a traditional vehicle.

- 3-01-2015** **That Is Why.** That daily blog for Volt has taken an odd turn since the reveal of the next-gen. They know that new Volt falls well short of both expectations & need, so even they have moved on. Unfortunately, the move hasn't been much of an improvement. In fact, the discussions there have become so non-constructive, participation is pointless. That is why I don't waste time on it anymore. The big discussion there 2 days ago showed a glimmer of hope with this: "*Most of your negative points on hydrogen for emissions hold for BEV as well.*" But the result was so many negative votes so quickly, without any attempt to actually discuss that point, it was clear the bother wouldn't accomplish anything. This was my favorite quote: "*Let's list all the Pros of a hydrogen fuel cell vehicle: 1. Fast refueling time. . um . . ah.. . That's it. That's currently the ONLY advantage they have over plug-in vehicles. Considering the mountain of negatives, is it really worth to build a whole new infrastructure (at the taxpayer's expense)...*" Having just pointed out that the reality of range for fuel-cell vehicles can now match that of traditional vehicles didn't matter. He's one of those few outspoken Volt enthusiasts who simply doesn't care still. Vote down facts you don't like and dismiss data showing unfavorable results continues to be his stance. The fact that infrastructure at taxpayer's expense is a major problem with oil right now doesn't matter to him. He doesn't care. That's sad. We won't need extensive cross-country pipelines for hydrogen. The existing infrastructure can be converted. Why not reuse? Solar/Wind/Hydro can be taken advantage of too. It makes far more sense than continuing to increase drilling & excavation of dirty, non-renewable energy sources. Not everyone will be able to own a BEV (battery electric vehicle) either. Some won't have a plug available. Some will need rapid refueling and long-distance capability. One size does not fit all. Of course, that fact that Volt falls short and discussions have moved on is a bit of an indirect recognition of that. Though, the negative votes don't confirm it. Oh well. They'll figure it out, but not with my contributions. That venue has proven quite unproductive.
- 3-12-2015** **Spring Has Arrived.** Yeah! Blessed with warm weather, finishing up the move to the new house has been quite pleasant. Temperatures above freezing were not the expectation. Watching them reach the 60's was quite a surprise. My round-trip commute, starting with a fully recharged better at both ends, resulted in an overall average of 126 MPG. That's great for a total of 37 miles driving in Spring-like weather. It has been odd in the Prius over the past 3 weeks. The car has been a 1-seater nearly the entire time. With both back seats down and the front passenger, you can fit a lot of cargo inside... and I sure did. It made our move easier. We could pack and pack has many boxes and loose items without any effort. That was really nice. Spring made it even better.

- 3-13-2015** **It's Gone.** The abrupt disappearance of Volt certainly was well timed. With all the craziness of moving into a new house, that was rather fortunate. Rhetoric from the enthusiasts was always quite informative. Topics they got defensive about were vulnerabilities they worked hard to conceal. That was a relatively effective approach, until the reveal of details for the next-gen Volt. Their standing depended upon uncertainty. With answers finally having been provided, the discussions ended. There's nothing to draw interest anymore... hence nothing to write about. Volt will continue to be a specialty vehicle, supposedly intended to compete directly with EV offerings, but clearly not able. Just yesterday, a 300-mile announcement was made. As expected, the automakers unable to deliver a competitive hybrid will focus on electric-only. So, that announcement from Audi about a SUV on the way with an expected 311 miles of range wasn't a surprise. Instead, it's yet another audience problem for Volt. Who's going to want a 50-mile range when there are competitive EV offerings instead? Even GM with Bolt is making that issue clearer to see. That's why Toyota and Ford's approach with smaller, no-compromise, affordable plug-in hybrids still make sense. That's what will threaten traditional vehicles. Their price and high-volume potential will end guzzler appeal and compliment the EV. It's a win-win. Think about how appealing the next-gen Prius will be with the improved thermal-efficiency along with upgraded hardware & software. Add the option of a plug, why wouldn't that be able to attract new buyers? Market expansion is vital. We need to end the guzzling now. Asking everyone to quickly switch from gas to electricity just plain is not realistic. That's still decades away for the masses. Hybrids can archive the next level of green now, while at the same time usher a generation of buyers who will gladly upgrade... ones who won't fight, claiming MPG in the 30's is good enough. That resistance is far too often, overlooked & dismissed. And with Volt gone from the spotlight, we stand a chance of the real issues actually getting attention.
- 3-14-2015** **Recall.** The intentional stigma created toward recalls is an interesting topic to ponder. Rather than preventative-updates being considered a post-purchase expectation, any after-the-fact change is bad. The thought of getting upgrades, like we routinely witness for software, there's an attitude of negative. It was taken to extremes back when Toyota had the spotlight. Lately, it's been GM. They tried to deal with it the best they could. But under the circumstances, along with the precedent they helped to set, what good can come from so many years of promoting the opposite. Anywho, the recall of 50,249 Volts makes a person wonder. What will the response be? The report is that 2 people have been injured as a result of carbon-monoxide exposure from the car running inside garages. With the pre-warm-up approach GM took, some of us wondered if that would ever happen. Of course, we were accused of spreading FUD, trying to undermine Volt as a troll. In reality, it was constructive consideration. But the enthusiasts became hostile if you ever questioned anything. That's why supporters did everything they could to keep a distance from enthusiasts. Long story short, this will likely pass almost completely unnoticed by many. Downplay has been the response for most problems lately.

3-14-2015 Gas & Stock. It's unfortunate that our market is heavily tied to gas & stock prices. But in better news, GM will be buying back 2 Billion worth of their stock to help boost the remaining stocks value. The United States government lost a massive amount of taxpayer money from that very problem. It didn't go up that entire time of ownership. Finally, when those shares were sold at a loss, the value went up a little. Not much happened since then though. And because this market relies so much on that, this step to improve became necessary. It makes you wonder what will happen with gas. The drilling & refining of oil isn't anywhere near as profitable as it had been. That's put some investors in a difficult position. Planned growth, especially from the sources more difficult to reach and dirtier to process, is impaired. Low gas prices don't do much to encourage the appeal of plugging in either. That's why the next-gen hybrids, most significantly Prius, is such a big deal. People find \$2.39 per gallon quite acceptable. The pain from filling the tank has subsided. Even more opportunity will be lost too, if there isn't a truly compelling choice offered. That's why Volt was such a mismatch. Who was going to actually buy it? The end of this year will be a big one, giving us a indication of what's to come. There's much to be lost or gained.

3-15-2015 Peak Oil. When a long-standing definition changes, you know a milestone has been reached. For decades, the term "*peak oil*" has meant arriving at a tipping point. Supposedly, it now means when supplies run low and prices skyrocket. The other day, that now dead (since Volt is no longer discussed) daily blog claimed experts were predicting that stage would be reached about 20 years in the future, sending gas to a price of about \$10 per gallon. I wondered where the heck he got that information. For those of us who have studied economics, we know that the pressure from rising prices stirs innovation and increases the willingness to take risk. In other words, some alternative means of fulfilling demand emerges... which is exactly what's happening now. And when you consider the fact that "*peak*" actually represents change (like the loss of stability), it's difficult to argue that we aren't already witnessing that. Looking back afterward, from a historical perspective, that's much easier to see & accept. But while those events are taking place, there's often quite a bit of denial... and this case, excuses disguised as reasoning. That's why I stopped participating there. The opportunity for constructive discussion fell apart as the excuses grew. It's exactly why I pushed so hard for goals prior to rollout. What are we attempting to achieve? For this discussion, how should we prepare for "*peak*" being reached. No need to fall into a semantic trap. Ask questions. Take action.

3-18-2015 **\$44 Per Barrel.** Way, way, way back, I remember \$39 per barrel. I never imagined us ever getting close to seeing that again. It's a problem getting bigger and bigger. The oil industry depended upon stable generous prices. Those proceeds were used to further develop extraction techniques & locations. Too bad they weren't invested into renewable energy instead... but I digress. Back on topic, we have cheap gas as a result of the low oil prices. Sadly, that doesn't equate to an opportunity to raise gas taxes to pay for roadway maintenance & improvement. Believe it or not, there is still strong resistance to that. I see everything else slowly incrementing to keep pace with the growing economy, as well as the growing demand due to population growth. Yet, the desire to guzzler continues to be a barrier to progress. This is a reality the Volt enthusiasts didn't understand. They didn't know what "*who*" referred to. Audience is absolutely vital. Just because it was built, does not mean people will buy it. This is why the approach with Prius has been so successful. This is why sales grew so high with the second generation, even before a tax-credit was offered. It was no where near as generous either. Less than half the amount and limited to 60,000 sales made its reach much less. Yet, more was still achieved. The enthusiasts know it too, hence the death of that blog. The almost total silence now has opened up the way for many automakers to show off their upcoming solutions. GM thought there was plenty of time... despite countless warnings... losing out to the oil providers. Back when gas was expensive was the time. It is now quite obvious what the "*too little, too slowly*" concern was all about. That opportunity was wasted. Sad. We're seeing the popularity of ordinary traditional vehicles grow.

3-20-2015 **EV Surprise.** Prius PHV is a plug-in hybrid. So if the engine runs briefly, who cares. The benefit of augmenting a regular hybrid with plug-supplied electricity is still achieved. Super efficient HV driving is the goal, not EV driving. Nonetheless, I was surprised to see that yesterday's stats for me revealed having traveled 30 miles from two recharges. That 15 miles for each, without any effort to achieve that, was a tribute to the technology. Clearly, my new commute to & from work isn't affected by all the rolling hills. Who knows, now that it's Spring, perhaps I'll see an improvement over the commute from my old house. The EV estimate has risen to 11.1 miles over the past few days. Range was always less anyway, due to the temperatures well below freezing here, especially with all the trips back & forth during the move. But there is definitely a curiosity about the operation after 3 years of ownership already. I won't be able to measure the capacity retention anymore. The new route ended my long run of consistency. Oh well. At least I'm still seeing really high MPG.

3-20-2015 The Best Choice. It's really frustrating when an antagonist makes up history. Most people assume what's being said is true, or at least close to what actually happened. Sadly, it is not often the case now. Those few who thrive on debate and get a thrill from dropping bait say things like this on a regular basis: *"Speculation had the plug-in as a \$3000 option to the regular model. That may have been low, but Toyota was in a position to eat losses on the first gen in order to grow the market. It is supposedly what they did with the Prius itself. But they didn't, and were the last to drop the price when it happened across the market."* It's an endless battle having to deal with that. Fortunately, I have the blogs to confirm that past. They do not. So, I usually post to draw attention away from them, rather than waste anymore time responding directly. State the facts, summarize, and move on: Being part of that history, I can tell you what actually happened. Keep in mind who the market was then and will be later. That makes a big difference. Think of the big picture, the true competition. First, speculation about plug-in was that the goal had been set for it to become a \$3,000 to \$5,000 option once the market had been established. There was no expectation of the price being that low upon initial rollout. Second, it made no sense eating losses when they were far from the only player entering the plug-in market. Making a design profitable means staying true to mainstream purchase preferences and not depending heavily on large tax-credits. Third, the approach with Prius was to limit availability and set a competitive price. There was no tax-credit back then. There was cheap gas, no concern for the environment, and a strong push for large guzzlers. Finally, why not wait for the second-generation for the big rollout? After all, that is what happened with Prius a decade back and we all know the cost of batteries has been steadily dropping now. The rhetoric was absurd and Toyota's approach has been validated. Look at the disaster Volt became, despite large tax-credits and a large price-drop. It suffered huge losses and GM chose not to make the second-generation competitive; instead, the decision was to endorse EV... the very thing Volt was intended to make unnecessary. Reality is, the true competition is absolutely crushing the plug-in vehicles. The losses GM has suffered were about the money, it's the fact that Malibu, Cruze, and Equinox are the popular choices and Volt is just an interesting model. It comes down to the decision consumers on the showroom floor make. Toyota is well aware that Camry & Corolla must continue to sell in high-volume but is unwilling to sacrifice Prius in the process. Take a look at the struggle Ford has had. What about the delay for Nissan? It's about making the best choice, not being first or last.

- 3-21-2015** **Europe vs. United States.** Very few know there's a PHV difference: "*The PiP there has City mode rather than PWR mode. City mode aggressively suppresses starting the ICE unless you really floor it. This is to comply with zero-emission zones in many European cities. Along with City mode comes the apparent lack of what is called in the US a *boost* mode where both the electric motor and the ICE are providing power at the same time.*" I was happy to see that posted. My response was: That's a nice explanation. Not being aware of Toyota delivering 2 different configurations of PiP has contributed to a variety of misunderstandings about what the system is actually capable of and intent of the first model. Flexibility has always been the key. In fact, that's why it was so easy to augment with increased battery-capacity. Those who wish to undermine twist that to appear to be a desperate attempt to redesign a system to do something it was never intended. We know that isn't the case. Toyota has carefully considered mainstream need and avoided succumbing to hype. Collecting extensive real-world data collection from Europe for CITY operation and from the United States for BOOST operation positions Toyota well for the next-gen model. That will go a long way toward the ultimate goal of delivering a profitable configuration for the masses.
- 3-21-2015** **2 Leafs.** That was cool. As we were walking across the street today, 2 Leafs drove by... from opposite directions... crossing in the middle of the intersection... the only 2 vehicles. It was perfectly timed. Too bad events like that are incredibly rare still. Sure, you can see that eventually with Prius. But with plug-in vehicles, nope. There simply aren't enough of them yet. Someday, but not anytime soon. There's many years to wait before seeing them sharing the same parking lot becomes common. I know. Patience.
- 3-23-2015** **RAV4 Hybrid, coming.** It's finally going to happen. We knew someday that there would be a small AWD hybrid offered by Toyota here in the United States. After all, Estima has been available in Japan for quite a few years now. But minivans are low-demand here. So, it didn't make sense to offer the same here, especially since that one was smaller than the minivans we see on select dealers lots. Remember that neither Ford nor GM even offer minivans anymore. So, targeting a small SUV makes a lot of sense. We'll get detail soon. With Earth Day a month away, pre-announcements like this are to be expected. Details will be interesting. How other automakers respond will be too. Don't forget that Ford discontinued its small SUV hybrid. The fact that Toyota will be offering one now makes you wonder. It will obviously feature the latest & greatest design too. Those improvements should appeal to many who still are not interested in purchasing a car. We'll see. 2015 is definitely shaping up to be a noteworthy year in automotive history.

- 3-24-2015** **Single-Mindedness.** This sure hit the nail squarely on the head: "*Volt was designed to reduce gas consumption, not for fuel economy. They are two very different things.*" Electricity is a fuel too, not just gas. Sending the message of guzzling all the electricity you want, just because you're not using gas, is wrong. It's still waste, just of a different type. We still have a lot of electricity generated from coal. That's dirty. The act of transmitted ends up consuming some as well. Then of course, there's the conversion from AC to DC then back to AC again. So, efficiency of the electric-propulsion system in the vehicle is important. Some just plain don't care though. That's sad. I jumped into today's discussion with: We need to remind people of the single-goal approach GM took. The fact that Toyota chose to address several goals all at the same time... cost... emissions... cargo/passenger room... in addition to improved gas consumption... with the most efficient use of electricity included... is often overlooked. Unfortunately, there's a past of outright dismissal too, in which we had to deal with "*vastly superior*" claims as a result. That single-mindedness of MPG with no regard for other priorities is something new Volt supporters must now deal with. Their predecessors set a terrible precedent that they have no choice but to address.
- 3-24-2015** **Allowing Mistakes.** This comment today certainly got my attention: "*Lets wait and see what they are like in the real world, how many are purchased for whatever reason.*" It's among the first signs to look for when something starts goes wrong. Recognition of purpose is vital. You cannot just build a product and hope for the best. Sadly, we have several good examples of rollouts going bad due to not matching market expectations. I decided to respond with: That's what caused problems with the first-generation offerings. Rather than clearly identifying goals, then addressing them directly, that stance was taken. Not being proactive welcomes trouble to come. Allowing that same mistake to be repeated is even worse.
- 3-25-2015** **Misleading Through Omission.** You gotta like this: "*For an average American car (26 miles per gallon), the report estimates that air pollution emissions altogether cost us \$1,700 in damages per year. In comparison, emissions from energy to power an electric Nissan Leaf would cost us \$840 even if purely powered by coal, and \$290 if fueled by electricity supplied entirely from natural gas. These costs would become negligible if the electricity came from renewable or nuclear power....*" It seems constructive. The summary stated why EV is better than traditional vehicles. That catch is, not all the information available was included. I responded to the discussion thread about that with: That's called misleading through omission. Some would identify sighting only the extremes as cherry-picking. Nothing in between is a red-flag, a warning of potential bias. The plug-in Prius is considerably cleaner than the average American car, but that information is conveniently not mentioned. Why wasn't it? We've seen reports showing emission levels, but never anything with respect to supposed damage. How is that actually quantified? What criteria is taken into consideration? Where is the detail? In other words, don't take a single vague report at face value. The real story is in the detail... or lack there of.

3-25-2015 **Wow!** Today, there was an unexpected announcement... one of great importance. Out of the blue on a big Prius forum thread relevant to the topic, I posted: Looks like GM has finally seen the light and will now be following the same path they heavily campaigned against for over a decade. In other words, the large & expensive battery in a small car clearly isn't appealing to a wide audience. That question of "*Who?*" has overwhelmingly been answered. GM was losing a massive number of customers on the showroom floor and has finally taken a stance to properly address that. All the nonsense, the rhetoric, the hype, the spin, and the propaganda has been confirmed as not the mainstream solution it was promised to be. Many of us will feel quite vindicated as news of this spreads. We were attacked on the premise this would never happen. The belief that blending was a waste & futile path to follow is now being taken by the most outspoken of opponents. Irony. Isn't it great? :)

3-25-2015 **Initial Thoughts.** This news is monumental. I cannot stress that enough. The benefits of a FULL hybrid have been discussed for 15 years. Throughout that entire duration, there was resistance from GM. It was maddening. Finally, after years of the "*stop gap*" argument against them, GM finally changed their attitude. They'd develop one, rolling out first a configuration for large vehicles, then later follow up with a mainstream car. That didn't happen; instead, they decided to pursue Volt instead. That effort fell apart... on a disastrous scale. It was all about diversity. I couldn't care less about what was offered as a specialty vehicle, as long as there was also something for the masses too. Clean, Efficient, and Affordable... what a concept... one that GM obviously didn't have as a priority. Thank goodness the first true signs of that changing have finally emerged. Yeah!

- 3-26-2015** **The Post.** My opportunity to sound off, after waiting for others to chime in, had come: I've been pushing FULL hybrids for 15 years. Since the beginning, it was always about getting something clean, efficient, and affordable for the masses. That meant a practical vehicle which didn't compromise to emphasize any particular trait. In other words, it would be an ordinary part of the crowd, an everyday vehicle you'd see everywhere. Prius fit that criteria extremely well. So, whenever someone passionately liked something else, they'd assume I was fighting against them. It was unheard of back then to endorse multiple automakers. If I was pro-Toyota, in there mind, it was impossible to be anything else. That's clearly not the case. My friends who own Leaf, Volt, and Tesla know that well. Some on this forum though and elsewhere still don't believe that though. Because I want a vehicle for the mainstream, they take great offense to words casting their preference as a niche... rather than just acknowledging a clean, efficient, and affordable also. That's why I pushed so hard on GM. I couldn't care less what happened to Volt. And I was constantly misrepresented as trying to kill it. Thankfully now, it's becoming easier to see that I was pushed for diversification. A niche is fine as long as there's also a choice for the ordinary consumer... hence having mentioned Malibu literally thousands of times and pointing out how it was the true competition for Volt, not Prius. Those losses on the showroom floor will be very, very difficult to deny now. GM's own customers weren't interested... which is why there was so much attention brought to conquest sales from former Prius owners... which cannibalized the market, rather than expand. That missed opportunity has been acknowledged, finally. I'll admit, it is very nice having been correct all along, but there's not really much to take credit for. The economics were pretty basic. GM's production of traditional vehicles didn't change when Two-Mode or Volt or BAS were rolled out. They never captured any sales beyond just special interest. Volt depended heavily upon a subsidy too. This new hybrid, a proper FULL design, won't. It will be targeting the appropriate audience too... those whom in the past provided profit for the business.
- 3-28-2015** **Cold Starts.** This type of misleading gets annoying: *"My beef, as it were, with people who ask if EVs are "cleaner" than ICE vehicles is that they should first talk about criteria pollutants and should not use terms like *clean* or *dirty* when discussing emissions. As you point out, there isn't anything particularly dirty about CO2 or similar gases. It's also why the Volt is far "cleaner" than a Prius or a PIP. Criteria pollutants are released on a cold start. Once the cat-converter warms up they are largely eliminated. Hence the goal is to reduce or eliminate cold starts. The Volt 1.0 eliminated 80% of all cold starts. The Volt 2.0 is designed to hopefully eliminate 90%."* Over and over again, this particular individual has been told the PIP (the plug-in Prius) doesn't have cold starts. Yet, he continues to claim it does anyway. This is the same person who still proclaims the "vastly superior" trophy. So, it isn't worth actually responding. However, I can post detail here. The depletion point for PIP is 23.5% battery-capacity remaining. At that point, the EV driving ends and the engine starts. But rather than the "cold" he claims, the engine runs in a protected state. That reduced burden reduces emissions. In other words, engine alone is not relied upon for power. Much of that is still provided by electricity. For ordinary warm-up, the state-of-charge level will drop to about 20.3%. In the circumstance of a hard-acceleration, it will drop to as much as 18.4%. Put another way, the battery is used to prevent engine from revving beyond 1500 RPM. And once warmed up (coolant to 130°F), the engine will run to replace the consumed electricity, so you always have a buffer available. That restoration level is typically 26.6%. Long story short, there are no cold starts for PHV.

3-29-2015

Who? (question) It's very interesting to revisit that question, now that things have fundamentally changed. There is already a growing attitude of inevitability, as if no one ever said this wouldn't happen over their dead body. I find it amusing. The pressures of economics can only build up for so long. Anywho, that puts Volt in an awkward position... allowing for comments like this: *The "Market" is as always: Someone not wanting to burn gas on their daily commute (and the related engine maintenance), in a fully functional EV, and yet they can take off for the coast at a moments notice!*" I accepted this invite: As always, that difference between WANT and NEED is something not properly addressed. The market described is a desire, what supporters of plugging in have wanted for a very very long time. Consequences of having hoped that would be a game-changing solution are now quite apparent. It's really unfortunate that lesson had to be learned the hard way, especially with so many warnings along the way. But it was a WANT they were willing to gamble on... and lost. The NEED was to replace the business-sustaining vehicles, those which sold in high-volume for a profit. That's a profound difference. We knew who those consumers were. Yet every time the "Who?" question was asked, the reply was focused on the WANT audience instead. It was a disaster in the making. Volt was declared victorious despite not fulfilling the NEED. We could all see that it did not capture the mainstream consumers as anticipated. GM's own customers simply were not interested. So rather than expanding the "market", emphasis was focused on conquest sales instead. That cannibalized what had already been achieved, getting people who had already switched to a high-efficiency vehicle to another. The popular smaller vehicles of GM... Malibu, Impala, Cruze, Equinox... continued on, totally unaffected by Volt. Meanwhile, Toyota pushed hard with Prius, diversifying into 3 distinct models and augmenting the most popular. That pushed the brand to top-seller in Japan and to mainstream quantity in the United States. All without tax-credit incentives. Prius has survived the test of time and will be getting a next-gen upgrade later this year. A new vehicle using HSD will be introduced as well. They are all helping to fulfill the NEED. Looking at GM plans, we see an upcoming introduction, the full-hybrid Malibu. As much of a WANT there was for Volt to become a high-volume profit-earner to help sustain the business with, we see that it is not. There is no expectation for that with the next-gen model. It will remain a specialty choice, a desirable vehicle for a niche. Focus and hope will be directed to the new Malibu. As a hybrid, there is potential to appeal to showroom shoppers, those intending to purchase a GM vehicle anyway. It will be able to compete directly, a strong advantage over Volt. That NEED is long overdue. The "*too little, too slowly*" concern has finally been taken seriously. Yeah! It's really unfortunate how much of a diversion Volt ended up being. Oh well.

3-29-2015 **Who? (answer)** The quote came from an outspoken antagonist, an individual who went out of his way in the past to spread misinformation about Prius. He had been a Volt owner who felt threatened by Prius, not accepting the possibility that co-existence was possible. Coming from a "vastly superior" background, getting over that realization of having been greenwashed is a challenge. No one wants to discover they've been misled. So, I was happy about the opportunity to change a foe to a friend. After all, that is the ultimate defeat... and the goal all along with Volt. Looking for an ally has been a long journey. Anywho, his response was: *"How and why would I 'acknowledge' something I know nothing about? I don't care to know what the current GM product line up is. I care about the Volt. It's an awesome, fun, inexpensive to drive car and I would have bought it if Hyundai was selling it."* Only seeing a single tree in the forest is often the source of a problem. There was no product gap as far as they were concerned. Volt enthusiasts went way out of their way to ensure that limited scope didn't grow too. That's why looking at the rest of GM's production caused so much of a stir. It's also what contributed to Volt supporters emerging, those who wanted true success rather than just some trophies. Sales enough to affect the true market were what's been important, those who would otherwise just purchase a traditional vehicle offered by GM... hence the "Who?" question... and finally an answer.

3-29-2015 **Malibu Sales.** I really got a kick out of reading this: *"Lack of a full hybrid version was not the reason for poor Malibu sales."* There wasn't anything at all posted by me with respect to that. He just saw the words "sales" and "Malibu" appearing in a post pointing out Volt's struggle and got came up with that to voice his anger. He's one of those upset about how things turned out. In fact, he even accused me of "I told you so" posts as a result of recent events. Wanting someone to use as a scapegoat is nothing new. Neither is my support for FULL hybrids. An for years, I've been pointing out how sales of Volt have been lost to vehicles like Malibu. So, twisting my words to make it seem as though my attention to Malibu was something else entirely was to be expected. It all comes down to that product gap. Having no affordable choice without a plug was an obvious problem which could only be denied for so long. Long story short, I wasn't pleased and expressed my feelings this way: That isn't even remotely close to what I posted. Again, the reason for no HIGH-VOLUME BUSINESS-SUSTAINING sales, something directly competitive, was due to nothing being offered. Nothing in the category was a blatant problem. There was a huge product gap that scores of outspoken Volt supporters refused to acknowledge. Thankfully, GM finally did. btw, I've been saying the same thing about FULL hybrids for over a decade now, to the point where people complain about me sounding like a broken record. So, I don't see how my stance could possibly be misinterpreted.

3-30-2015 **Progress.** It can be painful. But if you stick with principle (good business), it will eventually win out. This was interesting: *"The volt though, that created a new category. I can understand the doubt in some peoples minds, but I don't understand the lack of understanding that erev phEV's may expand the market, while another me to midsize hybrid is likely to add little growth. That is unless you see something I don't where the malibu hybrid is better tech than HSD."* The raising-doubt response to the news was to be expected. The pessimism was annoying. The assuming was frustrating. It was the growth part that got me in the end though. GM's stance changed from fighting to joining in. Contributing to the very approach the automaker had been opposed to for so long is a major barrier overcome. All that focus on Volt at the expense of FULL hybrids was always a problem. Rather than being part of the team, it was declared superior without justification. That obviously backfired. The result is bewilderment for some. I posted: The assumptions in this forum are what hold back constructive discussion. In this case, there's the belief of better/worse and success/failure causing the problem. People continue to assume that's the stance being taken when posts are made. And no matter how valiant the effort to focus attention on the market instead of individual automakers, some just plain don't see it. The lack of understanding fits that. The category... or whatever other identification means chosen to describe a technology... makes no difference. It's still the same problem. Paradigm shift simply isn't possible. Period. That's been overwhelmingly confirmed. So, no matter how great the technology, it just plain will not interest a majority of the consumers until their current offering is discontinued. They will just keep purchasing what they feel comfortable with instead. Some people have fought so many years for the advancement & acceptance of battery vehicles, they've lost sight of the original problem... which is what has allowed it to persist for so long. It is absolutely vital to be attentive to the predecessor. Focus solely on the end-state creates a new barrier to overcome... an avoidable challenge if you establish a bridge. Ironically, that idea of a "stop gap" being given a stigma of bad caused people to dismiss the very solution needed to overcome anchors to the past. In other words, that's why FULL hybrids have been so fundamentally important. They are what will bring the production of traditional vehicle to a drawdown, not EV alone.

- 3-30-2015** **Understanding.** It becomes a major problem if you hold discussions with the same person thread after thread after thread. They get mixed up, forgetting if you said something or if it was actually someone else. Remembering when a statement was said also becomes an issue. That's why I blog. The exact quotes are saved, giving me an opportunity to search back to verify who actually said it. As for the when part, the blogs are written as the history unfolds. So, there's no conflict ever related to looking back. The perspective at the time is documented in detail. Anywho, today is was this: *"And here I thought the discussion was about pushing forward technology that would help spread electrified cars (and here we can include hybrids, phev's, and bevs). So again, I will admit to not understanding your point."* Still attempting to convert foe to friend, since this is taking place on the big Prius forum, much effort will be expended to ensure clarity: Many people fall into the "advancement" trap. It's far more common than you'd ever expect too. The belief is that pushing forward technology can only be achieved by reaching beyond the current limitations. That makes a lot of sense, which leads to a lot of incorrect assumptions. Reality is though, the advancement requires sunset of the older technology. It's why traditional vehicles are still such a massive barrier. They are holding back steps forward. The gauge of progress is measured by how the step is taken. Using a carrot (tax incentive) or a push (government mandate) will only help to advance the technology itself. That will not change the attitude of the masses. They'll continue on, perfectly content driving their traditional vehicles.
- 4-01-2015** **Malibu Hybrid.** Details are have been released. Like what Prius already has and what Volt will be getting, it too will feature a Exhaust Gas technology. Being able to recover heat and recirculate air that would otherwise be lost is great. I really like the fact that attention to design features such as that are pressworthy now. Course, in the past, the reason some things were excluded by the media and by supporters was due to only the competition offering it. But who cares. GM is finally catching up. The rating numbers from GM (which EPA will certify) are 48 MPG city, 45 MPG highway, and 47 MPG combined. That truly is competitive... functionally. The system itself may be somewhat expensive still though. Interestingly, it has an EV limitation of 55 mph listed. How much do you want to bet that will be used to mislead? Toyota's non-plug hybrid limit is 46 mph and Ford's is 47 mph. But the values are basically just a note for trivia. Travel at speeds faster without the consumption of gas is a normal part of the operation. Having the engine pump with the valves open causes very little resistance. Anywho, the part I get a kick out of is the size of the battery-pack. It's just like what the other automakers. That's confirmation of what we've been saying all along, for many many many years. Thank goodness GM is finally on the right track. Volt will just fade into the background with other niche offerings. Meanwhile, we'll see growth hybrids and a decline in traditional vehicles. That makes taking the next step so much easier. This will help. Having a major automaker strongly against FULL hybrids was holding back the industry. Some sort of cooperation was needed.

4-02-2015 **RAV4 Hybrid, details.** Some were revealed today. Nothing about efficiency, performance, or price was shared yet. But at least there was confirmation that it indeed would be a 2016 model. Hearing the hybrid will deliver better acceleration and more horsepower was quite a tease. I'm sure some are now want efficiency information more than ever. Isn't marketing great? Speculation about MPG is that low 30's will be realistic. That's obviously a far cry from Prius, at least it helps to help end the reign of large SUVs without forcing people to actually give up SUVs... over their dead body. That's yet another reason it is so important to know your audience. Souring appeal for the larger guzzling SUV by offering a smaller that's more efficient and much cleaner is a decent step forward. It's too bad there have been many who didn't understand that. They just figured if you made a compact car appealing enough, the draw of the SUV would vanish entirely. They were wrong, very wrong. Now, that reality is easy to see. Unfortunately, we have to wait until this Fall to see them on dealer's lots. At least there's something to look forward to in the meantime. It's a category which seems to be well time for strong sales. Toyota should do well. It's an odd situation seeing that Ford chose to discontinue with the option of starting fresh again later with a small SUV hybrid. They were ahead of the time. No, they have the opportunity to diversify. So, all is certainly not lost. How long do you think it will take GM to offer a hybrid Equinox?

4-03-2015 **Told You So.** Only one person accused me of having an attitude like that. He's a well known antagonist, one who thrives on debate. So, there would have been a slight bit of disappointment had there not been any sort of negative reaction. He just wanted closure too... by claiming this outcome was inevitable, wondering how anyone could have ever thought otherwise. What load of crap! But that's ok. No one else had any issue with the recent developments. In a way, Volt was doomed from the start. With so much emphasis on performance and such a negligent approach with cost, there's no way it could possibly be competitive. That's why those like me never saw it being discontinued. As a specialty vehicle, it could thrive. After all, that's what Corvette & Camaro have been for decades. Why not Volt too? It did fail though... falling well short of sales goals. No excuse could cover the fact that expectations were for it to achieve mainstream popularity by the third year. That didn't happen. Not even close. It was a disaster. Had the approach of delivering a second model been addressed from the start, things could have been profoundly different. But instead of embracing the idea of sharing the technology with another vehicle, there was intense opposition. So, the fact that GM did a complete reversal and just announced plans to do exactly what enthusiast feared the most, there's been a quiet death. No, not Volt. Enthusiasm for it. The thought of just the hybrid portion of the design being featured as a premiere offering is devastating. They could have declared that a technology victory. Instead, their own precedent, looks upon that as terrible waste. They brought about their own demise. Seeing the "*vastly superior*" attitude not replaced by a fear of me playing the "*told you so*" card is quite vindicating. I welcome the FULL hybrid that we'll be getting from GM. Finally, there will be something for mainstream consumers. Yeah!

- 4-04-2015 Hatch-Open Driving.** This was an interesting experience, something I haven't done for decades. Back in college, I owned a 1984 Dodge Omni. It was my first hatchback, which proved to be remarkably convenient. That's what made me so excited about Prius becoming a hatchback too. Anywho, every now and then, I'd encounter a load of cargo to carry that was larger than the cargo area. With a small hatchback like that, it happens. With a large hatchback like Prius, not so much. In fact, that's never happened for me. Even that 11-foot folding umbrella we purchased last year fit inside, with the hatch shut entirely. This time though, we weren't so lucky. We accidentally had the 20-foot collapsible ladder transported by the movers to the new house. It was too long to fit inside the Prius to bring in back. So... I did what I had done all those years ago... drove with the hatch open. Securing the load & door was no big deal. What differed though from in the past was there is now a warning beeper. I had to listen to it for 29 miles. Ugh. Thankfully, it was a beautiful day out and the efficiency was still outstanding. Even with the aerodynamics of the Prius compromised and no plug-supplied electricity available, it delivered 52 MPG. You gotta like that.
- 4-05-2015 New Attacks.** The new "*borrowed technology from Volt*" marketing is really frustrating one particular EREV pusher. His arbitrary criteria to differentiate it from PHEV has been falling apart lately, as a direct result this sales approach twist. I find it amusing, since Prius was designed with plugging in from the start, but wasn't offered that way until recently due to lithium density & cost. He was one of the antagonists who refused to acknowledge that, insisting the plug was an after-the-fact scramble to compete with Volt. Anyway, it turns out he's simply against all vehicles offering less than a 40-mile capacity... which explains his near hostile responses at times when the topic of a second affordable model of Volt be offered in the past and his attempts to undermine now: "*Anyone who expects the Malibu Hybrid to ride like a Volt in range extended more will be sorely disappointed. The Volt's smooth EV ride requires a significant amount electrical power (kW) which the smaller battery pack in the Malibu Hybrid just doesn't have.*" That quote really caught my attention. There isn't a reasonable explanation for any difference. Depleted operation is hybrid mode. If Malibu is using borrowed technology and the Volt battery is drained to the same level, what would cause smoothness to vary?
- 4-08-2015 Choices.** There is growing hope. The market barrier Volt had been is fading away. Vastly superior? Certainly not! It reminds me of DIVX, when it messed up the DVD market. Most people have no clue it even existed, no idea there was a rental-disc format that had been introduced for the home-movie market that ended up causing major rollout disruption... then, abruptly disappeared. Volt will be more than just a footnote in history, but it did indeed mess up the automotive market. Was there much harm done though? That's an interesting question. GM paid dearly. But the other automakers found a way to take advantage of the fallout. They made it into an opportunity, despite what the antagonist spin would leave you to believe. This is proof of the changes being recognized: "*I have to admit I am getting concerned for the Volt. In another 18 months, the Bolt will be available, and for many this may be preferable, especially as a second car. Next we have this new Malibu. It has great styling, is relatively spacious, and the hybrid gets 47 mpg combined. ... For probably about the same price as a Volt, I can get a Malibu Hybrid. And with this I probably get more passenger room, a true 5th seat, power seats, and less mileage impact from cold weather. Choices, choices.*" Knowing who, I call that hope. The market is opening up. Choice is very important.

- 4-10-2015** **Stop Gap.** There's nothing to gain from posting on the Volt blog anymore. It's just a republic of what's on the parent-site anyway. The sacrifices made for the sake of EV range are simply too much. That lesson has already been learned by GM. Following the automakers with a smaller range and more efficient blending is what will appeal to consumers in large quantity. Know your audience. This post in its entirety highlights the situation well: *"If everything goes Voltec and they end up discontinuing the Volt, that would be great! But I don't think hybrids and weak PHEVs will get us there. Efficiency helps, but it's just a stop-gap – a Band-Aid for the real problem. We need alternatives to oil. And that's what the Volt does. Most of the Volt's miles are electric. We need more cars like that."* Notice how incredibly vague that is, how it doesn't actually address specific goals? What is the point of alternatives? He's one of those who couldn't care less about the source of electricity or its cost. The penalty of substituting one type of guzzler for another is a real problem. That's unfortunate. It is ironic that he's using "stop gap" as the label for attempting to undermine. That's what GM used in the past and what EV supporters use now. Also, notice his use of "weak" to demean? What would stronger achieve? Isn't anything using a combustion engine at all his true issue? Where is the gap?
- 4-11-2015** **62 MPG.** I used only 2 miles of EV capacity and drove a total of 187 miles. It was my opportunity to briefly escape up north for a few days of rest. Being able to get that kind of MPG without needing to use the plug-supplied electricity is great... especially since there is no where to plug in later. Of course, I don't care. It's my time to rest. Attempting to sell 2 homes and buy another inside of just 6 months is a major effort. Any type of rest is great. I'm so thankful for the large cargo area the Prius provides. I've done so many trips hauling stuff back & forth, my head is spinning. It will be worth it though. I'll get to enjoy Summer at this rate. Yeah!
- 4-12-2015** **Replenishing EV.** Taking a quick trip up north, I wanted to save EV capacity for when I'd be doing short drives, since I wouldn't be plugging in. That meant it would be worthwhile to take advantage of the HV/EV button. It's easy enough to switch over to HV to prevent depletion. The trick though is switching back to EV when there's an opportunity to replenish. When you're in EV mode, the recharge from deceleration is "marked" for use as EV driving. Switching back to HV right away will save it. That same recharge wouldn't be saved if you were still in HV. The system would use it immediately, bringing the SOC (state-of-charge) back to where it was when you first switched to HV mode. In other words, it remembers the SOC when you left EV mode and works to retain that level. The rise can be quite significant if you have a long hill to descend or have to brake from high-speeds often. Using up the electricity right away is how MPG is boosted. So normally, you'd want to take advantage of that design. But when you know you'll be unable to plug in for a few days, you want to save it. Unfortunately, it's easy to forget. I did this morning. It wasn't until I was cruising along at 60 mph that I realized the engine was still off from the intersection I had left awhile back. That used up 10% of the overall SOC available. Bummer. It's great being able to accelerate up to that speed while mixed in traffic without even noticing, but for me it meant less EV for later. In my circumstance, there's a recreation building just 0.7 miles away. Driving to & from it without having to start up the engine is nice. Oh well. More electricity would be nice, but I'll likely have enough capacity for my long weekend getaway anyway.

4-13-2015 **Aftermath.** It has been almost 3 weeks since that surprise announcement from GM... the one that was always the deepest fear of those who evangelized Volt. That group of enthusiasts who absolutely hated the idea of impurity, but kept changing definitions & goals to prevent people from drawing the conclusion of failure, was always angered when anyone brought up the idea of basically exactly what happened. It was a fear of blending. Mixing gas & electricity to achieve reduced emissions & consumption was unacceptable. The vehicle must be an EV until the entire plug-in electricity capacity had first been consumed. Embracing a no-plug hybrid which strived to deliver high-efficiency cleanly was unacceptable, period. That made it quite clear a vehicle adding a plug to that system was unacceptable as well. They declared that the enemy, the competition to fight... not traditional vehicles. Problem was, it wasn't their choice to make. GM's customers were always clearly identified. That's why I kept asking "Who?" Any answer other than what GM itself had identified was unacceptable, period. They'd attack me for pointing that out... even though I had nothing to do with any of it. GM's customers were defined by who was coming to dealers and purchasing GM vehicles, period. Denial has consequences. The aftermath of a disastrous reality shock is quite obvious now. Their adaptation of the old motto to: *"If it is built, they will buy it."* proved horribly inaccurate. Not wanting to accept the voices of reason is their own tragic mistake. I'm thrilled GM finally took the steps needed to deal with the mess it had created by enabling a group of enthusiasts with the hope of a miraculous product acceptance... even though it clearly didn't match purchase priorities of their own well known customers. Oh well. It's live & learn for the automaker. As for the enthusiasts, their effort to shot the messengers backfired. Now, they have to deal with the outcome.

4-14-2015 **Gross Oversimplification.** The very constructive question of why Malibu-hybrid is more efficient than Volt after depletion has begun a popular discussion topic. But since the Volt enthusiasts made great efforts to stigmatize Prius and undermine design information sharing, their own group is now suffering from an understanding of how MPG efficiency is actually achieved. Remember how hostile posts became when the "direct" issue came up? All throughout the design phase, Volt enthusiasts touted EV purity, how their vehicle of choice would never send power from the engine directly to the wheels. In other words, they assumed a SERIES hybrid was the best approach... despite all the evidence to the contrary. Conversion losses were outright dismissed. Then they found out there was direct energy transfer after all, that it was too inefficient to convert from mechanical to electrical. So, they downplayed as much as possible... which meant suppressing all information to that effect. Now, finding out the next-gen Volt will blend even more, they are really at a loss. All that time wasted. Opportunity lost. The "vastly superior" nonsense really caused quite a setback... for GM anyway. It actually ended up opening up the market for the other automakers. They fumbled, the others took advantage of that mistake. Anywho, they are now trying to overcome that loss: *"Its simple, the Malibu does not have to convert to electricity which is then sent to the wheels. Hence it does not experience two levels of loss, the first being gasoline into electrical put into the battery and the lost coming back and being converted into movement."* Clearly, that's not going well. That quote from a discussion on the Volt forum was followed by this: *"But if you don't get that, think of it this way: Simply put – the Malibu is optimized to run on gasoline – the Volt is optimized to run on electricity."* That's so horribly vague, it could mean anything. It's not correct either. They've created their own misconception & assumption trap. Oh well. It's not like they weren't warned.

- 4-15-2015** **Getting Interesting.** This opening line from an article published today certainly caught my attention: *"When the history books are written about Barack Obama's tenure as commander in chief, the Chevrolet Volt will doubtless be remembered as the most important car of his presidency."* It was an obvious attempt to make sure the president was directly associated with the failure of Volt to become a mainstream vehicle. It was frustrating to read. The reason was simple. It was cherry-picking. Not a single mention was made about Tesla. That's an American success story to make us proud, which happened during his presidency too. Yet, there was no mention whatsoever about it. Watching Volt fall apart is really getting interesting. We knew GM absolutely had to do something, to finally rollout something competitive. Finding out the next-gen Volt wouldn't be it, obviously there would have to be another vehicle instead. With all the attention the upcoming hybrid model of Malibu is now getting, some form of closure for Volt was inevitable. Recasting it as a niche moving on is a wise move. It was too small and too expensive. No amount of promotion will get around that. So, we are now seeing attempts to deal with the outcome. It's finally over.
- 4-15-2015** **The Next Prius.** It's nice to see a return of priorities. The media gobbled up every bit of Volt propaganda the various sources available could stir. Very few ever wanted to address what was actually important. Thankfully, Toyota always stayed true. Another article published that today with: *"The new Prius will be the first tangible result of Toyota New Global Architecture, or TNGA, which Toyoda bills as a rethink of the company's business model. Multiple vehicles will share common underpinnings and components..."* They ever stated the goal of cutting cost 20 to 30 percent. That's a really, really big deal. Achieving profitable high-volume sales absolutely demands it. There's also the expectation of delivering improved efficiency. The promise of about 15 percent is still sounding realistic. Yeah! The stakes have never been larger. Oil supply is up dramatically, causing prices to be pushed well below levels able to support alternatives. Expensive gas is no more. That makes selling the idea of high-efficiency an even greater challenge. It's become a nightmare for dealing with emissions. What incentive is there for the typical person to even care? Guzzling is simply too easy. That's why raising the low-end is so incredibly important now. We must find a way to wind down traditional vehicle production. That means delivering a clean & efficient choice which is truly competitive. Prius is the best hope for leading that wave of change for the masses.

4-17-2015

Understanding Failure. Today there was a special on NPR discussing how failure is perceived. The well-informed understand it to be a natural process of learning. You try something, the outcome isn't as expected, you note details of the circumstances to learn from that experience, then move on. It's no big deal. In fact, there isn't even a penalty if the goal was to eliminate uncertainty. That scientific approach is a well-proven method. It doesn't work with business though. Too much emphasis has been placed on getting a product perfect first try. Failure in that regard is heavily stigmatized and often comes with heavy penalty. That's why Volt was doomed from the start. Asking for goals confirmed the expectation of getting it right or losing everything. They didn't leave room for learning. That's why when it was first rolled out, attention was immediately diverted to the next-gen. There was a state of panic. Too much had been gambled on that initial offering. That's why talk of a second model was fought against so much too. The stigma of having to admit "*failure*" was, in the mind of enthusiasts, an admission of being wrong. Accepting the circumstances and acknowledging what was needed next was totally unacceptable. It was all or none. That absolute meant success was impossible. The business environment doesn't work that way. No one vehicle is perfect for everyone... hence so many different models of HSD from Toyota. That's also why the plug-in model was a limited rollout with a configuration different in Europe than here in the United States. Toyota would use it as a learning platform, rather than betting the farm on it being a "*game changer*" like GM did with Volt. The arrogance from all that "*vastly superior*" chest-pounding did a lot of harm. Volt supporters, those who genuinely wanted success, were embarrassed by the enthusiast behavior and quite willing to learn then move on. That's how we got to January of this year. They were the ones who sincerely hoped GM would swallow its pride as they did and adapt to match market need, rather than continue to cater to want. Unexpectedly, GM ended up doing both. The announcement in January started out underwhelming, then turned to disappointment. That next-gen Volt was well short of expectations. But to everyone's surprise, GM would also be rolling out a hybrid based upon the same "*technology*" as Volt. Realistically, it is that second model, initially without a plug though. That diversification is a major victory for pretty much everyone... especially those of us who endorsed Toyota & Ford from the very beginning for their FULL hybrids. The failure was GM not following suit from the start. That's ok. Even though they made a mess of the market and confused the heck out of consumers by misrepresenting a niche vehicle as a mainstream choice, the technology did indeed work. It just didn't serve the needed audience. That's well understood now. Just thing what things could have been like if that had been learned sooner. Oh well. The saying "*better late, than never*" is a more constructive way of saying "*too little, too slowly*".

- 4-18-2015** **Change.** It's over. Done. Complete. The chapter of triumph & failure has come to a close. At long last, we can move on. Yeah! What a relief. It's still hard to believe there was so much hate. The emotion stirred from having endorsed an approach that fell well short of expectations is extremely difficult to deal with. Lashing out at those who were correct all along is a nature reaction, one to be expected... to the point of it being necessary to prepare for. It was quite a mess. GM repeated the history of market fallout again. Volt was promoted as a "*vastly superior*" solution, but wasn't able to deliver the promised sales. To be successful, it needed to become self-sustaining quickly. The goal had been set to for the third year. Sales were to grow to the point where tax-credits would be used up, but it wouldn't matter. That would pave the way for the next-gen offering. Instead, the entire burden was placed on the next-gen. It was to rescue the effort. That didn't work either. Now, the industry is attempting to deal with backlash. Rather than Volt having usher in an efficiency technology for the masses, we are seeing the sales of small traditional cars and SUVs rapidly grow. That's a big step in the wrong direction. Volt burnt bridges along the way too, doing everything it could to tarnish the reputation of competitors. What a mess. Fortunately, to the frustration of some, Toyota was smart to wait for that to pass. We can look forward to the next Prius in a very different market... one not tainted by "*over promise, under deliver*". The careful balance Toyota strives for with Prius often gets mocked as compromises. In reality, it's a diligent effort to best match the purchase priorities of their customers... hence all the references to showroom floor importance. Remember all those stories in the past of Prius owners being ordinary mainstream consumers who discovered the hybrid while at the dealer? They we won over by the in-person experience. No amount of online hype & misleading can hide the importance of that. Automakers must sell profitable high-volume vehicles. Period. That is not anything a halo can achieve. Thank goodness change is bringing about recognition of that. Phew!
- 4-20-2015** **A Few Still Trying.** I get a kick out of those who blatantly lie by stating a history which can easily be confirmed as false. That kind of misleading by assumption is common. They simply hope no one will look up the true story. When confronted with the truth, they just change focus. It makes confirming their intent easy. Today, it was: "*Perhaps he should be reminded how poorly the Prius sold when first introduced and how many manufacturers are working to build cars of similar concept to the Volt in the next couple of years.*" Prius had strict inventory limitations and no tax-credit help. Yet, there were long waiting lists anyway. How is that translate to "*poor*" by any definition? That was back in the day when gas was cheap, there was no concern for oil dependency, and emissions were not even considered a topic of interest... different from so many ways compared to Volt, it's hard to believe that history would even be brought up. As for the "*working to build*" comment, who? I haven't heard anything at all to that respect. Plug-In hybrids are the interest now. That's what all automakers (except BMW) have embraced as a solution for their emission & efficiency competitiveness. I'm tired of the distortions and trophy-mentality, but there's no benefit in responding to the greenwash attempts. Business need is quite no longer a topic of debate. All automakers must deliver something beyond traditional, period.

4-21-2015 PHEV Announcement. The confusion from GM about what technology is really under the hood got even more confusing today. That's the best way to move beyond the troubles of the past and join the other automakers though. You obscure to the point where messages from long-ago are simply abandoned. It's quite vindicating to those who opposed to the one-size-fits-all approach. The upcoming Malibu hybrid will supposedly be using technology from Volt, but won't behave like it but also will. The details are self-deprecating. The contradictory nature of what were being told makes enthusiasts who were opposed to what's happening now hypocrites... hence, not bothering. Abandonment makes taking the next step so much easier. We've seen in several times in the past, with Two-Mode being the most prominent example. Those who fought the needs of the masses abruptly changed their stance when the reality of business finally could no be denied. That's what makes the announcement today so important. It represents exactly that. The very thing they fought with hostile vigor is happening. Cadillac CT6 will be offered as a plug-in... not like ELR though... it will be like the Malibu hybrid will battery augmentation instead. In other words, the Volt system has come full circle. Despite all the arguments trying to convince us that Volt was an entirely new approach, we knew all along it was really Two-Mode's next-generation design. Proof even came out later confirming it. This one is really the next. Volt was overkill, making many sacrifices to deliver EV as much as possible. That was a terrible business decision. Consumers weren't interested in the compromises it made. Those of us who suggested the very thing GM is now planning to deliver were attacked relentlessly. I'm so glad I took the time to document those reactions with quotes from those posts of the past. They were wrong, very wrong. Engineering alone will not win over mainstream consumers. If you build it, they won't necessarily buy it. And even with large subsidies, ordinary GM customers weren't interested. They recognized the "*too little, too slowly*" and purchased a traditional GM car instead. Now, GM is scrambling to rectify the situation. Starting with CT6, they will offer a PHEV. It will be similar to the approach Toyota, Ford, Honda, and Hyundai have already taken. It will be a hybrid with a plug and large battery-pack. In this case, a very large one: 18.4 kWh. That's massive capacity to squeeze into rear of the vehicle. Having an even smaller trunk than Fusion will make things interesting. But then again, a Malibu version of it would likely offer a smaller capacity... making it more affordable than the Cadillac version. After all, with a combined system output of 335 horsepower, the CT6 is far more than what consumers shopping on the showroom floor of GM dealers will looking for. It's all quite a relief. After countless years of insisting a plug-in hybrid was necessary, it's about time that message was finally acknowledged. The announcement today was the long-awaited change we've been hoping to get for many, many years now.

- 4-22-2015** **All The Same.** The belief that a single solution will satisfy all need is really getting in the way. People coming from a simplistic background don't see how essential it is to identify who. Doing that reveals multiple markets. You'd think this would be easy. After all, trucks were originally sold to fulfill a need cars could not. But now in the age of commuting with a vehicle capable of far more than just commuting, but never actually using those extra features, it's clear why the problem exists. Frustrated, I posted this and didn't bother with any follow-up: That's called effective greenwashing, when consumers misunderstand or assume intent. In reality, Toyota is against the one-size-fits-all approach. People don't realize there is need for variety. Not everyone uses their vehicle the same way. Diversity is required. The old-school single-choice business-model is no longer effective. This mindset of all-the-same is becoming a really big problem.
- 4-23-2015** **KNOW YOUR AUDIENCE.** For crying out loud. The fighting continues. It's really sad. No matter how much you point out GM's own product-line, all they believe is that it somehow really an effort to endorse Toyota. Some just don't get it and refuse to actually acknowledge what you post. I certainly try and stick with it. Here's the latest attempt: A lot of Volt "*hate*" came from pointing out sales losses on the showroom floor. We've seen many who's lease expired choose something else afterward too. The response was to focus on conquest sales instead, completely disregarding loyal GM customers lack of interest in GM's premiere vehicle. That obviously isn't a wise long-term plan. That's why the next-gen model look was chosen to make it blend into the GM product-line better. The sacrifices are still too many though. Cost is high. Seating is limited. It continues to exclude a rear-wiper. It doesn't offer adaptive-cruise or LED headlights. How does that make it competitive with the other GM choices? Not offering high-speed recharge keeps it from competing with high-capacity plug-on vehicles too. Appealing to the masses is a major challenge, even when gas is expensive. But now with the gallon so cheap, even more effort is required. Understanding the customer mindset is key.
- 4-26-2015** **The Next PHV.** We keep hearing rumors. There's a realistic expectation for battery-capacity to increase. From the very beginning, the outlook has been that more will be offered as cost justify. Making the vehicle expensive just for the sake of a big pack isn't how you achieve lots of sales. There's a careful balance. Watching the MPG and MPGe ratings increase from generation to generation makes sense. After all, we've seen efficiency improve with traditional vehicles over the decades, why not with a plug-in hybrid too? Sadly, we may not get details on what the next PHV will offer until a year from now. The regular model will be rolling out in the meantime, and we don't have any detail on it yet either. So, like usual, there's lots of waiting still. Oh well. Each generation has been totally worth the wait.

4-28-2015 **Vehicle Pricing.** The discussion began yesterday. It was an interesting read. What will be the price of the new Volt? Since it was a new platform without any variants, that was always an issue... quite unlike Prius, which was well established and had augment plans all along. In fact, Toyota stated had a upgrade package target price. We knew they were striving for between \$3,000 and \$5,000. So, that never really stirred any controversy. It was a simple, clear goal. For Volt, we still don't know what the heck the intent is. Being told the first year of the next-gen rollout would be a niche leaves you wondering. Then, hearing about the CT6, you have no idea what to think. As for that discussion, it was on that daily blog, so you can imagine what happened... nothing. The reality of profit need was only addressed by a single person, a strong supporter of Volt (unlike enthusiasts, who sacrifice well-being for the sake of prestige). Here's his entire post: *"\$29,995 is my guess even though I don't think that will be low enough for the GEN II Volt to be successful. GM may be forced to make this decision strictly due to profitability. If the price is above \$30K, GM is sending a clear message the Volt is strictly a "compliance" vehicle."* But since that audience still doesn't recognize the importance of cost, even a pricing comment like that from a regular falls on deaf ears. Much like ELR, it's obvious before rollout that formula for high-volume sales isn't there. That vital aspect of appealing to GM's own customers and making profit is not part of Volt's charter. The ugly truth is that business importance cannot be neglected. In the end, that trophy mentality held back progress. Not being able to competitively price a vehicle hurts. Think about how large of a problem there is to come when the tax-credit expires. Sales need to be very strong before that happens.

4-28-2015 **Missing The Point.** We found out today that production of the current generation of Prius PHV will end in June. That's no surprise. Most model-year production ends around that time anyway. What made this announcement stand out was it came directly from Toyota Marketing. From time to time, they tell us something by posting on the big Prius forum. We get information the same day as dealers as a result, firsthand. That's really cool. In addition to that tidbit, we were also told they are looking forward to sharing details with us about the next generation. That's really exciting! Those newer to PHV discussion lack detail and often don't have the background needed to understand intent. That makes sense, but you still have to somehow deal with their claims. For example, we had this as a result of the announcement: *"It's just a compliance car."* Most of the rest of us no that's not the case; however, it is easy to see how that assumption can be made. I simply responded with: Call it what you want. After all, it was a mid-cycle release in a highly volatile market. So, looking back is messy anyway. The point was to collect data from well informed consumers to strengthen the next-gen rollout.

4-29-2015 **More On Pricing.** Today's topic on that daily blog was about next-gen Volt sales. Price immediately came up as the factor of great importance. I couldn't resist chiming in. It had been weeks since they heard from me. So, the time had come to find out firsthand how much change had taken place with that group. Here's what I posted: Ask yourself what has changed over the past 5 years. That "*nicely under \$30,000*" price goal without tax-credit was set back then for the same reason it holds true still. To become mainstream, it must be able to compete with other mainstream vehicles. That means selling in high-volume without subsidy at a profit. We know that Malibu, Impala, Cruze, and Equinox are very appealing to GM customers. On the showroom floor, they draw attention. Volt's price is a major deterrent. The hope was that battery cost would drop significantly prior to Gen-2 being rolled out. 50-mile capacity makes it difficult to compete. So, without even considering any other sales factor, that in itself presents a big challenge. Those other choices GM dealers offer wasn't taken seriously with Gen-1. Focus was diverted entirely on other automaker offerings instead. It's clear now that mistake won't be repeated; however, that doesn't make the matter any easier to deal with. In fact, sales numbers show the "backfire" effect will become a big concern. Not capitalizing on the opportunity right away makes it even more difficult to overcome later. That makes the question of debut price for Gen-2 a matter of great importance. It sets a precedence for the generation, informing us of the approach to come. Think about what happens when the tax-credit ends and how price-drops later on affect resale value.

4-30-2015 **Question, Insult, Greenwash.** Yesterday's post went over well, with one exception. There were several constructive posts. I was pleased how things have changed over the past few months. The change of stance with GM has really influenced that group's approach with respect to responses. The "*vastly superior*" nonsense is long gone. Getting over that major barrier is a huge improvement. Rather than blindly praising with a one-size-fits-all mindset, we're getting more of that team effort instead. From the very beginning, it was a quest from me to find allies. That's why the local EV group we have here works so well. They don't care what automaker you favor, all they desire is the spreading of electrification. In other words, they openly acknowledge & champion the problems of business & consumer. Focus on engineering alone is not a problem... for them. As for the daily blog, there was one individual who was wrong to such a degree, he developed a hate. I became his scapegoat. So, when I posted today after such a long absence, his response was to question, insult, then greenwash. The question was simply re-asking the same thing he already had an answer to. That's a typical trolling technique, to provoke an online debate. I didn't bite. His next bait was to insult me. It was another effort to provoke. I didn't bite on that either. Finally, it was a greenwash attempt, by misleading about Toyota. He gets really irritated when I focus entirely on GM and point out the production & showroom concerns. When someone else mentioned Prius, that was the opportunity he had been looking for... with, of course, the hope I'd bite. It bet it was especially irritating for him, since that other post was about Toyota's importance for profitability & affordability. Anywho, this was his response: "*GM has chosen a different path to Faith: Early cross-pollination with the rest of it's line. Prius continued to be Prius for most of it's run (at least one attempt was made to spread the tech, but the Hybrid Highlander failed miserably). Perhaps Toyota doesn't have enough faith in it's own HSD, where the rest of the line is concerned.*" Knowing he intentionally excluded the hybrid Camry was quite amusing. The 39,515 sales here last year is the reason why. Even without a tax-credit or MPG being competitive with the very latest offerings, it still sells better than Volt. He didn't make any mention of the hybrid RAV4 coming this Fall either. That totally contradicts his claim. So what if the large SUV with a 3,500-pound towing-capacity doesn't sell in large volume. What about all the Lexus hybrids? For that matter, what about the hybrid Avalon? The hybrid minivan offered in Japan (called Estima) was pointed out to him countless times too. Needless to say, he was rather desperate for attention. I didn't bother. With the attitude of that daily blog changing to constructive discussion, there's no place for vengeance from failures of the past. It's over. Learn from those mistakes and move on with the rest of us. Geez!

5-01-2015 **Reminder.** It amazes me how vital pieces of information are just forgotten... especially with a really hot discussion topic? How can something so important be omitted from posts each time a new thread starts. Yes, some people intentionally exclude. But there are others who continue to overlook, even after pointing the fact out. What can you do about it other than just post reminders? So, today, I did yet again: Let's not forget about the recently expired NiMH patents. No longer having those restrictions will obviously have a positive impact on the regular Prius. Of course, that likely played a big role in the delay of Gen-4 rollout.

- 5-03-2015** **More Reminding.** Ugh. It makes you question the value of some discussions. What are people really getting from them? Needless to say, there's a lot of back & forth going on about Volt in the big Prius forum lately. This was yet another reminder needing to be reposted: The price is not competitive though. The other hope was winning over GM's own customers, rather than only conquest sales. Traditional vehicle sales will continue to overwhelm. GM's own product-line is the competition. Making it appeal to ordinary buyers was very important for this second generation. Not stirring interest from them will be a problem. When the incentives expire, the brand must be able to self-sustain at a profit in high-volume.
- 5-04-2015** **Clarity.** Some continue to argue, pretending certain detail still hasn't been made available. It's nice having closure, a finality to the nonsense of the past... even though some just plain don't want to accept it. I'm thrilled about the upcoming divergence. Some clearly are not. I'm making sure that clarity is known by all. We now have answers. Moving on should be easy. Maybe someday it will be: GM already stated this Volt will continue to sell at niche level and has moved on. They recently revealed a hybrid Malibu and a plug-in hybrid CT6. In other words, those of us who pointed out the business shortcomings of the Volt approach are finally relieved. GM didn't understand who. Now, it looks like they do.
- 5-04-2015** **Competition.** That word is carelessly tossed about on a regular basis. For example: "*Competition is getting tough.*" Rarely does that ever mean anything without a plug. Pretty much every time, they mean only the battery-centric market. Traditional vehicles still aren't considered a problem. It's a denial on such an enormous scale, arguing is almost pointless. Most think you are nuts to consider the "*competition*" anything beyond plugging in. Some of that comes from being overwhelmed. How do you take on something on such a massive scale? Whatever the attitude or belief, I continue on with the reminders: The competition is other traditional vehicles from the same automaker. Misunderstanding audience was the lesson learned from the first generation Volt. Conquest sales are not business-sustaining, especially when they depend heavily upon tax-credits. Volt competition is Malibu, Impala, Cruze, and Equinox. Those are what steal away GM's own customers. For Toyota, the next-gen Prius must be made appealing enough to compete directly with Camry & Corolla... which is a major undertaking.

- 5-05-2015** **Excuses.** They often prevent progress. For example: *"One other thing the Gen-2 does NOT have that the Gen-1 had: Development and market release in the middle of a GM bankruptcy and Federal government bailout that made it a political punching bag."* What does telling us that actually accomplish? Had there been information to follow about what to expect, that would be different. Instead, it was just the pointing out of a fact without any context to expectations we should have going forward. Ok, so it's not a punching-bag anymore. What does that mean for acceptance & sales? What should the next step be? What does it mean for the rest of the market? Too many questions. No effort to address them. Just excuses. So, I jumped up onto the soapbox: GM's marketing choices, which was complained about on a regular basis, contributed to it. Remember the uncertainty of who the audience even was? Everyone is now relieved about that is now over and that Gen-2 starts a new chapter. There is still a looming issue though. Approaching tax-credit expiration will stir change. Each vehicle must be able to deliver profit without subsidy. Nissan will reach that deadline sooner, so Leaf will put external pressure on Volt. Oil prices, due to over-supply, will remain relatively low for years to come. So, GM's own traditional offerings will put internal pressure on Volt. That means even without any political attention, Gen-2 will still have major challenges to overcome. Starting out with a higher MSRP than anticipated complicates matters too.
- 5-06-2015** **Labels.** This was today's issue of contention: *"In the Chevy Volt's early days, GM caught flak for declaring it an "extended-range electric vehicle" and not simply a plug-in hybrid, but this week the Idaho National Laboratory verified real-world drivers annually traveled 94-percent as far gas-free as did Nissan Leaf drivers."* Some get so hung up in labels, heck even semantics, that they lose track of purpose. Wasn't the goal sales? Calling it something different won't change what happens at the dealer. That's just marketing, which has little impact once the person is looking at the vehicle on the showroom floor. That's when all the other purchase priorities become apparent. Changing a configuration to make it affordable, without having to alter the design itself, is a factor. Yet, that reality was pushed aside many, many times over the years. It was all about bragging rights, what comes with having a particular label. Sacrifices, like leg & head room in the back seats, are a big deal. So, the arguments about definition is a complete waste. Again, wasn't the purpose to sell a lot? Needless to say, the broken-record reposting of facts is getting old. Fortunately, the gen-2 rollouts are helping to draw in new discussion participants. Here's what I posted: That's because by the time Volt was finally rolled out, it didn't actually fit the very definition which had been coined for the technology it was to deliver. That's also why the top reason sighted by supporters for low sales is marketing. Since then, the BMW i3 has been rolled out and series mode in Volt has been eliminated. So, there's nothing left to contend anymore. Take a look at the battery-capacity to identify what the 94% actually represents. Without changing any engine, motor/generator, clutch, or software, simply reducing the amount of electricity available completely changes results. Next, take a look at the way Ford approached plugging in along with an engine. In other words, there's no point in labeling. Unfortunately, it's not as straightforward as focusing on KWH or MPG. Results from initial consumers don't tell the complete story either. Fortunately, the same purchase priorities consumers had in the past still hold true. Ordinary buyers of vehicles look for a well-balanced choice. Making sacrifices for the sake of maximum EV has proven to be unappealing.

5-07-2015 **Vastly Superior.** This very well could be the last of the senseless vastly superior shoutouts: *"Well, after another attempt to skim over the difficult bits, it occurs to me that this wasn't so much a Gen II Volt as a generic E-drive system usable across much of the GM line; with acceptable performance in a Volt configuration just one of several design objectives. Works for me inasmuch as it lowers overall costs, and increases fleet mpg more directly than with one or two halos excusing a less-efficient "mainstream" fleet. Doesn't work for me as much when contemplating how much better an actual designed-for-Volt might have been; but overall this is a good approach at this stage of the game. No one will be able to touch it for years: Advantage GM."* That was the result of reading a thorough and constructive report on the upgraded system. There's no advantage. GM has joined the rest of the industry. BMW's design is clearly more technologically advanced, abandoning convention much more than any of the other automakers. i3 is very expensive though. But then again, their audience spends more anyway. That most definitely isn't the case for Chevy cars... hence all the Malibu & Cruze references. Long story short, there are a few individuals who never want to be part of a team. That EV club we have here has no issues with what brand of vehicle you drive. If it has a plug, you're playing the game with the rest of them. The team's competition is traditional vehicles, not each other. Some people never learn. They don't understand who.

5-07-2015 **Understanding Who.** Some people just plain don't want to. They'll do everything possible to keep debates alive. Today's example was: *"Who is toyota building the mirai for? I hear the who question from you on the volt, and to a certain extent I agree with you they missed the market. Where I disagree is toyota has done better in this market for alternatively fueled vehicles. EQ cancelled. Rav 4 EV cancelled. Prius phv suspending in june for at least a year with clear pr saying fuel cells are the future. Mirai only planned for 5700 total vehicles world wide through 2017. Have toyota learned from the low sales of these 4 vehicles, who they should target?"* Even though we have solid answers, he keeps asking the same questions and attempts to mislead. He gets so frustrated when I point out facts of the past. The only response left is to omit points already discussed in great detail and relate unrelated topics. The hope is to stimulate discussion. He, like a few well-knowns on forums, thrive on frequent exchanges of posts. That perhaps is a friendly version of a troll, where there's no ill intent, but the purpose of preventing a thread from ending is clear. Anywho, I responded with: Take some courses in business & economics. Among the topics covered will be audience, timeline, diversification, and willingness experiment. GM bet the farm on Volt, hoping for a quick & large payoff. It clearly didn't work. That's why it got so much attention. Thankfully, we are now seeing a change of approach as a result of the lesson learned the hard way. Toyota is getting attention now with fuel-cell rollout because people don't like multi-faceted approaches and long-term efforts with limited quantity. (It's also a common diversionary tactic used to draw attention away from other topics by those losing debates.) In an ever-changing market, Toyota has stayed true to the goal of focusing on the masses. They haven't fallen into the trap of sacrificing cost for the sake of niche praise. It's the ordinary mainstream consumers they are striving to deliver competitively affordable & profitable vehicles choices and patience waiting for that is a challenge with each generation.

5-08-2015 **500,000 Goal.** Most of the problems with Volt were and still are centered around cost. It's simply too expensive to compete. Even with heavy tax-credit subsidies, sales have been low. That's why efforts with smaller battery-packs have become most desirable, especially since the lesser size & weight is beneficial. Remember the "*too little, too slowly*" concern? That burned enthusiasts really, really bad. They absolutely hated hearing that. So, their unified response was to wait until the second-generation model was rolled out. Trouble is, the rapid success they always hoped for couldn't be achieved without consequence. Only 200,000 total tax-credits per automaker are available, then phaseout begins. It meant reaching profitability would have to become a reality very, very quickly. Achieving that in a world without competition would be a challenge. Knowing Nissan would be putting pressure on GM due to reaching their threshold first made it even worse. To confuse matters, GM declared an initiative to achieve delivery of 500,000 electrified vehicles by 2017. That goal was quite vague. What did "*electrified*" actually mean? Whatever the case, revealing Bolt stirred that pot. It would be consuming some of the 200,000 allotment for GM. It would also be stealing away some sales from potential Volt buyers. Needless to say, it was more of the mixed message problem. It also seemed unrealistic. That would require a major change in attitude from Chevy dealers... who currently are enjoying strong sales of profitable pickups. What would compel them to suddenly embrace such a paradigm shift? Long story short, news broke yesterday that we can already see that GM will fall well short of that 500,000 goal. Blame is placed on low gas prices and increased competition... both factors people like me warned about on a regular basis. GM took the gamble anyway. Enthusiasts continue to claim there's no way we could have known that would happen. Ugh.

5-09-2015 **Back to Prius.** The long lull from next-gen "*delay*" makes bringing up constructive discussion a challenge. The perception is that there are problems causing the wait, rather than the automaker simply postponing for business advantage. Engineering assumptions are quite abundant. It's really unfortunate. With our culture right now, discussing economic influence continues to be a thankless effort, at best. Fortunately, there are some who help to overcome that. This may not be one of them: "*I think sales of the pip will continue to be poor no matter what they do.*" It depends upon your expectations & background. Here were the thoughts I contributed: That's a relative measure. Upon early rollout of the next-gen model, sales will indeed be on the low side. High volume shouldn't be the initial goal anyway. We know how Toyota approaches advancement. It's been a successful strategy. The intent is to position their technology for a later upswing, to have a well-proven platform readily available. Lots of real-world data is needed for that. After all, many people don't buy first-year models anyway. They wait regardless of whether or not the brand is reputable. That's just the way ordinary consumers think. They feel more comfortable with their large purchase by exercising patience. The other factor is reliability & profitability. Refining production takes time. It's that simple. And since the non-plug model is the premiere product, of course the plug-in will have to play second fiddle. That's just the way it is. Delivering a product for the masses is a top-priority. The regular hybrid is that product. Eventually, the PHV model will be discovered by mainstream buyers... the ones who have that "*work out the bugs first*" mindset before seriously considering a purchase. At that point, we can see the affordability of the design shine. It will leverage off of the success of the Gen-4 model too... which obviously have to wait a few years for. Sadly, those not in favor of Toyota's approach will spin perception of the situation. Heck, it's pretty much inevitable that they'll label the current PHV as a flop, simply by seeing how much of an improvement the next will be. Of course, they'll avoid acknowledging the real-world data from those of us currently driving one to do that.

5-11-2015 **Waiting.** There are some who just plain don't have patience. They see something and want to draw a conclusion based solely on what's currently taking place. Having a reason to wait simply isn't part of what they consider. This concluding sentence wrapped that up nicely: "*...as the toyota corporate seems to have given up on the model.*" I find it quite hypocritical how the precedent for waiting was set for GM with Volt, but the same isn't acceptable for Toyota. Ugh. Of course, that was to be expected. It's the same reason goals are demanded prior to rollout. Having them available then is how you measure success. You can't just arbitrarily make up criteria after the fact. Yet, that's exactly what happened with Volt the first time around. It's too early for that with Prius PHV, since we basically don't have any information about it yet... other than production has finished... and is now being spun as giving up. Oh well. There's always someone to stir trouble. I responded to that with: That's the greenwash being spread. Please don't contribute to it. In reality, they have stopped investment in the current generation. Seeing the market struggle with the other plug-in vehicles were having, it just plain did not make any sense pushing forward yet. Waiting until the next generation is far more sensible of a business choice. Knowing the battery tech will be better is reason enough. But we are also all well aware of adoption effect. KISS. Remember how well that worked for Prius in the past? It took years before people finally learned how it actually worked. The PHV model has the same thing going for it. That approach requires nothing but a basic understanding and a simple 120-volt connection. Cost will be realistically competitive with traditional vehicles too. In other words, there's a big difference between giving up and waiting.

5-14-2015 **i3 verses Volt.** BMW delivered what GM promised. That still really upsets a number of Volt enthusiast. So naturally, they are attacking BMW's new plug-in anyway they can: "*For me, prestige isn't even part of the equation. Convenience, reliability, and price are key. For convenience, the i3's pathetic 2 gallon gas tank is a non-starter.*" I found that quite amusing. This is the same person who told us Volt's engine was only for emergency purposes, after the battery-pack had been completely depleted. He absolutely insisted a small tank is all that would ever be needed, even with just a 40-mile EV range, for Volt. Yet for i3, with an even much larger battery-pack, that same logic doesn't apply. It's sad to see such contradiction payout. Oh well. At least I can point out the hypocritical nature of the posting: Calling it a non-starter directly contradicts what we've been told for years. Think of how many Volt owners boast about going many months between gas refills. Also, we've recently been told the increased range of the next-gen Volt to 50 miles will cover 90% of owners driving needs. With a 72-mile electric range and around 78 miles of gas range (that's 2 gallons at the 39 MPG combined rating), it totally covers all but vacation needs. How often would the 2.4 gallon tank actually be inconvenient?

- 5-16-2015** **Red Herrings.** That's when something seemingly important gets attention, but in reality is just a distraction. We waste a lot of time on them. It's because they are presented as somewhat constructive, an innocent question like: "*What about those unexpected trips that last quite a bit longer than the range of the gas tank?*" That was asked by a Volt supporter about the small tank in i3. If you don't take the time to think about what is actually being asked, you'll waste time posting comments that aren't helpful. But if you take too much time to think about it, you end up wasting time anyway. It's a lose-lose situation. That's where the blogging comes in handy. It gives you alternate time to think. So when the topic reappears again later, and you know it will, you'll already be prepared to deal with it. This was such a situation: I honestly have no idea what situation that would apply to. Some of us simply don't have distant friends or family or have unexpected trips. Exceeding 150 miles of travel that wasn't planned without taking any time for a break isn't something that really ever happens. When I travel up north (175 miles), there's always a break for food along the way anyway. So, taking a few minutes to get gas isn't a big deal. Carrying around extra tank capacity only for the sake of a rare circumstance is what we're trying to avoid. It's wasteful if all you have to do is stop to refill, especially when you have the option of just carrying along an extra tank if that rare circumstance should ever actually occur.
- 5-17-2015** **Poorly Informed?** Certain people are clueless, starting arguments solely on what they observe in a forum. Not taking the time to study elsewhere, to really research what the situation is, doesn't happen often. But even so, you want to wait to be certain. Offending someone who simply didn't express themselves clearly in a series of posts is good to avoid. That means watching them, thread after thread, to confirm they really are poorly informed. Then when you do, it's acceptable to pounce. This was such an opportunity today: "*What other Toyota vehicles are hybrids?*" That came from a Volt enthusiast strongly opposed to the idea of diversification. Whenever I brought up the idea of a second model, something targeted at the masses, he'd get worked up. He also continues to lie about Prius PHV battery-capacity, claiming it's only 6 miles and those who say it's 11 are intentionally being deceptive. Ugh. Oh well. I got to respond with information that will give reason for pause. Whether or not he understands how vital it is for a technology to be spread will remain a mystery though. My guess is his obsession with the current Volt prevented him from ever stepping back to consider the big picture, the larger fleet rather than a single vehicle. Whatever the case, this is what I posted: There are more Lexus models available here, plus some European & Japanese. But this is a list to show the variety, with different engine & motor sizes... FWD 4-cyl small hatchback - Prius C; FWD 4-cyl hatchback - Prius & Prius V; FWD 4-cyl sedan - Camry & Avalon; AWD 4-cyl minivan - Estima; AWD 4-cyl SUV - 2016 RAV4; FWD 6-cyl SUV - Highlander (3500-lb tow); AWD 8-cyl sedan - LS600h; RWD 8-cyl sedan - LS460F.

- 5-22-2015** **Blind Hate, the post.** There was an article published today that brought attention to the Sonata plug-in hybrid. That was met with mixed feeling on that daily blog, where some fragments of disappointment still exist. Coming to grips with the reality of being part of a group of vehicles helping to advance emission & consumption goals, rather than being the undisputed leader, is difficult for some. So, when I read the misleading statement about Prius PHV, the choice was to patiently wait. Sure enough, a comment was eventually posted to allow me to respond in-context: *"I don't trust Ford, Hyundai or KIA with their AER or MPG "guesstimates".*" We know that even EPA estimates can be manipulated to misinform and there was just a reference made to Prius only getting 6-miles from plugging in. I knew that sounding off about it would stir hate. I'm still a scapegoat for Volt's failure to capture the market by storm. So, regardless of how much effort is expended to focus on need, the blind hate for being correct about the market will persist. I posted anyway: That's why we need to include stating kWh capacity. The whole misrepresentation issue with Prius PHV could have easily been avoided by doing that. The 4.4 kWh capacity is clearly enough to supply 11 miles of EV. And sure enough, owners consistently report getting 12 miles... a far cry from the supposed 6-mile claims from a few who clearly didn't want to be constructive. That and fallout from Ford & Hyundai are excellent reasons why taking estimates at face-value are not a good idea.
- 5-23-2015** **Blind Hate, the reply.** Reaction to my post was quite harsh by 2 particular individuals. Their hate was quite intense. An owner of a Volt who frequently posts on the big Prius forum came to my rescue. He politely corrected the misstatements. That was great! Those particular people just plain don't try anymore. I was pleasantly amused by one. He accused me of having no idea what I was talking about, sighted a source to validate his "6-mile" claim that was over 3 years old and clearly an early-rollout hype article, then closed with a personal insult. The other hate response hypocritical, a blatant double-standard for the sake of bragging to evade what had actually been posted. Both were childish. It always make me wonder what readers of the blog think seeing that. Anywho, my reply was: The local EV club met on Thursday. Those meetings are always a lot of fun. There's a wide variety who attend. We had everything from a custom EV convert to a new BMW i3. That audience doesn't have any hang ups about an engine running briefly to supplement power during high-demand. With them, it's all about having a plug and polluting less. Heck, one of the owners even joked about his "coal powered" Tesla. So from their perspective, I'm recharging a 4.4 kWh capacity battery-pack every time I plug in. That electricity is used to both provide propulsion-power and to reduce the environmental impact of the engine. There's none of the purity nonsense routinely brought up here. Range doesn't matter. Electricity is being taken advantage of. That's the point. I always got a kick out of those who pushed the "6-mile" range claim. It was a dead giveaway they had no intention of being constructive. Focus on bragging about EV didn't actually solve the problems we faced. That's why the EV club here is quite welcoming to anyone interested in plugging in. Volt isn't "vastly superior" there. It's just another player on the same team trying to overcome the terrible challenges traditional vehicles continue to pose against our efforts to reduce emissions & consumption.

- 5-23-2015** **Blind Hate, the answer.** It's best to disregard the rhetoric and stick to principle. Ask yourself what the goal is. Stick to that... which is exactly what I did with my follow-up post: Hyundai's decision to offer on-board recharging further reinforces the need to address more than just EV miles alone. Think about overall efficiency. When HV efficiency is traded for the sake of running the generator to replenish EV capacity, what happens? It's an ability the other plug-in hybrids could also offer, but don't. We get a hold mode to retain EV capacity, but battery recharging using the gas engine has been withheld to achieve better emission certification. The choice to deliver greater flexibility to the customer really emphasizes that need to understand audience. Who do they try to sell it to? How many do they intend to sell? What place in the product-line will such a configuration hold? When will we know if this is a compelling decision for other automakers to consider? There are many questions. All require the necessity to understand how plug-in hybrids actually operate and how each differs. For my Prius PHV yesterday, from starting with a full charge in the morning, recharging at work (via solar), then meeting with a friend for coffee on the way home, the result was a 135 MPG average for the 42.9 total miles traveled. Will consumers care that only 25 of those miles were EV and 16 miles HV? (Note that the computer truncates to the next lowest whole number.) Will consumers even understand that some of the HV miles took advantage of plug-supplied electricity but weren't counted as EV? The answer is simple. Consumers won't care. They'll look at price, efficiency, and how much room the battery takes.
- 5-25-2015** **Blind Hate, the pattern.** Seeing history repeat makes a bad situation worse. Things fell apart as the rollout of the first Volt drew near. Details confirmed Toyota was on the better path, in a far better position to capture enough market to self-sustain. It put those who supported Prius that pointed out the situation well in advance in a difficult position. The challenge to stir market interest simply wasn't there. The same thing is happening with this next-generation rollout. An essential requirement for becoming a mainstream seller is to not depend upon a subsidy. The vehicle must be able to survive on its own. Clearly, that's not going to happen with Volt. There are no expectations of it being able to draw appeal from ordinary consumers without the \$7,500 tax-credit available. This is why asking Who? and demanding goals is so important. The refusal to answer is confirmation of... for lack of a better word... failing. Remember that pattern? Evade was a dead giveaway there was a problem. The expectation was much more than a \$1,175 price reduction. That magic \$29,995 goal was set for good reason. \$33,995 is too much to be taken seriously by the masses. They just plain won't be interested. The incremental improvements aren't even appealing to the enthusiasts. In fact, just about all of them are quite content holding onto their current Volt. That certainly wasn't the case with Prius. We saw a balanced mix of keep & replace. We hear many positive things about Toyota's effort to keep costs contained. GM chose to increase battery-capacity to 18.4 kWh to deliver 50 miles of EV. Why? Was there truly an audience for that? Who are those people? The data I've seen points to around 25 miles as the ideal balance for a plug-in Prius. Trading off space, weight, and cost for the sake of capacity beyond need is a risky move, with that being the only choice offered. We've seen this before. Results were not good.

- 5-26-2015** **Rushing.** We've seen countless problems arise from announcing something too soon. Yet, the lesson isn't learned by some. They expect rushing anyway. No patience is a common downfall. Oh well. All you can do is point it out: Toyota was smart the first round by waiting to see what the market offered and how it reacted. Consumers overwhelmingly prefer to guzzle and the profit clearly isn't there yet. GM celebrated their victory before rollout even began... hence yet another "*over promise, under deliver*". The major price drop, repeated inventory pile ups, no demand growth, heavy dependency on incentives, and loss of loyalty upon lease expiration confirms the market is very weak. It makes no sense rushing Gen-2 announcements.
- 5-27-2015** **Diluting Design.** This has been a hot topic since way back in 2007. Enthusiasts of Volt were fiercely against any type of small-battery endorsement. That's why when Prius PHV came along later, all the online fighting ensued. It was brutal. Fast-Forwarding to today, we now get this: "*How is the 2016 Volt design "diluting the Volt" ?*" That was asked by a supporter who truly wanted to know, one who didn't participate in any online discussions related to Volt until after rollout began. So, he lacks the background. I do what I can to fill in that missing history: Step back and look at the big picture, then you'll understand what the situation was and is now. Don't just look at 2016 Volt. The "*diluting*" is with respect to other vehicles. Enthusiasts wanted everything to offer a plug and at least a "*40-mile*" capacity. They fully endorsed the same approach across the fleet. Those enthusiasts fought intensely, to the point of hostility at times, to prevent support of any new vehicle from GM using a battery-pack smaller than that in the current Volt. So, whenever the topic of a more affordable model was posted, the person suggesting it got labeled as a troll and personally attacked. It was quite amazing to witness. Long story short, they felt strongly about the "*40-mile*" range being a standard base for all vehicles going forward. In other words, this upcoming CT6 plug-in hybrid is what they absolutely didn't want. The enthusiasts used to make fun of hybrids to no end as well, portraying them as a huge waste of effort. So, the upcoming Malibu hybrid is the last thing they ever imagined would happen. Both are variants of Volt technology. One offers less electricity capacity. One doesn't even offer a plug. The product-line is diversifying. They didn't want that.

5-30-2015

Transition. During this time of transition, we are hearing very little about Prius. Attention is focusing heavily upon Volt. Having so many details about the one and almost none of the other makes it easy to see why. Sentiment isn't exactly encouraging though: "*The Volt could very well become the albatross of the century.*" You could imagine how much attention that puts on me as a result. Each post vindicates the position I've held from the very start. I want something for ordinary consumers, a vehicle part of the mainstream. That comment today was my invitation to post more observations about the upcoming next-gen rollout of Volt, at this particular point in time. Just think of what history will think of this: The choices GM has made with Volt 2.0 are setting it on that course. Many years ago, we watched the first GM attempt to deliver a high-efficiency technology fail horribly. Two-Mode was touted as the great successor, the advancement that would out-Prius the Prius. It didn't, not even remotely close. Too many tradeoffs were made. Volt was the effort to make things right. Early on though, we saw a misalignment of priorities. What they targeted for performance was not conducive to making it affordable for the masses. As details emerged over the development years, results wandered further and further from mainstream interest. Enthusiasts were thrilled though, absolutely delighted with the engineering achievement. Unfortunately, rollout proved that didn't pay the bills. Gen-2 should have been a correction, realigning goals. Reducing cost was supposedly the highest priority. Turns out, it wasn't. Having reduced the battery-capacity would deliver improved cost, space, and weight. It could have easily been done without loss of EV range too. Instead, that was sacrificed for the sake of increasing range from 38 to 50 miles. Will that tradeoff really be worth it? So what if the engine starts from time to time? The benefit of carrying around a gas engine is to supplement power. If the goal really is to use EV almost exclusively, avoiding HV for all but special circumstance, why not use a smaller engine like BMW does? The obvious sign of trouble to come is how the issue of cost is again passed on to the hope of later technology improvements. In the meantime, dependency on tax-credits will continue. That's contributing to low sales expectations and an emerging theme of "wait until Gen-3 rollout". How much will an automaker continue to invest in a vehicle unable to self-sustain? Dealers certainly won't want to carry a low-demand vehicle. Seeing GM make an effort to diversify by offering a plug-in CT6 and Bolt is encouraging, but their sales could shorten the duration of when tax-credits are available for Volt. Should we really just sit back and wait, again?

- 5-31-2015** **Mutually Exclusive.** We're starting to have a lot of problems with fuel-cell verses plug-in. The media is presenting the technologies in a polarizing manner. That sets a precedent for discussions to start in a this or that attitude. The idea of both being successful is outright dismissed. This is really unfortunate. So, when comments like this come along, I take advantage of the opportunity: *"I don't think --- or anyone here has said they are mutually exclusive."* It's implied to such a degree, most people never even realize a choice is available. They come from a background where there's a winner and a loser. Both cannot win. That just doesn't make sense to them. A simple look at the computer industry should be all it take to change attitude. How do you connect to the internet nowadays? Notebook? Tablet? Phone? All 3 of those have their place. They all win. Remember back when the only choice was a desktop computer? Anywho, I replied with: Quite correct. However, not going out our way to make that clear... an explicit reminder of goals... contributes to those assumptions. We become enablers by not taking the time to make sure everyone understands. As well informed and frequent posters, we should all be making an effort to prevent. Leaving opportunity for misunderstandings & misleading has had terrible consequences in the past. We can stop that early on with raised awareness and a continued message of purpose right from the start.
- 6-01-2015** **105 Miles.** Managing expectations is an on-going effort. You are constantly challenged from sources that aren't even credible. Someone will post a comment that is vague and without listing a source, readers just accept it as fact. Ugh. Nissan is the latest victim of this problem. Supposedly, next year's model of Leaf was to get a battery-pack upgrade which would deliver 200 miles of EV. According to who? None of the other automakers are planning to deliver until the 2018 model-year. That's over 2 years away still. Needless to say, the recent announcement that the capacity for the 2016 would increase to 105 miles was met with mixed feelings. Geez! Leaf started at 73 miles, then later got an increase to 84 miles. Without any change in the basic design, it will be improved to deliver 105 miles. That should be great news. Electric Vehicles benefitting from battery-tech improvements without needing a generation upgrade is fantastic. Yet, there are some who express disappointment. That's sad. Unrealistic expectations are a very real problem. Our mentality of bigger-being-better is major contributor. What about keeping cost down? What about not having to give up seating or cargo space? What about maintaining high reliability? It's really unfortunate how limited some people's views are on what a plug-in should deliver.

6-02-2015 **We Know.** The reason for Toyota's choices is well known; yet, some continue to dismiss it and focus on other argument points instead. Their goal always has been and continues to be the pursuit of clean & efficient vehicles that are both high-volume & profitable. It's easy to sell a vehicle with a dependency on tax-credits and HOV incentives in small numbers. The challenge of cost isn't taken seriously. So, we get post after post claiming Toyota has given up, despite the effort they've made to deliver something for the masses. The more-is-better argument never ceases to amaze me. Rather than actually consider mainstream need, it's always the same old thing, claiming the battery-capacity and highest EV speed is too small and too slow. That argument is weak, since it's easy to see how the resulting MPG is always intentionally avoided. No one wants to address the fact that the system delivers over 100 MPG at 65 mph. Those against the approach hope you'll just see that the engine is running and deem the system unworthy. Reality is, electricity provides a substantial efficiency boost while also reducing emissions. That's the purpose of a plug-in hybrid, which can be achieved with a smaller battery-pack... on that doesn't sacrifice what appeals to hybrid shoppers... interior space... hybrid efficiency... and selling price. With respect to EV delivery, it's even easier to see the goal of high-volume & profitable remains a major challenge. So to all those who misrepresent by not acknowledging the reason, we know.

6-03-2015 **Impressions.** This attitude is difficult to overcome: *"The PIP then came as a 2012 model year here. Which was just in time to go sale after the Volt. This let GM make a first impression upon the public of what a plug in hybrid is. If the PIP had arrived first, it could have been Toyota dictating that impression."* When the mindset is trophy-centric, getting someone to recognize business objective is like talking to a wall. They just plain don't understand what the heck you're talking about. They see the immediate goal in front of them and disregard all else, even if there's a penalty or sacrifice for doing so. As far as their concerned, initial impression is absolutely vital. Ask the typical consumer if they have any clue when a particular technology came about. They'll have no idea. Being incorrect by many years is common. Not knowing any detail is even more common. It's just vague recollection, at best. That makes the online squabbles rather pointless; yet, some will insist on trying to "win" anyway. This time, I dealt with that this way: That misses the point. Toyota already understood both the market and their audience. That's why they planned for rollout flexibility... which continues to be spun as a shortcoming, despite proving a wise move. They steered clear of the obvious rollout issues GM was about to face. They knew... which is why I blogged stop much back then about that very problem. The concern was clearly documented. Looking forward, we see the fallout as avoided. The mainstream consumer will have no idea and just see any of that history they stumble across as ordinary early-adopter issues.

6-03-2015 **Semantics, Labels, and Definitions.** When things start going bad, that's what discussions get overwhelmed with. Simple things like audience & purpose are lost to arguing points without any benefit no matter what they overcome. For example: *"Then questions on why it didn't have the EV range of a Volt could be countered with, 'the Prius plug in is a PHV and the Volt is an EREV.' That could have nixed direct comparisons between the two in the general public consciousness."* Simplicity is often a major problem. That's why they say *"the devil is in the details"*. Always be aware of the dangers from generalizing. Clarity is key. What will the debate accomplish? Here's some food for thought: Volt supporters tried, but the definition ended up weak and contradictory. Labels don't mean anything to those who don't consider engineering anyway. Sorry, but your looking-backward perspective is preventing constructive discussion. Remember who said what to who about dwelling on history? Take a look forward, considering the majority of the population who has yet ever give any plug-in any thought. Their introduction will be gen-2 offerings. None of what happened so far will mean anything to them. Pointing out that past won't accomplish anything either. Look forward. Recognize audience. Consider goals.

6-05-2015 **IF and ONLY.** Speaking of generalizations.... I looked back through a recent popular discussion thread. The words *"if"* and *"only"* were used quite a bit, so much so, they were controlling content of posts. People don't like multiple choices. As a result, they just prefer true/false and yes/no and either/or type responses. Those are easy to follow in the confusing venue of online posting. Forums present challenges. Many discussions take place all at the same time, at different paces, with a wide variety of participants. It gets confusing. That makes simplicity a draw. Unfortunately, that impairs constructive discussion. This is how those daily-blogs thrive. You start fresh each day. At least with a forum, you stand a chance of finding relevant content to build upon. After all, when the choices are *"if"* and *"only"*, there really isn't much to discuss. That's how topics become polarized. People choose a side and never consider balance. One extreme or the other is a problem. Remember the lesson from Star Wars, how absolutes led to corruption? Unfortunately, our society has stigmatized the word *"compromise"*. That had meant seeking out a balance. Now, it means making a sacrifice. That's really unfortunate.

6-06-2015 **Unrealistic Expectations.** We've been taught to recognize leadership as breaking new ground... progressing further... reaching beyond... exceeding limitations. The reason is simple, that's what results in praise. The other type of leadership is thankless. So, not only doesn't it get any attention, it is often dismissed as having any importance. Needless to say, that's a major problem for automotive advancement. The media just plain doesn't care about leading the way with ordinary vehicles. They pretty much only care about pushing the envelope. That means progress in terms of vehicles providing business-sustaining are almost totally overlooked. Powerful large pickups and super-fast sports cars get lots of media coverage. This is why Prius has faced challenges with mainstream penetration. This is also why Volt was hyped so much. That makes you think when this is posted: "*Frankly, I'm shocked Toyota didn't take the lead in plug-ins.*" Realistically, they did. Toyota was the automaker which took cost-containment seriously by making it a very high priority. With so many factors at play and the concern about dependency on tax-credits, you'd think expectations would be set with cost in mind... by GM, so there's been a lot of fallout to deal with. Nissan and Ford didn't sacrifice as much, so they've been doing better. Tesla obviously didn't worry about cost, but they made their intent quite clear. Toyota stayed true, rolling out a mid-cycle release with low-volume in limited markets, showing us a solution for the masses will follow. They chose to wait for affordability and set time expectations. Knowing approach is vital. Acknowledging it is a different matter: Knowing that making it affordable to the masses is the primary objective, the fact that batteries are still striving to reach that point should have been a clue. The failure of Volt taking the market by storm was another obvious indicator. There was wishy-washy response to both Leaf and Tesla as well. Rolling out mid-cycle made it much easier to keep the plan flexible too. Then there's the reality of low gas prices.

6-07-2015 **Advice.** I posted: "*Take the blinders off. Notice the traditional vehicles are absolutely crushing the sales of plug-in vehicles. Then join your local EV club for a dose of reality about the market.*" That daily-blog suffers from group-think. They've convinced themselves that only the plug-in market matters, that no other sales are relevant to their cause. That amazes me. To totally disregard all else is like ignoring the fact that the ship is sinking, simply because your cabin is still dry. You can do everything right and still lose. That's why looking at the big picture is so important. A perfectly executed rollout with plug-in vehicles, having the technology operate flawlessly, be practical & affordable, and easy to understand is not a guarantee people will actually buy them. Those purchases depend upon factors outside of what you have control over. The influence of cheap & abundant gas is a great example. Why bother with electricity? Even if you prove greater reliability and lower lifetime cost, some people simply won't care. They'll stick with the status quo. The market is everything. You cannot just pick & choose what you like and disregard the rest.

6-07-2015 ICEV label. The effort to win over the friendship of former foes is going well. Some were simply frustrated that things didn't go their way... which naturally meant anything I said as the perceived argument winner would be in some way an "*I told you so*" type remark. Thankfully, their desire to participate in active discussions trumps their desire to be correct about market response. Since they are well informed and aren't afraid to speak their mind, they are a useful ally. See, one way or another, I'm finding a way to build up a team of influential individuals who have a reach beyond the typical single-forum participants. Each routinely post elsewhere too. Anywho, this was the quote I jumped on this morning: "*The only hybrid I can recall that has an ICEV available here but isn't offered is the Fit.*" It was a sensible comment. The poor choice of wording got me though. I'm quite curious what the response will be, especially from this particular individual: Do you realize the disservice and unbalance the use of "*ICEV*" represents? People see the new term with "*EV*" in it and assume that actually means something is new. That makes sense if nothing is different. There are an endless numbers of examples of new labels used to indicate something is new. In this case, it's just a replace for the ICE term the rest of us have been using for many, many years now. What benefit does the new label bring anyway? If there actually is one, then you must also stop using the "*hybrid*" label and only refer to them as "*HV*" from now on. Lack of consistency can become a problem. Since you are one of the outspoken regular posters, I specifically highlighted your quote. Seeing it used by others is one thing, but you have more of an influence... hence asking you directly. If we want to all move forward, it's seemingly small details like this which really have an influence.

6-07-2015 Abbreviations. The label response was rather weak, sighting the official SAE definition. We know that mainstream consumers couldn't care less, that technical description is meaningless. Again, this is the difference between engineering and business. The way to market a vehicle often has nothing to do with the underlying technology. That's why the simplistic MPG advertisements have been so effective. Needless to say, I wasn't thrilled with his response. My own was an effort to, hopefully, keep some type of constructive dialog going. We'll see. After sighting the official terminology origin, he said: "*I started using it to keep from switching between conventional and traditional, both of which could have baggage for the reader...*" In reply, I posted: We've overwhelming confirmed abbreviations are problematic. By far, the better choice than introducing yet another is to simply say: *non-hybrid*. Notice how EV doesn't actually tell us much anyway? Prius PHV is just as much an electric-only vehicle in a wide variety of circumstances. In fact, I'm at a coffeeshop now typing this. I got here via a 55 mph highway and a little bit of suburb. Total distance round-trip: 8.8 miles. Total amount of gas consumed: 0.0 gallons. It was all EV as far as the energy consumption is concerned.

6-07-2015 **Surprises.** Even now and then, something constructive is actually posted on the daily-blog. It comes from someone who doesn't often post, a person far enough from the rhetoric to make a worthwhile comment or suggestion. I jumped on the opportunity today, which really surprised me: It will be intriguing when GM does finally expand the Voltec offering to something other than 4'ish passenger car. Prius Plus has been available for years and is exactly what you describe. (It's a variation of Prius V available to some countries in Europe and over in Japan). Like the model here, the back seats are on rails. Where it differs is the addition of 2 seats behind that, increasing the passenger count to 7. The seats fold down when not needed. The trick was finding an alternate location for the batteries. With Prius Plus, it was to switch to lithium for the higher density and smaller size, then moving it to between the front seats. If GM sticks to the 50'ish mile range promotion, rather than shrinking the battery and retaining current range as some of us hoped, that diversity opportunity is going to be a problem. Just think if GM had stuck with the current range. Cost would have been reduced while at the same time increase both seating room and depleted efficiency. But then again, this is where CT6 comes into play. Volt can retain its purity while still allowing GM to offer variety. It saves face for those who endorsed "*EREV*" by introducing "*PHEV*" labeling, even though they share the same technology. It's a good compromise, if it actually happens and in a timely fashion. Any comments about what you'd specifically like (similar to what current vehicle) and by when (next-gen or mid-cycle release)?

6-07-2015 **Reality.** It comes crashing down on some. I like to take advantage of the opportunity to make sure they understand the situation. This was such a case: I see frustration & denial from those who wanted Toyota to push the market into submission, rather than sticking to sound business decisions. We all know that the rollout of Volt turned into a disaster. GM's attempt to deliver a mainstream vehicle (selling at a rate of 5,000 per month by the 3 year of sales) will be major example of what not to do for decades to come. The warning signs were abundant, yet hope clouded judgment. Toyota clearly saw what was going on, that consumers just plain were not ready yet. Toyota also saw the inner-conflicts, where other plug-in supporters couldn't even agree on what & how to endorse. Toyota knew gas prices would be pushed lower and lower due to all the effort among oil suppliers to increase scope & volume. Toyota knew the expiration NiMH patents would end up stirring the market in an unpredictable way. Toyota knew the dependency on tax-credit subsidies and HOV privileges was very risky. As for claims of belief & direction, those are easy to spin. The facts about gas prices, oil supply, battery patents, and dependency risk are not. There's also the reality of CAFE and EMISSION standards. Any automaker can rollout a token technology. Changing their overall fleet is an entirely different matter.

- 6-07-2015** **More Is Better.** Sharing of owner experiences like this seem innocent enough: "*Cool story bro. I did like 6 different errands yesterday and drove 67 miles all electric without charging once. Still had 17% of charge left, and this with going 75 mph on freeways and hard acceleration.*" But when you back up and look at overall context, you'll see the reoccurring theme of more being better. Vehicles with smaller battery-packs are being shunned, even though they are contributing to the larger effort of endorsing the plug. We don't want packs so big only the elite can afford them. That's why I stand behind Prius so strongly. Toyota chose to make the most out of the least. The attitude of guzzling electricity is not good in the long run. You want motors that are efficient. Smaller systems strive to deliver that. Simply increasing capacity is not a solution. Increasing the depth-of-discharge isn't either. Yet, things like that are rarely ever mentioned. Notice how KWH is pretty much never included in posts. It's the same type of nonsense we dealt with from GALLONS being misrepresented by MPG. Does an increase in MILES really make a difference when your commute is short and you live close to town? What's the point of more? For that matter, why carry an engine if you try to avoid ever using it? The true competition will continue to dominate until those questions are addressed. I put it this way: Good example of how the market is not ready. Whether intended or not, the continued "*more is better*" message about plug-in capacity is a clear sign that the spirit of cooperation to compete against traditional vehicles is not there yet.
- 6-09-2015** **Progress!** We got a sensible question today: "*Why leave untapped market to competitors when you do have available stock?*" I was thrilled to reply: Hooray! An economics 201 question. That's real progress. :) Unbalance can work against a leader. When you're too far ahead, competitors will fight you rather than collaborate. Toyota wants the others to join in. It's a win-win situation, but requires a wait period for the leader. That works out nice, since the R&D effort never ceases. We've seen this many, many times in the computer industry. The automotive industry is only now discovering the potential.
- 6-11-2015** **2016 Volt Specifications.** It was fascinating to read this today: "*GM has quietly updated the 2016 Volt specs. Old: 41 mpg combined, 102 MPGe EV. New: 43 mpg combined, 106 MPGe EV.*" That's well below expectations. Should we expect another few years of fallout and backpedaling as a result? I'm not the slightest bit surprised. If cost-reduction had been taken seriously, advances in efficiency would be a natural tradeoff. Increasing expense doesn't make sense. Smaller improvement is realistic... which appears to be exactly what happened. I responded to the next this way: With such modest improvements... well below what had been hoped... the lack of fanfare is no surprise. Enthusiasts had anticipated a revelatory leap forward; instead, they got evolutionary... which is what "*next generation*" was always intended to represent. I'm glad the craziness is over and we can all join in as a plug-in team. The "*vastly superior*" nonsense really had a negative effect on the overall effort to end the reign of traditional vehicles. Sadly, this outcome had been predicted many years ago, when the "*too little, too slowly*" concern was first made. Finally having reached a state of closure is quite nice. I'm looking forward to more plug-in events. The looking down upon Prius PHV was counter-productive. Now there can be a variety of approaches and a recognition of how diverse the market really is. The more-is-better mindset has proven ineffective.

6-12-2015 **Prius Prime.** What an intriguing situation. Back in November 2008, the top online supporters of Prius were tossing around identifiers, trying to come up with universal labels for the various generations. It was that discussion which ultimately led to coming up with "*Iconic Prius*", a term now formally associated with the second-generation Prius. I was thrilled that a close online friend had suggested that and to have been part of the brainstorming process. My suggestion was "*Prius Prime*". It didn't appeal to many. Oh well. That was ok. After all, I was the very first person to ever use "*stealth mode*" as a specific label to identify the electric-only operation of Prius and my frequent promotion of it following that led to its mass adoption. It became the term now used universally throughout Prius discussions. Who knew a comment made way back in 2000 could have had such results? You never really know how what kind impact constructive contributions will have. That's why it's so exciting for our shared effort to find a name ultimately having this as an outcome... Toyota just Toyota registered the trademark "*Prius Prime*". Apparently, they are pursuing the official use of that term for something within their upcoming product-line. Who knew that brainstorming session would stumble across something useful for later! We were collaborating, to coin a label for the benefit of future owners. After all, that group did a great deal to promote the third-generation design. The 2010 rollout did well with our contributions. Many endorsements from owners go a long way, often more effective than any type of advertising or promotion an automaker can provide. We provide observations & advice. In this case, I got to provide an official name. Sweet!

6-13-2015 **Third Generation.** Wild spin about the distant future is emerging already. That's not a good sign. Ever since the first plug-in rolled out, the anticipated target battery cost for mass acceptance was \$200 per kWh. The primary reason for this is the high-cost for the second-generation Volt. It will continue the dependency on tax-credit money to assist with sales, a trait hoped to have been eliminated by the time rollout began. Much of that was the hope of cost having come close to \$200. Abruptly having changed that number of \$100 is yet another example of moving goal posts. That cliché describes the behavior of enthusiasts all too well. When their hope turned to disappointing outcome, they just change their expectation. That's not the slightest bit constructive, yet we see it all the time. It often comes in the form of cheerleading, like: "*Just in time for a 3rd gen Volt! :)*" It was surprised to witness such behavior already. But then again, we all know GM will be diversifying as a result of the decision to keep Volt a niche. Mainstream high-efficiency sales will come from the Malibu hybrid or a Chevy model using their PHEV configuration. The so-called EREV configuration quite simply isn't competitive. I sounded off with: It won't matter. Volt is no longer Volt already. An affordable choice for the masses will likely be something else anyway. Go over to the daily blog. Yet again, they are changing definitions & goals. Those changes have skewed the vehicle called "*Volt*" so far from the original intent, what difference does it make what comes out next? By the way, that's why there is still some resentment for Prius. Toyota has stayed true to purpose. Thankfully, the pointless chest-pounding is fading away. Business reality is helping to bring about plug-in cooperation. In other words, market need is finally being addressed. In fact, we're seeing that here now with more constructive discussion. The magic "*\$100 per kWh*" target will open up a wide range of battery configuration opportunity. It won't be possible to declare "*vastly superior*". There will be a variety of choices for a variety of buyers.

6-16-2015

Looking Back. The spin of history as a new chapter is about to begin is inevitable. People look back with a very, very different perspective. Already knowing the outcome of the previous chapter prevents a good understanding of how motivated people were from the uncertainty. Seemingly logical decisions were sometimes wild guesses and tremendous risk, others were based on lack of information and fear. That rarely gets acknowledged looking back. In fact, many have no idea after the fact. Not having participated in that history firsthand means a great deal of study is required to share sentiment with those who did. That rarely happens though. It's common for forum members to only know of past dealings based solely upon recent posts. Blogs like this, which were written as the history was unfolding rather than long afterward, offer a very very different perspective. Long story short, it's extremely difficult to look back. That's why this statement made today was so troubling: "*Others think the Volt is too much, too early.*" It offered nothing else, just that generic assessment without anything to actually support it. Ugh. All I could do was say: That's why the WHO question was asked over and over and over again. Who are those others? GM did indeed set a target for mainstream sales. It was for the end of the second year. By then, the plan was to grow beyond those sales of 60,000 annual to take advantage of their 120,000 annual production capacity available at that point. Knowing who they intended to sell to was obviously important information... which was evaded over and over and over again. The daily blog for Volt was the center of attention. They were who. GM took advantage of that resource, continuously feeding it to draw more attention to Volt. It started out as supporters there, a group who I thought could be an ally in the quest to end the reign of traditional vehicles. Sadly, they transformed to enthusiasts who declared Volt as "*vastly superior*". They spoke out against plug-in hybrids and EVs, coining the EREV label to distinguish their preferred design. That fell apart though, as other automaker offerings fit the same definition and Volt sales struggled. It's what brings us to the "*too much, too early*" assessment. GM clearly over-engineered the first Volt. In fact, that's fundamentally why those enthusiasts felt it was superior. Unfortunately, that too much resulted in business problems. There wasn't a market to actually sell it to. That extra made it too expensive. Only early adopters bought it, taking advantage of bargain leases, the tax-credit, and HOV privileges. As for the too early part, that's why the same questions are being asked again about the next-gen Volt... specifically, who? In the past, both the enthusiasts as well as GM itself spoke out against small capacity battery offerings and electric-only vehicles. Volt was the solution for all. An increase in EV range, combined with a more efficient engine and a much lower production cost, would fulfill business need to reach the masses. That would supposedly achieve those mainstream sales... which begs the question, will it? I see the next plug-in Prius as targeted to reach ordinary consumers. Toyota's choice to keep the battery-capacity on the smaller side (to avoid space & cost compromise) and the choice to take advantage of blending will make it more appealing. It's easy to see the MPG boost the plug provides. It's still very much a Prius after depletion. Full recharging with just a 120-volt connection isn't an overnight process. That sounds like just the right amount at just the right time. We know the details of Gen-2 Volt. We know the price too. With ever increasing competition and the looming subsidy expiration, what should we expect?

6-18-2015 **Unity.** It's a very real problem that some still don't take seriously. How many times do we have to see the same thing play out before they finally see it too? It just gets dismissed as something not to be concerned about. Not learning from history means you've got a good chance of repeating those very same mistakes. Ugh. Oh well, all we can do is try to point out the problem: Lack of any sort of unified message from Volt supporters led to a number of problems with its rollout. That raised a warning flag, which Toyota acknowledged by delaying their plans. Why would we expect any type of market expansion for any of the variety of plug-in vehicles to succeed when faced with such unity failure? No agreement on usage of public chargers sends a bad message. And that's just one of many problems. Thankfully, most consumers have no clue what's happened so far, nor do they care. But having faced some of the hate firsthand and struggling to get early-adopters of the past to move on makes the need quite clear. Progress will not be possible until we all finally work toward a single goal. Seeing that, they'll get the message. Fortunately, I'm part of a local plug-in owners group who doesn't hold resentment or place blame for mixed messages of the past. They all have the same purpose... to get vehicles electrified. So, even though I drive a car with the smallest plug-in battery-pack and a gas engine, I'm still using electricity. I'm also providing an endorsement for lithium. So, they're happy to share a charger. They see how starting small will contribute to a much larger impact. They realize how important it is to reach a wide audience quickly too. Quarreling amongst ourselves will not accomplish that. I've been told my encounters with "unfriendly" supporters have only involved a few individuals who are best to just ignore. Those of us with lots of online experience know all too well that isn't an effective solution. Choosing to disregard a problem doesn't make it go away. In fact, that's a terrible solution... since it can often backfire. We need to settle differences here & now. We are the people of influence. We can take agreed upon suggestions and actually make them happen. We're the vehicles of change, not what we drive.

6-19-2015 **Gasp!** The word "*dismay*" is only way to describe the following: "*Who could have possibly imagined ten years ago that the CUV would do so much damage to compact and mid-sized cars?*" It's hard to believe that level of naivety could have existed, now. Back then, people were clueless... despite the encourage to guzzle was obvious. Heck, back in 2001 my Prius was featured in a auto show at work. There was a wide variety of vehicles, from classic to hybrid. In that mix was a new category of vehicle called "*crossover*". That was the new type of SUV, one that was less truck and more car. It's what is now called a CUV... replacing the S for "*sport*" with C for "*crossover*". That was 14 years ago. It was very clear to see the damage about to come. Automakers were heavily pushing that new category, since it reduced consumption without having to sacrifice much. Unfortunately, what started out as small and less powerful didn't last long. Everything grew and became more powerful. The result all these years later is the belief that 30 MPG is doing your part to use less gas. Ugh. The hope of 40 MPG averages by 2010 became a long, lost dream. That's why selling a 50 MPG has been such a challenge. People in this market have a "*good enough*" attitude and only now are waking up to the obvious. The rest of us imagined this increasingly difficult situation ten years ago.

6-19-2015 **New Antagonists, introduction.** Just as we had worried all those years ago, Volt did indeed become a huge market distraction. Yes, it proved the technology. But unfortunately, it sent a message that it was expensive and impractical. Supporters we so blinded by the engineering, they didn't take ordinary consumer importance into account. Prius was mocked since way back in 2001 for being too small. That meant regardless of how well it performed, the car would still be outright dismissed based on size. That way it grew over the years. Being able to compete directly with midsize cars was no just important, it was vital. That gave Toyota the opportunity to diversify, offering 3 choices of size. Allowing it so reach a wide audience was a big deal. You'd think GM would have followed that wisdom. GM didn't. Supporters see the challenges the upcoming next-gen rollout present and have moved on. That's stirred antagonists on the big Prius forum. More and more, we see anti-Toyota sentiment. Their arguments are weak and based on just vague references & limited scope. Unfortunately, they don't get called out as trolls. That identifier doesn't work on forum members who have participated for years and only recently turned. So, just like with the big GM forum years ago, the big Prius forum now faces the same problem. Some of us are attempting to call them out, to draw attention to their intent to do harm. The detail reveals their criticism is not only not constructive, it's also purposefully misleading. Needless to say, it's troubling to watch these disenchanted frequent posters become antagonists. Their disappointed with Toyota's approach and have chosen to not listen to any reasoning. They've made up their mind and now want to take out their frustration using the forum.

6-19-2015 **New Antagonists, sounding off.** The chosen venue for that frustration release has been on a new thread about public charger abuse. The antagonists have taken advantage of the opportunity. Seeing the hate some have expressed, the hope is to attract more anti-Toyota support. In a way, it's intriguing to watch their obvious trolling methods play out. The avoidance of questions is obvious. The vague references and attempts to change the subject are desperate. It's sad. Two days ago, finally sounded off with this unaddressed (no quote) post: For those of you... and you know who you are ...that continue to come down on Toyota for not having expanded rollout of Prius PHV, this topic is a contributing reason. It never ceased to amaze me how dismissive some have been when I brought up how the market wasn't ready yet, sighting the conflicts between other plug-in vehicles as a barrier to still overcome. Thankfully, there are some who are more receptive. A plug is plug. You're using electricity for cleaner emissions and a reduction on oil dependency. That's the point and the numbers of those who accept that is growing. So what if a plug-in hybrid is plugged in? You have no idea how far they actually drove to get to that charger anyway. The goal is to replace guzzlers with affordable, practical, and profitable choices.

- 6-19-2015** **New Antagonists, diversion.** The distractions are endless. There is favorite though, fuel-cell vehicles. Rather than address the topic of discussion, the divert attention by simply complaining about something unrelated. This came up on the public charger abuse thread: *"Unfortunately Toyota is really trying to force the FCV on the consumer using politics and questionable marketing to more or less foist a technology a lot more limiting than PHEV and EVs."* What the heck does that have to do with a plug-in vehicles not being considerate of others by moving their vehicle when charging is complete? It's so far off-topic, you'd think people would complain. But coming for a long-time forum contributor, they don't see the act as troll behavior... even though that's exactly what it is. So, thread participants often take the bait. Successful trolling is a challenge to deal with. That sound-off didn't have any impact, so today this was my attempt: FCV is a product of many automakers, clearly a long-term work-in-progress not intended in any way to be rolled out in large volume. We'll be getting plug-in options far sooner. Affordable batteries offering enough energy-density to actually compete with traditional vehicles are on the way. Where is the conspiracy? What amazes me is the deliberate effort to not pay attention to the traditional vehicles. Those strong sales should be a concern. Instead, there's this on-going pointless argument about leading. It completely misses the point... and the market.
- 6-20-2015** **New Antagonists, introduction.** There's growing frustration. Fortunately, the obsession of the antagonists often causes them to expose their true purpose. I particularly like this comment: *"Feeling threatened by Tesla and BMW, Lexus puts out some anti-plug in ads."* It was obvious rhetoric with no intent to be constructive. They just keep trying though. That abuse thread is a perfect venue for the anti-Toyota sentiment. The reason is simple, most people have absolutely no idea how they would actually deal with the charging-station situation. What should happen when charging is complete, yet the owner leaves the vehicle parked in the spot? Should the owner have even plugged in at all? What if they were just topping off the battery-pack and someone else is desperate to recharge? Should the desperate owner have risk the chance that a charger wouldn't be available? It's a messy situation, especially when you consider plug-in hybrids and short distance travel. Anywho, I responded to that comment with: Lexus is a totally different entity than Toyota. Coming from the same corporation and sharing the same resources does not make their customers the same. So, it is inappropriate to think both will have the same approach. The audiences are very different. In fact, it's as absurd as applying truck selling logic to car buyers. This is why I keep pointing out the need to understand economics better. It makes no sense combining unrelated groups. Yet, people keep doing it anyway. One is targeted at middle-market, the other luxury.

6-22-2015 **Importance.** Moving on is a challenge. There's a fine line between stirring up the past and not forgetting it. You want to remind people how things happened; otherwise, it could happen again. After all, falling into that trap has proven very easy. The Volt enthusiasts got sucked in to an extreme, the entire time claiming their situation quite different from that of Two-Mode... even though I was continuously pointing out the parallels. It's quite amazing to watch mistakes being repeated. That's exactly what we saw. The disbelief manifested itself in odd ways. The most frustrating was taking out of anger on Prius PHV, using it as both an excuse and a scapegoat. Unfortunately, placing blame turned into misleading. Then when evidence emerged (like the videos I shared) to show what actually happens, some posts became outright lies. Those individuals simply didn't care. That allowed misconceptions to run wild. Some innocent readers would assume they knew what they were talking about, then help spread that misinformation. Thankfully, we are now seeing evidence of that coming to an end. Hooray! This was how I pointed out an observation of that today: Notice the "*just 11 miles*" in the article's introduction? That's a clue to the plug-in Prius importance. Until this year, there were some other plug-in supporters so desperate to undermine Prius PHV they'd intentionally mislead about it. For 3 years, we had to deal with the "*6 mile*" claim. It was really annoying, but at the same time confirmation that they felt threatened by the potential the system offered. It gives us a lot to look forward to with this next generation.

6-22-2015 **Intentional Omissions.** A common technique for misleading is to not include vital information. Without all the facts, it's easy for a reader to draw incorrect conclusions. They make assumptions. It's that simple. Recently, we've had an honest & constructive attempt to do the opposite. An owner of a Prius PHV purchased another. The second was used though, with an uncertain history, and performance results have been different. Not knowing how the driver recharged or even their driving routes & distances, observed variations in performance cannot be well identified. Many of the posts have just been anecdotal too, since the owner doesn't have any type OBD-II scanning device to note vehicle detail. How to you measure without a gauge? The well-informed active participants have been trying to help. The owners focus has been on EV miles. Right away, a former Prius owner who now drives a Volt jumped into the discussion. Unfortunately, he did the typical disregard. The amount of gas consumed was left out of the equation entirely. Despite several posts pointing out that the same amount of electricity is consumed in the end, the fact that HV miles were higher was all that mattered. Getting recognition of overall MPG was, again, a problem. That's a common theme. Obsessing with miles labeled as EV disregards HV miles, which include those known as EV-BOOST. It's maddening. The goal is the same. The outcome is the same. But as we see with those who greenwash, no mention of vital information is a problem. Omitting non-EV miles that take advantage of plug-supplied electricity is misleading, period. That's quite frustrating to know the act is intentional too. We try to ignore the attempt and direct our effort toward the owner instead. Hopefully, he'll come to recognize what's happening. I added: The one Prius delivering fewer EV miles is utilizing the same amount of electricity, which likely means the same is true for gas consumption. In that case, the EV/HV ratio really doesn't mean much. It's the overall efficiency that counts with a plug-in hybrid and that fact hasn't been taken into consideration yet. We still don't know what the resulting MPG is. Blending isn't count as EV, even though it takes advantage of plug-supplied electricity. You must look at both KWH and GALLONS to truly understand differences.

6-23-2015 **Conquest, the problem.** I'll admit, watching the "*vastly superior*" blog come crumbling down to join the rest of us has been rewarding. Falling to right where they should have been right from the beginning is nice. You really don't want any harm to come. You just want them to be the ally you've sought for all those years. But to be expected, there are a few bad apples remaining behind, those who absolutely refuse to be part of the end-traditional team. Oh well. It is intriguing to watch the denial playout. They've always thrived on conquest. No cost could be too great. The trophy was all that mattered. Volt has quite a few. That doesn't pay the bills. Praise isn't enough. People actually have to buy something. GM's diversity is finally happening. Yeah! It was quite frustrating to see the battle against Toyota. But to watch defeat coming from Ford, that's what really stirred reason for worry. Soon, there will be the new Cruze. Rated at an expected 40 MPG highway, it shows just how fierce traditional competition will be. Fortunately, there will be the Malibu hybrid. That's long overdue. There will also be a CTS plug-in hybrid. Later, the electric-only Bolt. Needless to say, Volt is being pushed into a category of many. No more trying to declare it superior. So, when the topic of plug-in hybrids was posted on the daily blog today, I was captivated. Only the troublemakers are left. No one else participates there anymore. Would they even try to be constructive? After all, acceptance is the stage which follows defeat.

6-23-2015 **Conquest, the post.** This is how I jumped in: Progress is made when overall consumption of both electricity and gas are taken into consideration. The problem for years has been the belief that EV miles are vital, important above all else. That has resulted in missed opportunity, not taking advantage of the gas engine during times of inefficiency and neglecting EV efficiency itself. It also required cost, weight, and space sacrifice. While cruising on the highway, it doesn't take long to see the battery-level drop. The miles go by quickly. When it's winter, that need for heat uses up electricity which could otherwise have been used for driving. And of course, there's the reality that electricity is a fuel that shouldn't be wasted either. It's why KWH and GALLON usage was brought up so many times when first-gen rollouts first began. Unfortunately, the rhetoric drown out those constructive discussions. Now, we find ourselves going back to that very same topic. Remember the "*too little, too slowly*" concern? This was part of that. Consumers understanding what's available and how it works is a really important. The blatant disregard for diminishing returns was an obvious problem. More EV isn't necessarily better. Blending offers opportunity. It's nice to finally see attempts to address that. Subsidies will end. Traditional vehicles will continue to become more efficient. Oil will continue to be inexpensive & abundant. The challenges to overcome never cease.

- 6-23-2015** **Conquest, the trouble.** Things immediately fell apart. The very first response was filled with denial and a clear pattern of repetition. We're seeing the same trouble emerge again. Ugh. I got attacked. Funny part was, it was a rant about my "*perfect*" Prius and how Toyota can "*do no wrong*". I found that quite amusing, since my comments were entirely about GM. It reminds me of the past when there was an individual who absolutely insisted I was lying, that there was no possible way that data was correct. Then when I posted a video showing exactly that, I got banned. Some people refuse to accept reality. Oh well. This isn't as extremely. It's more a matter of avoidance, pretending it doesn't matter. Naturally, I had to respond: It is so superior, yet it still feels threatened by mere mention of KWH and GALLON. Then when there's mention of COST and WEIGHT and SIZE, all hell breaks loose. The over-reaction is quite entertaining when TAX-CREDIT and NISSAN are added. I was beside myself in awe by how a rant could emerge, going on and on about Toyota and Japan, when neither were any part of what had actually been posted. That's an obvious sign something is wrong. Why is there avoidance of those particular design factors? That's a legitimate question and quite on-topic. Plug-In hybrid have to deal with them. There is growing pressure to reduce consumption (of all types) and reduce emissions (of all types). What we saw here today is proof some are not taking that seriously.
- 6-24-2015** **Conquest, the nonsense.** Sometimes, the problem runs so deep, it turns into pointless nonsense. In this case, it came to: "*If you were to be honest, you would admit that you are not a fan of a GM EREV but fully support Toyota's efforts in their hybrids and plug-in hybrid. You are not a fan of GM, period.*" In other words, there's nothing you can say that will ever be accepted. They establish a false belief and disregard all else. Put another way, they don't think it is possible for anyone to like more than a single automaker, that the idea of plug-in supporters joining together will never happen. That's sad. Long story short, I decided to make it ever longer... by climbing up on my soapbox: Over and over and over again, I posted the need to diversify. It has nothing to do with any particular automaker. It's simply good business. Remember all the SECOND MODEL posts? Those were to get Volt split into multiple configurations, one for the enthusiasts and another for everyday consumers. Notice that no matter how many GM references are made and no mention of Prius or Toyota whatsoever, all certain people see & hear is Prius and Toyota. It's amazing how blinded some can be to the obvious. Post after post I'd refer to the true competition: GM'S own traditional vehicles. Yet, they'd simply ignore that. The evidence is blatant now. My complaints about ONE SIZE FITS ALL were finally heard, not by those here though. Bolt and the CTS plug-in are what will come about as a result. They are that diversity of product. Watching sales of Volt getting lost to Malibu, Cruze, Impala, Equinox, etc should have been a concern. It was baffling to witness denial of such a major problem. GM's own vehicles were cannibalizing Volt. Instead, there was using me as a scapegoat and waving the flag of conquest. Didn't you see that happening?

6-24-2015 **Conquest, the continuation.** The push went on: *"I've suggested to you in the past that you take an extended drive in the Volt. You might be able to talk a dealer into letting you have one for a day or two. Please do so so that you can open your eyes and see the dawn breaking. A new era is upon us."* The same old belief that great engineering will deliver a popular product continues to spell doom. They truly don't understand the audience. The reason for asking the "Who?" question was lost on those without any type of business experience or education. That shortcoming is remarkable. They truly don't see what is so obvious for others. Oh well, that means this too will likely fall the poorly informed: I responded with a compliment of the engineering achievement. Unfortunately, all people seem to notice is the business concern part. A well performing design does not mean a well selling vehicle. That's why the COST, SIZE, WEIGHT aspects are so important. Having pointed out those concerns early on, then being proven correct, labeled me as a troublemaker and a hater of GM... even though I was actually just pointing out what needed to be addressed sooner (proactively) rather than waiting until sales later (reacting) when it was much harder to change. In other words, regardless of how impressed a person is with the test-drive experience, that doesn't mean they'll actually purchase it.

6-24-2015 **Conquest, the facts.** This particular response really got me: *"When faced with irrefutable facts presented in a discussion, you will not respond directly to them, conveniently ignoring them to put forth some other not-quite-understandable statements."* The close-minded attitude is a repeated theme that's easy to see. I get nothing but talking-points and accusations from certain people. Oddly, it's a good sign. The idea of conquest has fallen apart. That's the proof. Strong sales are the measure. They don't like talking about that. So, I kept on posting: Haven't you noticed that those facts are repeated? How many times would you want to answer the same thing? I bet you too would respond a few times, then ignore when they get asked following that. The topic here is PLUG-IN HYBRIDS. Why in the world is the non-plug model of Prius being referred to and the plug-in model ignored? When facts are selective, that's often called cherry picking. Toyota offers a PLUG-IN HYBRID. Ford offers two PLUG-IN HYBRIDS. Hyundai offers a PLUG-IN HYBRID. Honda (until recently) offered a PLUG-IN HYBRID. Heck, GM will even be offering a PLUG-IN HYBRID. There's also BMW i3 and GM Volt, if you want to include them in the category too. So... why the reference to a non-plug and disregard for the rest?

- 6-25-2015** **Conquest, the end.** It did finally come: This all-automaker topic was the ideal opportunity to find out what has changed, what will be different with the rollout of second-generation plug-in vehicles. It's troubling to find out there's still an obsession with conquest sales and a lack of understanding who the competition actually is. I was blown away by the response. We've watched the market saturate. With all the early-adopters already driving a plug-in, few else could be encouraged to buy. Sales opportunity was lost. The true competition, traditional vehicles, continued on strong. It's not GM against Nissan or Tesla or Toyota. It's not EREV against BEV or PHEV or even HV. It's just old verses new. GM's own traditional product-line is cannibalizing sales of Volt. Not drawing customers on the showroom floor, at the dealership, is a very big problem. Yet, focus has been entirely on conquest sales instead. How does drawing in potential customers from other automakers change the loyal GM buyer? Owners of older Malibu will just replace it with a newer Malibu. It's lost opportunity. Why isn't anyone else concerned? The senseless shooting of the messenger may make you feel better, but it doesn't help the situation. In fact, it's a distraction, allowing the problem to persist. That's really sad.
- 6-26-2015** **Conquest, the desire.** That plug-in hybrid topic was started with an article which included this information: *"Prius PHEV. Numbers based on 40 miles per day, 15,000 per year, 15 miles to work, 110-volt charging on both ends of commute. Eighteen gas stops per year. Other PHEVs with larger batteries are much fewer. The Volt would never need to stop for gas and could do much more than this with its superior AER. Source: EPA."* No link was provided. No actual data is either. Notice how the actual consumption value is missing and vague adjectives are used? My favorite part though is the use of "never" for Volt. That's an outright lie. Even if the vehicle's passengers or battery-pack don't ever need the heater, the system will eventually start up the engine anyway. There's a maintenance mode to prevent the fluids from getting too old. Running the engine briefly from time to time will happen. It's part of the design. EPA knows that; yet, for some reason this misrepresentation took place. I didn't get to question it though. The desire for conquest prevented any type of constructive discussion. Those few remaining regulars just plain don't care anymore. They are holding onto what's left and pretending the bigger market doesn't matter. And since they no longer are presenting a barrier to progress, it's best to leave them to their niche. We see that mainstream consumers will just look elsewhere. Who knew it would take an entire product-cycle of struggle before change finally happened... the game has changed.

- 6-27-2015** **Conquest, the solution.** There isn't one. That desire for conquest is a trap. Enthusiasts of Volt were so obsessed with dethroning Prius that they allowed the sacrifice of GM's own customers. It didn't matter how much you pointed out the "*cannibalization*" effect either. The market wasn't actually expanding. Instead, it was just a small base of plug-in supporters taking advantage of incredible prices. When leases expired for those who chose not to buy, many moved onto trying some other plug-in from another automaker. Yet, there was a solid denial theme, diverting focus to outdated statistics instead. When details of the new Volt were revealed, many who chose to buy stated they would continue driving their old model. How will GM draw in their own customer base? From the "*vastly superior*" perspective, the desire for conquest cannot be achieved. Superior compared to what? Sales of traditional vehicles have been absolutely devastating. Toyota sees that. Ford sees that. Nissan sees that. Each has acknowledged the challenge by stating intentions to better compete directly against their own traditional offerings. The purchase-priorities of mainstream buyers are goals the upcoming releases are striving for. GM, on the other hand, decided to continue on with their approach. Why? It makes no sense increasing EV range, knowing that choice requires a cost which pushes much higher than vehicle that will share their showroom floor... especially with so much smaller of an interior. Becoming larger and achieving a more competitive price was a very big deal for Prius, the key to its success a decade ago. That level of success was reached without a tax-credit too. Needless to say, Volt will continue on as a niche. Malibu hybrid offers a glimmer of hope though. Larger and without the burden of massive battery-pack, it stands a chance of drawing interest from within, from GM's own loyal customers. There is finally recognition of business need. Phew! It's too bad the remaining enthusiasts don't see that. Oh well. Supporters of profitable high-volume sales will.
- 7-01-2015** **Co-Exist, moving on.** It's going to be a challenge. Moving on when there is no shared goal is a very real problem. Lack of clarity from plug-in owners leaves everyone wondering... which is a barrier that holds people back. Supposedly, the purpose of the EV is to eliminate our dependence on oil. But with all the domestic drilling taking place right now and the resulting surplus, that priority has essentially been dropped. Since it is no longer a foreign dependency, the argument for EV becomes a very big challenge. Gas is cheap and air-quality still isn't important to the majority. That's where fuel-cell vehicles slip in. It's a technology able to take advantage of renewable energy on a larger scale. When the sun isn't shining and the wind not blowing. Where does the electricity to recharge come from? For that matter, how is electricity not needed immediately stored? People just assume the grid is a repository. It's not. That's only a means of conveyance. There is no infrastructure for storage... hence converting that energy into hydrogen. It's clean and will be available for rapid refueling. It's not perfect though; however, it does reach an audience EV cannot. That's where co-exist comes into play. Rather than one solution for all, consumers will have a choice. It posted this, knowing the thread was an obvious attempt to stir post activity: The media treat FCV and EV as mutually exclusive. That draws lots of attention, which is how they operate. It's their business. In reality, automakers will explore both options... since they have very different audiences. After all, we can already see how different the markets will be.

7-01-2015 Co-Exist, no free lunch. That's what hybrid owners were constantly being reminded of. The electricity being used was ultimately derived from gas. Antagonists wanted to make that overwhelmingly clear. Well, having sent that precedent, they now have to deal with the reminder of storage. Electricity has to be stored somewhere. EV owners are too use to the idea of the grid always having plenty available for them to recharge with whenever they plug in. That's not realistic on the massive scale. Capacity is costly. It's inefficient & wasteful to always have maximum available. That's why storing is so important. Heck, that's the very benefit of hybrids. The battery is used for opportunistic charging & discharging. Hydrogen serves a similar purpose. True, there's a loss from conversion. But how's that different for an EV. The electricity must somehow be saved before being delivered to the vehicle. Needless to say, there's more to the situation than the brief online encounters reveal. That's why the idea of co-existing is becoming an issue. People assumed it to be a simple situation. In reality, it's not. We will have different approaches to fulfill different needs. Just look at the computer industry for examples. Notice how internet access is no longer limited to just desktop computers. We have notebooks and tablets and cell-phones and smart-tvs and now even cars to connect & interact with. One size does not fit all. Each has a cost too. Price varies. None are free.

7-01-2015 Co-Exist, mixed feelings. There were some outright attacks. That's to be expected. When people don't have all the information or understand intent, they lash out. What do you think this particular comment was: "*The primary advantage of the EREV is the mature gasoline infrastructure. An FCV would abandon that and would rely on two different inferior refueling infrastructures.*" I find it hypocritical how the group on that Volt blog use the word "*mature*" when it's to their advantage and "*obsolete*" when it's not. In this case, the situation is a matter of not seeing the big picture. That's quite common for enthusiasts, since they tend to focus solely on a particular implementation or approach. In fact, that's why I had to deal with so much hostility in the past from them. Their refusal to even accept the idea of a second model of Volt was met with fierce resistance. Looking at the larger market was beyond their grasp. Thankfully, there are many who do see much and recognize the greater need. This is how I responded: FCV retains the "*infrastructure*" already in place. We all know the oil/gas providers won't go down without an intense fight. Rather than trying to force them out of business (and at great expense to the electric effort), it makes far more sense to have them become the hydrogen providers. We can have our plug at home and still have commercial refueling. Since those markets are for different types of driving/owners anyway, it could work. Oddly, that plug-at-home and hydrogen-at-station, is a simplified model of what we currently have. How many stations currently have to deal with gas (3 different octanes) and diesel and E85 pumps? Offering just hydrogen would be easier and reduce storage variations.

- 7-03-2015** **Back to Prius.** The dust is beginning to settle. My drive out to celebrate the holiday weekend with family involves about 150 miles of travel, each way. The results of the trip there were just like every other long drive during the Summer with no opportunity to recharge. It was 59 MPG. That's the basis to which the "60 MPG" expectation has derived. People see how easy it would be to squeeze out just a little bit more efficiency... even though that is an ideal example, rather than average outcome. Oh well. It is still impressive, despite being somewhat misleading. But then again, that's only using half of the small plug-in battery-pack. Imagine the results from using more electricity or not driving as far. Anywho, it's good to finally get out... my independence day! Having went through all that work to sell the old houses and get settled in this new one really left me drained and with very little free time. At least I was able to take advantage of the large cargo capacity the Prius offers. That sure came in handy.
- 7-05-2015** **New Attacks, Same Desperation.** I wondered how the silence would go before being broken. With all that rhetoric of the past, the upcoming next-gen Prius is inviting... very inviting to antagonists, especially for the disenchanted Volt enthusiasts. The pressure to break out beyond niche is hard enough. But to have a strong mainstream player come along and show an upgrade with even greater potential, it's too much for that particular group to resist. They have begun their greenwashing again. Ugh. Reading this today was both annoying and amusing: *"Prius outsells the Volt because people are sheep and think Japanese cars are better than a Chevy. The Volt is simply a much better car to drive than the Prius and it is more efficient as well. If you haven't driven a Volt you might not know. If you have and you think the Prius is still a decent car, you don't know cars."* His explanation of how his Volt saved more gas than a 50 MPG from Prius (complete with a gallons chart) was then followed by saying it was *"lame"*. Needless to say, I had no interest in biting on that bait. He was clearly looking for someone to take out his frustration on. The childish name-calling is bad enough. But to go out of your way to pretend there isn't a plug-in model available and to completely disregard the cost difference, that's blatant greenwashing. I do wonder though if people will notice the omission. Comparing the two as if cost & size was the same is just plain wrong. It's the same old nonsense as with the previous generation. Back then, some became absolutely desperate for attention by attacking Prius. Looks like we'll see that repeating again. Blah.

- 7-08-2015** **Europe Trip.** I will soon be abandoning all I know at home and venturing off to Europe. That's a place where roads are quite different... busy, narrow, and filled with small cars primarily fueled by diesel. That should be very interesting. I'm looking forward to the sight-seeing and trying as many new foods as possible. We'll be traveling to 3 different countries using a large tour bus which will be towing a large trailer. That should make the experience especially interesting. We'll end up on the Autobahn at times. So, I'm sure there will be many sightings of vehicles flying by us at amazing speeds. What I'm most curious about is what will stand out... the differences or the similarities? It's really difficult to imagine or to even set realistic expectations. I know there will be Prius used as taxis, but I have no idea how many I'll see owned by ordinary consumers. I also have no idea how many electric-only vehicles I'll encounter. For that matter, will there be any SUVs there (the smaller type, of course)? It's exciting to have the opportunity to make those discoveries firsthand, in addition to the vacation itself. Heck, even the long flight from the center of the United States to Iceland to Germany will be an interesting experience. I certainly cannot drive to this destination. Watch for blog updates. I'm not sure how much time I'll actually have to document my observations, but I'm sure there will be a few key things to write about.
- 7-09-2015** **Small Cars & Roads.** What I've seen so far isn't encouraging... small cars, parked on small roads or small driveways, almost all running diesel. At least back at home, the suburbs stand a lot of potential. I have no idea how adding a plug would work. Do they have the amp capacity to support that? Where exactly would the plug go? It's a difficult situation... not as bad as apartments, but not much to show promise. Hydrogen really makes sense in those situations. Hybrids without a plug present a challenge too. What's the incentive to purchase one from Japan or the United States, especially with the wide variety of European automakers selling diesel vehicles there?
- 7-13-2015** **Superchargers!** What a bizarre place for my first Tesla Supercharger sighting. We just crossed the border from Germany to the Czech Republic. There at a fuel-station to use the pay-lou and get some Koruna (since they don't use Euros) was a row of superchargers. I couldn't believe it. Needless to say, I ran over to get a photo. Play first. Business later. I certainly wouldn't have expected to encounter a piece of new American infrastructure established there. But then again, we were on a major highway where a Tesla potentially could do some long-distance driving. Next is to look for an actual Tesla.
- 7-18-2015** **Tesla Delivery.** I did end up spotting a Tesla on the road. That did seem realistic to happen at some point. What surprised me was another stop along the highway. There was a delivery truck loaded with Teslas! I couldn't believe it. Again, I ran over for photos. The encounter was much more of a surprise than I had anticipated. The truck driver was quite happy to show me the load he was hauling... to the point of opening a Tesla, insisting I take photos inside. When a friend of mine caught up, he jumped in behind the wheel and actually started the car up. I had no idea what the European impression of a Tesla would be. Clearly, they like that type of luxury vehicle. Of course, who wouldn't be impressed by a 691-horsepower electric-car? (It was the P85D model, which starts at \$105,000.) The estimated range for it is 253 miles.

- 7-21-2015** **Cost.** This question from the big Prius forum was rather timely: "*What does it cost in Europe?*" Seeing another part of the world, one that still depends upon driving personal vehicles for primary transport is quite vindicating. I studied as much as I could using online resources, but there's nothing like actually being there. I posted in reply to that: Cost is just part of the equation. Right now, I'm in Munich, Germany. Talking about getting first-hand research about audience. The European situation for plugging in faces many challenges, in addition to the issues related to driving... road & parking space, along with pollution from the large number of diesel vehicles. Yesterday, I visited BMW world. It's quite clear they achieved what GM did not. They too faced high cost, but the decision was made to focus on making the design practical instead. This next-gen Volt is clearly a specialty configuration, not one for the masses. Look back at the original goals. Look at what i3 delivered. btw, I've seen a ton of Prius-Plus (the European wagon model) used as taxis during my travel. And yes, I even saw a Prius PHV.
- 7-22-2015** **Done.** It felt good drawing the remaining rhetoric (from certain particular individuals) to a close with this: The generic "*anti*" comes from those tired or unwilling to discuss the actual issues in detail. It's the same old nonsense we've seen for years when it comes to the "*leap frog*" topic. Reality is, the "*bad*" is undeniable. When an automaker is unable to capture the interest of its own customers, what's the point? We've witnessed Toyota's struggle to keep Prius a top-seller here. They've managed though, despite pressure from low gas-prices. Success came from identifying consumer need, the balance of appeal-factors resulting in high-volume profitable sales. GM didn't do that with Volt. Focus was on want. That's fine, if also given a choice. That's where the upcoming Malibu hybrid and CTS plug-on hybrid come in. Those are the "*good*", since they address what Volt does not. In other words, they are being targeted at people who have simply chosen to purchase a traditional GM offering instead. Why some refuse to acknowledge the true competition and recent diversification is a mystery. My guess is old habits die hard. It's easy to overlook audience and not notice change.
- 7-23-2015** **Responsibility.** You gotta like reading this: "*Then why isn't Toyota making a big push for fuel-cells by building a "Super Hydrogen" network the way Tesla did with Supercharging stations around the country?*" We live in a do-nothing society, expecting someone else to take make things happen rather than joining in ourselves. Reality is, Tesla only established some stations. Others around the country have joined into the network by building their own, at their own expense. The newest one to open in the Minneapolis area by me was exactly that. The station owner paid for the charging equipment and power-lines himself. Toyota will help establish, but it makes no sense to not encourage others to contribute. For the benefit of many, why not? After all, many other automakers have also experimented with hydrogen. All need filling stations. In fact, that's why the state of California setup the hydrogen highway. It serves as a template for others to learn from. Somewhat frustrated, I replied: Why must someone else take responsibility for our own well being? Our country is horribly behind in the acceptance of renewables. I just got back from a trip to Germany & Austria. Seeing how common solar & wind is there makes us look like really bad, like young children selfishly complaining. It's embarrassing. We should be doing it ourselves, creating that electricity locally for immediate consumption along with hydrogen storage.

7-24-2015 **30-35 Miles.** The discussion today on that daily-blog for Volt was about possible configurations for the next-gen Prius PHV, specifically a model offering 30 to 35 miles of EV range. I was really irked when this was posted: "*It isn't 11 miles, it is only 6! Blended burns gasoline. Toyota and their fans are misleading everyone!*" My emotion didn't come from the content itself either, which is a blatant lie and easy to disprove. It came from the fact that no one said anything. The entire group there is nothing but enablers. They allow the spread of false information. That's just plain wrong. It's like watching someone get hurt and not doing anything at all about it. Allowing slander is something we now teach our children to stop. Too bad the adults aren't taught the same thing. Oh well, at least I can point out the problem and try to refocus on what's actually important: As for the 6-mile greenwashing, that shows true desperation. We all know the 4.4 KWH capacity delivers 11 miles total and that the 6 is simply the result of a hard-acceleration. Following that particular point in the EPA driving cycle, there's still electricity remaining... enough to drive roughly 5 more miles in EV. So if you don't drop the pedal, the engine stays off for the entire 11 miles. My old commute on a mix of suburb roads (from 30 to 50 mph with a few stops) and 2 short stretches at 55 mph routinely delivered 13 miles of EV during the summer and 9 in the winter (without heater). That makes the claim of 6 an obvious attempt to mislead. It's also an attempt to distract from the plug-in hybrid purpose. Blending still greatly reduces gas-consumption and emissions. That's the point. If you want purity, buy a Leaf or i3 instead. This thread clearly confirms there's worry about the upcoming Prius, as well as serves as an endorsement for the other plug-in hybrids. Notice the sales numbers for the Energi offerings? Ordinary consumers simply what a reasonably priced plug-in option to boost MPG. It's that simple.

7-25-2015 **Progress?** Here's an attempt, in response to: "*If you don't have a spare 12 amps, you've got bigger problems to worry about than an EV.*" It was a quote for a long-time troublemaker that I saw as an opportunity for progress. Who knows if it will work. But at least I tried: Looking back doesn't accomplish anything at this point. Let's try looking forward. It's time to move on. After all, who isn't tired of the oversimplifications and outright dismissals? Address what is needed to make some progress getting people to plug in. Not having a 15-amp circuit (for a steady 12-amp draw) available is a big deal, something still not addressed in discussions here. Can we finally? Many home garage outlets are shared, used as a primary during initial construction. That means the same circuit uses the same line somewhere in the center of the home and somewhere on the outside. It's a common practice to make building the home itself easier. That's a problem later on though, if you maxing it out all night for recharging. Just go in the bathroom and startup a hair-dryer for confirmation or go outside and startup a vacuum. You'll immediately pop the fuse the car was plugged into while recharging. 13 hours for a full recharge on level-1 isn't exactly practical either. Getting home later in the evening would mean you went somewhere else after the work commute, resulting in a battery-pack being totally depleted. Plugging in then wouldn't allow enough time to completely recharge before having to head out the next day for work. Getting home at 10 PM and having to leave for work the next day at 7:30 AM would only provide 9.5 hours for recharging. You stay out even later, you have even less time. 13 hours is too long, period. (Note, that is what GM states gen-2 of Volt will need for level-1.) Level-2 is required for large battery-packs to be realistic. That adds expense and may not be an option for older homes without a large-enough box capacity. Additionally, there's the problem of needing to plug in more than one vehicle at the same time. With a small battery-pack, you can get away with a timer. 2.5 hours for a full recharge at level-1 for Prius PHV is easy to deal with. There's more than enough time for even 2 to plug into the same circuit at the same time. Set one for 12 AM recharging and the other for 3 AM. Simple. But with a larger battery-pack, you're basically screwed. In short, there are challenges for recharging at home. Finding a way to recharge at an apartment or condo is even more complicated. This must be addressed. Progress for plug-in vehicles is impaired dwelling on issues of the past. Let them go! Give this topic a serious consideration.

8-17-2015 **Goals.** No entries for several weeks should be a clue that something major happened in the meantime. That is indeed was the case. I got married! The love of my life just settled down. The wedding was a blast. All the prep work totally paid off. The outside ceremony went extremely well. She made the program on a stick, so it could double as a fan... and it did. It was on the hot side. Rather than a unity candle, which clearly wouldn't work with any type of breeze, we had roses for us and a white carnation each person attending added to the bucket at the alter (a bridge over a small stream). That worked well in the warm & bright setting. It looked really nice too. At the reception there afterward, my best man pointed out to everyone how he knew it was true love... I started talking less and less about the Prius. Everyone there was quite amused, since that indeed what happened... an indication I wasn't even aware of. She likes the Prius. It was incredibly practical during the move to our new house. It even helped in the wedding itself, since I needed to transport an arbor for the alter and a special bike. (We started our relationship through a biking trip.) We stuffed ever last bit of remaining space to bring back gifts and leftover food. It was a great evening with family & friends, a memory I'll cherish. The lesson taught by the Prius and repeated several times over the past 15 years is that some things are worth waiting for. That special day most definitely was.

8-17-2015 **Argument Points, looking back.** The time is quickly approaching. That chapter in history covering first-generation plug-in vehicles is coming to an end. The rhetoric is starting to ramp up already. It's quick surprising to see some of the same old argument points coming up all over again, the greenwashing crap is even worse than the hybrid nonsense too. Think about how much more obvious the claims trying to raise doubt about climate change are. They're rather desperate at this point. Yet, some continue to attempt that anyway. Fortunately, since battery reliability is proving reliable and the desire to plug-in fulfilled by each automaker in some fashion, the argument for delay is very difficult. Sadly, there are a number of argument points that persist. They're all weak, lacking substance & credibility, but still a force to be reckoned with simply due to the reality of most readers not being well informed. So, I'll take the time to document recent observations.

8-17-2015 **Argument Points, copy cat.** The supporters of the plug-in model of Prius are quite abundant in the plug-in market. Leaf and Tesla get a lot of upgrade and secondary buyers from Prius PHV. They clearly understand the endorsement it provides for lithium batteries. Ford Energi is less clear, mostly because the second-generation will likely be competing directly, without an idea what the market will be. In other words, it's mostly a matter of awkward timing. The BMW i3 is the only true EREV available, which is pretty obvious due to the ever-changing definition coming from the Volt enthusiasts. Rather than focusing on results, they persist with focusing on semantics. It's sad. They're the ones who will still trouble for the next-gen Prius PHV too. The obvious power increase coming from improved electronics and the capacity increase will have them claiming "*copy cat*" instead of finally acknowledging priorities. Like always, they'll do everything they can to avoid dealing with the market. Know your audience. What got copied and why? Based on goals, it's easy to see that Toyota has been following a natural progressive to keep their system affordable, practical, and competitive with high-volume traditional vehicles. GM clearly is not with Volt; the goal of 25,000 sales for the first year of gen-2 rollout removes all doubt. Tesla and BMW have a luxury audience, whose priorities are different. Leaf is targeted directly at mainstream buyers though. The Energi vehicles are too. Heck, Hyundai is even pushing for being competitive. Selling at a profit without dependence on a tax-credit is vital. We see most automakers striving for that. Obsessive attention on "*copy cat*" with complete disregard for actually selling in high-volume is a dead giveaway that intent of those online posts are not sincere. We saw the trophy-mentality emerge way back in 2007 and continue on strong until now. Don't expect that misplacement of priorities to change. They'll continue to turn a blind eye to who the competition really is.

8-17-2015 **Argument Points, no plug.** The hypocritical & contradicting nature of some posts is a good indicator of status. It's the most basic type of greenwashing. We'll see a lot more of that too. Expect it to be a strong theme coming from Volt enthusiasts. Just like with gen-1 rollout, they'll do everything in their power to compare gen-2 to the regular Prius... the one without a plug. You'll see comparison after comparison, complete with spreadsheets & graph, explaining how the 55 MPG won't in anyway be able to compete with the 50-mile of EV range. No mention will be made about the plug-in model of Prius. They pretended it didn't exist for years. There's nothing signifying that behavior will change. (They'll also dance around the reality that the Prius interior is larger as well.) It's frustrating to constantly have to deal with such desperate misleading, but in no way a surprise. And like I said, it's a good indicator of status. Doing that shows us those individuals doing that just plain don't care. Watch, they'll even avoid mention of GM's own non-plug hybrid, the upcoming Malibu hybrid. Not being able to compete without deception tells us what?

- 8-17-2015** **Argument Points, hydrogen distraction.** This is an argument point I find quite amusing. Whenever an antagonist stumbles in a debate, the topic of Toyota's current attention on fuel-cell advancement gets thrown out there. It's an obvious distraction. That's quite clear when scope is mentioned in a rebuttal and there's an effort to evade. The reality that audience is very narrow and timeline is very long simply gets dismissed makes the hopelessness undeniable. The market is set small, showing the current rollout program is to advance the technology through real-world feedback. You cannot go wide scale without that. They don't care. They use the many hydrogen greenwash beliefs to spin the situation as Toyota having lost purpose... even though we know there is a next-gen regular Prius followed by a next-gen plug-in Prius on the way. Those are targeted at ordinary car buyers, intended to compete with the true competition (high-volume profitable vehicles) right away. Sales of hydrogen powered vehicles have nothing in common with that. It's a long-term effort, quite different. Hydrogen will exist in parallel to electric power anyway. They will co-exist. So, the distraction is just that... more evidence of not acknowledging actual need.
- 8-18-2015** **Argument Points, size disregard.** That's the most obvious sign of intent. We saw that at the very beginning here, back in early 2000. Honda Insight was a 2-seat hatchback. Prius was a sedan with 4 seats and leg & head room larger than many of the midsize cars of the generation being replaced, plus it had a surprisingly large trunk due to the extra height. Yet, people constantly compared the two as if they were equals. Insight was primarily made of aluminum too, making it impossible to be sold at a competition & profitable cost. Sound somewhat familiar? Volt is clearly smaller and profit is clearly a challenge (tax-credit dependency), yet the same thing happens. Arguing online makes points like that easy to overlook. Thankfully, the test-drive experience makes it blatant. An enthusiasts places size as a non-issue. A mainstream buyer considers that among the higher priorities when choosing what to purchase.
- 8-18-2015** **Argument Points, profit achieved.** This one makes me laugh. Toyota has sold well over 7 million hybrids. Yet, some of the most stubborn antagonists will still argue that profit wasn't achieved until very recently. Wow! How could they believe that people are so stupid that they'd won't question how that could be achieved. Selling at a loss for nearly 15 years at that volume just plain does not make any sense. But then again, the vast majority of troublemakers have a strong engineering background and little to none experience in business. You can tell their lack of accounting & economics background by just asking a few basic questions. They'll respond with a personal attack or something completely off topic. Evade is their motto. Reality is, automakers are in the business to make profit. Although the motive to have the spotlight is compelling, that isn't what pays the bills. Remember the massive amount of money GM got from the government and didn't pay back? Remember how much Ford struggled to pay back their government loans? Remember how painful it was to fill the tank when gas was \$4 per gallon? How much longer can automakers remain dependent on large guzzlers for a majority of their profit?

8-18-2015 **Argument Points, tax-credit.** It's terribly dishonest to disregard tax-credit dependency. How is ignoring cost helpful? Yet, we saw that all throughout the entire lifecycle of the gen-1 Volt. Supporters gambled that sales would pick up over the years and cost would fall dramatically before the gen-2 rollout. Neither happened. So, expect this to be a big argument point in the years to come. GM has made an effort to set expectations by clearly stating the first year of this next Volt will only have a production volume of 25,000. That has quietly angered Volt enthusiasts who, for many years, have stated the second generation will sell even better than the second-generation Prius. 53,991 was the sales total here for 2004... all without a tax-credit... for that first year with gen-2 Prius. The importance of the \$7,500 for Volt cannot be overstated... especially when you consider the 2005 sales. They were 181,221... again, with any tax-credit. The subsidy was a major problem... for a car being portrayed as a "*game changer*". Proving a technology is viable is quite different from selling to the masses. That distinction kept getting swept aside though. So, it will be interesting to see how, or even if, it gets argued with the second generation.

8-18-2015 **Argument Points, profit achieved.** The goal of mainstream automakers is to sell vehicles at a high-volume profitability. We all know & praise the other type, which makes a small number of vehicles for a much different audience. They make a profit too though. They are relying on a subsidy or accept loss for the sake of reputation building. It's business. The engineering achievements are great. But when it comes down to what's important, it's paying the bills. With GM in particular, we've seen how having the money necessary turns into a disaster. So, when Volt gets hyped, it is appropriate to ask about goals. What will it compete against the GM product-line and how will the other automakers react? One of the biggest points of contention in that regard is when profit was actually achieved for Prius. We know back in 2002, during to the first-generation sales, that particular goal was reached. Toyota had improved & diversified. What we call the "*first*" was actually the second. Rollout to the United States for Prius was really an upgrade from Japan's model. But with so much bias here, our attitude of what happens elsewhere so bad, and the simple being able to disregard the initial 3 years made the topic of profit easy to spin. After all, how many people still remember Echo? The engine in Prius was detuned, the hybrid system replaced with a traditional transmission, and the body simplified. It shared the same platform. That's a cost-reduction measure which Prius directly benefitted from. That reality is evaded. None of the antagonists even want to address that. Anywho, the point is the date is still argued. After all this time. It's hard to believe anyone would attempt to convince people that Toyota continued on, selling millions of hybrid systems at a loss for another decade. Yet, we still encounter such arguments..

8-18-2015 **Argument Points, engine runs.** The is the pointless argument point... again, coming from the Volt enthusiasts & supporters. The original intent of Volt was to deliver an EV with a backup engine, for when those times come along when you need range outside of the battery-capacity. GM didn't deliver that. Turns out, the capacity much be much larger. So, the engine gets used far more frequently. To make matters worse, using the engine routinely rather than in rare circumstances, it must be larger... and well as the tank, radiator, exhaust, the vehicle itself, etc. Heck, even the cost must be more. Needless to say, that didn't work out well from profit perspective. To make matters worse, BMW did actually deliver. So naturally, we get this on-going argument. Personally, I find it quite amusing since much of the detail ends up contradicting itself and fails to acknowledge goals. Prius PHV is a plug-in hybrid that reduces emissions & consumption. What's so complicated about that? So what if the engine runs, the goal is still achieved. Unfortunately, the rhetoric is so bad at times, the online posting never get beyond what "runs" actually means. Spinning without consuming any gas is apparently the greatest of all sins, according to them.

8-18-2015 **Argument Points, only 6 miles.** Throughout the entire duration of Prius PHV production, the specification for "*electric only*" range was sighted as 6 miles. Everyone attempting to undermine its acceptance would completely disregard the 11-mile stated capacity in favor of drawing attention to the arbitrary 6-mile mark on the EPA testing-cycle. They'd all want you to believe that hard-acceleration point meant no electricity remained. It was an outright lie, often in the form of intentional omission. The same people over and over and over again dismissed the facts, even when presented in video detail, with the hope readers would assume they were being honest. Well, you know what will happen with the next-gen is rolled out... They'll all state 11 miles instead. That's so the percentage of capacity increase will look smaller. It's a classic hypocritical response. We've seen it many times before. When Prius was first rolled out to the United States, the first year available was overwhelming stated as 2000... even when the topic was about the technology itself. They'd complete disregard the 3 years Prius was available in Japan prior to that. But now, the first year available is always stated at 1997. It goes to show you how easy it is to be misled and how poor research some writers are. A true journalist would never make that mistake, but someone wanting to undermine would think nothing of omitting or limiting scope. That's sad. But then again, it makes it easy to discover who's sincere and who has ill intent.

8-18-2015 **Argument Points, no experience.** Among the biggest points of argument derive from information sources without any experience. We seeing review after review from writers who use a stock-photo in their article written about some supposed road-trip with the car. Many supporters scratch their heads wondering if that person ever even touch the vehicle. The strangest descriptions came be found in what they publish. Clearly, many have little knowledge in the engineering. We find lots of examples of anecdotal experiences written up. These are obviously based about observations rather than research, but sometimes they are so wrong you can't even tell if the reporter had actually driven or just witnessed what happened. Needless to say, the lack of detail gives reason for suspicion. That doesn't matter to an antagonist though, they'll refer to the article relentlessly, sighting it as an authoritative source and dismissing contributions from owners proving the claims false. Think about it. How much training would you need to teach others about a new technology? A road-trip certainly won't inform you of wide variety of circumstances the system is designed to deal with. That's why the reputable publications do 1-year reviews. Collecting just a small sample does not tell the whole story. You need lots of real-world data and some knowledge on how to properly analyze it. That requires experience.

8-18-2015 **Argument Points, diminishing returns.** Forcing people to look at the big picture is a problem we'll always have to deal with. There's simply no way to know what the a person's perspective or intent is. They recognize whatever the issue is, then attempt to find a solution often based upon arbitrary information. In other words, they're doomed to fail if what is presented to them is incomplete. That's the goal of greenwashing, when misguiding someone through omission is the desired outcome. Undermining is when the wanted result is for the person to make incorrect assumptions. Diminishing returns is a great example of both. MPG is presented only for certain vehicles. It shows the improvement (decrease in MPG) for the selection. What we see left out all the time is anything above 50 MPG. In other words, the plug-in Prius is intentionally excluded from many arguments. They don't want you to see that efficiency begins to level off significantly beyond 75 MPG. So to undermine, they exclude. To greenwash, they'll sight real-world data for Volt. Seeing MPG beyond 200 gives the impression of a major improvement, when in reality there is little gain. More electricity does not necessarily mean an equal savings in gas. The return is less and less, even though MPG grows more and more.

8-18-2015 **Argument Points, guzzling electricity acceptable.** This is by far the worse for environmental improvement... when a plug-in supporter just plain doesn't care about how much electricity is consumed. They focus solely on not using oil anymore. Thankfully, these particular individuals are not common. However, the disruption they cause to those who truly want EV to be success sure is a problem. Using more electricity is not the answer. Figuring out how to drive further with less is the key. Just like with MPG using gas, you've got Miles/kWh using electricity. A plug-in vehicle that guzzles is bad too... especially with a most of our electricity coming from coal and natural-gas. Neither is a renewable resource... and sadly, we have little wind & solar in this country still. If you were charging up at home using the sun, the situation may be different. But who wants to have to plug back in right away. Why wouldn't you want more driving opportunity? That reason is simple: impatience. Some supporters are so fed up with the slow pace of adoption, they want to get more plugging any way they can. Some of us don't want to sacrifice doing it right for doing it quickly. In the long run, that type of tradeoff ends up being costly. It's best to be patience... though, very trying at times. There's a balance. The compromise of inefficiency electric travel isn't worth it.

8-19-2015 **The Reveal.** Today we got the official announcement that the reveal of the 2016 Prius... the next-gen model... will be in a little less than 3 weeks from now. It will be in Los Angeles, where there and the rest of the country will have just finished celebrating Labor Day. Finding out some detail about what's to come then sounds like a nice way to conclude the holiday weekend. In the meantime, there's going to be quite a bit of speculation. I'm sure we'll get a big mix of posts too, including some using the argument points, as well as the usual greenwashing. Being able to see the vehicle itself will be nice. There's always horribly vague posts whenever a reveal takes place. People will exclaim "*ugly*" but never bother to actually share any detail. They just express there feeling without any explanation. How is that helpful? Whatever the case, we'll be anxiously awaiting information that has nothing to do with cosmetic appeal. Performance detail is a really big deal. Who knows what spin will result. But the more impressive those specifications are, the more intense the attacks. With 4th generation though, there's nothing we haven't heard or faced many times already. Price will naturally get lots of attention. With gas so inexpensive, selling any hybrid is a challenge. But then again, there's new one coming from Toyota which has nothing to do with Prius. That's the new RAV4. A smallish SUV hybrid should address the market issue quite well, especially when the hybrid system itself is so well established already. Anywho, a large chunk of the wait is almost over. Hooray!

- 8-21-2015** **Spy Photos.** It appears as though, some halfway decent photos were taken and shared online. I like the look of that new car. Good thing too. The plug-in model isn't suppose to come until next year sometime, most likely near the end. So, I'll end up seeing quite a few new regular models on the road before having the chance to upgrade my current PHV. That's ok, I'm still thoroughly enjoying it. The new house is yielding an average of 135 MPG for the commute to work & back, with a recharge at each end. I'm quite curious how that new location & route will do in the winter. It's further than before and has a number of large hills to climb & descend. Looking at those spy photos, my favorite color is red and I haven't ever actually owned a red car. Perhaps this 5th will be that. I'm just saving up for the opportunity while I wait. As for everyone else, who knows. I'm amused by the initial comments posted online. I'm focusing specifically on the general automotive sources, nothing devoted to any specific vehicle. That's where you draw out a lot of the diverse activity. And sure enough, the attacks from Volt enthusiasts began right away. They are easy dismiss though, since claims there are so many substanceless and misleading comments. There are some insults too. It's the "*ugly*" posts wasting time though. Hopefully, actual detail about the car will cause all that to fade. Right now, there's a lot of childish nonsense to sort through. Makes you wonder what those same people say when seeing the new Camry and new Corolla... especially have being told how well they've been selling.
- 8-21-2015** **8 Million Hybrids.** That milestone was reached by Toyota last month. It works out to 10 months to sell 1 million. What does that mean for the rest of the industry? Numbers like that may be nothing but trivia to ordinary consumers, who may not even notice just how many are actually sharing the road with them. The majority likely don't even care. But then when you start naming off the variety available, the perspective changes. You can see the automakers having dismissed them for years. Being expensive and a challenge to sell for countless greenwash excuses, what is a dealer to do? It's far easier to let sales staff to do what they've always done... stick to simple sales with a decent commission. I can't imagine how difficult it is to explain how the hybrid system operates, hoping they'll not waste your time and leave confused... or wondering why Toyota's system delivers better MPG. But that was the point of having started worldwide rollout way back in 2000. It takes time to establish a reputation. 8 million now speaks for itself. From Prius C to Highlander, there's a variety of choices available (30 of them worldwide) and more on the way. It's a moving target with uncertain competition. What does that mean for the rest of the industry?

8-22-2015 **Human Nature.** You bet! Having followed Prius since late 1999 and owned 4 of the models available since September 2000, I've heard it all. There are a lot of hypocrites out there. Some respond to the urge to resist & contradict, others are totally oblivious to their actions. Whatever the case, the "*ugly*" claims will pass. I remember when the minivan was first introduced. Wow! The number of "*I wouldn't be caught dead in one of those*" comments were quite abundant. And sure enough, some of the people who made that comment ended up buying one anyway. On the opposite end of the spectrum, you've got the auto enthusiasts who praise certain style, yet never actually buy one themselves. They end up with an ordinary vehicle like everyone else. Watch the "*ugly*" comments. People are so vague, you have no clue what aspect of what they're seeing they don't actually like. That's more of the human nature reaction. Many simply aren't ready for change. If it doesn't resemble what's familiar, they aren't interested. Like countless stories of the past, owners ended up deciding to buy from the test-drive experience. It's the practical design of Prius, combined with the affordable emission & efficiency technology, which ultimately wins people over.

8-24-2015 **Market Issues.** Upcoming rollout of new hybrids and new plug-in vehicles is stirring online interest. Every source is ramping up hype & rhetoric. As usual, we've got GM attempting to gain attention. It worked on me. A presentation featuring Gen-2 of Volt caught my attention. They stated customers wanted: more range, better fuel economy, and more power. No mention was made seating or price. Those countless complaints about interior space were simply ignored. Instead, the "*What we did*" had 4 bullet points. The first was "*fun to drive*". The following three, all mentioned "*powerful*" as the first item of importance for battery, electric drive, and range extender improvements. In other words, we have solid confirmation of who... even without addressing the cost issue. With the stock market having dropped dramatically today (closed at 15,871) and a barrel of oil almost to the point it was back when the Classic Prius was still being sold (below \$39 today), selling high-efficiency vehicles is becoming even more of a challenge. Toyota is the other attention-getting, but not by actually doing anything. This is all coming from leaks. The specifications even appear to be legit... and exactly what will feed the spin. Toyota appears to be right on target, staying true to the original mission of being practical & affordable rather than seeking trophies. That's not exciting... hence the antagonists trying to shift focus over to Mirai (the fuel-cell vehicle) instead. The next Prius will seek out ordinary consumers. That goal of mainstream sales of high-volume isn't threatened the hype & rhetoric, simply due to the source. We've got the nonsense coming from Volt and the continuing problem of understanding. The real push for profitable & popular plug-only vehicle comes from Nissan & Tesla still. In other words, it leaves Prius standing alone. That doesn't make appealing to traditional buyers any easier, but at least market issues are being addressed. Ford, Honda, and Hyundai all stand potential. But then again, with gas so cheap and the oil supply greatly outpacing demand... their challenge is enormous. Put shortly, we've got a messy market to deal with.

- 8-28-2015** **Smooth & Quiet.** Using the word "*luxurious*" to describe Prius over the years would have been laughed at. But secretly, everyone has always known there's no possible way a combustion or compression engine could ever be as smooth or as quiet as an electric motor. There's no debate. It's quite obvious. The fact that Prius delivered those highly sought after traits luxury buyers desired has always been a source of irritation for antagonists. They have no way to rebut. A large motor with a large battery could deliver an unchallenged amount of torque as well. Engines simply cannot compete. Combine that with the necessity to reduce emission & consumption, the choice is blatant. BMW has acknowledged this. An announcement today stated within the next 10 years, "*Virtually every BMW model would be converted to electric drivetrains, including range-extending engines and plug-in hybrids.*" The upcoming carbon emission standards for Europe has been putting a lot of pressure on BMW. Known for delivering basically nothing other than powerful guzzlers, we could see this as the first domino to fall. 17,793 sales of i3 worldwide last year may be an indicator of positive expectations. If nothing else, it does serve as yet another endorsement for battery & motor acceptance and will introduce people to the smooth & quiet some of us have been enjoying for almost 15 years.
- 8-31-2015** **Change.** The rhetoric began again. Government measurement data was released today for the gen-2 Volt. I watched posts for a bit, then posted this: So... after all these posts... we've found out that the "*leap frog*" will be lower CO2 emissions and the "*competition*" will be H2 vehicles. Volt has wandered so far from the original goal of attracting ordinary consumers and selling at a mainstream rate, what's the point of giving attention anymore? We'll continue to see some make gallant efforts to try to promote, but there's a big difference between proving a technology viable and selling large quantities without assistance for a profitably. Who cares about bragging rights? That's not what pays the bills. Automakers must produce something for the masses. Volt isn't it. The message is that simple.
- 9-01-2015** **Teaser Photo.** Just like with the previous generation rollout, Toyota is releasing teaser photos. I was fortunate enough to host one all those years ago. This time around though, the online world is quite different. Photos have been leaked & shared. We have many to look at already. Oddly, it doesn't seem to affect the excitement & anticipation. Today, from Toyota itself, we got a teaser photo of the tail-light illuminated. That's all you can see. It's just a line of red. But the shape & length is so distinctive, it caused the internet to rumble. There were posts everywhere, on any website even the slightest bit interested in automotive topics, exclaiming how "*ugly*" that was. Knowing that the leaks have already informed those audiences of what the entire vehicle will look like, it's easy to imagine the backlash. The message of change coming is crystal clear. Prius is pushing the market again. Racing ahead of the competition like that is good reason for supporters of those automakers to lash out. What the heck will they compete with? The only logic next step is to try to convince readers that new styling isn't appealing. It's a paradox though. The more attention brought to it, the less the impact... it becomes familiar... which is the very thing those antagonists want. They self-deprecate, resulting in an endorsement for change rather than successfully holding it back. That's very difficult to see today, just hours after the reveal. But we've seen the effect play out over the past 15 years. Toyota is marketing to the way we instinctively react. It's human nature. Change is coming. We react accordingly.

- 9-01-2015** **August Sales.** Gas is cheap... so low, traditional vehicle sales are very strong. 37,592 sales of Camry for the month is a difficult number to acknowledge. 31,726 for Corolla is another. This is why I was always so hard on those spreading Volt rhetoric. It's a dose of reality to significant to accept. When it's only \$2.39 per gallon to fill your tank, why consider any type of high-efficiency vehicle? Prius remains the leader. 10,450 sales is too distant though. It puts Volt's 1,380 sales (with a \$7,500 tax-credit and heavy overstock discounts) into a very uncomfortable place. Comparing to 3,119 for Prius V and 3,844 for Prius C makes it even worse. What does that mean for the future? The next PHV will be rolled out nationwide. The promotion of EV will advance. The exposure of FCV will continue. Automakers without anything competitive will have no choice but to continue to push their traditional vehicles. Gas will likely remain cheap for quite awhile, since the over-supply of oil has no end in sight. Change doesn't come easy. The future is going to be a challenge.
- 9-01-2015** **1,000 Times.** We've watched goals change... not from learning about market need... it was from finding out about shortcomings... promises not delivered. Volt became a major disruptive force and we don't want to see it again. Watching it follow that mistakes of Two-Mode was bad enough, but now with the market working to offer a diverse choice of reduced emission & consumption vehicles, we really don't want to go through that again. It looks like we won't have to either. Today, I read a "1,000 times" quote. In it, this antagonist who fought me intensely recite my very words. He's now in favor of what I had been saying for years (hence the count) about needing to offer more. Back then though, my words were responded to with hostile posts. It was amazed. The assumption was that my intention was to kill Volt by diluting it. The paranoia was remarkable. I'm sure glad I took the time to document it in great detail as it was happening. Looking back now, who would believe there would be such an intense reaction to something that should be so obvious. Wasn't the goal to spread the technology?
- 9-02-2015** **Styling.** This is a hot topic now. I had no idea my contribution to it would get so many likes. That's incredibly encouraging. Change is usually slow. The new Prius is breaking new ground, pushing mainstream to transform faster. After all, how else do you advance forward? Concealing technology into the familiar was already successfully achieved. This is the next logical step. Remember when the second-generation Prius was first rolled out. There were no other midsize hatchbacks available. Prius as all alone. Now, there are many to choose from. In particular, I liked this particular lookback at the situation: "*This is the Prius that will get back at all those people that made fun of its older generations.*" Between performance & styling, this Prius will be all alone too. I joined in with: The spin from those contradicting their own statements of the past will be entertaining. For me, I'm still totally amazed how so many think the old-school car is the only thing considered attractive. As time goes on, the divide will grow. The unique shapes of exterior lights will draw wider audiences. After all, the automakers can only do so much with the already refined car shape. Something new is needed to interest buyers.

- 9-02-2015** **Design.** It's shifting from heavy engineering emphasis (to the point of business neglect) over to truly new styling. It's about dang time! The flexibility of LED lighting helps a lot with that effort. No more Physical size & shape constraints is a big deal. We're not stuck choosing among vehicles that basically all look the same. Problem is, people are resistant to change and an increase in variety makes it worse. The other problem is that automakers are struggling with MPG shortcomings. That's a non-issue when gas is so cheap. As soon as it goes up though, things get ugly. If all the cars look rather similar, how are they going to attract sales? Getting stuck with inventory that cannot be sold is costly. So, why not embrace different looks? What do you really wanting to be driving years from your purchase? It's so obvious this change is coming. You can see it beginning with the luxury vehicles already.
- 9-02-2015** **Newbie Observations.** It isn't often I get to interact with Prius owners anymore. Letting the less new answer the new owners questions is beneficial for both. So, unless confusion emerges from lack of information, I just lurk. Today, that silence was broken. A discussion about when the engine shuts off and why got rather messy. It was time to step in. And I did, with this: There are 2 electric-only modes. STEALTH mode is what we got way back when Prius was first rolled out, it's a fundamental part of the hybrid system. The engine automatically shuts off when the power from it is not needed, relying exclusively on the battery & motor from that point. EV mode is what came later, but instead you get a button to engage it. The difference is it trades off speed for power. You'll discover climbing a hill is much easier; however, you cannot go as fast. With the plug-in model, since more battery is available, the EV mode offers both more power and faster speed. You still have STEALTH mode too, same behavior as with the other Prius models.
- 9-03-2015** **Modern.** The upcoming new look of Prius sure has stirred a lot of style posting. I get a kick out of how people back themselves into a corner without even realizing, then sometimes step out with the greatest of ease. Sometimes, all you have to do is point out what they did. That's happening a lot with visual appeal. The mindset is "a car must look like this", so why ever change. Working in the computer industry and having to design & support user-interfaces, you learn quickly that people typically have no idea what options are available to them and that designs of the past were due to limitations which no longer exist. Once they realize flexibility is at their discretion, new opportunities suddenly open up. I've experienced that firsthand many times over my 2.5 decades of design for my career. Seeing the same happen with the automotive industry is quite refreshing. Anywho, here's what I chimed in with into the online discussion: It's 2016 model year, time to abandon the shape & look of cars that has been shared since the 90's. After all, these new models will be on the road in the 20's. Think of how quaint it is to not have the screen on the dashboard and a fob in your pocket. Some of us have moved on years ago. Many more may be waiting for the opportunity. In other words, the thought of "*modern*" is changing.

9-04-2015 **Remembering The Past.** How much detail is actually important? Will anyone care that Toyota stopped production early to avoid having leftover inventory as the product-cycle end approached? Will anyone care that GM got stuck having to clear out their leftover inventory at incredible price reductions because they didn't? Will anyone remember the spin & rhetoric as a result of those business choices? Those are the final glimpses of questions related to the generational end. What about remembering the beginning? What about those original goals? Long story short, we encountered a lot of problems with the first-generation rollout. It had nothing to do with the technology either. It all came down to audience. Who the heck were those vehicles for? The intention for Volt was to be a "*game changer*", to crush Prius with sales so strong it would become a mainstream seller by the third year of sales. That didn't even come close to happening? Will anyone remember? For that matter, will anyone care? That failure taught us a valuable lesson. A symbol of change does not mean change. It became a "*someday I'll get one*" vehicle, rather than be a vehicle people actually purchase. In fact, that distance effect grew so bad, Mitsubishi didn't even bother rolling out its PHEV to the United States. 48 other countries can purchase them, but not us. It's a plug-in hybrid SUV offering a 32-mile range capacity! You'd think in this land of SUV guzzling, that would be an ideal product to sell. Instead, we get nothing here. Fortunately, all the craziness in the market didn't impair EV advancement. Thankfully, Nissan & Tesla have been pushing hard. But cost remains a major barrier. That's why gen-2 rollouts are so important. That's why we need to find out who they are intended for... prior to rollout. So, finding out directly from Volt enthusiasts that Volt will remain a specialty vehicle is an fascinating development. No more undermining like in the past? No more hype about strong sales? No more changing of definitions, arguing semantics, or forgetting goals? I wonder if they'll remember that a year from now when the new Prius sightings become common. Hmm.

9-05-2015 **Similarities.** I'm intrigued to find out what kind of responses I get. This is what I posted the following on the big Prius forum, in a discussion about reasons not to buy a plug-in Prius... Reading through this new thread turned out to be rather inspirational. I hadn't noticed some similarities until now. For example: PHV is a mid-cycle rollout to a limited market. CLASSIC was a mid-cycle rollout to a limited market. PHV calculations are done to see if it will save money. CLASSIC calculations were done to see if it would save money. PHV comments about how its design are based on assumption & observation and are often wrong. CLASSIC comments about how its design were based on assumption & observation and are often wrong. People didn't know what a hybrid was back then and most don't know what a plug-in hybrid is now either. That makes me feel like we're starting all over again, which is great. I recognize the potential. It's a new audience, new market, and there's lot of new opportunity.

- 9-06-2015 Delay.** The expectation was that we'd be seeing the new Volt being sold nationwide soon. Instead, the word is that only select states will get them for the first few months. You can imagine the stir that news has caused. I posted my thoughts on that this way: Searching online, the current inventory is listed as 2,634. That's 2 months sales, based upon heavily discounted prices in August to clear out what's left. As the calendar advances, that rate will become increasingly difficult to match. Other automakers march on. Obviously, Toyota will be stirring the pot with Prius. BMW just announced their entire fleet will add a plug in some fashion, they even just announced 2 new plug-in hybrids on the way. Mitsubishi Outlander plug-in hybrid has been selling well outside the United States, which means we'll eventually get it here too. And of course, there's a variety of EV choices. GM's decision to delay prior to sales beginning will bring some interesting spin. Whatever the case, we things can happen beyond the automakers control. We also know the market still isn't ready... especially with gas so cheap. Heck, I saw it at \$2.22 today. Ugh. The problem with Volt the first time around was lack of clarity. There were so many mixed messages, the chaos was a challenge to document. Though, it isn't difficult to remember certain goals being missed and weak sales. The original goals were set so it could become a high-volume profitable seller. This next-generation didn't focus on them. Why? We've been told production for the first year has been set to just 25,000. That's well below the mainstream minimum of 5,000 per month and pales in comparison to sales of other GM cars. In other words, even without any delay, what difference will it make? More is needed. The technology must be spread to make it feasible to sustain the business. Should hope for change come from Malibu hybrid instead?
- 9-06-2015 BMW 225xe and 330e.** There are two plug-in hybrids coming from BMW. The name of the same is "*eDrive*". 225xe will use a 3-cylinder, 1.5 liter, 134 horsepower engine connected to a six-speed automatic transmission for front-wheel drive. It will include a 87 horsepower electric motor powered by a 7.7 kWh battery-pack connected to the rear wheels. Apparently, this is what Dodge set out to build 15 years ago, but ended up giving up. Through the road connectivity is rather complicated. But then again, the technology nowadays is much better and there is a certain desperation to actually deliver. 330e uses a larger 4-cylinder, turbocharged, 2.0 liter engine that delivers 181 horsepower. It will also send power to both the front & rear wheels. The electric motor is the same, but the battery is 7.6 kWh instead. 25 miles of EV range is the expectation for both vehicles. Price has not been announced yet.

9-08-2015 **The Reveal.** Toyota finally showed us the new Prius. It's a standout, very much like we had anticipated. We've heard lots of "ugly" comments already. But now there's this growing sense of they-will-sell-a-ton-of-them-anyway feeling coming from the outspoken anti-Prius crowd. I find it very appealing, especially the red color of the reveal model. The point is to draw in new buyers. That makes styling important. Heck, we have already seen how the recast of Corolla worked in its favor. Claims were made that Prius screamed "*I'm green*" and that's exclusively why people bought it. (Remember, those claiming that were also disputing the efficiency.) We know owners aren't that vain, that the practical nature of it being the only midsize hatchback back then was a major draw... as well as the efficiency & emission benefits. Irony is to now capitalize on that very premise. Why not? This evening's photos & video show Toyota is doing exactly that. What gets me is how people say they want a "*normal*" looking car but have a strong sense of fascination when new car styles are shown. What do they expect to fall in love with? Do they want something unique or something that resembles what everyone is already driving? What does "*normal*" actually mean? Those are mutually exclusive qualities. The beautiful super-model is not a normal-looking person. Of course, neither is someone ugly. You either stand out in a crowd or you don't. You can't have both. Needless to say, getting noticed is the choice that has been made. That's interesting, since virtually every other high-efficiency mainstream offering (including Volt now) has chosen to blend in instead. The exception is Leaf... which is still selling quite well, despite the model at the end of its product-cycle. Time will tell. I really like what I got to see tonight. More to come as the rollout itself approaches early next year...

9-09-2015 **Speculation.** Even though expectations for change were set, I suspect many followers of Prius could speculate this way: "*The fact that they announced nothing in terms of specifics leads me to believe that they are having a very hard time meeting the numbers they have touted of 10% efficiency improvements.*" It's more fallout damage from Volt. Ugh. The campaign to make MPG more important than anything else should have made that quite predictable. Some people just don't pay attention though. They don't notice. Other detail just slips by. Hopefully, my response will be found helpful: That requires an assumption that Toyota is marketing this generation of Prius to the same consumers as in the past, ones who deemed efficiency among their highest priorities. We've clearly been told that isn't the case. Attention won't be on MPG anymore. Read the quotes. "*Prius set the global benchmark for hybrids, but now is breaking its own boundaries with more engaging style and fun-to-drive dynamics.*" & "*What was once a rational purchase that for many customers focused on fuel economy, is now so much more. This Prius will invite new drivers into the category by delivering an impressive look and feel, built on the foundation of safety and eco-consciousness that define the vehicle's heritage.*" This new Prius is intended to draw a new audience, expanding even further into the mainstream. The technology is so well proven and so well known as this point, focus has shifted to other aspects of ownership. Those buyers simply don't care about the detail you've grown to expect in the past. They won't care if it's 9, 10, or even 11 percent. All they'll want to know is that the motors, engine, and battery have all been improved. The other part is just ordinary business. The reveal is just first step down a long road to attract customers. It makes no sense telling everything all at once when there are many major autoshows to come still. Why not build up anticipation each step of the way?

- 9-09-2015** **Waste of Time.** I originally joined that daily blog, all those years ago, looking for an ally and helping to end the spread of misconceptions. Today, I decided there's no sense even bothering. There was a clear effort there to create new material for undermining. I was actually rather stunned to see that. It was sad. The post that caught my attention was a reference using vague data. I knew it had been cherry-picked from the second-generation model. No one else would though. The part which got me was the claim that the fourth-generation would work the same way. I know the third doesn't even do that. Unfortunately, no one else would know that either. It was pure desperation on his part. He hoped to attract attention. Discussions have dwindled. That venue has shrunk down to just a small number of enthusiasts. It's just a waste of time... hence not even wanting to mention specifics. The same topics can be found on other websites.
- 9-10-2015** **Moved On.** I was fascinated. Watching the same old rhetoric tried all over again didn't interest anyone. Arguments that were clearly a desperate attempt to mislead fell on deaf ears, this time. These blogs are filled with examples of that nonsense, so it isn't even worth the bother repeating them. We've moved on. Watching the final remaining enthusiasts go down without a fight is worth the time, but not enough to post. Curiosity about what excuses would be reused is difficult to resist. Who's going to bother to listen at this point though? I simply wanted to see what would happen. After all, we've seen promised fall apart before. This was no different... hence being so cryptic. The technology in Prius is extremely well proven. 15 years later (since rollout here) everyone knows its reliable. Generational improvements made it more appealing. It's much easier now to take the purchase into serious consideration. What else needs to be said? The antagonists have certainly run out of ideas.
- 9-11-2015** **Choice.** It's easy to see Nissan has moved on. They just announced another model of Leaf will be available in May next year. This one will include a battery upgrade, as well as a range increase. The electrodes have been improved and the chemistry revised. That's the incremental progress we've come to expect from EV offerings. What's not is that the original will still be available. Not everyone will need or even want to pay for that extra 23 miles or be interested in the battery change. The key is having a choice. It's a good move on Nissan's part. As Leaf ages, shifting to a next-generation can be challenging... as we're seeing play out with GM right now. Toyota introduced their variety along the way too. New features in Prius could be found in their other hybrids first. That's how we figured the two-stage PSD would end up in Prius. It was in Camry already and had proven to be a worthy upgrade. Anywho, the market is adjusting. Inflexibility can be a problem on the commercial scale. It's nice to see that isn't a problem when it comes to the utilization of motors, batteries, and electricity.

- 9-11-2015** **The Plan.** You gotta like it when goal-posts are moved... *"That WAS the original plan."* ...but there is no new plan. How many times must it be asked for? Certain individuals leading the rest of the enthusiasts really don't have a clue. You'll get something, then contradictory statements will follow. It's a dead giveaway that trouble awaits. No clear message of intent is a recipe for failure. What should we be expecting? I replied with: The expectation was ordinary distribution, just like any other vehicle from GM, so strong sales would occur right way. Enthusiasts even boasted that those sales would be even better than the second-generation Prius... which were so good, the industry was taken by surprise. It's obvious that Volt is stuck in the middle. GM needs to rethink approach. It cannot compete with the small-capacity plug-in hybrids, which have the advantage of size & cost. It cannot compete with the EVs striving to reach mainstream consumers, which have the advantage of covering an entire day's travel with a single charge. How will the new Volt be promoted and to who?
- 9-11-2015** **The Surprise.** Ugh. Watching this Volt fall apart is amazing. No one really thought the same mistakes would be repeated. Or would they: *"This roll-out schedule of the 2016 Volt is not a whole lot different than it was in 2011, so why is everyone surprised?"* I was beside myself reading that. For years, we had been told this new Volt would be different. Now, those same people are surprised we would ever believe such nonsense. This is yet another sign of trouble to come. My response was: The expectation was set that the next Volt would be different, that it would break away from being a niche. Instead, it continues on as vehicle set apart from mainstream offerings. There are countless posts on this website telling that. We heard that same message for years. Just wait for gen-2. What is the point if we just continue to watch GM's other vehicles overwhelm Volt sales numbers? Should the focus be set on popular sellers getting Volt tech instead, like Malibu?
- 9-11-2015** **The Niche.** There's a growing hate for the word niche. That's because there's no semantics to argue this time. The count is quite clear. No label will change that. What amazes me is the denial. The enthusiasts act as if none of this has ever been discussed before, that the numbers are completely made up and arbitrary. Acknowledgement of the same standard having been applied to Prius over a decade ago is impossible. They do everything they can to evade that reality. It's quite amusing, and yet another dead giveaway. I posted: MAINSTREAM has been clearly defined for well over a decade now in this market. It is a minimum of 60,000 annual sales, which averages 5,000 per month. That is why GM chose that as a target rate for Volt to reach by the end of the second year of sales. Many common vehicles (Malibu, Cruze, Equinox, etc) sell at a rate much larger faster than that. NICHE is simply a vehicle selling at a rate well below that. NICHE is also a vehicle requiring a subsidy.

9-11-2015 **The Failure.** Gotta like this obvious desperate effort: "*So based on sales, the Mirai & PiP must be engineering failures.*" It's quite telling when the subject is abruptly changed. But since you invited me to provide a response specifically about Toyota, I will. Mirai is a long-term project, an investment of profit which just entered the next stage in development... specifically: infrastructure. By getting a small number on the road, focus on fuel improvements can take place. At the same time, the technology can continue to be refined. And since we all know FCV and EV are not mutually exclusive, that they will co-exist, it makes sense to use profit for that now rather wonder if funding will be available later. PiP is a package-upgrade, rolled out as a mid-cycle release to a limited market. There was not a goal to make it a mainstream seller. With the next-generation Prius on the way, which shares the same profitable platform, simply waiting has proven a better business choice. After all, it is quite clear the market isn't quite ready for plug-in hybrids anyway. As for that platform, the center-of-gravity of the hybrid-system was lowered, the weight of the vehicle dropped by 200 pounds, and the suspension system refined. Thermal-efficiency of the engine was refined as well. With respect to Prius in general, it is no longer held back by patents. They recently expired. How NiMH can be used is no longer restricted. As a result, the battery-pack is now smaller and more dense... allowing it to fit underneath the rear seat. In other words, it will be able to reach out to a wider audience at a competitive cost. The package-upgrade known as PiP will take advantage of cost-reduction from high-volume production of the platform and high-demand for the regular model providing opportunity to expand.

9-11-2015 **The Disruption.** My favorite example of disrupting the status quo is when Ford rolled out C-Max Energi. Some people on the big GM forum completely lost it. There was now another plug-in hybrid offering less than half the range-capacity of Volt. The fear of diluting Volt's heavily promoted "*40 mile*" necessity (range-anxiety campaign) was in jeopardy, so some lashed out to stop the posts anyway they could. Same thing we're seeing emerge here now... use misleading info, make it personal, change the topic, deny previous goals, etc. Ultimately, the person attempting to encourage taking the next step would get labeled as a Prius supporter and the group would return to the status quo. Now, with the advent of Gen-2 rollouts, that's happening again. Trouble is, business success requires looking at how Prius was able to attract consumers. That cannot just be ignored, especially since conditions have changed. Mitsubishi has had success with their plug-in hybrid, adding to variety of configurations on the market. BMW has had success with their range-extender, using the approach GM originally pursued for Volt. Toyota will be upping the ante with an upgrade to their plug-in hybrid offering. Combined with EV popularity and low gas prices, getting some type of coherent message out to consumer is a major challenge. What is that message for Volt now? The idea of leaving it as a niche and focusing on making an affordable choice for the masses from some other vehicle seems to be the theme, specifically, to offer a model of Malibu hybrid with a plug instead. However, the thought of Volt not getting as much attention as a result really rubs certain individuals the wrong way. Placing blame on anyone who makes reference to Prius is somehow suppose to make the situation better. Whatever. Change is coming. The choice is to either participate now or react afterward.

- 9-11-2015 *The System.*** Amongst the pointless, we do get some constructive points across: "*Toyota built a system that could be extended to a PHEV with minimal effort.*" That's a statement the stubborn don't want to acknowledge. Technically, GM built an adaptable system too. So should the need arise, with minimal effort, GM could exploit that with Volt. Although the system is expensive and inefficient, the battery-capacity could easily be reduced. The resulting weight-reduction would help improve efficiency as well as increase interior space. The lower production-cost could give it a chance to compete. The new look could attract more conventional buyers. After all, let's not overlook what's hidden in plain view. This new Volt was made to blend in, to look much like any other common car. In fact, the new exterior is so mainstream, it closely resembles a very popular we're all quite familiar with: Civic. (It also looks remarkably similar to a Kia Forte.) In other words, if things go especially sour later, GM does still have an option available for Volt.
- 9-11-2015 *The Shortcomings.*** Being unreceptive and knowing the end is coming, there's no reason not to stay on the soapbox: Back when Honda rolled out Insight, they knew it was too small and too expensive to become a competitor of any sort. Only 2 seats wasn't realistic. An all-aluminum body wasn't realistic. Yet, they continued on anyway knowing the lesson it could teach would be valuable. This group here had that same attitude about gen-1 Volt. They absolutely insisted we wait patiently for gen-2 Volt to address the shortcomings that were revealed & confirmed along the way. GM didn't address them though. 50 MPG. More leg & head room in back. MSRP below \$30k. All of them remain shortcomings, goals requested but not fulfilled. Instead, range & power were increased. For who? That wasn't the lesson taught. Volt is still too small and too expensive. Why?
- 9-11-2015 *The Reality.*** The stubborn and thoughtless replies kept coming, so I continued to let them have it: Reality is, the system in Volt was derived from Two-Mode. There's a blog on this website explaining the evolution in great detail. We even saw prototypes of that system with a plug, before Volt. GM has been working on high-efficiency design for much longer than you want to admit. As for cost-reduction, the simple choice GM decided against was to keep EV capacity as is. The resulting smaller battery-pack would have delivered a vehicle with a higher efficiency (due to less weight) and increased interior space, as well as reduced cost. Instead, we are getting a gen-2 that will allow Malibu, Cruze, and Equinox sales to continue to dominate for years to come.

- 9-11-2015 **The End.**** It's rather captivating to watch things fall apart. That's mostly because so much of it was predicted, shared, and denied. You cannot help but to wonder how they'll respond later. After realizing the same mistake were repeated, it will be a difficult situation. Or will it? Whatever the case, expectations were not met. The rest of us could see it coming. Oh well. It's not as if the wasn't a major effort to point out the concerns. Now, it's just pointing out the unanswered questions and summing up: That's horrible. A bunch of gassers? What about the future? Where is their leadership? Their vision? Who is the market? Typical. Do whatever it takes to avoid real-world data. Reality is, consumers won't have a clue nor will they care. They'll focus on facts... like price, size, and MPG. Prius is competitively priced, offers midsize seating with a large cargo area, and delivers MPG well above other hybrids. And reality is, looking at the entire fleet, that saves far more gas overall than Volt. Dismiss, ignore, insult all you like, but it won't change the reality that mine is currently delivering 111 MPG (average as of 512 miles). Leadership is finding a way to reach ordinary consumers. That's the future, their vision, and the market. Volt can continue being a specialty vehicle, targeted at EV buyers instead. That is GM's choice. Many had expected gen-2 to be different.
- 9-14-2015 **VW Plug-In Announcement.**** This is a rather unexpected twist. VW just announced that they'd be delivering 20 plug-in vehicles by 2020. Amusingly, I took that literally as just 20 total, not the count of models. Knowing that their hybrid went nowhere, adding a plug makes sense. It wasn't too much of a surprise that Jetta hybrid was almost dead upon arrival. Delivering 170 hp, the expectation was never for it to be competitive with Prius on term of MPG... which meant their own diesel sales wouldn't be harmed either, especially with a price of close of \$2,000 more. Also, note that it requires premium gas. As for the announcement, very little was actually revealed. That makes you wonder how they'll actually meet such a short schedule. Most likely, there is something close to production, beyond the concepts they've been toying with. After all, plugging in has been growing as an appeal factor. People are beginning to understand how that can help hybrids. Obviously, there will be a few EVs coming. VW already has that option for Golf. No detail is my concern. Vague has always been a problem. Cost is the other big issue. None of whatever is on the way will be affordable. That takes generations of refinements to achieve competitive pricing... just ask GM. Regardless, it is an endorsement for plugging in. That's a huge step forward away from guzzling gas and dirty diesel. My lifetime average for the 2012 Prius PHV is 72.9 MPG, with just a 4.4 kWh battery. Much potential awaits. Too bad we still have to wait. Nonetheless, it's progress having VW join in.

9-15-2015 **The Lookback.** It's hard to believe the dialog lasted for so long. Many give up after the daily blog has run for a day. We kept at it for a week. I re-read the posts. This is what stood out, worthy of further comment: *"For the Volt community who gave feedback. You know, the customer base. Crazy isn't it?"* Looking back, that's my favorite quote... a response to the who question. It's confirmation of GM not focusing on ordinary consumers for gen-2, coming from one of the most obstinate of enthusiasts no less. Rather than show any concern about showroom sales being lost to popular GM vehicles like Malibu, Cruze, and Equinox, just stay focused solely those already in the group showing support. Abandon hope of market-expansion for the sake of pleasing existing interest. Yes, that is crazy. We've been through RANGE ANXIETY, watching Nissan and Tesla overcome concern. We've been through VASTLY SUPERIOR, watching loyalty vanish as leases expire. We've been through BE PATIENT, watching disappointment as gen-2 details emerge. Wasn't the point to actually sell Volt in large quantity to ordinary consumers, those who would otherwise just purchase a traditional GM vehicle?

9-16-2015 **The Point.** Knowing reveals were on the way at the upcoming autoshow in Frankfurt soon, there was good reason to push. Jumping back into the fire on that daily blog revealed a chaotic mess. There is still no clear purpose for gen-2 Volt. In other words, who will it be marketed to? There's a huge difference between the way you'd go about attracting those considering a traditional car verses trying to appeal to an EV shopper. Yet, the group still hasn't addressed that. Some see Prius as a threat, since supposedly that's who GM targeted... which seems sensible, until you realize they are discussing the regular model, not the plug-in. Huh? Others see the Volt approach as the *"range anxiety"* solution, meaning those specifically interested in purchasing an EV but concerned about range are the target... which seems reckless, knowing that leaves it as a niche, not able to sell profitably in high-volume simply because the audience is too small. A poster summed up the situation this way: *"People don't want to hear things that contradict their beliefs."* That explains the lack of any agreement and wildly confusing messages. Wasn't the point to replace traditional vehicles? We were told Volt would out Prius the Prius. That would require it to share the same goal. It obviously didn't happen with gen-1 and now gen-2 looks the same way. The reason is simple... Frankfurt. More announcements of plug-in offerings were indeed made. In fact, VW declared they'd deliver 20 different plug-in choices by 2020. Pretty much all the automakers have battery plans of some sort now. They all know the instability in the oil prices and increasingly strict emission standards will be increasing the pressure to deliver cleaner more efficient vehicles. That, combined with growing consumer-confidence in the technology, means demand will grow for choices with a battery-pack. It's impossible to ignore now. Change is coming. Wishy-Washy isn't good start for gen-2. That's why Volt is already in a difficult situation. You don't want a limited audience with so many other choices on the way. Prius will be a major player. Next year is going to really exciting.

9-18-2015 **Canada.** We have learned the gen-2 Volt rollout will be nationwide in Canada without any delay. What the heck? Knowing GM's reputation for an ever-changing story and the business-blindness of supporters, I saw this as an chance to get up on the soapbox again: *"I wish the management of GM was as outstanding as the engineers."* It's really unfortunate how long it takes (many years) for some people to realize what the situation truly is. Ugh. I posted: The engineering aspect of Volt simply worked, there was nothing to prove after gen-1 got rolling. So, everyone shifted focus over to the business aspect. That's why the 60K goal ended up getting so much attention. There was not clarity of purpose though. GM didn't really know how to promote Volt. Opportunity was being lost. That's how the animosity for the other plug-in hybrids came about. Now with gen-2, that same feeling of business uncertainty and time slipping away is emerging. It wouldn't be much of a concern if intent was to join in as part of the movement toward plugging in, becoming one of the many choices helping to end the reign of traditional vehicles. We see Toyota, Ford, BMW, and Mitsubishi already making progress with plug-in hybrids. There's Honda and VW striving for that as well. Then on the plug-only side, we've got Nissan and Tesla well ahead of everyone else, with GM intending to become a big player too. That's why the positioning gen-2 Volt keeps getting questioned. What is it? Getting grief on a regular basis for asking how the approach has changed for gen-2 is getting old already. It's pretty clear there's growing frustration and I'm one of those easy to target as a scapegoat. What a waste. Finding clarity of what GM's goals are as early as possible will be greatly beneficial to everyone. Let's focus on that. The EV club I'm part of is very welcoming to anyone providing support for the shift to electricity. Any type of plugging in represents a huge step forward. It doesn't matter how the battery cells are used, just as long as there's success in making the production high-volume. That's where the major cost-reduction comes from. Lowering the price is key. We all know that extremely well. The plug-in hybrids with smaller packs come with a lower premium and don't require anything beyond an ordinary household plug. The plug-only vehicles require a large premium up front and require at least level-2 connection for plugging. So, it tends to make sense that GM made the business decision to position gen-2 Volt right in the middle, striking a balance between the other choices. Reality is though, the market is not that sensible. Purchase decisions (here in the United States, anyway) have been far from logical and in no way balanced. That's how we ended up with so many grossly oversized & overpowered guzzlers on the road. That's also why it is so important to find out what the intent with gen-2 Volt is now, before the market gets really messy when the other gen-2 offerings become available. What is the next step?

9-19-2015 **VW Cheated.** To the amazement of everyone in the automotive industry, we found out yesterday that VW cheated on emission tests. Apparently, special software was added to give false data. No surprise to me, one of the biggest antagonists on the big Prius forum included this tidbit on his post about the topic: *"It's not hybrid news..."* Since he thrives on debate, that was to be expected. I took the bait too, since we're all going to jump in on this new revelation anyway: Quite the opposite, this is huge positive news for hybrids. We were attacked for many years by diesel supporters with claims of how much better the *"clean"* versions would be, making hybrids a pointless technology. But as ULSD (Ultra Low Sulfur Diesel) rollout approached (required for *"clean"* diesel systems), the hybrid supporters noticed something was amiss with VW. There was a massive over-supply of 2006 models, enough to last well into sales the following year. This is my favorite quote from back then: *"The Detroit Free Press reports that Volkswagen of America will drop the diesel versions of the Jetta, Golf and Beetle models from its USA line-up for the 2007 model year due to their inability to meet the new, incoming stricter emissions standards nationwide."* When the newer diesels finally did roll out, the MPG wasn't as good as hoped. However, VW was somehow able to deliver *"clean"* without having used urea for emission cleansing. Hybrid supporters were surprised by that, but too busy dealing with misleading MPG claims to follow up. They saw reports on a regular basis that were blatant greenwashing attempts. It was dishonest and nasty. Now, all these years later, we find out VW never actually delivered what they claimed and owners of those *"clean"* diesels face the possibility of reduced MPG and reduced resale value. This is an amazing new twist in automotive history. The next round of emission regulations are on the way and one of the biggest opponents to hybrids cannot even meet the current level of clean required. It explains that strangely cryptic announcement from VW the other day. They provided a strong endorsement for plug-in vehicles, declaring they'd deliver 20 by 2020 but didn't include any detail. The vague nature of such a bold new approach for them seemed odd... especially since we've heard so little about the current VW hybrid. Now, for anyone who was suspicious about such an abrupt turn of attitude, there good reason to understand why.

9-22-2015 **Clean Diesel.** The response online has been explosive. VW is in a world of hurt now and there are lots of opinions about the situation. I decided to follow-up with more of my own: We had to endure *"clean"* diesel spin for years. They knew gas hybrids offered greater potential, yet the rhetoric continues on anyway. Sadly, some has continued on even after being exposed for not being as clean as claimed. We knew that the *"clean"* claim was misleading right from the start. That simply meant it met minimum requirements. Exceeding them, as the SULEV & PHEV rating indicate, was certainly not what *"clean"* diesel delivered. It basically just made diesel vehicles like ordinary gas vehicles. No one imagined the *"clean"* level wasn't achieved either. What we want is significant improvement. Watching Toyota push into new territory with gen-4 Prius should serve as inspiration for others, not result in more undermining. That potential should be obvious. Adding a plug to Prius pushes it far beyond what diesel could aspire to. Even with the current 4.4 kWh battery-pack, there's no match with either efficiency or emissions... not even close. Put simply, diesel shouldn't be used for passenger vehicles anymore, just like our effort with hybrids to end the production of traditional vehicles. Offering viable hybrids is the key. Keeping our air clean and relying less on oil is a big deal. Having learned there are some who don't share those values and caused harm on an epic scale should help us all take that next step.

- 9-22-2015** **11 Million.** As I was busy typing the previous entry, news broke about VW outside of the United States. Until now, we only knew about the problem here and some vehicles in Australia. The big unknown was about Europe. Diesel is far more common there and Germany is the home of VW. Did the cheat take place there too? Turns out, the answer is yes. The true number is uncertain, but the potential is for another 10.5 million. Ouch! How could any automaker deal with such a massive problem? There is no easy fix. Retrofitting a vehicle for urea treatment of emissions is complicated & expensive. Owners won't like the loss of some truck space either. The engine will almost certainly need to be retuned too. To make matters worse, there are owners who collected tax-credit money for their diesel vehicle purchase. How is that going to get paid back? Stock value as dropped about one-third so far. People are losing confidence. What a mess.
- 9-23-2015** **Upcoming Models.** Details are flooding in about the new Prius. All the information is from other markets though. Some isn't accurate either. Nonetheless, it is still telling to review what's collected and get feedback. Supposedly, there will be a regular model, an ECO model, and an AWD model. Currently, the regular model gets a rating of 32.6 km/L on the Japanese testing. Results come out more efficient than here, since the driving is so different. Regardless, it still gives you a relatively good idea of improvements on the way. We can consider the gen-4 a success simply by looking at the estimate for it on that same scale of 37 km/L. That's certainly more than a 10 percent increase in efficiency. The ECO model is expected to deliver 40 km/L. Cool! For the AWD model, the expectation is 35 km/L. We don't know how that will translate to EPA measurements, how much it will cost, or even how it will be achieved. It's still exciting though. We hoped for the best and it looks like that is what we'll actually get.
- 9-25-2015** **Crazy Days.** Details leaking out about several new models of Prius liftback on the way combined with the fallout of diesel is fascinating... and somewhat crazy. The CEO of VW stepped down. Several class-action lawsuits have been filed. EPA has announced plans to road-test (rather than just dyno-test) vehicles subject to question. That's all quite big. But what gets me is that several people have told me their interpretation of what's happening with VW. Each report comes from sources attempting to downplay the situation. Reality is, the automaker can't fix the problem. Even if reputation is restored back to where it was for gas vehicles sales, the damage is already done. Those diesel vehicles sold since 2009 either need hardware retro-fitted on the car to treat emissions leaving the engine or software to manipulate the engine to operate cleaner. The latter will sacrifice efficiency, which most owners won't want to accept. That leaves only the option of adding equipment the vehicle should have had in the first place. Ugh. That effort (time & expense) boggles the mind. Advocates of diesel will have a hard time dealing with so many disenfranchised owners, who will now take a close look at the other high-efficiency, low-emission choices available. So, regardless of the effort to make the public at large feel comfortable with VW again, it's too late for those directly impacted by this mess. Who would have ever thought things would play out this way... and in just a matter of days? Crazy indeed.

- 9-27-2015** **Hydrogen Attacks.** An extremely popular way of distracting is to bring up the topic of hydrogen. It tends to rather effectively undermine discussions. The choice is to ignore the antagonist and hope for the best or to address them very directly. None of the casual responses make any difference, since their goal is to prevent the topic at hand from progressing. They'll just keep at it. Interjecting new information into their argument tends to do the trick. It's difficult to evade facts without revealing intent. So, I gave it a try after having read some vague claim about efficiency conversion: How outdated is that loss data and where exactly will that electricity be stored prior to reaching the vehicle? I find it amazing how many people think the grid can just hold all the electricity we need indefinitely. It provides transport, not storage. Reality is, the sun only shines and the wind only blows at limited times. The energy captured must somehow be stored until it is needed. Hydrogen provides a means of doing that.
- 9-27-2015** **Count of Six.** This particular comment caught my attention: "*Audi is the 6th car maker to say they will make a 200+ mile BEV by the end of 2018.*" With the diesel fallout and the rapid increase of downplay, the topic variety in forums has rapidly expanded. We're seeing a look more of the old rhetoric return... without any new twists. It's basically the same arguments re-emerging. I don't expect much of that to last though. Their facts are so weak at this point, there's not much to bait for trolling attempts anymore. We are definitely in a state of change. VW prompted those hesitating to take the next move. Hopefully, that will equate to opportunity. I worry about token gestures, where big announcements are made but very little actually delivered. Here's what I had to say: From all the lessons learned over the years, that's a trap none of us should be gullible enough to fall into anymore. We've seen many, many token gestures. Sure, the automaker delivered, but what's the point if the vehicle isn't something people actually buy? GM had the 2 biggest disappointments, both were heavy hyped and neither panned out. Two-Mode was supposed to change the industry. Instead, it wasn't anywhere near as good as promised and it was very expensive. Volt ended up the same way. They were promoted as technology for the masses though. What will these 200+ mile EVs be like? If they're small and expensive, who's going to be interested? Sure, it's nice having the choice, but the expectation of them attracting ordinary car buyers will go unfulfilled.
- 9-27-2015** **Upgrade Plans.** It's interesting to hear thoughts of other Prius owners, some with an older non-plug Prius and some with a PHV already. They're considering their purchase criteria, before details are unveiled. That makes you really think about what's important. I jumped into the discussion thread with: My 2012 Prius PHV has been great. The 73.0 MPG overall average over the past 3.5 years (64,000 miles) speaks for itself, especially driving here in Minnesota. This weekend included a 176-mile drive. With 80% of the plug-in capacity still available, the average was 62 MPG (displayed). So, it holds it's own without even needing to plug in. That makes looking forward to the gen-4 improvements even more enticing. It already outperforms what the so-called "*clean*" diesels deliver. Errand running is great. We live only a few miles from grocery, hardware, and retail shopping, as well as recreation & entertainment. So, that's usually done entirely using electricity (during the warm months) already. Increased capacity isn't really necessary, though it could come in handy and there's an obvious benefit for other travel. The plan is to upgrade right away, when deliveries begin next year. I'm looking forward to refinements in the technology. Each of the other 3 upgrades over the years were certainly worth it. The plug adds a dimension to the already practical Prius platform.

9-28-2015 **Change.** We're seeing the downplay, rhetoric, and trolling really ramp up. That's a sure sign of change. Recent posts provide a very interesting read. They're all over the place. VW troubles continue to grow. Emission standards and testing methods are being updated. Tesla sales of its Model X are about to begin. More information about Prius has been found. Each is pushing discussions in different directions. Heck, even within individual communities (forums) we're seeing the dialog change. For Prius, that's just part of the generational shift, which is what you'd expect from any major upgrade. EV discussions are no where near that clear. Some say the 100-mile range fulfills most owners needs. Others say the upcoming 200-mile range offerings will be absolutely vital. It's polarizing in nature, much like the contradicting messages from those in support of Volt. Interestingly, emissions are getting more attention. The diesel fallout is helping with that. Sadly though, it likely won't change attitudes of ordinary consumers. All the mindset alterations are coming from those already haven't taken a step toward a cleaner environment. Nonetheless, it is progress. Breaking away from the status quo, by any means, is welcome.

9-28-2015 **Single-Minded.** That's one of the biggest challenges to overcome. We saw that in the past with Volt and we are seeing it a lot now with EV verses FCV. There's no reason electric-only vehicles and fuel-cell vehicles should be competing against each other. But with the mindset we've been taught to have, falling into that "*one-size-fits-all*" trap is surprisingly easy. I had to sound off about that yet again: How many times must CO-EXIST be mentioned before it is finally accepted that this isn't an either/or situation?

One solution will not fix all. We grew up in a society that worked hard for single solutions. It was always thought of as one technology replacing another. The duality of our future isn't going to come easy because of that. Fortunately, we are seeing glimpses of hope. Look at the computer market now. There's a wide variety of ways to interact with the digital world and it's for the most part working just fine. People have come to accept differences, rather than fight for just one approach. Transportation will have a similar outcome. The other choice won't be looked upon as an alternative, like some fuels are now. It will simply be the norm. Some people will have this. Others will have that. No big deal. Remember the goals, all of them. We are not simply replacing transportation technologies with the intent of using the least amount of electricity possible. After all, it is renewable. There is a pressing need to also reduce overall emissions, while at the same time not cause economies to fall apart.

9-29-2015 **Investments & Tokens.** Anger at Toyota for not announcing an EV right away is really stirring the pot. Other automakers can make a token gesture, just vaguely stake intentions to deliver one at some point, and all is fine with them. No commitment of any sort is needed, only an "we're in too" claim. That complete lack of obligation shouldn't be acceptable. There should be a goal spelled out... how many, for who, and when. That's why Toyota is focusing on the hybrid offerings first. We know the new Prius is coming nationwide within the next few months and will be targeted at the masses. What follows is anyone's guess. It could still be right on par with those other automakers making uncertain promises too. In other words, to some, diversity doesn't matter. All some care about is EV offerings now. That impatience and nothing-else-is-important attitude is really becoming a problem. Toyota is investing in hydrogen fuel-cells, for the long-term. Antagonists spin that as a "token" effort though, which clearly doesn't fit the definition of what token identified in the past. It would have to be at minimal cost with no plans to further advance the technology to qualify for that. Unfortunately, they see it as a big step in the wrong direction. It's that single-minded approach. Diversification is meaningless to them. Even though fuel-cell vehicles also use batteries and electric-motors, some just plain don't care. They want EV offerings as soon as possible, regardless of cost. How is rushing helpful? Know your audience. Ordinary consumers will just dismiss them as expensive toys for the rich. Gas is so cheap now, why would they even bother to consider an EV anyway?

9-29-2015 **New Thrills.** Certain individuals gobble up new opportunity for online discussion. Now is the time they are especially thrilled. With the diesel mess and fuel-cell advancements getting attention, it's fair game for them. Unfortunately, they don't play fairly. Today, it was: *"This is not fraud, it simply is another misleading fuel-cell statement."* I was annoyed and didn't want to let that go. So, I didn't: Notice the source of some misleading? The original post established an assumption, portraying an exception as if it was the norm. How many people read the statement and completely overlooked that? Here it is again: *"Toyota, Mercedes, and Hyundai claimed 1 minute of refuel time for each kilogram of hydrogen pumped into the FCV's tanks. So a 5 kilogram tank requires 5 minutes. In reality real-world drivers say it takes 4 minutes per kilogram. That means the Mirai's real-world refuel time is closer to 20 minutes..."* Notice it this time? Under all but extreme circumstances would an owner ever drive into a filling station with their tank 100% empty. The normal refill quantity would be around 75%. So, it wouldn't take as long to reach 100% capacity. They start with 25% still in the tank. Yet, that vital bit of info was not included. In other words, some people take advantage of vague statements and turn them into misleading expectations. Also, it would be absurd to assume the newest fuel-cell vehicles would settle for old refilling hardware. Yet, that's exactly what the poster hopes we'll do. Combine that with lack of clarity from automakers, you end up successfully misleading.

- 9-30-2015** **Rants.** Some of the rants against fuel-cells are already getting quite amusing. The one-size-fits-all portrayal share the same signs of desperation the Volt enthusiasts had back when gen-1 was all the rage. The technology-will-never-advance portrayal is just plain sad. It reminds me of the battery claims back when Prius was still new to most people. The rhetoric doesn't take timeline or impact into consideration either. Long-term projects should not be judged using short-term expectations. There's an extremely well established oil-industry that will fight back too. Thinking you'll be able to just tell them to take a hike goes well beyond naïve. Hydrogen will serve consumers that EV won't. The oil industry isn't going to miss out on the opportunity to take advantage of their transport, manufacturing, and distribution resources to capitalize on the new fuel as complications with their current endeavors grow. The abrupt fall of diesel passenger vehicles is a rather obvious example of unanticipated change with impact on a magnitude never imagined. More will come. That will show how EV alone is not the solution.
- 9-30-2015** **The Truth, part 1.** We're seeing an upswing on the attacks. A well known diesel support is quite upset and is now lashing out any way he can. His choice is to attach Toyota's fuel-cell advancement. This snippet really got me: "*...and you can't handle the truth.*" He was going on and on about tank refill time. It was obviously a desperate effort. But it was still enough to make you think about how to respond. What should the expectations be? How should they be set? Who should be setting them? I replied with: If a phonemaker sells you phone able to recharge in X minutes, but you don't have a high-speed recharger, what's the problem? If an automaker sells you a vehicle able to refill in X minutes, but you don't have a high-speed pump, what's the problem? Sounds more like denial of the true situation.
- 10-01-2015** **The Truth, part 2.** It took me a bit to come up with some analogy material, really good examples that would bring this particular rant to an end. Turns out, it was quite effective. He still hadn't responded after a day to this: What happens when you plug a USB 3.0 device into a USB 2.0 slot? What happens when you connect an AC wireless device to a N router? Slow performance from those devices isn't fault of the device manufacturer. It's not fraud, it's the need for good labeling and properly informed consumers.
- 10-01-2015** **Lawsuits.** We hearing about class-action lawsuits being filed on behalf of TDI owners. The legal action is to go after VW, to somehow help those diesel owners with the predicament they are now stuck in. It's really strange not knowing what they will be seeking. Online pop-up advertisements list details of the situation, but what to expect as an outcome is a bit of a mystery. There must be some filing deadline. With so much uncertainty and so many affected, the scramble is understandable. What can be done is anyone's guess. Clearly, this will cost VW far more than they are willing to spend. So, it does make sense that legal battles are being prepared. As an owner, I would simply want to continue driving the car I purchased operating the way it was delivered. Those after-the-fact alterations were never anything an owner would ever consider, especially knowing they will reduce efficiency to some degree. What an ugly situation.

- 10-03-2015** **Better.** The attitudes of those few antagonists we routinely battle on the big Prius forum are getting better. Today, it was: *"Of course hybrids will be part of the answer. But since they seem to max out under 4% market share, we need a better solution to pick up the slack."* My choice of rebuttal (to point out what better really meant) was: Speaking of making blanket statements... Drawing a conclusion already that hybrids maxed out is premature. Only now are other automakers working to deliver competitive offerings. Their participation is required for serious market expansion to occur. Up until this point, they've been mostly just watching Toyota to see how far the technology can be taken before investing on the grand scale themselves. Sure, anyone can make an expensive hybrid. Making one that is able to compete both in terms of cost, reliability, efficiency, and emissions is an entirely different matter. There's the economic principle of change to acknowledge as well. The general population waits years to purchase new technology devices. That's the way it is. They don't spend their money until the next generation has proven itself. For vehicle purchases, longer use-life and higher price-tag means decades of waiting. They expect product maturity before making a change. In other words, when the automotive industry shines their spotlight on plug-in offerings, it will indicate that hybrids are ready. This is why we thought the Volt enthusiasts as crazy when they expected sales to be competitive just 2 years after rollout began. Coming from a Prius background, we already knew there was a decade wait for it to even be considered a viable purchase choice. Sure, the technology worked, but ordinary consumers simply wouldn't be interested yet. Gen-4 of Prius will be the first to reach out into middle-market, hoping to attract buyers here who would otherwise just purchase a Corolla or Camry. That's a hefty goal, but it's a big step contributing to the shift away from traditional offerings. Reaching out to those buyers is vital, since the cars they purchase is where a bulk of the business-sustaining profit comes from. That's what will pick up the slack, not a better solution. As exciting as the newest technology is, it won't pay the bills. The so-called *"boring"* vehicles do, since they use refined older technology... which is produced in high-volume at low-cost... which makes it better.
- 10-03-2015** **Attack Ads.** We're getting misleading advertisements now. That's not an encouraging sign. From the one titled: "Chevy Volt Battery Technology: Time Capsule", here's a quote: *"This is the 2016 Chevy Volt. It uses state-of-the-art battery technology. The Prius uses battery technology developed 15 years ago."* The lithium-ion battery, which is what Volt uses, was commercially released back in 1991. That's 24 years ago. What else can be said. Newer isn't necessarily better for all applications and they certainly didn't explain why it could be in this case. It was just another older isn't a good attack, in this for of a television advertisement. I wonder what people seeing the commercial will actually think. Will they brainlessly fall for that? Will it result in more sales? Will they even care?

- 10-04-2015 Battery Cost.** Interesting discussions are emerging. Not all are well thought out, but at least there's attention getting directed in the right place. Who knows if it will make any difference. But at least cost are indeed going down, even if they are misrepresented or misunderstood. Here's a little bit of information to that affect: \$145 would be for the cell itself, not the casing, controller, or cooling. You also have to factor in a some amount for profit, since the final packaging obviously won't be sold for cost. \$200 has always been the magic milestone the industry has been shooting for. If that represents final consumer price, not production cost, it would seem that will soon be reached. The catch is, a price-point of that nature makes everything with a battery more competitive. (Remember, the NiMH patents just expired too.) That means ramping up the volume to make them a sustainable product, to break out of the niche. The big question comes down to who the expected buyers will be. The advertisements target those looking for a high-efficiency choice, not loyal GM customers. Conquest sales don't take the automaker to the next step, since their traditional production will continue on unaffected. The goal of replacement remains unfulfilled. Think about how important it is for the product-line to finally shift.
- 10-05-2015 Sonata Plug-In.** The official rating for the upcoming plug-in hybrid from Hyundai was just released. It will have a 27-mile EV capacity. There's a growing consensus that around 25 miles is the target to shot for. Remember how Ford strived for that? Heck, the thought is that Toyota will be too. Prius PHV had an original goal of 20 km. That was delivered precisely. The hope is for double that as a goal for the next: 40 km. That's 24.85 miles. Talking about close. Even the EPA has adopted that measure. 25 miles is now listed as a cost metric in the rating detail. It's a distance which takes full advantage of the capacity without requiring excess. Why pay for what you truly don't need? After all, we're talking plug-in hybrids, not all-electric. The intent is to use a highly-optimized engine. With the "*right size*" capacity, there shouldn't be a space sacrifice or the need for level-2 charging. In other words, this should be another one of the affordable choices that isn't dependent upon tax-credit subsidies. Hopefully, it will sell well.

10-07-2015 **No More.** It's over. There aren't any Volt enthusiasts anymore. Remember, they were those how saw the plug-in hybrid as the ultimate solution. Not only was it "*vastly superior*" in ability, it was also so compelling that high-volume sales would come easy. We had to endure their hype for years. Then when rollout began, the situation turned into disaster. Reality came crashing down so hard, the decision was to give up that fight and wait for the next. Everything would be resolved when the next generation came to be. There was to be a miraculous cost-reduction. They declared the goal of \$10,000 less achieved. That would have indeed made it a game-changer. Instead, we're hearing it turned out to be just \$3,500. The most common complaint of seating-room in back wasn't addressed either. Legroom was only increased 0.6 of an inch and headroom was actually decreased by 0.2 of an inch. Range was increased from 38 to 53 miles. The catch is, that sacrificed cost & weight. Turns out, it increases price too. Using an ordinary household sockets requires 13 hours for a full recharge. That means, if you go out anywhere in the evening, there won't be enough time to completely replenish capacity before you leave for work the following morning. Getting home at 10:00 and leaving for work the next morning at 7:30 is only 9.5 hours. You have no choice but to invest in a level-2 charger. Do you have a 220-volt connection available in your garage? Then of course, there's the competition. Volt was supposedly targeted at EV buyers. GM is really ramping up the publicity for Bolt. It will is expected to be available a whole year before Tesla's model 3. As an article on the topic recently stated: "*Volt will struggle to find an audience.*" It drives well and owners will be happy, but there simply isn't a draw. Even the look makes it just blend in. Those high-range EV offering completely overcome the range-anxiety concern. Volt is already trapped in a niche, nice for commuting but too expensive. And since there's no one hyping it up anymore, it's over. No more. We'll just have supporters who are interested in plugging. Rhetoric will still be stirred, but that continuous source of meritless cheering is gone. Yeah!

10-07-2015 **Getting Weird.** With Volt out of the picture and diesel for passenger-car use quickly soured, we are left wondering what comes next. VW has withdrawn their EPA application for 2016 diesel models. They simply won't be any sold here this coming year; instead, there will be massive recall effort. The latest is that some of the vehicles will also require injector replacement, not just emission equipment. Think of what that will do to mechanic work and resell value. What a mess. It's becoming somewhat of a concern too. VW is offering an incentive of \$2,000 to current owners to get them to purchase a 2015. There's a long list of vehicles eligible. The catch is, it excludes the hybrid. What does that tell us? Like Volt, there's the struggle to find an audience. What exactly do they want to sell going forward? With Tesla having made a big splash lately and both diesel along the so-called EREV sunk, it's an interesting new market. When details of the new Prius are finally revealed, we'll be looking at a reset situation. Starting over sure wasn't expected. We'll get to be part of the rollout with a fresh audience. What a great thing to look forward to!

- 10-08-2015** **Spin.** This post speaks for itself: I see a lot of effort being expended to evade the timeline. Those doing that want to draw a conclusion now, based upon work in progress rather than waiting. It's quite telling. The fuel-cell project has long-term goals. Along the way, of course there will be some gains & losses. That's how development on that scale works. You build test vehicles. Takes what's learned from them, then improve. Involving governments & consumers in real-world data-collection is a vital phase. But every time something like that emerges, the antagonists pounce. We've seen the same thing happen with Prius PHV. Consumers were offered the opportunity to join in on the limited-market rollout. We all knew it was a mid-cycle upgrade. We all knew the next would be improved and offered to wider audience. Toyota knew those willing to spend the money right away would be ideal candidates for early purchase. It's quite obvious the data collected from that will go a long way toward reinforcing success of the next. Notice that neither had a large production planned? Unlike Volt, which had a mainstream volume goal set for the second year, these were clearly stated as limited quantity & location. The spin of trying to make them more than they actually are isn't constructive by any means.
- 10-08-2015** **Religious Fights.** Looking back, the whole situation looks quite crazy. I'm amazed at what we had to endure, for no reason. There are a few of us who fought. It was, as many have stated, a religious crusade. The devoted simply would not give up under any circumstances. They stood strongly behind what they believed, even when evidence started to raise question. Who knew it would fall apart like this. I couldn't help but to keep the very active discussion filled with comment: That religion was quite intense. We fought the diesel people for years with their cherry-picked data. It never made any sense. Their technology barely passed emission regulation minimums (which now we find it didn't). Ours was far cleaner, earning a PZEV rating. Ours could also be augmented with electricity to deliver even higher efficiency and lower emissions. Yet, the fight continued on anyway.
- 10-10-2015** **Missing The Point.** It's an on-going problem. Some people focus so intensely on just the facts presented that they simply refuse to acknowledge anything else is important. It's rather maddening at times. They've made up their mind and just plain don't care that something could have been missed. So, the big picture continues to be disregarded. That's sad. Oh well. All you can do is present the information: Toyota's choice to "*right size*" the battery is still a wise one. They didn't sacrifice cost. That meant they could deliver something profitable & affordable without requiring subsidies or upgrades. Then when the technology allowed, they could deliver a larger range. GM did the opposite, gambling that they'd be able to have a competitor right away. It didn't work. Yet, they get credit for having made a better choice anyway. Admitting the challenges to meet still, they set a goal of reducing cost by \$10,000. That didn't work either. The reduction of \$3,500 while improving a variety of things is noteworthy, but still falls short of the need. It's really unfortunate so many continue to disregard need (replacing the fleet) in favor of arguing specific performance statistics. Selling a small number of conquests without changing loyal customer purchases misses the point.

10-10-2015 **Like In School.** If you don't do what was assigned, no matter what you deliver, it will be incomplete. GM thinks it can change the game... quite literally, but giving the "*game changer*" label to Volt. They felt some wants would justify not fulfilling need, since that would supposedly draw much stronger sales. That's what supporters hyped for years, both prior to rollout and following. The approach fell apart though. Sales did not materialize. Instead, it turned into a long struggle to retain attention. After awhile, people stopped caring. Volt has turned into an expensive offering for very few as a result. It works. In fact, both enthusiasts and owners couldn't be happier with that aspect. But since the assignment was to achieve mainstream sales, homework is far from complete... as with the analogy I provided: The assignment was to deliver a high-efficiency, low-emission, profitable vehicle for the masses. No amount of reasoning will earn the homework turned in an "A" grade, since that need remains unfulfilled. In other words, the goal to replace traditional vehicles is how success is measured. The point is to please ordinary consumers, not enthusiasts. The vehicle of change is the one people purchase in large quantity, not one that only wins engineering praise. It makes no difference what words are exchanged here. What happens on the dealer's lot is what counts. That's how the business is sustained. It's why none of the arguments that don't include all aspects of the purchase decision fall apart. Know the audience. Know the goals. Again, what was the assignment?

10-11-2015 **Complexity & Detail.** I particularly liked this perspective: "*People can make a case that the Volt might be lower total cost of ownership than a Prius but the details of that message are way too complex for the average buyer. It involves a discussion of gas prices, electricity prices, EV range, mpg, and driving patterns. Few want to delve into those details. All they see is the price tag.*" Being constructive can be quite a challenge. Then even when you do come up with something informative, the antagonists will just quote you out of context anyway. And sure enough, that's exactly what happened when I replied with this: It's even more complicated than that. Gen-2 owners will have no choice but to purchase a level-2 charger. Overnight is not realistic if you have any kind of life after work with just a level-1. A full recharge with level-1 takes 13 hours. If you have to leave for work by 7:30 AM, you have to make sure to start recharging by 6:30 PM. That means no going out after dinner to have that full EV experience they've been promoting so heavily. The price of a level-2 charger isn't ever included in any of those number spreadsheets. That combined with the cost to add a 240-volt line to your garage for the install isn't ever included either. It's another up-front cost most people are clueless about. So, making that case is really a challenge. And that's just on paper. In person, no matter how nice the driving experience is, the passenger experience is an entirely different matter. Volt is a compact. Prius is a midsize. That difference is quite obvious when sitting in the back seat. Yet, that doesn't get accounted for in ownership cost. That price tag gets ugly when the tax-credits expire too. With the way GM is now promoting Bolt, it's easy to see those credits getting used up long before the product-cycle ends. How will they competitively sell gen-2 Volt profitably and at high-volume without the subsidy? The situation just plain doesn't add up.

- 10-11-2015** **Misses The Point.** Is it worth summarizing at this point? Probably not. Moving on will take far more than just the hope certain outspoken individuals have. It's the quiet crowd this was more for, those many who lurk rather than participate: Toyota's choice to "*right size*" the battery is still a wise one. They didn't sacrifice cost. That meant they could deliver something profitable & affordable without requiring subsidies or upgrades. Then when the technology allows, they could deliver a larger range. GM did the opposite, gambling that they'd be able to have a competitor right away. It didn't work. Yet, they get credit for having made a better choice anyway. Admitting the challenges to meet still, they set a goal of reducing cost by \$10,000. That didn't work either. The reduction of \$3,500 while improving a variety of things is noteworthy, but still falls short of the need. It's really unfortunate so many continue to disregard need (replacing the fleet) in favor of arguing specific performance statistics. Selling a small number of conquests without changing loyal customer purchases misses the point.
- 10-11-2015** **Oh well.** What else can you say? I'm now witnessing the same "*cornered animal*" reaction. It's the behavior an enthusiast exhibits when having lost the fight, at that point when there's nothing else left. They'll lash out anyway they can. It most common comes in the form of a long, well thought out response. Complete with detail, it looks worthy of thoughtful reply. But in reality, it's an elaborate effort to evade. That's all they can do at that point. You've pointed out goals not achieved. They hear "*failure*", even though you never actually say it. What they supported did have the desired results. In other words, it failed. They'll spin & argue as much as possible. That will eventually turn hostile. The attacks will become pitiful & pointless. Going down with a fight is much better than admitting defeat... in their minds, anyway. I don't want to be part of that, yet again. So, I just wandered away with: It has been interesting to watch history repeat with such predictability. You wouldn't expect so well of a match. The same reactions from the same questions, despite different participants & circumstances. Recognizing the pattern means knowing the outcome. So, there's no real reason to continue. You'd think lessons of the past would have more of an influence. Apparently, that's not the case.
- 10-12-2015** **Greenwashing.** We're seeing the same old tactics return, again... Evading business goals. Quoting out of context. Vaguely implying someone else's references are yours. Pretending the market of the past was the same as it is now. Claiming the timeline was planned all along. Contradictions of previous statements. All that is so predictable and so easy to see. Yet, they do it anyway. The antagonists know they've run out of hope. There's nothing left to hype. It's that cornered animal response. Pushed any harder, they'll just lash out at you with personal attacks. Long story short, Prius PHV endured the greenwashing. Staying true to need allowed it to survive. Volt, on the other hand, catered to want. That made a mess out of things. Business cannot sustain on just that. Far too many consumers purchase based on need. That's where profit to sustain comes from. It's not as exciting as engineering. In fact, many call that dull & boring. Oh well. They learn the lesson the hard way.

- 10-12-2015 Lesson Learned.** The timing of this couldn't have been any better: *"If you're looking for sales, and I'm not sure GM is all that excited about selling the Volt, you want to look where you can get some volume."* This too: *"Pretty sad that, five years after introducing the Volt, GM is still flailing about."* Both quotes came from a single post. It was a short & sweet set of statements from one of the most *"vastly superior"* supporters. Put another way, it accepted defeat. Remember, that battle isn't Prius versus Volt, it's Volt versus Malibu, Cruze, and Equinox. GM's own loyal customers chose to continue buying traditional vehicles, rather than the fancy new EREV. The option offered for greatly improved efficiency simply wasn't appealing enough to get them to switch. GM knew it had a serious problem. That's how the Malibu hybrid and the CTS plug-in came about. Volt will continue on as a specialty vehicle. After all, there's nothing wrong with selling to enthusiasts. Corvette & Camaro have been that way for decades. Trouble is, they don't pay the bills. Business sustaining profit comes from high-volume sales... those ordinary vehicles, like Malibu, Cruze, and Equinox. It's what I've been saying since long before Volt was rolled out. Too bad certain individuals chose not to listen... until now.
- 10-13-2015 How?** Rather than asking the *"Who?"* question anymore, it has now changed to *"How?"* I expect much of the same behavior in response. No matter how objective you try to be, the emotion clouds judgment. That's too bad. Oh well, at least I try: Volt is experiencing an identity crisis. It attempted to dethrone Prius by becoming a popular seller among GM customers. That just plain didn't work. So, focus was turned to conquest sales from outside the loyal buyers instead. That didn't work either. Gen-1 just flailed about, not drawing attention beyond enthusiasts. That leaves us wondering what the changes are. What should we expect? Suggestions from devoted supporters were taken and a mix of them fulfilled by Gen-2. That spelled trouble immediately upon reveal. Even though performance aspects had been enhanced, the simple consumer needs of cost reduction (for lower price) and more interior space (rear leg & head room) were obviously not a priority. We're seeing the fallout of that already in the form of disappointed posts by those supporters. Meanwhile, marketing is a becoming disaster. The compact size prevents it from competing with the very electric-only vehicles Gen-2 hope had been set on. The upcoming competition (Bolt) is causing direct contradictions of what previous promotions had emphasized. The design of the gas-engine & gas-tank conflict with the message that either will be needed in all but rare circumstances. Meanwhile, the two types of offerings Volt was to prevent from being needed (hybrid & EV) are progressing toward availability next year. It's a big mess. How do you sell a vehicle that doesn't target any specific market?

- 10-13-2015 Hypocrites & Greenwashers.** They really stand out. With comments like this though, you have to wonder: *"The Volt is a transitional vehicle that bridges the stark divide between gasoline engine cars and engine-less cars at a reasonable price while retaining all of the advantages of full power EV driving, a path forward for efficient carbon reduction, and fast refueling on longer trips without need for massive new infrastructure."* What the heck was he really trying to say? Since it is sales which measure the progress forward, the purpose of a vehicle doesn't matter much if it only looks good on paper. The difference is made in neighborhood driveways and local streets. Without actual purchases by large quantities of consumers, what's accomplished? I chose my words carefully: Gen-1 Volt pointed out that "reasonable" price only applied to early-adopters, that even with tax-credit help sales were a struggle. Gen-1 also revealed that full-power EV driving wasn't the big draw, that people were more interested in using as little gas as possible. Gen-2 Volt offers greater EV range, but at the tradeoff of cost, weight, and size. That makes it a harder sale compared to the larger plug-in hybrids offering less capacity and highly-efficient blending. If you don't drive far enough to take advantage of Volt's entire battery-capacity, what's the sales draw? Gen-1 PiP demonstrated that faster engine shut-off was what owners most wanted. Their goal was to significantly reduce gas consumption, not to use as much electricity as possible. Seeing the benefits of blending made that easy. MPG was well above what a regular hybrid could deliver. Keeping engine use brief was key. Gen-2 PiP will deliver an engine even more efficient along with some level of increased battery-capacity. That will draw interest. Keeping cost as a high priority will allow it to be competitively priced. We'll find out next year what the targets were. The point is, it too is a transitional vehicle. As always, the catch is how many the automaker produces & sells. Technological achievement is validated by consumer acceptance, not engineering praise. Put your way, the bridge is only effective if people use it to cross. It must be used. Automakers are in the business to make money... which is what Gen-2 is supposedly for.
- 10-16-2015 This Week, diesel.** Looking back, it was quite a week. The disaster with VW continues to get worse. Most of the diesel updates here in the United States will require extensive work. Harm to reputation, not to mention resale value, is profound. With so many cleaner and more efficient choices emerging, there's no real hope for diesel anymore. There's simply no way to compete. Part of the growing trouble comes from the proposed solution. It involves the very thing I complained about many years ago: AdBlue. That's the urea liquid product used to treat emissions. Turns out, even the systems currently using it weren't squirting enough out to reach the level of cleansing required. Having to bring in your car to the dealer more often is something VW was attempting to avoid. Now, they'll have even more dealing with this new problem, since the diesels without that tank & sprayer need it too. Things just plain did not add up in the past. Finding out later that diesel owners who had harassed hybrid owners had been deceived is quite odd of a situation. They didn't question the facts we had disputed. They had cherry-picked data in their favor too. The final victory is hurtful to those who didn't participate in that. They are true victims. So, it is best to simply move on... just like with all the other wins of the past.

10-16-2015 This Week, anti. There are some who thrive on debate. They really don't care what you say. Their responses are to provoke discussion. So, by their very nature, the language is vague & ambiguous. That draws a lot of posting. The most recent has been implying that if you're in favor of NiMH batteries, you're against Li-Ion. Their intent is to polarize. The idea of a variety of choices being available, rather than one being an obvious successor, is something they can't handle. Diversity is not welcome. That's sad. Toyota is going exactly that direction too, offering choice. They clearly despise that. This week, specs of the upcoming batteries were revealed. The regular (non-plug) Prius will be offering both NiMH and Li-Ion. One is less expensive and more robust. The other is cost more, but is lighter, smaller, and offers more power. It's an interesting tradeoff consumers have never been able to decide between. That's coming next year. Coming next decade is the choice between electric-only and fuel-cell. If you're in favor of one, the antagonists present it as you are against the other. They hate the idea of co-existence. The very idea of apartment & condo dwellers not having access to a plug infuriates. EV is the only solution as far as their concern. Hydrogen, regardless of source, is considered a waste. That's sad. What I find amusing though is the attempts to misrepresent. Someone pointed out how I was against fuel-cells, but now in favor. They absolutely refused to acknowledge that my stance was taken well over a decade ago, based on the technology of the time. Things have changed dramatically since then. That exclusion of when was obvious greenwashing and he got caught doing it. Despite that, the effort to make that subject polarized continues. Endless online debate is what some enjoy too much to allow it to end.

10-16-2015 This Week, plugging. A meeting of the EV owners took place last night. As usual, we had a blast. That group is profoundly different from the troublemakers online. They readily admit shortcomings and welcome feedback. There is no brand loyalty. The effort is to promote cleaner, more efficient transportation. The fact that I have the smallest battery-pack doesn't matter, it's my effort to demonstrate how easy & affordable it is to achieve that goal. Size doesn't really matter. Heck, I'm typing this blog right now at the coffeeshop, which is 4.4 miles from home. I can reach it and travel back, using a 55 mph road, entirely with electricity. Goal achieved. No need for greater capacity in this circumstance. This group clearly understands how power & capacity will just naturally improve as the years pass. Heck, there were a few who have upgraded from older models. We heard stories of both Leaf & Volt differences over the years, despite being the same generation. That leaves them with a very objective look at the next plug-in Prius. They see the potential. None of that arguing we experience online ever happens in person. When we meet, discussions are about how to better educate. Our preparation is paramount. Quibbling over obvious shortcomings doesn't achieve anything. It's all about recognition of goals. They want the masses plugging in.

- 10-17-2015** **More Detail.** Those little tidbits of new information continue to trickle in. The latest is finding out there's a MPH bump up with the top EV speed for the plug-in model. True, you're better off in many cases using boost instead. But nonetheless, the faster does offer greater flexibility. For now though, it's mostly just speculation: *"Or, if we take the PiP as the half-generation improvement, it's 100km/h to 110km/h :) I know, it doesn't sound as impressive. It could also hint at the capabilities of the PiP since (it's safe to assume?) it'll use similar hardware to the Gen 4."* That's fun to ponder nuggets of knowledge we stumble across. Eventually, we'll nail down fact. But in the meantime: At the local EV club the other day, we had an extensive discussion about tweaks Nissan did to Leaf over the years. The 2015 drives much better & further than the 2012, despite being the same generation. Engineers were allowed to release an array of updates along the way. It's quite realistic for us to see a collection of performance improvements with the next Prius PHV. Toyota never stopped research & development, despite what the naysayers spin. Too bad so many people get hung up on maximum ratings. As a result, they totally overlook actual utilization. Put simplistically, what is the point of a 60kW rated electric-motor when you only have a battery-pack delivering 38kW of electricity? Making the two better match is an optimization easily not recognized. Yet, things like that are what contribute to overall improvement. We already know the engine has been improved, delivering a 9% gain in the winter. That's a big deal. Some will complain anyway, focusing on the fact that the engine still runs at times... even though the resulting efficiency is noticeably better. Both the regular model and plug-in will benefit. It's a well thought out, versatile design. We have many things to look forward to.
- 10-19-2015** **VW Electrification.** The only true option Volkswagen has at this point is to embrace hybrids and plug-ins. No amount of damage-control can help them beyond just recovering to status quo. They need something to break pass that. Even with a restored reputation, diesel simply cannot compete. The Prius PHV that I drive now has been averaging 73 MPG over the past 65,000 miles. It's quite obvious the automaker must take a step forward. The question now is: how far? We have already seen a variety of prototypes from VW. Heck, they even sell a hybrid. None of that was taken seriously though, since diesel was king. But not much more can be squeezed out just an engine alone. In fact, the current MPG was achieved by cheating. It's quite clear to everyone that a dirtier system can be more efficient. Sacrificing of gas for the sake of cleansing isn't something Toyota got much credit for. But now with the mess VW created for itself, there's new attention to non-carbon emissions... the kind that contribute to smog. Oh well. Better late than never.

10-20-2015 **To Summarize:** GM created Volt based on want. Executives & Enthusiasts expressed their desires and many were fulfilled. It was an engineering achievement worthy of praise. Awards were presented. Celebrating lasted for awhile. Then, reality set it. There was recognition that business need had been sacrificed. No worries. Gen-2 would address the goals which remained outstanding. All we had to do was be patient. To everyone's surprise though, the plan changed. Volt would remain the premiere vehicle it was designed to be and other vehicles would satisfy need instead. Suggestions to diversify would be taken, the very approach which had been strongly outspoken against would now become the plan. Rather than focus entirely on a single solution, Volt would be complimented by an EV, a plug-in hybrid, and a regular hybrid. Toyota stayed true to business need. That's why Prius was constantly the source of comparison. Even though Volt was declared "*vastly superior*", it could never escape being compared. And now that details of gen-2 plug-in Prius are being revealed, Volt enthusiasts are doing everything they can to avoid discussing it. That's quite telling. Still only including the regular Prius, how could that possibly help Volt? GM's own offerings... Bolt, CTS plug-in, and Malibu hybrid... will get more and more attention if that type of misleading continues. People will see the omission and move on. There's want & need, two very different things with very different priorities. No amount of spin will prevent the facts from being discovered. Let the data speak for itself. Geez. Different people have different priorities. But one thing is the same for all, the business must sell vehicles in high-volume at a profit to continue paying the bills. That's paramount to want. Need always wins in the end.

10-22-2015 **Progress?** We're seeing hints of it emerge. Comments like this are helping with the move-on process: "*My main irritation with the Prius is the EV mode is completely anemic. You can't accelerate at all (not even normal acceleration) in EV mode or it turns off. There would be a lot to gain in MPG if they had a usable EV mode.*" Dialog of that nature wasn't possible in the past. Even now, it still comes off as condescending. But carefully read, there's a little bit of a constructive element to work with. So, I took it as an invitation to inform: You just described the PHV model. Having a larger battery-pack and plugged-supplied electricity increases EV power quite a bit. I climb steep residential hills and accelerate onto the local highway (55 mph) without triggering the engine with my 2012. Here's my stats: 65,124 miles; 890 gallons; 5,535 kWh; 73.2 MPG. That's 3.5 years of ownership in Minnesota, where winters are quite harsh. So as you could imagine, that 9% increase in hybrid winter-operation efficiency from gen-4 will be a nice upgrade. Also, note that the gen-2 PHV will raise the top EV speed from 100 km/h (62 mph) to 110 km/h (68 mph). Above that speed, you'll still have the boost (electricity being used to allow the engine to run at a lower RPM for better efficiency).

10-26-2015 Contradiction, observation. The time to draw a conclusion has arrived. We're seeing the next step forward take place. But with progress, there comes winners & losers. The EV was argued against intensely. Volt was superior to Leaf, period. It was perplexing to witness such self-deprecating arguments to take place. How could the advancement of battery technology allow Volt to be competitive? The inevitable cost drop would make the electric-only choice more appealing. It was a simple matter of increased range. No more range anxiety. The approach Volt took was a dependency on batteries being expensive and low energy-density. An improvement in either would favor the EV... as well as the plug-in hybrid, which use a smaller pack and deliver high efficiency even without plugging in. Unlike BMW's i3, which uses a small engine & tank with a much larger battery, Volt was this odd configuration stuck in the middle. We watched an identity-crisis play out. Who would the gen-2 be for? With Nissan, Tesla, and even GM striving for 200-mile ranges that are actually affordable for middle-market buyers, the audience for Volt remains a mystery. That's where the contradiction comes into play. We're seeing certain individuals now say that the Bolt was expected all along, that Volt's purpose was to usher in EV choices. That most definitely is not what he said before. Contradicting their own claims is an implicit admission of defeat and an effort to move on. Cool.

10-26-2015 Contradiction, statement. This is what I ended up posting, on what used to be a daily blog for Volt: There was a strong fight against the BEV, plug-in hybrid, and hybrid. Don't remember how intensely those concepts were disliked? The very idea that they are now being embraced is quite a shift, to the point of being contradictory or even hypocritical. Voltec was the only approach to be followed. Nothing else was needed. We heard that sermon preached hundreds of times. Nissan was looked down upon, with great emphasis on "*range anxiety*" fear. Yet now, Bolt is accepted as a sensible move. With Bolt and Leaf and Tesla becoming the choice for those wanting to abandon gas, it leaves us wondering what the appeal of Volt will be. Why would you want a full size gas engine? What the heck is the 8.9 gallon tank for? How will ERD TT be explained as an EV feature? Ironically, the lashing out at those who were correct about how this would play out is the very thing holding back progress. Are they really going to repeat mistakes of the past again? The most obvious problem is the evading of goals. What the heck is the purpose of Volt? How does that fit with the rollout of Bolt? Why will Malibu hybrid be offered? It's the supporters who make a difference. Their purchase & promotion is what entices others to seek learn more. No clear message about Volt hurt gen-1 sales. It was a chaotic mess. Ordinary GM customers simply weren't interested. What will be the gen-2 draw?

- 10-27-2015 That Never Happened.** Confirmation of having entered the next chapter in this history was surprisingly obvious today. There was outright denial of any type of fight against diversification from ever having happened. It never did. Period. They claim to have absolutely no idea what I'm talking about. And yes, their own quotes to prove otherwise are easily found here in these blogs. What's the point of bringing any of that up though? An empty victory is still a victory. It's their way of moving on. We're not looking for spoils anyway. And for them, rather than trying to play the victim-card or hearing any more of the fruitless excuses, it's denial. Ok. That works. It's hard to believe the end has come. It's finally over. We had the one-size-fits-all attitude for so long, gambling business need by focusing everything on engineering. That failed... miserably... again. Two-Mode was the first to crumble. Volt is now the second. No other automaker hypes to that extreme or has enthusiasts who blindly celebrate like that. In other words, this is how a financial disaster plays out. You don't even bother to count your losses. You simply move on. That never happened.
- 11-02-2015 EREV vs PHEV, horsepower.** I wondered how long it would take for this nonsense would begin. When all else fails, labeling is the default argument. The latest spin is that more horsepower will win consumers over. Ugh. Don't they study the market at all? I sounded off with: How is that any different from comparing a traditional vehicle offering high horsepower? Even though they've been available for decades and clearly deliver a much more responsive drive, people continue to purchase the lower horsepower offerings anyway. It's easy to entice an enthusiast. Getting someone who is perfectly happy with less power and unwilling to spend more for it is a major challenge. That's why all the attempts to establish EREV versus PHEV categories haven't made any progress. As far as mainstream consumers are concerned, the difference doesn't matter. The criteria is arbitrary to them. They see purchase-decisions factors like PRICE, MPG, and SIZE as more important. They aren't going to be dropping the pedal to the floor. They aren't going to cruising at speeds well above the legal limit. They aren't interested in sport handling. Mainstream buyers have different requires. It's that simple. Know your audience. PHEV still deliver electric-only driving, just not under times of high demand. The gas engine assists.
- 11-03-2015 EREV vs PHEV, simple.** They weren't happy, not in the slightest. So, I fired back: The effort to separate EREV from PHEV has failed miserably. The criteria has been arbitrary. Nothing has been achieved by the labeling approach taken over the past 5 years since rollout began. Some of those claims of the past were contradictory too. Outlander offers 32.5 miles of EV range CT6 is expected to offer 34 miles. Prius PHV gen-2 offers 68.3 mph EV top-speed. C-Max offers 85 mph. How do those "weak" and "limited" criteria apply for PHEV? They resemble EREV when rolled out. It would have been far more effective simply stating the engine differences instead. EREV uses a standard engine as a backup to alleviate range-anxiety. PHEV uses a highly-optimized engine to supplement clean & efficient driving. It's that simple.

- 11-05-2015 EREV vs PHEV, engine.** That exchange the other day was intense. I knew revealing shortcomings in their claim would do that. It's how you confirm & refine. The feedback is quite valuable. Promotion of a technology becomes easier and easier as exchanges like this take place. So, I dove at the opportunity to sound off to this: "*The green media insistence on not accepting the EREV designation and not highlighting Volt's full EV capabilities vs. ordinary PHEVs (this appears to be changing).*" You could imagine my excitement to comment and the desire to want to post the descriptions again: That's because the category criteria has been so arbitrary and over time has become contradictory. The approach taken over the past 5 years to differentiate has clearly failed. Factors like short-distances, suburb-speed, and freezing-temperatures are fundamentals problem were not taken into account. They contributed to the confusion and lack of acceptance. It's time to move on and try a new perspective, one that actually informs about the non-electric side instead. Simply point out how the gas engines differ... EREV uses a standard engine as a backup to alleviate range-anxiety. PHEV uses a highly-optimized engine to supplement clean & efficient driving.
- 11-05-2015 EREV vs PHEV, emotion.** When the moderator post this, it's a golden opportunity: "*People can get emotional about these subjects.*" That was in response to the personal attacks that resulted from my previous post. Rather than trying to be even remotely constructive, it was an all out attempt to shoot-the-messenger. That's the confirm I was looking for. Not wanting to address what was posted in any way can indicate you identified the issue correctly; otherwise, they'd try to spin it in some way. Instead, it was the blog's webmaster adding his observations. I followed with: It's quite interesting to observe how riled up some people actually get. They'll even lash out with personal attacks. Meanwhile, the rest just wait, knowing it will eventually pass. Studying automotive history, you'll see the early hybrids went through basically the same thing. Civic was an ASSIST type hybrid. Prius was a FULL. Explaining the difference over and over and over again educated supporters, but did nothing to reach ordinary consumers. Seeing that, some supporters stopped providing the complete definition. They focused on just a single trait instead... hoping that would reveal the distinction better. It didn't. The same thing is playing out again. As much as the "*full electric*" seems an appealing draw, it really hasn't amounted to much. To make any new technology the next standard, mainstream buyers must show interest; instead, they've shown they simply don't care. After all, they have no idea how their current traditional vehicle works. Heck, with gas now below \$2 per gallon, why would they bother to find out? Know your audience. Ordinary consumers will do the same now as they did in the past. Engineering detail will get lost in the search for a good all-around vehicle. They'll continue to focus on the basics. The difference between EREV and PHEV is only a technical specification anyway. The average joe will see that efficiency is at the top of the 100 MPG scale while cruising at 65 mph. They won't care whether or not the engine is running. Forgetting to plug in after getting back home is the only real concern they'll ever have. Gas consumption will be significantly lower, regardless of what happens under the hood. All plug-in hybrids deliver outstanding MPG. The augmentation of battery with plug is quite obvious, a draw to even the most untechnical shopper. I filled my tank today. 7.024 gallons of gas took me 746 miles. Sure, I could point out the 81 kWh of electricity consumed displayed on the dashboard. But we know they won't be interested. They'll only want to know about the resulting 106 MPG. The next-generation promises to improve upon that, which is what consumers will be interested in... not a branding or category label.

11-06-2015 EREV vs PHEV, same page. The previous night's posting went well. This morning, it was this to stir the post: *"People made fun of the GM 2-Mode hybrid trucks and made the "I told you" comment when they stopped making but it appears GM never gave up and now we have the wonderful Voltec II power train."* What a great way to blur the supposed line between EREV and PHEV. These exchanges are proving to be fruitful. Evading certain realities is becoming more and more difficult. I was happy to contribute to that: Many, many here made the claim that Volt was a fresh start, a completely new design that should be treated as first-generation. They absolutely refused to acknowledge any of the expertise gained from EV1, Two-Mode, and BAS/eAssist was part of Volt. It was delay-tactic to make us wait for Voltec-II before placing judgment. We saw what was really happening. We knew Volt was really a second-generation Two-Mode. The reason for that friction was simple: COST. It was a major risk for GM to attempt to deliver an end-product first, then use subsequent generations to find a way to reduce cost. As a result, Toyota's approach was ridiculed & belittled to no end... always excluding cost-consideration in those claims. In reality, Toyota made the choice to offer more as cost permitted, improving each generation along the way instead... the opposite approach from GM. The end goals are the same and always have been. The difference is one depended heavily upon gas prices remaining high and tax-credits being generous. The other did not. It's really unfortunate so many fought so hard against what ended up happening anyway. Product diversity is absolutely essential for business-sustaining profit. Those *"one-size-fits-all"* arguments look silly now that GM is indeed delivering a hybrid and a plug-in hybrid, in addition to Volt. Oh well. At least we're all on the same page now.

11-06-2015 EREV vs PHEV, the past. It becomes very easy to validate the next chapter is going well when the past changes. Saying that another way, spin is in full swing now. Rather than claiming whatever didn't happen, those who supported that thing which failed to reach its goals will alter perception of prior events. That's why I document things in such detail as they happen. Referring back to them later, with written record of what actually played out along with the reactions at that time, is quite vindicating. After all, this isn't rocket science. For that matter, it isn't even science. It's just basic business. For a product to continue, it must achieve self-sustaining profit. That simple fact meant reality would eventually catch up with even the most stubborn of deniers. In this case, it's the disassociation of Volt with Two-Mode. I had to endure years of claims that they weren't related in any way, that Volt was truly a first-gen vehicle with nothing from the past contributing to its rollout. That continued too, right up until the details of the second-gen were released. That seemed a bizarre stance to take. Why wouldn't you want to build off of the past? That answer is obvious if you know the history, the past before this past. Two-Mode was expensive and not as efficient as hoped. Sound familiar? That's why so much importance was shifted over to gen-2 of Volt, that upgrade would overcome the shared shortcomings. Problem though. Seating space in back didn't increase, a request countless many made over the years. Cost didn't come down anywhere near as much as hoped, still not achieving the goal set for back in 2010. Improvements focused on engine & battery, nice generational upgrades had the other goals also been addressed. Instead, emphasis was on power... a quality no one ever complained about. In fact, that was a factor often praised. Why spend so much on something already meeting expectations well? Didn't any study the past?

- 11-07-2015 Irony.** By far, the most common insult to Prius PHV from Volt troublemakers was the supposed fact that it was just a "*compliance*" vehicle. That's a vehicle built for the purpose of earning EPA credits... practice used to offset emission shortcomings from other vehicles in the fleet. This was a big reason why they absolutely hated when I'd point out sales of other GM vehicles. Anywho, we know that the effort from Toyota was to advance the technology by real-world data collection. They needed to better understand how a plug-in hybrid would actually be used. Getting that type of feedback from consumers is priceless. It gives you a very good idea what to invest in for the next generation. That's why both GM and Toyota offered free connect service for 3 years. It's how the data was collected. Every single vehicle sold was routinely delivering lots and lots of driving detail. With that, you'd expect the next offering to better match consumer need... rather than want. Ironically, the revelation from that data was that consumers desire an all-electric driving experience... in other words, a system without any engine at all... not Volt. That's how Bolt came about, an approach GM was dead set against only a few years ago. Even more ironic is the reality that the new Volt is currently limited to "*compliance*" markets. Having availability of a premiere product match the very thing troublemakers had used as an insult in the past is quite humbling. No one should wonder why Toyota tries so hard to keep a distance. Being associated with the spin is good to avoid, especially when irony is involved.
- 11-07-2015 RAV4 Hybrid.** Patience is redeeming. Detail is now available. We now have something worthwhile to move on to. The AWD (all-wheel drive) RAV4 delivers 25 MPG combined (22 city, 29 highway). That's competitive with offerings of similar SUVs from other automakers. It makes the hybrid especially noteworthy. 33 MPG (34 city, 31 highway) is quite an improvement. That's the news we've been waiting for. 194 horsepower, 206 ft-lb torque, zero to sixty in 8.1 seconds, and a variety of goodies available... Pre-Collision System, Dynamic Radar Cruise, Lane-Departure Alert, Automatic High-Beams, and Blind-Spot Monitor with Rear Cross-Traffic Alert ...will make it a nice choice. It can tow too; capacity is 1,750 lbs. Starting price will be \$28,370 along with \$900 delivery. In other words, it will be very interesting to see how this new hybrid is received. With gas now \$1.86 per gallon in Florida, \$2.25 here in Minnesota, and \$2.45 on the West Coast, this hybrid will be entering a strange market. Having no competition helps. People know gas prices will eventually go up again too. We'll find out soon enough. Sales will begin in a few weeks.

- 11-09-2015** **\$500 from VW.** That's the offer TDI owners are getting. It's a prepaid Visa card they can use for anything, also included is \$500 of dealer service and 3 years of roadside assistance. But what kind of compensation is that? The very thing they purchased the car for (efficiency & performance) will be taken away. The conversion to become cleaner requires that loss. It's really sad... for the honest owners, especially since their resale value will plummet... far more than \$500. As for those who gloated about "*clean diesel*" and harassed hybrid owners, an apology would be nice. We put up with years of their dead-end nonsense only to find out we were right all along to question how their clean was actually achieved. It never added up. The approach seemed flawed and in no way guaranteed like the strict requirement for SULEV and PZEV certification. Simply meeting the minimum 50-state criteria was a weak attempt to be clean. And that was just clean enough to be compare with low-end gas cars. The ordinary ones, like Corolla, were clearly cleaner with their ULEV certification. Oh well. The truth has been revealed. We were correct. Of course, it didn't matter anyway. There was no way in the world a diesel-only car could possibly compete with a plug-in hybrid. My 73 MPG average is so much better than the 42 MPG some diesel owners were getting, it wasn't worth the effort to argue.
- 11-11-2015** **Shameless.** The topic of misleading through omission has surfaced again. Over and over and over again, we'd see some Volt owners gloating about their efficiency. Always being in terms of "*gallons*" and almost never hearing about "*kilowatts*" was frustrating. It was blatant greenwashing in the eye of many. Speaking out against that terrible behavior is happening a lot now. This time of change has some of the honest owners seeking a better way. Why the reputation of a few tarnish everyone else's? The unfortunate reality of it having been delayed so long is sad. We put up with that nonsense for years. But then again, so much hope was placed on gen-2 Volt, they didn't think having to play friendly with others would be necessary. That long sought after partnership is becoming inevitable. Many Prius owners were simply looking for an ally in the quest to squash traditional vehicles. We didn't expect a "*vastly superior*" conquest would emerge. Thank goodness that is over. Looking back, I state the situation as: Those particular owners had no shame. Even after terse exchanges many times pointing out the blatant misleading by omission, they keep doing it anyway. But what really soils the reputation of owners are the enablers who watch it happen time and time again, never bothering to speak out about the poor behavior. It's quite telling when you see that. A strong candidate for mainstream acceptance wouldn't rely upon such actions. The data should speak for itself. Using MPG alone doesn't tell the whole story.

- 11-11-2015** **Context.** It's fascinating to witness a foe trip over their own argument. In this case, it was the claim that I didn't provide context. What he meant was context for that particular comment. I pointed out the context of which the comment was actually made. There's a huge difference. He was treating the situation as if it happened today. I was more than happy to explain things were far from the same now as they were: Back then (late summer 2013) was a time of desperation for Volt hopefuls. Sales had not grown to expectations by year-end 2012. That meant the next 12 months were critical... and the first 9 had already went poorly. The attacks on Prius PHV had growth to an amazing level. Remember the effort to convince people that the entire plug-in capacity was only 6 miles? It was intense and an obvious sign things wouldn't get any better for Volt. The next generation was still 2 years away. Ford's Energi models were seeing growth. Leaf was gaining appeal, despite "*range anxiety*" and heat-degradation issues. Tesla was causing quite a stir. GM remained stubborn, insistent upon not offering an EV, any type of hybrid, or even a more affordable version of Volt. Inventory was piling up. The price got dropped by \$5,000. Sales didn't increase though. The "*who*" question was getting asked more and more. With BMW's i3 beginning to draw interest, there was good reason to wonder who Volt would appeal to. After all, early-adopter purchases were complete. Meanwhile, people were learning to tolerate the gas prices around \$3.35 per gallon as the norm. Remember what came just a month later? The disastrous second-generation BAS called eAssist was canceled and the Cadillac version of Volt was announced with a price of \$75,995. It was a mess. GM was betting the farm on Volt success. You can imagine the type of pressure that put on supporters.
- 11-13-2015** **Sonata Plug-in Hybrid.** It's available now. This offering from Hyundai come with 5 times the battery capacity. That 9.4 kWh is able to deliver an EV range of 27 miles. Pricing of the vehicle is \$34,600. Following depletion, the system is rated at 40 mpg combined. It should be very interesting to see how it is welcomed by our market, especially with Outlander and a new Prius PHV on the way. We wonder how Ford & Honda will respond too. As awareness & availability of plug-in hybrid choices grow, sales should pick up. It's such a painfully slow process to get all the automakers contributing. And of course, we have GM still sending mixed messages. Perhaps the isolation of Volt will allow the Malibu to reuse the CT6 plug-in hybrid configuration. Supposedly, they share the same hybrid system. Volt lacks the refined engine, so it should stand apart. Sonata seems to fit right in with the rest. That's a good sign. Hopefully, these crazy low gas prices offer a bridge to plugging. Rather than being in desperation, as back with the \$4 gas, we can get people to try them out without feeling like it's a big step. True, the 75 to 100 average MPG is a tough sell when gas is just \$2 per gallon, but at least opportunity still exists. It's not like there's an outright pushback anymore. The batteries themselves have proven themselves up to the chore.

11-15-2015 **Big Picture.** Even those attempt to be constructive sometimes miss the big picture: *"Hybrid tech germinated in the 20th century. They've ridden those coattails for almost 2 decades now."* He was attempting to summarize the problems with fuel-cell rollout, but didn't take into consideration the other issues we face. That's quite common of a mistake, especially when it comes to public funding. I interjected with the following: Plug-in hybrids (available at your local dealership) and lithium chemistries are still quite new, so are some technologies for combustion engines, like direct injection. Trying label something as old to downplay it won't work. You can't just turn a blind-eye to the heavy investment still taking place with traditional vehicles either. Also, notice where the oil industry is currently? The long timespan we enjoyed of relative stability is gone. A time of unpredictability has begun. We've arrived at the so-called "*peak*" everyone worried about. There's plenty of oil still, but getting it to consumers is a chaotic mess. There's missing & aging infrastructure. New pipelines will need to be built. We have no choice. Are we really going to ride the coattails of the 20th century with oil, repeating another 4 decades of what contributed to a planet now dealing with climate change? Wouldn't it make a whole lot more sense switching to a fuel that can be generated using renewable energy? We know that EV won't work for everyone. There are apartments & condos which clearly cannot accommodate plugging in. There are also countless old neighborhoods with detached garages and exposed power-lines that simply won't be able to handle the addition of large quantities of level-2 chargers. There's the reality that the oil industry won't give up without a fight too. There will not be a single solution for all. Having fuel-cell vehicles co-exist with electric-only vehicle will happen.

11-17-2015 Toyota Embargo. Patience is always required when it comes to Prius. This is especially true now. Tomorrow (well, actually very late tonight) we'll learn a lot more about the upcoming 2016 Prius. There were some people invited out to the West Coast to see it firsthand, ahead of the general public. They got a lot of information, including the opportunity to drive it and take video of the experience. The catch is, they have to wait for the official "ok" before revealing any of that. Toyota has an embargo; those who got to see it early are not allowed to release anything about that yet. So, we wait. The speculation is wild. A few minor leaks happened, of course. But we have no solid idea what to actually make of those incomplete tidbits. My guess is this generation focused on refining the system as a whole, rather than focusing primarily on efficiency. We know the platform will get a nicer suspension. The tradeoff is that costs more and it would add weight. It also has a wider stance and a lower center-of-gravity. That is what many had hoped, so... it would be great news to get a confirm. The system is likely more robust for plug-in support too. Even though the existing generation supported that already, there's always opportunity to upgrade. That's how technology progresses. Batteries, motors, controllers, and software all improve over time. It's a realistic expectation. How people react is an entirely separate matter. I'm quite curious about that. Remembrances of the 2010 bring back comments to mind about how radical is looked, especially the headlights. The back end is getting emphasis this time, though the front looks much more sleek. I like the new back. It really stands out, both day & night. That's the point. It's a family car that looks anything but, which will likely cause quite a stir. Critics prefer a traditional look, period. Breaking the mold with a radical look is too much change all at once. Fortunately, the critics aren't planning to purchase. Radical looks tend to grow on people over time. So, whatever the first impression, later on will be different anyway. I'm sure there will be some spin about MPG not being what was hoped for, even though we know there will be a standard and "eco" model, where the latter delivers exactly as anticipated. We'll find out those details soon enough.

11-18-2015 First Impressions. I did a search for newly published articles. The first I stumbled upon was from Detroit. It wasn't too bad. The observations were reasonable. I wasn't thrilled about the false information though. The writer made a comment about how the battery-pack had been moved to under the rear seats, so now the cargo floor could be flat. Ugh. It was always flat. He just assumed it wasn't. He also claimed this was the first Prius to offer a lithium battery. It's really the third. The one I've been driving (the plug-in model) for 3.5 years was first. The second was the 7-passenger wagon model in Japan & Europe. So, like I said, it wasn't too bad. To my surprise, the next article gave a "*pretty amazing*" comment about the rear lights. I guess the boring traditional look is on the way out. My only irk though came from Toyota itself. The rear legroom in back got reduced by almost 2 inches. Ironically, Volt supporters set the precedent for the smaller size, so anything they say would be a double-standard. I'm keeping my mouth shut, since they'll obviously try to spin it to make me appear hypocritical. Though, I could point out that front legroom increased by 0.7, making it 1.4 inches more than what Volt offers. Of course, they'll probably focus on the horsepower anyway. The new hybrid-system measurement give an impression of having been reduced, when in reality, we're getting ordinary incremental improvements where beneficial. That's what should be expected from generational upgrades. So, no change in 0-60 acceleration, but a noticeable improvement for 0-30 acceleration. We get active grille shutters now. There's a wide array of smaller improvements too. We'll find out more as the day proceeds.

11-18-2015 **2016 Prius Details.** Interesting timing. Along with the details we got today, we also got news of the price of a barrel of oil dropping below \$40. It hasn't been that low since 2002. As expected, the price of gas has dropped too. It is now \$1.99 per gallon here. Seeing that made quite an impression. Prius should be able to weather the pressure of cheap gas better than some other choices. Details of the 2016 model appear to confirm that too. The system will be getting generational improvements. The platform itself, that's different. Some improvements are rather dramatic. Rather than focusing heavily on efficiency, much attention was devoted to improving the drive experience. The stance is wider. The center-of-gravity is lower. The handling is more dynamic. Things like the new suspension in back make that obvious. Weight was traded off to make a car of greater appeal. Heck, even the look itself shakes the stereotype Prius itself created. It's not a sports-car by any means, but it is clearly not just a family transport either. As usual, it puts current owners in an awkward position. Prospective buyers on the other hand, they are quite different. There is much opportunity to take advantage of. It's like a fresh start, so much has been invested in making Prius draw in new interest. The plastic look is gone. The seating area is more spacious with the center console change and dashboard refinements. It's well thought out. Toyota obviously took suggestions from online comments very seriously. The consideration of what people were asking for, clearly outside of what the hybrid system delivers, is easy to see. That's a sign of maturity. Now that the original purpose of emission & consumption reduction has been achieved, it was time to focus on other elements even more... more so than some anticipated. But then again, with all the controversy related to MPG estimates, it's no wonder Toyota played it conservatively. Initial reports say MPG observed is much higher than we expect the official EPA values to state. More to come.

11-19-2015 **Hydrogen Traps.** Supporters of "green" are falling into them at a surprising rate. Rather than actually research their information, they just recite data of the past. They have no idea it's outdated. They have no idea it's limited scope. They even have any idea what the overall goals actually are. It's just "*electric is better*" chanting. So, when I get a post like this, I can't help but to be both amused & concerned: "*And you think building out a nationwide H2 network will be more affordable? lol*" His assumptions were obvious from the discussion, just blindly accepting claims at face-value. Much of it stems from not believing the co-exist is possible. It's a terrible mindset to assume only one solution will fit all. Yet, that's quite common. It contributes to the "*not reading*" problem. That's why some Volt enthusiasts only hear "*Prius*" even though the discussion is entirely about GM with no mention at all of Toyota. The same thing happens with "*affordable*" when it comes to fuel-cells. They don't bother to research existing infrastructure. They just assume existing electrical distribution is up-to-the-chore without the need for an overhaul... especially with at the level of expense some of us have already begun to deal with. Anywho, I posted: You clearly haven't actually read what I've been posting. There was no comment related to being affordable. It's taking everything affected into account. For quite awhile now, I've been saying that individuals, landlords, and private business owners aren't going to foot the bill. The large industries with something to lose will. They'll want in on the new fuel as oil demand falls. Think about how much easier it will be for those big players to setup that infrastructure, already having land, labor, and expertise available. The goal is to establish something sustainable that's clean. It doesn't necessarily have to be the most efficient or the lowest cost. Balance is more important.

- 11-21-2015 New Attack Attempts.** The troublemakers are re-emerging. The 2016 is obviously stirring the pot. In this case, it's another Volt owner who's hate for Prius is quite evident. I found it interesting to lurk upon his posts in the Volt forum about the same topics on the Prius forum. His intent is obvious. Of course, we can see that somewhat here: *"If you want a PHEV that you can just drive and not have to 'consider' when and where to use it as such, you'll need a better design than the PIP."* Needless to say, this is another one of those bomb & leave posts. If he doesn't get anyone naive enough to reply, he doesn't bother. When those of us well informed attack back, we rarely hear back. That was certainly the situation here. I clearly called him on his greenwashing attempt: It's 23°F outside. I just went out into the garage, unplugged the Prius, and drove to the coffee-shop. Top speed was 55 mph. Distance was 4.4 miles. Efficiency was 999 MPG. What part of that needed consideration? Spin of the past attempting to downplay the abilities of PIP fall on deaf ears now. We have proof those claims made were misleading. We're tired of that blatant greenwashing. Plugging in significantly boosts overall efficiency. It's that simple. Our driving results clearly confirm that.
- 11-22-2015 Identical Path.** We've heard this nonsense countless times: *"It is identical to the path Toyota took."* Anyone taking the time to do a little bit of research, perhaps just read the synopsis on wiki, would see that's not the case. In this situation, it's a well-known antagonists who is quite upset with Toyota and unwilling to listen to reason. So lately, the tables turned. He had been posting other people's own quotes to mislead about context. Upset by that, someone used one of his own quotes against him. His rant from a little over a year ago started with that *"identical"* claim and was followed by: *"They introduced a hybrid car which was not profitable and didn't sell a lot... Why not give them the same chances since Toyota is no longer leading the way for electrification?"* He was wrong, very wrong about Volt's future. Looking back, we were quite curious how he would respond. Sadly, he chose to abandon that thread which had been active for that entire duration. Regardless, I was happy to post this: No, it's not even close. Toyota limited initial sales to a quota and diversified right away, resulting in a profit by the final year of gen-1. That first offering was targeted directly at middle-market too. GM took a very, very different approach. GM also had a decade of battery & motor experience prior to Volt rollout... EV1, Two-Mode, and BAS/eAssist. Let's not forget about all the fuel-cell development either. As for giving them a chance, you still don't understand what *"leading the way"* even means. **It's the ability to get ordinary people to change.** Any automaker can create & sell a niche, which is exactly the GM chose to do. We don't see any high-volume plans for Volt in the future. In fact, GM is now promoting the very things they claimed Volt would make unnecessary. We were told for years that EREV was all anyone needed. It was the best of both worlds: EV without range-anxiety. No need for a plug-in hybrid. No need for an electric-only vehicle. EREV was the solution for everyone. This week the CT6 plug-in hybrid was revealed for our market and there was an announcement that the production-ready Bolt EV would be revealed in January. That's in direct conflict with the *"leadership"* we had been told about for years. Anyone who claims otherwise is in deep denial of what happened with Volt gen-1 promotion. We're tired of the excuses & spin. We simply want an affordable & profitable vehicle for the masses that's clean & efficient.

11-23-2015 567,000 Problems. That's what the count of non-compliant VW diesel vehicles has grown too, here in the United States. Oddly, the impact in Europe is quite different. Rather than the after-the-fact recategorization of "*clean diesel*" to a niche as an excuse to do so little, VW is choosing to not do anything at all. Here, they claim buyers understood diesel wasn't mainstream like gas, which implies they accepted consequences of whatever might happen. Over in Europe, diesel is more popular than gas. So, as far as VW is concerned, there is nothing to say. Everyone knows diesel is dirty anyway. With the many millions of VW vehicles in all those countries, the cost to correct & compensate would be overwhelming. We are witnessing the death of diesel for all passengers vehicles from all automakers. It's so bad, it's pulling down VW's reputation with gas vehicles too. Who could have ever imagined the end would be so abrupt and so undisputable? The VW owners here will suffer from lower resale value, as well as lower efficiency and lower power. All that "*fun to drive*" celebrating is over. It never made any sense. Even with all the cleansing hardware, diesel could just barely qualify as clean enough to meet minimums and efficiency wasn't competitive with hybrids. There's nothing left to promote them. Why bother, especially with plug-in hybrids delivering dramatically higher efficiency and a far quieter ride? The problem with diesel have grown to an unbelievable level. Wow!

11-25-2015 Thanksgiving. The holiday is tomorrow. A well-known troublemaker who has recently had a complete attitude-change posted a commentary highlighting this: "...*but being profitable at mainstream prices is a whole different story.*" That quote from him certainly caught my attention. It's quite a mindset shift from rhetoric of the past. So, I responded by giving thanks: Thanksgiving, for me, is seeing you say what I've been posting for the past 8 years here. Welcome to the other side. The wait for a partnership to begin has been a long one. A nice benefit of such a delay is the education picked up along the way, for all who participated. It was clear from that start what Volt was designed to be. The engineering praised by enthusiasts was simply too expensive to make it competitive. That's why attention shifted over to gen-2. Cost reduction, enough to make it profitable at mainstream prices (MSRP, no tax-credit or HOV incentives), would allow it to compete with the true competition. My local EV club recognized that competition right away: traditional vehicles. Showroom losses are painful opportunities missed. They've been working hard to generate a spirit of cooperation among plug-in owners. It starts with acknowledgement of overall goals. Don't let the implementation of technology interfere with the effort to shift from fossil-fuel consumption to renewable electricity use. GM's step to release a PHEV, that very thing the automaker (and this group here) campaigned heavily against in the past, is progress. EREV never really had a proper distinction anyway. All plug-in vehicles with an engine are a hybrid. They just vary in performance. It's like how gas-only vehicles have varied for decades. Mainstream buyers haven't cared about operational details or how a technology was labeled. They just take the vehicle for a test-drive to judge performance, then decide if the extra it costs for that is worth it. If price is too high, they move on. It's that simple. Now that "*being profitable*" gets discussed routinely without quarrel, what should happen? HOV incentives in CA will run out soon. Tax-Credits will expire in a few years. Gas prices will remain low. That's far from an ideal market to promote plug-in vehicles. That means plug-in offerings must become well established (in other words, mature to becoming profitable) in the meantime. We can see that Toyota just did a major overhaul to Prius. The gen-4 is basically a redefining of what "*hybrid*" means... including the plug-in model. That will encourage more to shift away from traditional vehicles. The hybrid version of RAV4 will obviously stir new interest as well. What about the other automakers? Think about what Nissan & Tesla will be doing. Will GM target a PHEV at mainstream buyers, some affordable model of Chevy? Will Volt's MSRP drop more? Will the hybrid Malibu be heavily produced & promoted? What about Bolt?

- 11-27-2015** **Ugly.** This is an interesting topic. The discussion was started by a current Prius owner looking to upgrade, but not pleased with what he sees. I homed in on this particular reply to sound off from: *"This is the first thread to call the new prius ugly. Could a trend be starting?"* There was a variety of approaches I could take with my post. This is what I decided upon: This seems quite familiar, much like what we went through in 2009... when gen-3 was first introduced. Gen-2 looked plain in comparison. Yet, there was a group who preferred it. After 6 years, there are some who look forward to a refresh introducing a more aggressive look. Keep in mind, there are some who didn't think gen-3 was stylish enough. It became the face of hybrids, working itself into a self-deprecating stereotype. Breaking away from that to introduce a more capable system to a new audience will naturally disenfranchise some of the current. Think about how radical the headlights of gen-3 looked like to that audience back then. Think about how "common" they've become since. Change is inevitable. How do you make a vehicle noticeable without losing its connection to the past? Something to compel new interest is needed. LED lighting offers a great deal of opportunity, something many automakers will capitalize on... eventually. The fact that Toyota is so far ahead of the rest makes their vision questionable. Will people really stick with the more bland design? How many have praised futuristic concepts in the past that will dismiss them now that the distant future they imagined has arrived? True, there will be some cosmetic aspects that don't catch on. But then again, there will be some that do. What would you prefer to drive? Gen-3 certainly drew a lot of interest.
- 12-01-2015** **89 Degrees.** We had our first snow storm this year, which represented the first true "normal" commute for Winter from the new house. Traffic was plenty heavy, enough to allow me to push the plug-in system. I hit the stop & slow traffic with a warmed heater. That meant I should be able to stay comfortable the entire duration, as much as 15 minutes before the engine would need to start up again for heat. Sure enough. I got through the crazy mess of crawling along the highway. That much longer than usual delay to cross the river was entertaining. I watched the coolant temperature drop and drop and drop. I got all the way down to 89°F before the engine started back up again for heat. It's not often I can reach tolerance like that. I usually reach my destination at that point or run out of electricity. Staying in EV that entire duration was nice. Keeping the engine isn't necessary, since blending is so efficient anyway. But in those circumstances when traffic is impaired by so much, the smooth & quiet is pleasant. Think of everyone else crawling along running their engines non-stop. Wasted gas. Added population. Easily prevented with a hybrid.
- 12-02-2015** **VW Trouble.** As you could imagine, Volkswagen sales for November were down. The disaster with their diesel vehicles has caused reputation damage. That's no surprise. There have been reveals of more people covering up more acts of deception. The fix will reduce both efficiency and "fun to drive". Those were the very aspects of the cars that drew people to them. It certainly wasn't the clutter of the diesel engine. There's the obvious higher fuel cost here too. What else can be said? It's a mess and harm has been incurred. The question is how will owners respond. Posts on the thread in the TDI forum are in excess of 13,500 now. So far, we haven't seen any type of shared outcome desire. There are pokes at EVs, the EPA, and lawyers filing class-action lawsuits. That's it though. They basically wait with an expectation of disappointment. It's an interesting end to a war filled with biased battles.

12-03-2015 Global Warming. There's no need to use the more informative name anymore. "*Climate Change*" is easy to see. Human contribution to it can no longer be denied. Human ability to deal with the challenges is no longer a hope for the future. That time has come. It's not 2000 anymore. Remember how different the world was, back when the first Prius sales began here in the United States? I do, quite clearly. Mine 2001 Prius was among the first delivered. I was one of the pioneers... who discussed what would happen in the future... which is now over 15 years ago. That future is today. A remarkable next-gen Prius is about to begin sales. Not only is it the leader of clean & efficient hybrids, it's also greatly improved in terms of driving dynamics. Body stiffness has been increased by 60%. That's amazing. For perspective, the newest Camry only saw an increase of 10%. The rear-suspension is another big improvement. The ordinary setup of the past has been replaced by a double-wishbone independent suspension design. That's a really big deal. The "*numb*" and "*disconnected*" feel of the past that enthusiasts complained about was very directly addressed. In fact, space & weight in the rear were traded off for the sake of that improvement. Combined with the lowered center-of-gravity and wider stance, drivers will notice the grip around corners and hard turns. That was a change which will draw in new interest. People will see the more sporty look and discover upon test-drives that Prius has transformed from a very practical family transport to a vehicle with some fun-to-drive appeal. The 0-to-30 upgrade should make that an easy sell. Long story short, we now have a tool to combat Global Warming more effectively with. There's no more excuses. Having the technology readily available, we can help lead the way.

12-05-2015 New Questions. Audience was by far the biggest question. That was not understood by those who supported Volt. As a result, the first generation was a disaster and the second is already struggling to capture new interest. The market is excited about the potential the 200-mile EV offerings. That's range well beyond that of any daily-driving need... which completely eliminates "*range anxiety*" arguments. It's quite clear now, since focus emphasis has already shifted over to long-distance travel. That's where a plug-in hybrid, like the upcoming second-generation plug-in Prius, will really shine. Both short & long driving will be clean & efficient. It's a balance of many factors of importance... hence, answering the many questions. "*Who*" is obviously paramount. If the masses don't embrace the technology, what's the point? "*How Much*" is vital. Sustainable profit without subsidies is required. That means no depending on tax-credits. "*Why*" should be obvious. We can't just keep spewing carbon & smog emissions at such massive rates. "*What*" should be obvious too. Electricity, whether it be from a plug or derived from gas, is the bridge to being both cleaner and more efficient. "*When*" is the catch. That concern about "*too little, too slowly*" was not taken seriously. As a direct consequence of Volt not capitalizing on opportunity back when it was available, we now see Bolt, CT-6 plug-in hybrid, and Malibu hybrid filling in its shortcomings. Deniers will say that was the plan all along. Evidence in forum-posts and blog-entries clearly confirm otherwise. The fiercely stubborn, blinded by engineering, did not see the true need or even who the competition actually was. I'm pleased to report, those battles are long over. That war was lost. We've moved on, now asking new questions.

- 12-07-2015 Defeat.** Accepting it can be quite a challenge for some. Volt uses parallel hybrid operation. It blends power from the engine to propel the wheels. Electricity is still taken advantage of, but it's not what GM promised... nor is it what BMW actually delivered. Now, it looks like Nissan will be doing the same. That pushes Volt even further into the hybrid category. Rather than having "*backup*" engine as the range-anxiety campaign promoted, it uses as engine for supplemental power. Nissan will truly take the backup approach, just like BMW did. That frustrates some, which this quote made evident: "*It's very obvious that Nissan wants to join GM and BMW in the range extender EV market (EREV), so they just designed a "copy".*" Not wanting to accept the obvious is sad. The approaches are different. What benefit is there to blurring categories? People don't care about definitions anyway. It annoys purists. Acknowledgement means accepting defeat, as far as they are concerned. I rebutted with: GM's original reveal of Volt presented the system as a series-hybrid. Actual implementation was a design that took advantage of blending though, where the engine provided some propulsion power rather than just electricity-generating. That's not the same as BMW or what Nissan is planning. Long story short, automaker decisions change over the years and labeling really doesn't mean much. It's the end results as a whole that count... MPG, MPGe, EPA rating, production COST, and of course SALES.
- 12-07-2015 82 Degrees.** That cold, snowy commute the other day was trumped by this evening's experience. Rather than the temperature being at freezing, it was balmy 45°F outside. We took the long way home. There was a beautiful neighborhood elaborately decorated for the holidays. The lights on the houses and around the landscapes were spectacular. We were both impressed so much, neither of us had paid attention to how long we had been driving around using only electricity. The coolant temperature had dropped to 82, even lower than the 89 that I witnessed the other day. To still have the heater blowing warmth for such a duration without the need to startup the engine again is great. It catches many off guard. They expect the engine to run far more often. But when you think about it, 82°F is quite warm... so much so, that's when some people turn on the A/C in Summer. That's more than enough warmth for the heater in Winter. Allowing the system to exploit that opportunity is what makes the MPG so impressive. Far too many see the small battery-capacity and dismiss. They don't think about other factors that also influence efficiency.

12-08-2015 Sales in Japan. They have begun for the 2016 Prius. Yeah! We'll be getting ours here next month. It's been a long wait. We knew it would be. There was no point to rush. Battery technology could continue to improve in the meantime. Other automakers could commit to their own hybrids without a lot of pressure. We can all see the sign of climate change. There's no denying the penalty for oil demand. It's an been an ugly situation, especially with the rough start for some automakers. The multiple disasters for GM has only recently been overshadowed. Both Ford & Hyundai misrepresented their MPG. That hurt. Honda's struggle is no secret. The big surprise though has been VW. Who ever imagined diesel would fall apart so spectacularly. Wow! The resistance hybrids has to deal with from diesel suddenly vanished, literally overnight. The timing couldn't have been better too... at the verge of gen-4 rollout. We eagerly awake first reports from owners. The importance of understating MPG is obvious. Far too many real-world conditions, like Winter cold, made the estimates misleading. So, it's easy to see how the early reports from industry experts were uniformly above the officially stated values. The new way of determining horsepower does the same thing. Lower values than in the past give the impression of degraded performance. That isn't what drivers observe though. But that does take factors usually not accounted for, like full passenger & cargo loads, into consideration. It's more realistic. Expectations are easier to met too. Though, it doesn't look as impressive on paper. Behind the wheel is more important anyway. That's happening now in Japan. Soon, it will be happening here as well. Sweet!

12-09-2015 Partnership. We're seeing cheap gas now. Under \$2 per gallon is a very real problem for those of us trying to promote clean & efficient choices. It's far more of a delay than any of us ever wanted, but at least there's a spirit of cooperation. Locally (here in Minnesota), there's a group of plug-in owners coming together to help promote plugging in. There aren't any superiority complexes to deal with. That's a profound difference from that of the past with Volt enthusiasts online. They really caused a lot of harm. It's too bad we had to go through all that nonsense. Oh well. At least that experience made it clear how important it is to have a partnership among owners. That was unheard of in the past. Old-School beliefs of automaker rivalries set a mindset of quarrel. Encounters were thought of as challenges. Each was expected to fight the other. The very idea of uniting against a common foe was fantasy. The thought of a Toyota owner joining forces with a GM owner was a joke. Now, who's laughing. That situation is being considered quite serious. We have guzzlers guzzling again. The small SUV is extremely popular. Even though battery technology is well proven and rapidly becoming affordable, the majority of consumers simply aren't interested. That's a very real problem. Partnerships are vital. We need to send a clear message of purpose. Volt enthusiasts in the past did everything in their power to prevent that. I'm glad that ugly chapter in history has come to an end.

- 12-10-2015 5 Years Ago, Dead.** Today's discussion on the long-ago daily blog for Volt was a reflection upon 5 years ago. With all the automakers... even VW... making commitments to hybrids and plugging in, the idea of standing out has vanished. Leading is an entirely different matter, but that's based upon sales... the very topic Volt enthusiasts have been quite distant from over the past 5 years. I was amused to see this posted: "*Well, exactly 5 years ago on Dec 10, 2010, we were commenting on this, LOL! GM CEO: 'I Wouldn't be Caught Dead in a Prius.'*" " I thought that nonsense was dead. Oh well. It was opportunity provided to comment. So, I did: That "*vastly superior*" attitude caused quite a bit of damage. Partnerships just forming now were delayed years as a result. Remember what we learned on 11/30/2010 about GM's production plans for Volt? It was to deliver 240,000 of gen-1. Much was learned along the way. Notice all the back-pedaling? GM will now be rolling out a full hybrid, the very thing the CEO back then wanted no part of. We'll also be getting an EV from GM. That too was heavily criticized against. It sure is nice how things have changed, but it certainly confirms the original concerns and emphasizes what was needed all along.
- 12-10-2015 5 Years Ago, Denial.** That was as expected. Oh well, again. This was the follow up: Denial of what happened then and denial of the situation now, along with some attitude, was very easy to predict. \$1.89 per gallon for gas is the reality we currently face. The market is quickly filling need with a wide variety of choices, some more capable than others for dealing with the obvious lack of MPG incentive due to cheap gas. Tax-Credits will expire at different times for different automakers too. The time for change has arrived. The new Prius is a fresh build, rather than an upgrade. So much of the operation of the vehicle has modified, it cannot be denied that lessons learned from the past have been acknowledged & implemented. Driving dynamics have been altered to appeal directly to the masses. The target is clearly mainstream. Profitable high-volume sales is the goal. Go ahead. Keep cheering for niche engineering. Meanwhile, don't deny that true leadership is the ability to get ordinary people to change.
- 12-10-2015 5 Years Ago, Easy.** Same old resistance. It comes from the "*trophy mentality*" mindset. The person thinks that because it looks good on paper, it should sell well. Great pep from electric-drive. Outstanding MPG from being able to plug in. Impressive price due to the tax-credit. Why wouldn't it be a winner? Factors like dealer overhead, salesperson commission, and consumer understanding get pushed aside. Volt is "*vastly superior*" to Prius, so there's no reason to be concerned about anything that Toyota learned. GM is better. After all, American engineers have achieved incredible accomplishments over the decades. Why worry about the business aspect? Ugh. His response was: "*Every post you will make from now till 2025 is easy to predict.*" It was intended as a dismissal... not sharing of valuable knowledge learned. Oh well, yet again. Here's how I responded: 15 years ago, I was saying the same thing. Deny. Dismiss. Distract. It won't change the reality that we need clean & efficient choices for the masses. Whether or not Volt joins in with the rest of the mainstream offerings is what we cannot predict. Again, the vehicle must be able to take on the true competition: traditional vehicles. That means production-cost must be low enough for it to draw large interest (from both consumers & dealers) and still earn a profit, without any tax-credit or HOV incentives.

- 12-11-2015 5 Years Ago, Alone.** No one else shared his sentiment. We have found the very last of the stubborn enthusiasts of the past. Hooray! I was tired of unwillingness to recognize need. Being part of our larger effort to end the reign of traditional vehicles is far more important than earning top honors for engineering. More and more, judgment of success is based upon subjective measure anyway... which, in a way, can be better than arbitrary measure... since the market is too diverse for any type of one-size-fits-all measure anyway. Looking back at the previous 5 years, it doesn't take much to see how much opportunity was lost. The market for plugging in was simpler than and gas was expensive. Now, there are a variety of new choices on the way and cheap & abundant oil will make efficiency a much harder sale. That's why the balance Toyota is striving for with Prius is so important. Rather than delivering a huge MPG improvement, this gen-4 will provide a modest bump. The tradeoff is not trimming as much weight for the sake of offering greatly improved handling. GM will be learning the hard way that heavy focus on the battery-capacity increase wasn't worth it. Some tradeoffs just aren't worth it. Remaining a niche will be hard to bare. To GM's credit, the automaker has recognized & acknowledged the issues related to sales by diversifying. That effort to offer choice is an important step in the right direction. Betting the farm on Volt wasn't wise. Look at the variety of hybrids Toyota offers. Look at how Ford has been struggling to offer choice... and Honda... and Hyundai... and VW... and Chrysler/Dodge... and even Nissan.
- 12-12-2015 5 Years Ago, Change.** The fallout from Two-Mode was so bad, disassociation was preferred response. Everyone knows now... 5 years later... that the system really did live on, but with a huge redesign to deal with the obvious shortcomings. Much of the problem derived from the setting of unrealistic expectations. GM's problem with "*over promise, under deliver*" was not addressed. Executives kept promoting too much. That's how the "*vaporware*" backlash with Volt came about. How could all that be achieved within just 3 years of development? The following 5 years of sales revealed it was indeed unrealistic. So, that begs the question of asking what is realistic. Looking at the other automakers, we've see an effort to target their own customers. Only GM neglected its own, sacrificing opportunity from within for the sake of conquest. Thank good that has finally changed. We aren't really sure what to expect, but at least we can see the change. It took 5 years for the turn-around to take place, but better late than never.

12-17-2015 **Hyundai Ioniq.** This coming March, we're expecting a new hybrid, new plug-in hybrid, and new EV all bearing the "Ioniq" label. Hyundai will rollout the new vehicle platform in those 3 varieties. Interesting new competition for Prius, eh? This is what one participant on the big Prius forum had to say about that: "*Maybe it's me, but I foresee a quite tough future for the cranky Prius IV with the Ioniq around...*" It's easy to get that impression, not considering the market as a whole. It's far too easy to fall into the trap of comparing vehicle-to-vehicle. I presented the situation from this perspective: A vehicle offering similar characteristics will compliment the other, drawing in a larger overall audience. In fact, growing the market cannot happen without some type competition. Sales plateau without a cross-competitor endorsement. It's easy to understand how increasing the size of a battery and adding a plug will improve the efficiency of a hybrid. Seeing more and more of those choices on the road will make selling them easier. Rather than competing with each other, they'll really be promoting the category. We'll have PHEV offerings from Toyota, Ford, Honda, Hyundai, Mitsubishi, and even GM. Those augmented hybrids will be compared & contrasted. Battery capacity will become just another aspect of purchase decision. Since each operates as a hybrid when plug-supplied electricity is used up, they'll still have an advantage over traditional vehicles. Adding a very small engine to an EV is another easy to understand design. Its purpose of serving as a backup power-supply when the battery is depleted is obvious. We'll have that EREV category, currently occupied by BMW alone, but Nissan plans to join in. The minimum cost, size, and weight differences from an EV keeps it competitive while also addressing charging concern. Of course, there's Volt too. The term "*boutique*" is being used more and more to describe it... since the design stands alone and there are no plans for anything to like it from other automakers. GM isn't planning on widening appeal beyond special interest either. Sales will speak for themselves. Remember, there's a race to profitability. When the tax-credits run out, these vehicles will need to face traditional vehicles head-on. That's tough competition when gas is so cheap. Right now, here in Minnesota, I saw \$1.79 per gallon today. Some in a few states have posted about even lower prices. That's a very real problem when trying to promote cleaner and more efficient choices. Having shared goals with other automakers will help a lot.

12-18-2015 Observations, new gauges. We're seeing a big turn-around. It comes as a result of observing. That can take years. Thankfully, the gen-2 upgrades provide an acceleration to the process... as this illustrates: *"My observations from this trip (and subsequent trips that I have taken) is that ERDTT will run the ICE until your coolant temperature reaches 145°F, at which point the ICE shuts down. Once the coolant temperature cools to 120°F, the ICE starts again. So my observation is that ERDTT maintains the coolant temperature nominally between 120°F and 145°F."* That came about from the new Volt offering coolant data on the display. Not having that in the past meant drawing conclusions on nothing but anecdotal evidence. Actually being able to watch an instrument showing real-time detail is a profound improvement. I joined in the discussion with this: The local EV club in my area has been a great source of information about the other plug-in vehicles. When we get together, we share detail difficult to get any other way. It's nice to see some of that popping up here now. After all, gen-2 offerings are taking a different approach. There's also far more choices that will be available. Anywho... With my Prius PHV, the range is quite different. Warm-up completes at 130°F and the heater will continue to blow out heat until the coolant temperature drops to 82°F. That's long enough to allow me to get through the entire river-crossing winter stop & slow on my commute without the engine having to start back up. Similarity to Volt is they both take advantage of engine waste to provide cabin warmth. That is indeed a nice benefit for overall efficiency. Sacrificing plug-supplied electricity for the heater isn't a good use of limited battery capacity. And yes, being able to see coolant temperature on the gauge cluster is great!

- 12-18-2015 Observations, ironically.** I now have a group intrigued by what I share. It's the same old information as in the past, but now presented in a using an alternative approach. The difference is they actually have something to contribute now. That's what makes an "enthusiast" become a "supporter". All those years of fighting principle blinded them to what is not rather obvious. The problem came from them not wanting to discuss anything whatsoever related to Prius. They were so fearful of Volt becoming lost in the crowd, it never dawned on them that the information exchange was really an invitation to join. It was fight, fight, fight. Ugh. Oh well. Now that the "*too little, too slowly*" has been overwhelmingly confirmed as having been a legitimate concern, all is acceptable. I can go on presenting the same data all over again; though, this time they are interested. This is how I responded to the positive feedback: Thank you for sharing details of that drive experience, especially those photos. That's really helpful toward filling in the information gaps... a major problem we had with gen-1 understanding. Remember all the tar & feather events? Quite a number of enthusiasts weren't aware of factors that influenced operation of the system back then. Pointing that out resulted in a lot of misinterpretation of intention... contributing to misrepresentation. Sure is nice to see the effort to get beyond that. It's the support we really need. The factors themselves still remain. The need for cabin warmth is a big one. Using the A/C has a heat-pump is only so effective. The less efficient choice is resistance-heaters, but that uses even more electricity. Turning to the gas engine by capturing its waste heat can be a decent tradeoff. The more informative screens really help with the understanding of impact. Other factors, like blending rather than pure EV all the time, are also very difficult to grasp beyond just the concept with detail. Seeing new data that's available to the driver in real-time is a very nice gen-2 improvement. We must keep in mind that the true competition is traditional vehicles, not other plug-in vehicles. That's why sales are so important. Watching customers leave dealers with a gas-only purchase is really a let down, something we (not the dealer) need to change. Topics like this are a big contribution toward that. Thanks!
- 12-19-2015 Observations, disbelief.** Ultimately, you want to have some of your much stubborn enemies become friends. Their unwillingness to give up is a strength. It's not good to hold them responsible for the damage their misunderstanding caused, since working with them is a powerful way to recover. To look back and see all those personal attacks, when they chose to completely ignore the issue at hand for the sake of shooting the messenger. It's a huge waste. But then again, collateral damage as a result of a paradigm-shift is to be expecting. There's always some type of cost when change is required. The goal is to minimize, not eliminate... which ironically, is the point of hybrids. They minimize gas consumption, but don't eliminate its use entirely. Evidence of the turn-around is to actually quote me. In this case, it was: "*We must keep in mind that the true competition is traditional vehicles, not other plug-in vehicles. That's why sales are so important.*" One of the simplest greenwashing techniques is to misrepresent by implying, rather than quoting. So, I was in disbelief as much as he was: "*Who are you and what have you done with John???*" The attitude of the past is fading away. I had really hoped gen-2 would usher in new understanding. Real-World data has always been the most effective tool. All you have to do is take the time to observe.

12-20-2015 Observations, revolutionary. Gas is only \$1.79 per gallon here. Diesel is rapidly dying for passenger use. There is a growing list of upcoming hybrid & plug-in choices from a variety of automakers. This is an unusual and unexpected situation. What was expected was for gen-2 of Volt to be revolutionary and for the gen-2 Prius to continue evolving. In other words, the belief was Volt would remain "*vastly superior*" as a symbol of leadership. Instead, we have a complacent market with everyone playing catch up... and Toyota still leading the way. Lack of clear direction has always been Volt's problem. Not knowing who the audience was meant continued confused messages of purpose. GM needed a mainstream choice, but enthusiasts kept begging for a niche. That's why it was so vital knowing who. Second generation requires clarity. That's how Prius was so successful. You can only make major changes when goals are concise. They still aren't for Volt, hence the mess it is in now and only a collection of small improvements were rolled out. Prius, on the other hand, had a clear message of competing directly with mainstream vehicles. That meant trading off huge efficiency gains for the sake of handling upgrades worthy of drawing lots of new interest. No more "*eco-box*" image. There was a clear effort to make Prius more than just evolve. It needed to be revolutionary. Changes had to be so noticeable that people would recognize this generation was different. With a reputation well established for reliability. Proving it was "*up to the chore*" for taking on salesroom floor opportunity was obvious. That's the observations I've made over the years. It sure is nice getting confirmation of that being exactly what Toyota was pursuing. Too bad those Volt enthusiasts who fought me up to the bitter end are only now seeing the light. It's quite amusing too. The spin is that my attitude has changed. I'm still posting the same messages though. Only now, they understand the importance. The trophies they sought have been earned. Volt did indeed deliver some impressive engineering; however, that wasn't the assignment. Each automaker needs to change their own offerings, to replace traditional vehicles with new clean & efficient choices. Being a "*halo*" didn't achieve that.

12-23-2015 Observations, fear. It started with Prius. There was fear it would extinguish Volt; which ironically, Volt had fire scares to deal with too. So, it needed to be "*vastly superior*". That meant comparisons to the only truly successful clean & efficient new technology would happen over and over and over again. Treating a vehicle without a plug and without a massive tax-credit the same as one that had both really bordered on the edge of lunacy. It simply made no sense. Yet, that was the formula agreed upon by enthusiasts. A small number of those online posters attacked and the large remainder were enablers. That's not the kind of observation we wanted to make. The desire was to form a partnership by exchanging knowledge & experience. Thank goodness that's finally happening now, long overdue. Unfortunately, the fate for Volt is already sealed. Rather than taking the opportunity years ago to steer the next-generation in the direction of mainstream, it became a confused mess. Today was great proof of that. The topic on the Volt daily blog was all about Bolt. It's quite remarkable how dramatic of a change has come. Some posts totally contradict intentions of the past. Others don't even acknowledge Volt as a player anymore. GM will (somehow) be delivering an affordable 200-mile EV. This is why I blogged so much about history as it was unfolding. The now hypocritical claims from years ago are difficult to believe, but well documented. They see this outcome as obvious. Really!?! There are still comparisons to Prius too. What the heck? I could understand the plug-in model. But how does the hybrid even remotely share the same category? Ugh. Needless to say, there's more to this than what meets the eye. HOV stickers in California are gone. The last "green" was distributed recently. That means a major purchase-incentive for Volt is no longer available. For Bolt on the other hand, there are a number of "white" stickers still. BMW's i3 qualifies for them, despite having a gas engine. That engine is tiny (650cc) and the gas tank is tiny (1.4 usable gallons). That makes it an EV with nothing but a short-range, limited-power backup. It's a true EREV. Enthusiasts of Volt lashed out when cornered in the past. Now, they've switched loyalty over to Bolt. Seeing Volt abandoned like that is bizarre. It's doomed to remain a niche without any way to draw ordinary consumer interest. Who will the support come from? The observation of what comes next will be interesting. The time to file a \$7,500 credit without having to wait until 2017 is quickly drawing to an end. The HOV stickers are already gone. Initial demand has been fulfilled. With the Detroit autoshow promising to stir interest with new plug-in offerings, what will happen to Volt? Remember, 2016 Prius sales are about to begin soon and the price of gas is at record lows.

12-24-2015 **Beyond Possible.** This 2-minute video-advertisement for the 2016 Prius from Toyota is making rounds on the internet. It shows Prius tearing around an industrial area, screeching tires while tightly maneuvering through abandoned buildings, and sliding sideways on graveled roads. Comments were made about how unrealistic that was: "*I think the add portrays a false expectation...*" You can't help but to roll your eyes from comments like that. The pointless things we've seen along the way should make this a complete non-issue. How many times have you witnessed a pickup pulling unbelievably massive loads? I remember one showing 32 refrigerators being transported on a flatbed, towed by a consumer-grade pickup. Why? Who in the world would ever do anything like that? There isn't even a rough equivalent. Same goes for all the SUV off-roading advertisements. How often does that actually happen? People are using their SUV, with heavy-duty suspension and massive tires, for commuting to work... sharing the same roads as everyone else. Why is that overkill acceptable, but not watching a Prius being driving as if it was on an obstacle course? Needless to say, some perspective is needed. We've watched far too many sedans racing across open salt-flats to have to accept a double-standard. This marketing isn't anything different from countless other advertisements... but with a twist. Prius can also point out that it's green too. Anywho, this was my post about it: We have literally seen thousands of commercials like that over the years. It's how cars and trucks have been advertised. Seeing that is the expectation. Whether or not you ever do that with your vehicle is an entirely different matter.

12-26-2015 **Observations, the problem.** The muddy mess of issues & solutions continues to get worse. Even though there are obvious signs of SMOG emerging around metro areas, the snap response to dismiss our pollution problems is to just write off "*climate change*" as human caused. Volt has become the lightning-rod for arguments centered around the issue too. It's really unfortunate enthusiasts focused so highly on "*gallons*" and basically ignored the bigger picture. They never bothered to help point out CARBON emissions are not the same as SMOG emissions. That fundamental difference is now hurting their cause. Of course, had they used SMOG as an argument point rather focusing entirely on CARBON, we likely wouldn't have as much of a mess to still deal with. Reading an article published a few days ago praising the gen-2 Volt, it was easy to observe the problem. There were 165 comments posted as of writing this. The nature of many arguments against Volt centered around being vague. The premise of "*cause*" instead of "*contribute*" is the primary inhibitor preventing any detail. The enthusiast obsession with absolutes makes it worse. People simply don't care as a result. The final nail-in-the-coffin though is the tax-credit. Dependency on that provides an excuse to reject. So, regardless of whether or not the automaker earns a profit from sales, that government-assistance cancels out any benefit as far as they're concerned. This an the aspect of business the enthusiasts fought against for the first 5 years of Volt availability. Now, consequences of that choice are revealing the problem they allowed to grow. Very few posts are constructive. Many on general-audience articles like this are political in nature (due to the obvious government involvement.) My favorite post was this: "*84,600 sales in 5 years, resounding success?*" It highlights shortcoming of engineering focus. No matter how impressive performance of any vehicle may be, people won't make their purchase decision on that alone. That's basic economics. Too bad enthusiasts refused to acknowledge that. Even with the \$7,500 incentive, they're wasn't enough interest anyway. The problem was (and still is) much more complicated.

12-26-2015 Observations, change. There is no precedent for gen-4 offerings. There is stereotyping though. That's a very real problem... unrelated to emission issues. People establish a mindset and stick to it. Breaking away from that is tough, as marketers are well aware. Campaigns to change pre-established views presents challenges. Advertising can be effective, but there needs to be something compelling to draw new interest. With the case for each new Prius, expectations have been for a more efficient system with a decent cost-reduction. In other words, the system would be further refined... making it even more appealing to those wanting to reduce emissions & consumption. The reality that Toyota would not have that focus anymore is perplexity to some. We've already observed many, many, many posts from those not understanding the overlying need. They continue to assume priorities won't change. That change is absolutely vital though. Gen-4 is designed to achieve that. This new Prius trades efficiency performance for handling performance. There's more power for city driving and the suspension has been upgraded. Combined with a lower center-of-gravity, this is a noticeable departure from what the first three generations of Prius offered. That's why the standout look was chosen. This new offering will easily be recognized as a Prius, but the styling is doesn't conform to the ordinary pattern we still see. The new Volt is the ultimate example of this. Gen-2 looks remarkably like a Civic and a Forte. The style was dumbed down (for lack of a better description) to look like other popular sedans. In fact, that's why it doesn't offer a rear-wiper, despite being a hatchback. GM decided to make it look like it's part of the traditional crowd to help promote sales. The catch is, that only works for earlier offerings. With just a second-generation design, refining the system and retaining an ordinary look can be beneficial. However, with a fourth-generation rollout, doing little to alter visual appeal can become a barrier. A bold, new look can draw lots of interest. People get too distracted by other factors to notice that importance though. Unless you study consumer behavior, it gets overlooked. Competition at different generational stages makes the understanding of what really influences behavior very difficult is hard enough. Change in a market with so much pressure to succeed often causes the obvious to go unobserved. Remember purpose. Focus on goals.

12-28-2015 Observations, audience. How many times and how many different ways can this be addressed: *"A plug-in hybrid that has to use its ICE before the battery is depleted is much less desirable."* I climbed up on the soapbox one more time: Know your audience. Ordinary consumers won't be interested in electricity purity, especially if there's a high-cost required to achieve that. If they did want purity, they'd just purchase an EV instead. The 200-mile capacity offerings will be targeting them. The strength of plug-in hybrids is balance. You still get EV, just not 100% of the time prior to depletion. Rather than sacrificing electricity for the sake of avoiding any gas consumption, the system takes advantage of having an engine available. Running that engine in the most efficient manner is key. Blending (using plugged-supplied electricity) for augmentation is how. RPM is lowered significantly and revving is reduced. Ask yourself how much more an ordinary consumer would actually be willing to pay for the purity tradeoff. Ordinary consumers won't care whether or not the engine runs at times. Heck, most don't even know what their current vehicle actually delivers for MPG. Seeing a plug-in hybrid deliver +100 MPG while cruising on the highway is what will draw interest. Late night local errand-running locally in EV has obvious appeal too. Remember, the audience is people on the dealer's showroom, those who would otherwise just purchase a traditional vehicle.

12-29-2015 Observations, support. Watching things fall apart for Volt just as the new Prius is about to arrive makes for interesting observations. It's weird how enthusiasts continue to draw attention like this. It's a repeat of what we saw 5 years ago. Wasn't anything learned? Reading general-audience automotive blogs, you can see the pattern. The behavior that closely resembles that on the Volt blog. Rather than Volt being a player on the plug-in team, it is still portrayed as superior. Ugh. Yesterday's stir came from details revealed about the 2017 model coming early next year. That's the one which will be available nationwide. Expectations were to get a variety of improvements here and there along with some type of price drop. Instead, only a premiere package was revealed. That's it. Basically, rollout was held to 11 initial states for incentive benefits. California was about to run out of HOV stickers. Sending the bulk of inventory there, especially when there is also both state & federal credit to be had, seemed to make sense. Though, there was the mystery of why production simply wasn't ramped up instead. After all, that is what Toyota did for gen-2 and we were told for years from enthusiasts that GM would also do that. The double-standards, the hypocritical claims, and the contradictions were quite informative. We knew issues weren't being addressed and that certain shortcomings weren't a priority. It's the denial though that's telling. Who the heck is going to support the technology? Remember, a big chunk of the success of Prius came from the empowerment of owners. They'd share their knowledge and experiences with others. That type of endorsement is far more powerful than any business entity could provide. Without that, who will interested consumers turn to? What will their resource be if there's a collection of enthusiasts reciting the same failed messages as in the past. Move on already. Geez! Notice how the new Prius traded efficiency for handling? MPG wasn't abandoned; it was simply not given as much priority. Owners pointed out and even demonstrated with their own upgrades how Prius could be improved to appeal to a wider audience. Toyota took suggestion and implemented it... without sacrificing cost. Volt is still expensive. Volt is still small. Volt still lacks common new-tech, like LED headlights. Heck, those are standard on Corolla. Why in the world aren't they offered on Volt? For a vehicle that was supposedly going to leap-frog Prius, it still doesn't show the potential to draw enough sales to actually do that. Rollout of the 2017 model will be overshadowed by Bolt hype. Who is the audience for Volt and where will its support come from?

- 12-30-2015 Observations, new topics.** There are some glimmers of hope. New topics provide that opportunity. When an Leaf attack began on the daily blog by Volt enthusiasts, my interest was captured. It was an opportunity to introduce a new perspective on what could otherwise be just a repeat of old discussions. This is what I homed in on: *"You missed the thermodynamics classes. All vehicle engines and motors are *air cooled* since all the heat is expelled to the air. The difference is the heat transfer mechanism. An active transport, such as liquid coolant used..."* His missed the point entirely. It's quite common. People will fixate on the wrong thing, often a symptom rather than the actual cause. I jumped in ready for battle with: Ugh! Everyone continues to miss the underlying problem: HEAT IS A WASTE PRODUCT. Using liquid to transfer that heat is really just a Band-Aid to deal with that unwanted situation, rather than preventing it in the first place. It makes no sense to disregard that waste. The goal should be to create more efficient operation, which will reduce losses from heat. Less energy consumed overall will increase range and/or decrease battery-size too. Not needing to add the complexity of extra cooling reduces weight & cost as well. Focus on the bigger picture. Don't get hung up on approaches that fail to address the ultimate need. That fundamental improvement still being overlooked is the real problem.
- 12-31-2015 Observations, look forward.** That basically killed the discussion. Posts wandered, totally off-topic. There was a solitary response to my post. It started with the typical *"no free lunch"* rebuttal. That's a dead-giveaway the person didn't take the time to actually consider what had been posted. Focusing on absolutes doesn't accomplish anything. What extreme ever represents an expectation or even a goal? I ignored that and waited until this morning to respond. I quoted this part: *"Obviously engineers of some vehicles decided that active liquid cooling for their batteries and electronics was worth the weight. Forced air cooling would likely require even more power, more room, and not capable of the same level of performance."* It was worth bothering with the *"always"* part in the first part of his post. My comments were: Not requiring extensive cooling is the goal. Decisions of the past were based upon technologies of the past. Look forward now. Notice what the computer industry did over time? They too had battery & heat issues. Designing more efficient processors and optimizing software reduced the power-consumption, which in turn reduced waste in the form of heat. As much as people here hate to consider Prius, you have to admit Toyota did its homework. The inverter/booster was made more efficient over the generations. The unit itself underwent major revisions, including size & voltage alterations, as well as upgrading internal components. The latest improvement was elimination of external wires. Rather than having to connect wires, it attaches directly to the propulsion system now. The traction-motor was made more efficient by making the wires thinner and wrapping them tighter. The electric-propulsion was made more efficient by increasing the number of power-carriers within the power-split-device and replacing the reduction-gear with a second power-split-device. There's the benefit of battery chemistry & manufacturing improvements too. The end result has been a system that uses less electricity to accomplish more... so much so, the newest battery only needs half the total capacity of the previous generation. That equates to less heat.

- 1-01-2016** **39 MPG.** Today was nothing but driving. We traveled over 700 miles. Much of that was straight west over roads with very few hills and very few curves. Specifically, the drive was from the eastern side of Minnesota, clear through the entire state of South Dakota, over to a remote town in the eastern side of Wyoming. After leaving the state, the speed-limit increased from 70 to 80 mph. Maintaining a cruise at 80 mph for hours on end isn't something I've ever done before in the Prius. Of course, we couldn't do it today either. But on the way back, that might be possible. Heading west means driving on the north side of the highway. They don't plow in South Dakota. There's no sanding or salting either. That means the snow blowing from the north over the road gets smashed down into the pavement. Over time, that builds up ice. Slowing down to 70 is the best you can do without over-braking. The small patches appear randomly and far apart. You can go a long way without encountering one. Then suddenly... you have to glide over it. Surprisingly, that's actually safe. Most are very short. Anywho, I watched the efficiency average drop. With temperatures around freezing while traveling at that speed, the 39 MPG average was rather impressive.
- 1-03-2016** **Too High, Too Fast.** This is a very real problem: "*Over the last year I've been trying to decide what I would do once my Volt lease was up. Buying it as a used car was out of the question for two reasons. The residual was way too high (at \$27,628) and electric-car technology is changing too fast.*" What would you do? Leases aren't anywhere near as generous nowadays either. Years back, low lease prices were used to draw in buyers who would otherwise just dismiss Volt as a possibility. Since then, MSRP price has come down and the used market is saturated with lease returns. As a result, those once considered "*conquest*" sales are becoming lost customers. They just move on to something else. Enthusiasts absolutely refused to acknowledge this was a possible outcome. How do you sell an outdated early-model plug-in vehicle? What do you buy as a replacement? It's an ugly situation saying "*I told you so*" to doesn't help you even feel better. We tried to point out the recklessness of those leases. Oh well. It's an everyone loses situation. That's why I'm glad Toyota limited both gen-1 of Prius and gen-1 of Prius PHV to small audiences. Heck, for the first 2.5 years, the only way to get a Prius was online order. Talking about not having any showroom presence. That was useful with the real-world data-gathering though. It kept the used models in check to. PHV has been limited as well. That problem of "*too high, too fast*" is an interesting retrospective on the "*too little, too slowly*" concern. That's why clarity of purpose is vital. It's unfortunate there are still efforts to keep intent vague. Some lessons are never learned.

1-05-2016 **1,602 Miles.** That round-trip sure was interesting. The stretch through eastern Wyoming and the entire length of South Dakota was with the adaptive-cruise set at 80 mph. With so little traffic this time of year and the road hazard free (no ice or snow and little traffic), it was smooth sailing. Of course, even at that rate of travel, it still took 16 hours to get home. Once in Minnesota, the speed-limit does slow down to 70 mph, but that really doesn't equate to much. Stops for food & gas are a welcome break from the almost turnless journey anyway. To our amazement, despite winter cold and going so fast, the average for that whole long weekend getaway came to 42 MPG. With only a single battery-pack charge the whole time, you'd think the plug wouldn't have made any difference. From an efficiency point-of-view, it really didn't. But from an enjoyment perspective, you bet. We drove through a park elaborately decorated with massive animated holiday-light displays. Being able to drive all of that using only electricity sure worked out well. Anywho, I had a good time and the purpose of the Prius was fulfilled. We were delivering a baby crib. The large cargo area made that easy. The radar to slow down the Prius when it approached a vehicle going slower on the highway was great.

1-06-2016 **Sales Perspective.** With the second-generation of Volt so new, there's obviously going to be peaked interest. Purchases would be strong simply due to that. But leaving out any mention of the tax-credit and posting this as the opening line in a sales perspective article is quite misleading: "*Chevrolet is back in the saddle again with a relatively healthy 2,114 Volt sales in December.*" In fact, some may call that greenwashing. I expect the typical spin to come from my post about that: The last-minute rush to purchase before year's end was expected. Buying before the start of 2016 means you can collect the \$7,500 tax-credit with 2015 filings; otherwise, you have to wait until 2017. Avoiding delay of an additional year is good incentive to buy right away. That "*back in the saddle*" assessment requires waiting for January results, especially since we all know the reveal of Bolt will have a direct impact to Volt interest. The minimum milestone for mainstream vehicles in this market is 60,000 annual (5,000 per month). A quick look at GM sales for December of popular cars show that is easily exceeded... Equinox 21,827. Cruze 16,849. Malibu 12,155. Impala 9,060. Sonic 7,293. Camaro 5,366. What are sales expectations?

1-06-2016 **Obsolete?** I questioned why that label was given, pointing out RAV4 was just due for a generational update. This was the reply: *"Are you saying there is a PHEV SUV in the pipe for Toyota? Toyota is all Fuel Cell, hater of plugin... at least that is what they are telling the public."* Sometimes, it's difficult to see the perspective from someone with only a tiny bit of information. They focus in on something trivial, not seeing what was actually at play. Knowing how to respond to the can be a challenge. I chose: Overlooking the obvious... that RAV4 is due for an update anyway... shows how effective the greenwashing campaigns have been. Toyota got labeled as an *"all Fuel Cell, hater of plugin"* by those greenwashers. Their most common technique was to post information out of context. Simply limiting perspective is an easy way to mislead. For example, when the first-gen PHV model production came to an end, they claimed the entire PHV program had been ceased, that support for plugging in had been abandoned. They were relentless too, continuing to make that assertion without any data to actually support it. The fact that Toyota didn't want to get stuck with inventory that would have to be marked down when the next-gen Prius was revealed was outright dismissed. They just kept on with greenwashing efforts. Another example is Toyota's effort to diversify. We all know that EV won't work for everyone. We also know that the oil industry will wage a massive campaign against them. To portray Toyota as a fuel-cell only supporter, the greenwashers did everything they could to suppress plug-in endorsements by changing the topic to fuel-cells. That desperation to mislead about intent was amazing. They were relentless. We've seen quite a bit of that in the past too. But there's no need to look back any further than 2015. Some have went to great extremes to build up false impressions... so effective, overlooking the obvious becomes common. In this case, we know Toyota is expanding hybrid offerings to every passenger model vehicle they produce by 2020. The hope of eventually being able to provide a package-option choice with a plug should be obvious. Gen-2 PHV is helping pave the way, just like the original Prius did for expansion to other models over a decade ago.

1-06-2016 **Desperate, no data.** It has been quite remarkable over the past few months. We've witnessed both VW diesel and GM's Volt fall apart. The grand plans are no more. Those automakers are moving on. We're staging the final battle. A friend of mine posted this: *"Bring us data - we don't need sheet metal art or bluster words. We need engineering metrics, facts and data. If you don't have them, be calms and wait until they are available. But don't prove you don't know anything by posting nonsense speculation. At least don't embarrass yourselves like VW. Better to be quiet and thought the fool than to post and remove all doubt."* He's tired of the nonsense and sees no sense having to endure it anymore. I jumped in with: Great words of wisdom. Sadly, we've seen this nonsense far too long. "SHOW ME THE DATA" dates all the way back to 2004, when the gen-2 was new and got routinely attacked with claims that didn't have any merit. The real-world detail clearly revealed greenwashing efforts. Post were kept vague to avoid getting caught. The rollout of Two-Mode and sales that followed were a disaster. Cause was obvious. Expectations were based on speculation, not actual facts. Real-World data brought hope to a sudden death. Volt is even more of a mess. It was as if nothing had been learned from Two-Mode. In fact, when gen-1 expectations fell apart, focus was shifted over to gen-2 instead. Repeating the same mistakes, yet again! With Hyundai's rollout of Ioniq, we're seeing the same careless hype emerge out of factless claims. They feed the speculation, becoming part of the problem.

- 1-06-2016** **Desperate, step up.** I've seen the pattern repeat so many times, it boggles the mind that the same old desperate tricks would be attempted. We see the cycle. Doing nothing to prevent it from starting up again is nuts. Yet, most participants online don't take that extra step. They settle for winning a battle rather than drawing the war to a close. Even with the wisdom of seeing the forest, most are unwilling to speak out beyond the moment. That big picture is lost. Some pointless trolling post will get a bite. A newbie will unknowingly fall for the invitation to become supportive of a greenwashing effort. It's misleading with recognition. The victims are clueless to what they contribute. Anywho, I simply put it this way: It will drag on for years of someone doesn't step up. After all, a growing problem in forums & blogs is enablers... those who don't speak up. The direct approach is quick and leaves no doubt.
- 1-06-2016** **Desperate, scapegoat.** The ultimate is a summary, where the troller (disguised as a faithful group member) makes claims about what you did over the years. It's quite obvious they are painting a picture of deception. The references are clearing from others. Lurkers won't realize that though. Veterans of the group won't care. They simply want someone personified as the cause of their peril. It's surprisingly vindicating. Their desperation is so obvious. There's no point in arguing. All you want is the confirm. I find it very amusing. They just make stuff. Looking back through my blogs, I can see exactly what was actually said. It doesn't match what they claim, not even close. Today, it was the desertion of Volt in favor of Bolt. GM is joining the very effort it had once fought intensely against. The reveal of production detail pushed the few (only a handful left) to the brink. We saw that play out. I drew it to a conclusion with: What was hoped for, what was said, and what actually came to be is well documented. It's not the never-ending spin we have to put up with here. What happens here is good confirmation though... of what worked and is still being waited for. The rhetoric simply doesn't hold up. Vague claims online don't accomplish anything. We see difference being made by watching the road, parking lots, driveways, and garages. Those are the vehicles of change.
- 1-07-2016** **Desperate, leadership.** It's interesting to witness an ending and a beginning. Bolt is taking the stage. Hyundai is working hard to get it. Toyota will begin deliveries of the new Prius shortly. Things really are moving on. A handful just plain cannot with that though. To them, I posted: Leadership is getting ordinary people to change. For 5 years, many here dismissed priorities and simply focused solely on engineering achievement. They assumed the impressive power & handling traits along with a \$7,500 tax-credit would be enough to entice. Consumers didn't respond well to that though. Yet, the accountability of automaker need was dismissed. Becoming a self-sustaining vehicle (high-volume, profitable sales) remained out of reach. Thankfully, the necessity of diversification is finally being addressed by GM... which seems to be going well. Unfortunately, it leaves the die-hard enthusiasts in an uncomfortable position. They will appear to be supporting a double-standard or be labeled as hypocritical for embracing that change... hence lashing out at a scapegoat. That's annoying, but not the end of the world. The required adjustments to achieve change are being made. True leadership is taking place... whether they want to accept it or not.

- 1-07-2016** **Desperate, denial.** The experience of failing is difficult to accept. From those with the most to lose, we get denial. The pattern is very easy to recognize. They just move the goal-posts and claim mission accomplished. It's rather sad. That's what the blogs are for though. You can look back to see what was actually claimed and hoped for. The disconnect is obvious. With this particular experience, it was best summed up with: "*Gen1 plug-ins have crushed Gen1 hybrids.*" All along... years prior to rollout... Volt would crush Prius. Over and over and over again, we'd here how sales would be far greater. When that didn't happen with gen-1, they simply shifted focus over to gen-2. When it became evident sales wouldn't even be close, focus shifted back... but rather the entire category, instead of just individual models. Whatever the cause, the comparison is a blatant attempt to alter circumstances. Way back when hybrids were introduced, there weren't any tax-credit or HOV incentives. Instead, there was a teeny-tiny tax-deduction and a massive effort to greenwash. Remember the early 2000's? Climate-Change was a joke, were encouraged to guzzle, and very few cared about smog-related emissions. Now, every automaker is scrambling to deliver something and battery-technology is well-proven. In the end, it doesn't matter. We know what happened and what was said. Those in denial just plain don't care. They'll do what it take to save face and be convinced they were right all along. Just make sure they don't ever look back and actually read old posts documenting history as it happened, not the way they claim to remember it. Ugh.
- 1-07-2016** **Moving On.** We've got other problems to deal with. The latest is Ioniq promotion. Accuracy is lacking. Much of it has come in the form of outdated information about Prius being used to make Hyundai's upcoming offering more appealing. Naturally, there's some vagueness contributing to the problem. But in this particular case today, the issue to refute was obvious. I posted the following in response to what was supposedly a rival introduction... It's frustrating to see how an upcoming new hybrid is compared to an older generation with the claim of competing rival. We've all known for months that Toyota is switching all but one of the Prius packages from NiMH to Lithium batteries. Yet, this was posted anyway: "*The newcomer also uses a modern lithium ion polymer battery as opposed to the older Nickel-Metal Hydride unit preferred by Toyota.*" It's bad enough we still have to endure attacks from disenchanted Volt supporters. But coming from a supposed automotive expert professionally writing an article, there's no excuse. That type of misinformation feeds greenwashing efforts. We've seen it countless times in the past. An article like that will get quoted as an authoritative source over and over. People will blindly believe those claims too, accepting them at face-value without bothering to do any research of their own. That's really unfortunate. In other words, we need to speak out. Making sure misleading "facts" aren't spread is a big deal.

1-08-2016

Fear. That's what pushed those final die-hard enthusiasts to the brink, lashing out at anything they could. Having something to blame was what they were desperate for. It's very easy to see looking back. No mention of the true threat... BMW's i3. That's the design they had been promoting all along. Problem is, that's not what got delivered. Volt fell short. Trying to bring i3 down has proven impossible. Having lost countless battles fighting Leaf made that quite clear the effort was futile. The i3 only has one weakness they could exploit... the gas tank capacity. A little bit of research reveals a shocking reality though. That limitation is strictly a matter of battery-capacity. To qualify as a proper EREV (as per CARB qualification for "white" stickers), the total amount of available gas cannot exceed travel range to that of the EV capacity. Electricity range must be greater. Any type of improvement of energy-density or cost-reduction allows the quantity of gas to be increased. That's inevitable. Better lithium technology is a hot research & development market. A ton of money is being spent to achieve exactly that. It's why i3 isn't mentioned anymore. Pretend it doesn't exist. Make sure people only focus on Prius. Of course, there's a problem with that too. Hyundai's promotion of the upcoming Ioniq is threatening to eclipse GM's hybrid technology by going after Prius. Who's going to notice the Malibu with 2 other players stealing the spotlight? No detail whatsoever is being used to defend Volt anymore as a result. Real-World data is absent now. Too much showing shortcomings is a very real problem. That sales thread provided a great example of how efficiency data has vanished. It's simply not talked about now. That's a fundamental difference from the past. i3 abruptly ended those debates. Hyundai will be joining in along with Mitsubishi later this year, adding to the choice of plug-in hybrids offered. There will be a next-gen Prius PHV as well. How do you sell a product supposedly "*vastly superior*" without anything to actually support the claim? Fear caused those enthusiasts to lose track of goals, to get distracted by wants which didn't contribute to progress. They got incredibly defensive... rather than just joining in the team trying to help change along. It's too bad. That type of persistence could have been a valuable asset. There's a lot of pressure against the clean & efficient tech market. We need them to help make things happen. Not giving up is a strength. Holding on to an implementation proven unable is counter-productive. Take what was learned and apply it to the next offering. It's flabbergasting how tightly into a corner some people can back themselves. Move on already!

1-09-2016

Tired of the Nonsense. Some of us are tired of the few troublemakers working so hard to upset. We're starting to take a terse stand in response. Why should we have to put up with that anymore? For example: "*YOU expected 3rd generation pricing and sales from gen 1 Volt, nobody else did.*" That's such a blatant distortion of history, I couldn't resist jumping on the chance to rebut it. From another, this got my goat too: "*It appears that getting the mainstream public comfortable with the idea of plugging in will take longer than any of us expected.*" His claim of appears is a joke. We knew about that a very long time ago, with quite a bit of confidence too. I climbed up on the soapbox with this single post to both of them: Any? Only me? That's called denial. Look back. This blog is loaded with daily topics where gen-1 shortcomings were eventually acknowledged and hope was shifted to gen-2. There was a some group of us who pointed out the concerns before Volt gen-1 rollout. We got labeled as Prius supporters and were outright dismissed. When we pointed out what gen-2 needed for successful high-volume sales, we got attacked for disturbing the "*be patient*" crowd. Ironically, it was the original posts which did the disturbing, not ours. But there isn't a label for an internal-troll, someone interested in retaining the status quo rather than embracing change. The disruptive nature of their activity is conveniently overlooked. Thankfully, GM listened... somewhat. We got the diversification which was long sought. Branching the technology to a variety of choices is a win for all. Hybrid, plug-in hybrid, and pure electric will all work to entice the switch from traditional to something with a battery. Unfortunately, Volt cost didn't get lowered to the mass-appeal level as hoped. The choice was to push it even further into the specialty category. The outcome is already becoming apparent. It will please enthusiasts. They'll thoroughly enjoy that configuration. Ordinary consumers will look elsewhere though. I had to endure countless posts boasting over the years about how gen-2 rollout of Volt would absolutely squash Prius gen-2 rollout history. That meant 54,000 sales the first full year, following the first few months of initial rush buyers. The second year here in the United States drew 107,900 buyers... without a tax-credit. Notice all the resistance to numbers now? That's a dead giveaway those boosters see that volume goal will not be met. As for "*my*" supposed expectation of gen-3 prices for the gen-1 offering, that's a crock. No one talked about gen-3 back then. For that matter, gen-2 wasn't even discussed until the huge disappointment that came about from the announcement of gen-1 pricing. Until then, enthusiasts seriously thought the "*nicely under \$30,000*" price goal for MSRP would be achieved... hence the vaporware fights. Some of us clearly stated how unrealistic that thought that was... hence the hostility toward that topic now. It's nice that recognition of the trouble adopting plug-ins is being addressed now. But we already knew all those years ago why it would take so long. Cost & Capacity should have been obvious barriers to mass-appeal. A small pack is very appealing if the cost is competitive. A large pack is worth the extra expense if capacity will cover driving range needs with certainty. Attempting to deliver both is much greater challenge than many cared to admit. There was a few of us though. That can't be denied.

1-09-2016 **MPG Mindset.** The automotive enthusiast magazines embraced Prius because it drew in readers. Online publishing was new. So was Prius. Rather than horsepower, it was technology that sipped gas. People gobbled up the articles their writers provided. It was a draw source to help a struggling industry... especially back then, when the price of gas kept breaking records. Now, times are quite different. The mindset isn't though: "---- , *you should be ashamed of yourself . So how many MPG did you receive during your drive with the 2016 Prius? The main reason why consumers will purchase a 2016 Prius. You never told us did you.*" That was from a Prius forum member, who tried to shame the magazine publisher for not continuing to capitalize on the old single-mindedness approach. I wonder if he'll realize how absurd that was to do. We want change. He unknowingly was holding it back, insisting on the status quo. Ugh. Somewhat befuddled, I ended up posting: Haven't noticed the change yet, eh? MPG is not the highest priority anymore. This market has other preferences finally being addressed. It was really unfortunate how hybrids got stereotyped as delivering MPG by sacrificing of other appealing ownership traits. With all the other automakers jumping on board to offer there own hybrids and MPG being all over the place anyway (since driving circumstances vary dramatically from person to person), other aspects of the vehicle are now getting attention. Expansion to reach more consumers requires it. Toyota has embraced this. Drawing in a wider audience is what's needed at this stage. Once 50 MPG is achieved, increasing appeal by upgrading driving dynamics is a no-brainer. Now, you've been told.

1-09-2016 **Contradictions.** We get them routinely, especially from those who have posted for many years. It's rare though to actually catch that happening on the same forum topic less than 2 hours apart. I'm very curious what his response will be after having been called out on it. This is how it started on the big Prius forum: *"I don't see the Prius as expanding reach. Hybrids have acquired a 3-4% market share, years ago, and then plateaued. It is the king of using gasoline efficiently. But has not been able to expand the market share of hybrids for years."* When I pointed out my disappointment in his lack of confidence, I got this: *"Really? I've been cautiously optimistic and have even stated a hope that the gen 4 would help break hybrids out of the 3-4% rut they are in."* He first says is doesn't see it; then he states a hope that it will. What is that hope based upon? You'd think someone so active in online forums would know that sending mixed messages causes a world of trouble. But then again, that is what stimulates discussions. They aren't productive though. My guess is he'll just dismiss this as not understanding what he meant anyway. It sure is nice to have such a great example though of how problems online come about.

- 1-09-2016 Diesel Disaster.** The nightmare for VW keeps getting worse and worse. Last week, the estimate of unfixable vehicles here in the United States was revealed as roughly 325,000. That comes from taking into account the cost of the vehicle verses the cost of the upgrade to make it clean enough to meet regulations. That got people talking about buy-backs. Recently, that guess of quantity came to about 141,000 vehicles could be eligible. That would offset the environmental impact, but what about the other vehicles? What about those who get the upgrade, which will come at the penalty of reduced efficiency, reduced power, and reduced cargo space? Needless to say, the situation is a disaster. In fact, it's so bad, diesel for use in passengers vehicles is quickly dying. There's no appeal, especially with gas so cheap and diesel more expensive than gas. That plug-in hybrids absolutely devastate MPG in comparison anyway. A diesel cannot even remotely compete in that respect. Emission levels are obviously much lower overall with the plug too. A week from now, we'll have a ruling from CARB about the proposed solutions. That should be quite interesting.
- 1-09-2016 Who?** Pointing out the problem of audience can be fulfilling. Hopefully it will from this: *"I think we all had hoped that the gen IV would blow us away..."* Since it's so easy to lose perspective on a dedicated forum, a dose of reality is helpful if nothing else. My guess is some simply have no idea what the ordinary person thinks. Being well informed from online sources has the consequence of forgetting what it's like not to know. Anywho, I replied to that with: That's the confusion. We have already bought into Prius. We don't share the same priorities. We don't matter. To appeal to others, expansion of reach requires consideration of their criteria... not ours. Look at it this way, growing the market means appealing to those not already in it. The greatest potential is snapping up those shopping the showroom floor. They are people who couldn't care less if gen-4 delivers more than a solid 50 MPG. As far as they're concerned, that benchmark is so far above the efficiency they currently experience, more doesn't matter. Put a check in that box and move on. The criteria they'll focus on is what it looks like from the curb, which clearly the new Prius excels at. Do they want a blend-into-the-crowd ordinary look or something that looks sleek & modern? They'll look at what the driver sees behind the wheel. There's 2 impressive screens up on the dashboard, clearly an advanced interface for those drawn to electronics. There's a big screen that's fast and will interact with their phone. There's a wireless charging-pad for the phone too. Also, the cargo capacity & convenience is outstanding, no battery interference whatsoever, just a vast open area with fold-down seats. Aren't those aspects that will stir interest with only a brief look? Then there's the driving experience. The refinements to the hybrid system combined with the obvious body-stiffness and suspension improvements won't leave potential customers on the fence. Isn't this upgrade what they've been wanting all along? Other vehicles sell well for similar reasons. Why wouldn't appealing to those same traditional buyers the same way not attract them to Prius?

- 1-10-2016** **Chrysler Pacifica.** We just found out Chrysler will be offering a plug-in hybrid... only they will be calling it just a "*hybrid*" to avoid confusion. Ironically, that will likely be the source of many misunderstandings. It will indeed have a plug. The system will include a 6-cylinder 3.6-liter gas engine, two electric motors, and a 16 kWh lithium battery. The expectation is that it will deliver 30 miles of EV range. The anticipated rating is 80 MPGe. Will people really understand? Who knows. It's a minivan. Concealing a fairly large battery-pack below the seats isn't too terribly difficult. In fact, it fits entirely below the second row of seats. The third row will retain the stow & go ability (folding down that seat to make a flat cargo surface). There's enough room still for that. So, there is no practicality tradeoff... quite unlike most of the plug-in hybrids we've seen so far. Prius choose a smaller pack for the sake of not giving up storage space for large cargo. C-Max Energi certainly did. Volt gave up seating room. The sedans have tiny trunks. So, this new offering is a welcome addition. It will be available late this year... around the time Prius PHV rolls out. Makes you wonder when we'll finally get details on that. I bet it around Earth Day.
- 1-11-2016** **Change.** Last week, there were technology reveals at CES (the big tradeshow in Las Vegas). This week, there were more technology reveals at NAIAS (the big autoshow in Detroit). From both, we learned about upcoming vehicles. The effect has become quite apparent. After reading a surprising number of posted related to the tax-credits available to GM on that daily blog for Volt, I joined in with this: Dramatic change as a result of Bolt details being revealed. Interesting. The mere mention of \$7,500 tax-credit dependency stirred much anger among Volt enthusiasts... back when EV was the very thing Volt was designed to prevent the need for. Now, it's being discussed... in a somewhat civil manner. Solving "*range anxiety*" was the goal for Volt. The hope was cost would drop so much prior to gen-2 rollout, that would make it a top-seller. Instead, it remained so expensive to produce that gen-2 would continue the dependency. Catch is, the system as a whole is expensive. Cost of just the battery did indeed drop... so much so, the once unaffordable EV with substantial range is becoming affordable. That has left Volt in a position of uncertainty. In fact, many here have given their endorsement for Bolt. Their support is now for the very thing that had once been shunned, what Volt was supposed to compete against. In other words, Bolt is so appealing, it is getting even the most staunch advocates to rethink goals... which brings us back to tax-credit dependency. What are the goals? Year-End sales results brought the automaker total for Volt, ELR, and Spark EV to 95,403. That doesn't leave a lot going forward. In fact, it seems fairly realistic to see the phase-out being trigger by the end of 2017. That's only 2 full years of sales, then the tax-credit gets reduced to \$3,750 for 2 quarters. Following that, just \$1,875 for 2 quarters. In other words, nothing by 2019. How will sales be then, especially with the pressure Nissan & Tesla will be dealing with? Their tax-credits will be used up sooner. Their innovation to overcome having no more subsidies available will be even harder on GM, since the Nissan & Tesla responses won't be known until then. What will be the response to that? Let's not forget about the upcoming plug-in hybrid from GM either. That could bring about tax-credit expiration even sooner.

1-12-2016 **VW Plan Rejected.** The news is big, really big. EPA says it's not enough. CARB says it's vague and too slow. Supposedly, solutions have been in the works since 2014. Cleaner systems on a few of the other VW diesels show the automaker was well aware of design & approach differences. Yet, we keep hearing that this was a misunderstanding. How? Some of us Prius owners were questioning claims for years. It just plain didn't make any sense how both power & efficiency could be so much better than competing diesels. There wasn't even any reason to mention the extra effort Toyota took to make Prius quite a bit cleaner by trading off power & efficiency. Why didn't Jetta need urea treatment? Something didn't add up. The other automakers selling diesel had smart engineers too. The difference was troubling. Now, we know what the true story was. The federal & state governments here don't like it either. Steps beyond retrofitting those vehicles are now getting a lot of attention. Talk of buybacks is growing. Compensation in the form of rapid EV sales is a possible consideration, but that really doesn't seem realistic either. Damage to reputation, as well as the environment, is enormous. Downplay has dwindled away. Now, the die-hard supporters are attempting to raise doubt that the fixes may not impact performance or mileage. How could they not? What sort of miracle are they hoping we'll believe. It will be expensive and it will have an impact. This isn't rocket science. Cleaning emissions requires tradeoff. Not having a battery-pack available means altering the way the engine operates is the only option available. Exhaust will be altered enough to be cleansed properly by an after-treatment. Needless to say, this is seriously souring the appeal of diesel cars... which were already struggling to compete.

1-14-2016 **Import From China.** How bizarre. We just learned the upcoming CT6 plug-in hybrid will be produced in China and shipped over to the United States. For an automaker recently bailed out by the United States government (some debt never got paid back and huge losses were taken from the stock purchase) to conduct business that way... what can the flag-wavers say? The "*American Built, American Fueled*" looks even worse. Of course, with the majority of Volt came from Korea and a substantial amount of electricity & gas coming from Canada, it was never an honest portrayal anyway. Nonetheless, it was the message conveyed. Now, that precedent stands in direct conflict with this next-step by GM. Initial comments posted expresses anger, dismay, and disappointment. For me, I'm intrigued. The move is quite unexpected, even from the automaker who keeps changing plans, is often ambiguous, and is known for sending mixed messages. I'll take the apparently "*lame*" approach from Toyota instead. At least the results have been fruitful. Who knows what this will result in. Bizarre is the only way I can describe it, here. For there, local production & sales in China could be a very good thing. With pollution so unbelievably bad there, this does offer a glimmer of hope.

- 1-15-2016** **What Is It? Definition.** The really lengthy blogs are the result of change happening, finally. With so many new-tech offerings in the works, all to reduce emissions & consumption in some manner, patterns are emerging. That's when definitions become apparent. You can see the categories and the vehicles which belong. This was an attempt to provide some substance to the discussion: *"As an analogy, it's like switching to LED light bulbs in your house. Some people may obsess about going 100% LED, but the reality is that using incandescent bulbs for your refrigerator, clothes dryer, attic, etc., the amount of energy saved by switching these bulbs just doesn't make sense. That's why range extended EVs work so well. And in 5-10 years, when Li/Ion prices drop to \$50/kWh, we'll see range extended EVs that go 100 EV miles. Think about that. With 100 all-electric miles plus a range extender, how much gas would you really use?"* If you think about it, the trouble with Volt lost between categories becomes apparent. I hoped to continue along that thought with: That's why the EREV definition only uses a minimum-sized engine, the approach BMW took with i3. Sorry, but it simply doesn't make sense having a larger engine, knowing battery energy-density will be going up and production-cost going down. That's why the PHV designs are augmentations (package upgrades to add capacity and a plug) of hybrid models; they use a smaller battery-pack and will use the engine somewhat routinely. That's also why clarification about Volt intent has been asked about, especially since the reveal of details for gen-2. It's currently between categories. Will it's battery-capacity increase and engine-size decrease?
- 1-15-2016** **What Is It? Important.** The significance of knowing who the targeted market is comes down to finding out what the supposed goals are. The response to my post led to this: *"Guaranteeing the same performance/characteristics in RE mode as CD mode is important."* That's an enthusiasts claim. The mainstream consumers asked about their need certainly didn't ever specify that. They sighted cost, size, and range as being important. Performance following depletion hasn't been any sort of priority for the masses. Either you get enough range to cover virtually all driving needs or you get a system that operates as a hybrid afterward. That's why sales of Leaf stayed on par with Volt. That's why I kept nagging about who. This was my post in reply to that claim: That's the description of a PHEV (plug-in hybrid). The selling point of an EREV is there's a gas engine as a backup, just in case. With Bolt offering a 200-mile range, getting only 53 miles from Volt puts it in an awkward position. It will be considered a PHEV, especially with the inevitable upgrade to i3 offering around 100 miles of EV range. Note that the capacity of the gas tank comes into play too. If the vehicle offers far greater range from gas than it does electricity, it may not be used primarily as an EV. For an EREV, that guarantee is what's important.

1-15-2016 **What Is It? Spin.** Ultimately, you'll get someone quite upset with the outcome to change a definition. Rather than just acknowledge the mistake and move on, it's a choice to deny what happened. They'll do they're best to spin the situation. For example: "*The i3 is more BEV-with-backup than EREV, as we take it.*" Suddenly, it's all about our perspective. That's an attempt to disassociate past comments, predictions, and hope of the past. He wants the you to believe there was a consumer perspective that was different from the very beginning. I gladly pointed out that line of reasoning was pointless: We didn't matter. That was the lesson to be learned from Volt. Put another way, definitions of the past didn't match either intent or outcome. Bolt is helping to change the mentally, moving us away from what clearly didn't work. Sales approach will differ from gen-1 offerings. People won't care about the differences based upon labels that never took hold. They'll base purchase decisions upon cost & benefit, just like they did for decades prior to vehicles that use electricity.

1-15-2016 **What Is It? The Point.** Goals were always the focus for a reason. Who the heck is this vehicle designed to appeal to and how many are intended to be sold? It's that simple. Enthusiasts fought intensely though, in the end, always directing attention over to Toyota to distract from GM woes. In the long thread today about what Bolt actually is, the topic of Volt kept coming up. That's a new problem for enthusiasts. They can't use Prius as a scapegoat anymore. GM's effort to diversify & compete is causing the struggle to internalize. That stings. It's what I had been doing all along. The competition is other vehicles on the showroom. They had an extremely difficult time accepting that. Soon, they'll have no choice. In the meantime, it's conclusion like this: "...which is the whole point of the Volt." Still dealing with the twisting definition of EREV is amazing. To change goals that often and assume no one will notice. Ugh. Anywho, that was a response to my own reply. So, I followed up with: That was your response to this question: "*Why not favor EV and demote the role of the gas-engine to just backup?*" There's a clear conflict of understanding at play here. The purpose of "backup" is to have a means of continuing in the event of a unexpected situation. In the case of hardware, it is never as robust or thorough as the primary. Cost of that level of redundancy is unrealistic. It's not necessary either, since it is only for limited use. The point is to ensure operation doesn't come to a complete halt before restoration of the primary. For example, some businesses and some households have backup generators. Neither has the purpose to continue on as usual. The power available is only enough to keep items secure, people comfortable, and perishables from spoiling. Capacity is minimal. Duration is short. Scope is limited. As pointed out, that importance of Volt needing to deliver "*the same performance/characteristics*" was guaranteed. That clearly conflicts with "*backup*" purpose. The gas-engine is overkill in that regard, much more than needed to get you to your destination. i3 stayed true to the approach of keeping to a minimum. That leaves Volt in an awkward position, especially now that Bolt is so heavily promoting the upcoming lower cost of batteries. So, we ask for clarification. What is the point?

1-16-2016

What Is It? Attack. Making the issue personal is undeniable evidence of desperation. It's an expected outcome when an enthusiasts become disenchanted. They turn to antagonism, lashing out at whomever they can place blame on. It gets old and is quite transparent. Everyone can see the behavior. Yet, they continue it anyway. In the on-going discussion about "*compliance*" as to whether or not Bolt will sell profitably at a high-volume, he posted this: "*As always, the only definition that seems to matter to you is your own.*" The reason for making it personal was so obvious. Volt underwent the same scrutiny. Sales beyond early-adopter were a struggle. Gen-2 is following the same pattern. He isn't happy. I'm the scapegoat to place blame on. Whatever. Since he invited me to respond, I did: Haven't noticed how that definition got labeled as my own since everyone else abandoned it? Reality is, BMW delivered on the goal GM originally strived for, but didn't. So, the question of why was repeatedly asked. Over time, the answer changed... despite the fact that the definition didn't. Sales results were the reason. We were told a no-compromise (tradeoff after depletion) design was essential and that GM did a fantastic job of delivering it. I agree, they did. Kudos to the engineers. As for the enthusiasts, they absolutely insisted that level of performance was all that would be needed to attract customers. That approach failed miserably. In other words, they learned the lesson the hard way that turning in homework that wasn't assigned won't get you an "A" grade, regardless of how well done it was. That's why attention has shifted over to Bolt. Even though gen-2 of Volt did deliver improvements, it wasn't the assignment... high-volume profitable sales... hence this topic of discussion: "*Not a compliance car, GM says 2017 Chevy Bolt can meet demand of over 50,000 per year.*" We've seen this before. The very same thing happened with gen-1 of Volt. That's why the original goal was reiterated. Knowing why the question was asked before is how you find out what's different now. Clearly, the fear of "*range anxiety*" didn't draw consumer interest the way GM had anticipated. Nissan's upgrade of Leaf to deliver an official EPA range rating of 84 miles made it a strong competitor for Volt. BMW's rollout of i3 with an 81-mile rating along with a range-extender left Volt in an awkward position, which gen-2 did not address. Instead, we've seen the shifting of support over to Bolt with its 200-mile range and no extender. Meanwhile, the rest of the automakers have been announcing their plug-in plans. The most impactful has been the recent reveal from Chrysler... a plug-in hybrid with the same capacity battery-pack as Volt, but in the form of a large people/cargo mover (minivan). It will be available by year-end. Also coming later this year will be the Mitsubishi plug-in hybrid (small SUV), which is already a popular vehicle in Europe. We will be getting gen-2 of Prius PHV from Toyota later this year as well. Heck, even GM is experimenting with the approach of augmenting a hybrid by adding battery-capacity and a plug. That brings us back to the ultimate question. With GM stating it has the capacity to deliver up to 50,000 orders for the 2017, what does that mean for Volt? The answer tells us about definition, it explains why.

1-16-2016 **What Is It? Oil.** Sometimes, the online battles do end up stirring some constructive exchanges: *"But the public is fickle, and has a short memory. Will low gasoline prices be the predominant factor in car choices? Will energy independence and environmental concerns take precedent? Can the smooth quiet electric drive seduce the public away from fossil fuels?"* I was elated to have something worthy to join into that discussion: Notice how the rhetoric has faded away? We no longer have to deal with blatant greenwashing anymore. The Volt fires and Prius PHV capacity were good examples of people spreading false information with the intent to mislead & confuse. That's gone now. We've moved on to addressing the harder questions. Low gas prices... clearly, they are having a major impact. The barrier they create toward the adoption of plug-in acceptance is huge; however, unforeseen consequences of *"drill baby drill"* are now starting to become apparent. Over-supply of oil is harming the very market it was intended to help. Environmental concerns... has become an interesting topic. VW diesels were supposedly able to meet minimum emissions standards. At that level, they were emitting 5 times as much as an ordinary Prius. Few seemed to care though. That made marketing even cleaner vehicles basically impossible. But now that it's been revealed that those diesel vehicles were far dirtier than claimed to be, the topic of air-quality is finally getting proper attention. Energy independence... is a mess. Changing the status quo is tricky and there's quite a bit of support for keeping things as is. Drilling more oil has backfired and has been some pushback of renewables by the electricity industry. What else can be said? The *"too little, too slowly"* has been overwhelmingly confirmed. Smooth & Quiet drive... hasn't worked as a draw. For decades, that's what the luxury choices offered. Ordinary consumers purchased expensive guzzlers instead, ones that trembled & roared became top-sellers. The allure of EV is lost among the masses. The *"know your audience"* advice cannot be understated. This is why the topic of *"compliance"* is such a big deal. If we can't even provide well-stated goals here, there's no way mainstream buyers are going to care. Simply ask yourself: How will these new offerings be marketed?

1-17-2016 **What Is It? Compliance.** Another long, drawn out thread that didn't address the topic itself. Asking whether or not Volt was a compliance vehicle never really happened, since it was always promoted as mainstream. Of course, it irritated enthusiasts to no end when you pointed out what that actually meant. So, bringing up the same thing for Bolt did what? You guessed it. So, I pushed to have looked at it from the other perspective. The so-called *"compliance"* vehicles are those produced by automakers to fulfill some type of legal requirement. Typically, it has been to earn enough clean-credits to continue business in the state. This would often be costly for the automaker. They'd lose money just for the sake of meeting the qualification. Is that what either of those GM vehicles with a plug are? The same can be asked about Toyota. The catch is, the plug-in Prius was a mid-cycle release. We all knew the next-gen upgrade wouldn't require the wait of a full generation, since it was rolled out halfway through the product-cycle. Neither Bolt nor Volt fall into that situation. Both will have a full cycle. So, it makes sense asking what the expectation for that duration will be. But rather than focus on any specific count, I simply posted: In other words, if it isn't a *"compliance"* vehicle, what is it?

1-18-2016

Colorful Adjectives. Posts like this always annoyed me: *"I agree, the 11 mile range is a total joke and pathetic. Not only that, they take sooo long to charge for a pitiful 11 mile range even with an L2 charger. That probably explains why they have plunged in resale value. Toyota better have at least 25 to 30 range especially now that they have a lot of competition."* It portrayed a misrepresentation. The use of "joke" and "pathetic" makes it worse. Range was never a concept meant to be applied to plug-in hybrids... since they blend. The goal has always been to boost MPG. The resulting reduction of emissions and increase in efficiency was the result of increased battery-capacity and a plug. There wasn't any intent to deliver an EV experience to the level of purity-at-all-costs until depletion. Sadly though, that's what many assume. Some of that is the result of successful greenwashing by Volt enthusiast... hence the obvious animosity. But what are you going to do? In this case, I posted: Applying 2016 market expectations to a design targeted at 2012 consumers is what? Think about how the mindset was back then. Back when PHV was first rolled out, battery-capacity was expensive and it required seating/cargo compromises. Toyota worked hard to deliver a design that had the potential to earn profit and would not require interior room sacrifice. It was a careful balance effort to address tradeoffs of the time. Market change is why there are generational upgrades. Insulting an approach of the past that clearly achieved the goals it was set out to fulfill isn't constructive. Toyota delivered what the market had been asking for and it performed well. What other hybrid of the time offered so much space inside with a solid efficiency boost and a production-cost kept in check? None. As for resale value, all the plug-in values have dropped quite a bit. That's simply the nature of first-gen rollouts. It was an expectation that selling on later would include a big depreciation hit. We hope the technology advances quickly enough for that to happen. Slow growth is not a desired outcome. Hopefully, the early buyers understood that. As for competition, there's more to selling plug-in hybrids than just battery-capacity. Cost to produce (not selling price) will have a significant influence on how sales are approached by both dealers & consumers. There's also the practical nature that's appealing, the same things people look for in other vehicles should be present in the choices offered with plug. The true competing vehicles are what can be found next to the plug-in on the dealer's showroom floor. Remember, appeal of offerings from other automakers falls off as generations advance.

1-18-2016 **Changing Definitions.** Long after the fact, a changing of definition can be a sign of trouble emerging. But if the trouble has already arrived and you've been dealing with it for awhile, what's the harm in tossing around some ideas? That's what happened today: *"EREV provides equivalent performance in _both_ CS and CD modes (Chevy Volt). AREV (Augmented Range Electric Vehicles) provide _degraded_ performance in CS mode (BMW i3). PHEV provides _degraded_ performance in CD mode (Prius Plugin)."* I didn't like idea of breaking away from simplicity. Come up with a label to identify the obvious... like EV or Diesel. The meaning should be meaningful. Those were not. For kicks though, I took the time to toss back some consideration of the suggestion: An introduction of revised definitions and a new label to clarify the existing category confusion... interesting. That makes sense for technical comparisons, but how would they translate into real-world driving? The idea of degraded performance only applies if you are actually using the system to the fullest. For example, the 0-60 acceleration only matters if you drop the pedal to the floor. If you don't, the number doesn't serve any real-world purpose. It's the same with the top-speed. Ford's Energi plug-in hybrids have can go up to 85 MPH using only electricity. Whether or not the engine will go faster never even comes into play, since that's a EV speed faster than many people ever real-world drive. What about city, suburb, and local highway travel? Using a plug-in hybrid with a lower top EV speed wouldn't be differentiated. A gen-2 of Prius PHV can drive up to 68 MPH using only electricity. How would a label be associated to that resulting real-world MPG? Notice how Chrysler is planning to call its upcoming plug-in hybrid just a hybrid? If they don't ever offer one without a plug, what difference would the label make? Shopping on their showroom floor, the choice of *"hybrid"* or *"traditional"* will be unmistakably clear. In other words, what is there to gain by applying new labels... or any at all?

1-20-2016 **\$28.46 Per Barrel.** That was the closing price of oil yesterday. At the moment, the price is even lower. My guess is we'll dip to \$26 something... especially since I saw a gas station this morning with an advertised price of \$1.59 per gallon for gas. Anything below \$30 for a barrel of oil presents a serious problem. Even the worst-case scenarios don't go that low. No one ever imagined the situation where over-supply would get so out of hand. The belief was that we'd drill more oil locally, resulting in a significant reduction of what we import. The assumption was the importers would reduce their pumping to match up with the shift in demand. That's rather naive. Those countries depend upon a continued flow of their oil to foreign destinations. After all, some depend almost entirely upon that for their income. Look no further than our coal-producing states to understand the problem caused by supply/demand shifts. With the scale this is at, signs are beginning to show that we have serious trouble on the way. Gas prices staying low for the next few years sounds like a blessing for consumers. But in reality, that will harm businesses depending upon that revenue. Scope reaches well beyond the oil industry itself. Damage from lower prices will have a terrible ripple effect. Sorry for delivering the bad news, but that is why hybrid penetration has been so important. We need to keep demand basically on par with population growth. The increase of vehicles on the road combined with the resulting increase in time required for commutes shows obvious need. It should go without saying that this hurts renewables too. Wind & Solar cannot compete at such a low cost. Dirt cheap oil is bad, really bad.

1-20-2016 **Direct Confrontation, why?** That recent "*What Is It?*" argument came about from trying to figure out what Volt was, if it's not a "*compliance*" vehicle. There are some staunch enthusiasts who viciously defend reputation. No matter what, they have to be right. They have no purpose to actually achieve anything of substance. It's baffling. Anywho, the very same pattern is emerging with Bolt, already. This ultimately came up in the blogs: "*Oh, GM... Why do you do this to yourself?*" Immediately, that resulted in defense posts. I jumped in with: It's hard to believe the same mistakes get repeated. It's the mindset of management. That's why the enthusiasts here praising Volt engineers (who did very well, kudos) had no clue what was coming. Their focus was limited to just the propulsion system. Technical success cannot overcome the misguided approach taken by the business side. We saw this with Two-Mode, with Volt gen-1, with Volt gen-2, and now it's happening yet again with Bolt. The pattern should be obvious at this point. It's unfortunate. But what are you going to do? Seriously. I heard over and over that gen-2 Volt rollout was going to surpass gen-2 Prius rollout, to an embarrassing degree. Based on what? Great engineering isn't enough to compensate for poor executive decisions. Sorry, but reality is that's not going to happen for gen-2 Volt. It's why I ask what's realistic. Setting more appropriate expectations works out to be a win for everyone. When has the "*over promise, under deliver*" not been very painful? Ambiguity from "*available*" wording isn't encouraging. So again, what should we expect? For some perspective, the first month of sales of gen-4 Prius in Japan has resulted in over 100,000 orders. Think about how cheap gas is now. Despite that, demand is shockingly high. How was that success accomplished? What must other automakers do to achieve reception on that scale?

1-21-2016 **Direct Confrontation, excuses.** A long string of excuses followed. They all emphasized the importance of being patient and waiting. It's the same old story. The target is always moving. Some just don't get it. Fortunately, many more do. I pointed that out: Our plug-in owners club met this evening. Among the crowd, there was a 2016 Volt. It is nice looking car, but dang is it ever small for headroom in back and the cargo area. The owner (who had it shipped from CA to here in MN) was in full agreement when I pointed out just how closely it resembles both Civic and Forte. GM's choice to make it blend into the crowd is an obvious move to give it mainstream appeal. Our guess GM's gambling the lithium cost will come down very soon, giving it the opportunity to stand on its own competitively. As for you, the attitude against Toyota and fear of anything constructive being said about GM in an imperfect light is not shared by other owners. (Thank goodness!) I had many there make comments about how effective Toyota's contribution to high-volume lithium-cell production will help the overall market. They also complained about the mess gen-2 Volt rollout has been. We had a lengthy discussion about how to get accelerate plug-in acceptance. None of this nonsense of having to wait many years. We are working to find ways to attract customers now. Our push is shared by a state representative, who was there speaking with us at the meeting. Her presentation was great. The political issues & support are being well addressed. We're also sponsoring a room at the upcoming Minneapolis Autoshow... dedicated entirely to plug-in vehicles. This is a major effort to stir interest and a fantastic venue for doing that. It's really too bad you constantly fight back and don't embrace the idea of a wide variety of plug-in owners getting together to overcome the true competition: traditional vehicles. They know all too well the subsidies are a short-term benefit that will have painful consequences if the technology cannot become profitable soon and sales achieve large numbers. They also know that regular (no plug) hybrids contribute a great deal toward changing the way people look at the benefits of batteries. As much as I tried to get you to see the light. It's just not worth the effort. The plug-in owners club made it quite clear there are many people who do and many more who soon will.

1-23-2016 **Direct Confrontation, sad.** The choice to make it personal was vindicated: "*No, what is sad is you trying to change history. We all wanted more Voltec. Since day one. What you always were trying to sell was that GM put too much EV range in the Volt and the wimpy range in the PiP was the way to go. Well GM did come out with a Gen2 Volt and they listened to the customers, who wanted MORE EV range.*" He pushed aside need. He just wanted to celebrate. Twisting events and disregarding facts only takes you so far. The victory was hollow and continues to be. I responded with: Interesting perspective. The range claim is a distortion of what I said, if anything. These blogs here and my own clearly confirm that I said a second model of Volt should be offered, one with less range to reduce cost & weight while increasing interior-space and depleted-efficiency. I often find that people misquote me, thinking I said something in the past and it was actually someone else. With so many attacks from anonymous posters, that shouldn't be much of a surprise. Think about it. As for the range in PiP being enough, that's just plain wrong. From day one, back when the aftermarket prototypes started appearing, I said the same thing... Toyota would aim for a target price and adjust range accordingly. The specific price range was even mentioned routinely, to ultimately deliver a package option \$3,000 to \$5,000 more than the no-plug model. That means we expect a considerable capacity increase with gen-2, since the battery-cost has dropped quite a bit over the past few years. With respect to listening to customers, you've lost touch, just like GM. The question of "*WHO*" was asked over and over and over and over again. For range-increase to be a customer priority, that customer would have to be an enthusiast. Ordinary traditional vehicle buyers most definitely are **NOT** asking for more range. Evidence of that is absolutely overwhelming. Cost reduction for competitive pricing is by far more important. Just think if GM had targeted gen-2 at those customers, the people SHOPPING THE DEALERS SHOWROOM FLOOR. You've lost your mind if you think the loss of those sales aren't important. So much opportunity is being lost... That's the only way any automaker will be able to sell their plug-in vehicles profitably at high-volume without the tax-credit. All those excuses you posted above about being patient tells us your focus is different, that you want a very appealing plug-in that doesn't see direct competition with traditional vehicles as important anytime soon. That's sad.

1-23-2016 **Direct Confrontation, debate.** Someone else joined in, another one of those unhappy enthusiasts looking for someone to blame: "*...and I will shun him. He is not an honest debater.*" The very concept of debate online is flawed. There is no moderator to oversee & judge. Interjections of off-topic subject matter are not penalized or even pointed out. Posts simply wander aimlessly. I often get attacked for attempting to restore the discussion back to the topic... getting called a "*broken record*" and being told my posts are "*mind-numbing repetition*". Those are the same people who hate accountability. They don't care about paying the bills. They only want to win battles. My words to deal with the nonsense were: Why is there a debate about who potential Volt buyers are in the first place? It seems absurd for GM to set a goal of mainstream sales (5,000 per-month average with annual sales of at least 60,000), then back away from that twice... especially when the need is there. It was understandable with gen-1. Some of us, including myself, pointed out the reasons why that was unrealistic... and got shunned for doing it. But why get shunned again for gen-2 having the same struggle years later with the same goal? There is obvious upset about how much attention Bolt is drawing away from Volt and that several automakers are rolling out new plug-in hybrids this year... Hyundai Ioniq (hatchback), Kia Niro (SUV), Chrysler (minivan), Mitsubishi (SUV). The fact that BMW is now working toward delivering double the range for i3 compared to Volt isn't exactly welcome news either. Using me as a scapegoat, redirecting attention to Toyota, and claiming I don't support any other automaker isn't constructive. Why a debate? Answer the question of audience. Who is the market for Volt?

1-23-2016 **Direct Confrontation, who?** That response of "*Who is the market for Volt?*" deeply angered the defender (a well-known veteran member who posts often, stirring trouble by claiming to challenge trolls): "*Look in the mirror. Then look at the Volt and imagine a Toyota emblem instead a Chevy one. SOLD!*" It always makes me wonder how many readers notice the transparency of that behavior. It's an obvious provoke to serve as cheer-leading. The hoped for outcome is simply agreement. There is no expectation of any actual progress, hence defend. I choose offense, hence the direct confrontation: You're saying gen-2 Volt is an enthusiast vehicle then, continuing to remain a niche until the next generation. Interesting. If you had said my Mom or Grandpa or Aunt or Father-In-Law, that's an entirely different group of consumers. They represent ordinary people, consumers who are perfectly content sticking with traditional vehicles. That's a hard-sell getting those who don't consider performance as a priority to pay so much for it. They simply aren't interested. Continuing to avoid acknowledging it, rather than face that reality and finding a way to deal with it, is your choice. Good luck. Personally, I'm baffled how you can watch so many sales be lost to GM's own customers. Each month's statistics show Cruze, Malibu, and Equinox absolutely devastating Volt, despite the generous tax-credit. So much opportunity is being lost, right there on the showroom floor. It's quite disheartening. Making fun of me and Toyota won't fix that. Leadership is the ability to get ordinary people to change. Sales are the measure of that progress. No amount of spin will hide the fact of traditional vehicles dominating interest still. Remember, the overlying goal of the tax-credit money is getting the business to a position of having sustainable (on-going high-volume profitable) sales before they expire. That **BEFORE** cannot be stressed enough. Time is quickly running out for Volt. What can be done to help in the short amount of time still left?

- 1-24-2016 Direct Confrontation, purpose.** Simple, or so you'd think. Who is the market for Volt? It doesn't seem like that question would be so complicated to get an answer to. It's a fundamental to know. How can you properly fulfill a need if you don't even know the source of the requirements? It's why Volt has had so many problems and the other high-tech, high-efficiency choices have not. It's actually quite bizarre for it to be so unique. The others just plain don't have that trouble. Leaf has a clear audience. In fact, that's why Bolt hasn't struggled. It's obvious who GM is attempting to appeal to. Same with Prius from Toyota. Tesla, we easily see that too. There are several upcoming plug-in hybrids. With each, the targeted group is apparent. We see pricing. We see styling. We see intent. Without a clear purpose, you end up with a mess. Direct confrontation of someone trying to support it ends up a disaster. They struggle to reason. They end up convinced you are somehow wrong. There's no way to win.
- 1-24-2016 Direct Confrontation, finally.** The discussion had lingered for days, rather than dying after just a few hours like usual. Out of nowhere, a new poster appeared. We'll never know who it was. That person had attitude and was quite to the point: "*Groundhog day :(Maybe this year Feb 3 will come for John and he stops this nonsense.*" They get tired of having to be held accountable for past claims. The anonymous identity is a way of relieving the stress. After all, who wants to admit their own beliefs were based upon incorrect assumptions? Anywho, I was happy to post: Dislike for business accountabilities will always be there, even if I'm not. That "*nonsense*" is what pays the bills and keeps the automaker viable. Sorry, but that's the reality of the situation. Set expectations, then do what it takes to achieve them. Dismissing the message of status doesn't actually accomplish anything. Refusing to state goals or even identify the target audience is clear indicator of problems. Allowing the status quo to continue is how history ends up repeating.
- 1-24-2016 Direct Confrontation, unqualified.** It was easy to see an end approaching. The point of direct confrontation was to achieve some type of closure... hoping to do that by identifying root cause through an extra hard push. I got lucky. It actually worked. Seeing a theme emerge was a relief. The pattern held. People tend to justify an outcome, convincing themselves that was the goal all along. I'm not the type. That's why I state intent right from the very start. If what was set out to accomplish doesn't happen, I'll know with certainty... since I have my own blogs documenting thoughts, beliefs, and hopes of the time. Heck, even milestones along the way are often included as guides to ensure focus is not lost. That's not the kind of people I have to deal with though. The specific group of individuals fighting back are quite different. Turns out, they aren't qualified to participate. The inability to answer a few fundamental questions reinforced that observation... which was really more like an epiphany. Some people simply don't have the background. That's why they had no idea what I was talking about. It made my response easy. Rather than risk stirring the pot any more, I just suggested: Take a business class... economics, accounting, marketing, etc.

- 1-25-2016** **Direct Confrontation, how.** Providing some sort of template to follow is always helpful. You really don't want to risk insulting someone who really doesn't understand the problem. After all, they're stuck making the same mistakes. Finding a means of breaking them out of that harmful repetition is priceless. I'll attempt that by proposing how: State goals... timeline, quantity, cost, profit... then work to achieve them. The classes teach the importance of those goals and how to respond when milestones are missed. Clearly, that isn't what has happened here.
- 1-25-2016** **Direct Confrontation, confirmation.** It was overwhelming. The rudimentary nature of the response I got was treasurable: "*Words. Words words words. Words?*" There isn't anything more senseless to say than just posting gibberish like that. It was childish and obvious. The stereotype of being clueless was confirmed. My choice was to not bother responding. That was the conclusion I had been looking for. Rather than provide some type of logical reasoning, what he posted bordered on throwing a tantrum for not winning. Wow! So much for trying to have some type of constructive exchange. He was polite. Though, the anonymous post in between was very suspicious. He was thoughtful. Though, the statistics posted had blatant omissions. He was persistent. Though, the strong-will turned into desperation. I'll give him credit for trying. But in the end, this was excellent confirmation of an effort turning sour. Good intentions. Unforeseen consequences.
- 1-25-2016** **The Next Step.** With the Volt craziness behind us now, is it possible to get off to a fresh start? I tried with someone else, another who was rude & insulting... having also loss a long drawn out series of battles. The war is over. What should the next step be? I was impressed by his attempt: "*What you must remember is that cost was the most important feedback GM got about Gen I, and most of these suggestions would have would likely made Gen II much more expensive.*" The problem was time. He absolutely hated me for pointing out it was limited, that delay would be costly. Opportunities being missed made it worse. Over the years, he could see I was right. That became a distortion of what had originally been suggested... thinking I wanted that from the very beginning, rather than just hoping for a mid-cycle upgrade or for gen-2 to deliver a better aligned purpose. Frustration will cloud memory. Written blogs serve as a cruel reminder of what actually happened. It's not worth pointing out those facts of the past though. The hope is to move forward. That means looking to the future, this new year specifically. So, I did, but also included a reminder: The suggestion of offering a second model with a smaller capacity would have lowered cost. Increase in volume from that choice and the obvious improvement due to reduction of size & weight combined with smaller price tag would went a long way toward gaining market-share and advancing the tech. Notice how many automakers are now planning something in that smaller capacity category... Hyundai (Ioniq & Sonata), Kia (Niro & Optima), Mitsubishi (Outlander), Ford (C-Max & Fusion), Toyota (Prius), Honda (Accord), and Chrysler (Pacifica)?

- 1-26-2016** **Easy To See.** The hate from that new person became quite undeniable. Attack posts popped up today. One started with this: "*Again, WTF are you talking about? Goals? More nonsense? There's a surprise!*" It then went on with a rant about Prius. Reading it was amusing. The expression of frustration was immense. There was some parroting too. That's the ultimate. The person will simply just recite back what they found most aggravating from you. It confirms you struck a nerve... which wasn't the point, but that does serve as verification that a shortcoming was correctly identified. When something is incorrect, they'll explain why. Having nothing whatsoever to respond with speaks for itself. As for the not knowing what I'm talking about, it's clear the person doesn't have a background in business. That's to be expected. Some things you know a lot about, some things you don't. It's important to know what subject areas you aren't well informed of, then listen. Posting insults and questioning purpose is most definitely not constructive. That pattern of behavior is easy to see. Today, that was epically true.
- 1-27-2016** **Understanding, Past & Future.** How would you respond to this: "*I still stand by my assertion that most people simply don't understand plug in hybrids, and this will most likely keep them from ever becoming *mainstream*.*" My choice was sighting an analogy and pointing out consumer behavior: Many automakers are betting against that belief, since it has recently become outdated. Technology improves so rapidly, it makes sense. After all, the typical consumer expects that. The computer industry has seen this many times. Many who missed the early generations have no idea there was even any issue. For example, USB 3.0 and Bluetooth 4.0 connections: both are fast, seamless, and reliable. The mainstream buyer is clueless to barriers/limitations/issues of the past. The upcoming next-gen hybrids with plugs will take advantage of high-density, low-cost lithium batteries. That opens up opportunity which hasn't existed until now. Another is wireless charging. The convenience of simply parking over an induction-charger in your garage cannot be understated. The connection is effortless. Consumers are becoming comfortable with smart-phone apps too. Being able to check on the status of their vehicle, along with getting a slew of handy statistics, is both enticing & empowering. Again, this is something that wasn't available until recent. Looking at hybrids specifically, the MPG value is all consumers have ever focused on. They couldn't care less about EV purity. If the vehicle has an engine, they expect to see a very high number for MPG. The plug-in hybrids deliver exactly what they expect. That meeting of expectations is what will draw mainstream interest.

1-27-2016

Playing Catch-Up. Most of the problems stemming from the antagonist Volt owners came from their lack of experience. It was all new to them and they were too naive to believe mistakes of the past could be repeated. So when the question of electric-only or plug-in hybrid comes up, they really don't have much of a background to support an argument either way. That's why the struggle with Prius was so intense at times. They just plain did not understand the influences of market acceptance outside of their engineering knowledge. The logic they were applying didn't correlate with the way people actually behave. Oh well. At least we can see progress being made, as slow as it is. They are indeed catching up. Too bad so much time was wasted waiting for that. They made it worse by refusing to accept what was actually happening. This is what I had to say about the topic today: With respect to what makes more sense, EV or Plug-in Hybrid, it boils down to when the purchase will be made. If it's just an individual making the choice for a purchase tomorrow, there are very few options actually available. With over 17,000,000 of the vehicles sold last year here without plugs, inventory is very slim. This time next year, the story should be quite different... though, gas will likely still be cheap. Cost has a huge influence on EVs right now. If you're willing to pay a higher price, you'll get decent range. If not, you'll have to be very aware of your driving needs and plan accordingly. The upcoming range-increase, cost-decrease next-gen models will directly address that. Until then, buyers must carefully study the choices. This time next year should be engaging for plug-in hybrids. Finally, there will be many more available, new models and a next-gen to draw consumers. That variety of endorsements from automakers combined with the growing pressure to deal with the upcoming tax-credit expiration for some will push the market too... hopefully, in a helpful way. Whatever the case, it will make the rollout of affordable 200-mile range EVs a situation the industry has never faced. Making a purchase even later, who knows? The problem of not having a place to plug in will likely become a driving factor (pun intended). There are many properties with challenges preventing easy access to electricity. Perhaps the end of tax-credit opportunities for automakers will be followed by increased/renewed tax-credits for homeowner & landlords. A shift of focus at that point would stimulate further growth. After all, the intent of the current tax-credits is to help automakers become established. If they squander that money, it's their loss. Upgrading infrastructure provides benefit too. In other words, it's complicated. That complexity will hinder interest. Consumers will still be strongly attracted to traditional vehicles until simplicity arrives. The choice will eventually become a no-brainer. But right now, many don't care about efficiency... or sadly, emissions. They choose neither.

1-28-2016

Automaker Pushback. 3 Leaf, 1 Volt, and my Prius PHV shared the plug-in parking area at the ramp today. Sadly, that's considered impressive. For a parking facility with an 85 kWh solar-array (which is just plain sweet), only having 6 chargers for the 1,600 parking spots is disheartening. It's through no fault of their own. They've been quite supportive. It's the automotive market. Interest for plugging in simply isn't there, especially with gas so cheap now. Reading today's article about automakers pushing back against MPG increase requirements should be no surprise to anyone. It's magnitudes easier to sell a guzzler than it is a high-efficiency, low-emission vehicle. The larger ones with lots of extras return a generous profit. Since they are so inexpensive (relatively speaking) to operate, deliver great power, and offer generous seating & cargo space, people gladly pay the premium sticker-price. For the small "*economy*" cars that offer just a basic profit, automakers produce them because they provide steady income for sales & service. The "*green*" vehicles don't fit either category. Unfortunately, not everyone is in agreement that those vehicles are the competition. Much of the cooperation disconnect comes from approach. Which is more effective, a large quantity with small impact from each or a small quantity with large impact from each? Time and time again, the computer & device markets have shown us that small impact results in greater overall change. In the automotive industry, look no further than ethanol usage. Having nearly all of the gas vehicles running on a 10% ethanol mix has resulted in dramatically more ethanol displacing gasoline than the flex vehicles capable of running on an 85% ethanol mix. Change is difficult, especially for the masses. Finding ways to work around their natural urge to resist is a challenge, but can be very rewarding. So, what does that mean for fuel economy standards? Knowing those are going to be fought, the reality of that pushback must be clandestinely dealt with somehow. Take the subtle approach. Hybrids (both with & without plugs) advance battery production. Their high-volume is a win for electric-only vehicles, even if those remain a niche until energy-density increases enough to deliver range similar to traditional without compromise to interior size or vehicle weight. That means hybrids have a better chance of getting the industry to actually step away from guzzlers. It's more of a gentle push while actually achieving a lot; though, the true impact scale won't be recognized until much later.

1-29-2016

New Rhetoric. It's not as bad as it sounds, I think. Seeing this yesterday gives an impression of much worse: "*You know when you are talking about Prius' it is all about self righteous indignation.*" There's hate from a few Volt owners like that still, thankfully they are far from the norm. Unfortunately, he went on with: "*The only way I could drive the Prius and not want to hit myself in the head with a hammer...*" That's the kind of stuff which contributed to the group-think in the past, allowing greenwashing to flourish. That led to facts being voted down, where readers simply didn't care anymore. It was something of amazement to see. An opinionless statement conveying nothing but information about the topic of discussion would get outright dismissed. Sadly, we see that on a regular basis with politics. People have grown use to choosing not to acknowledge what they don't like. Remember how popular Volt was claimed to be? Many of those early-adopter sales were achieved with great lease bargains. When those leases expired, many moved on to other vehicles. The claimed "conquests" were lost as a result. It was a short-term victory. What kind progress was that? As that technique for drawing sales began to slip, the bargain pricing was shifted over from lease to heavily discounted long-term sales. That actually did seem better; however, it overlooked profit & tax-credit sacrifices. In the end, hope was refocused on the gen-2 rollout... which brings us to where we are today. Gen-2 Volt has been compared over and over to Prius. The catch is, those reports totally disregarded the new Prius... which has only been available for roughly 2 weeks and in very limited locations. Thankfully, the very first article actually comparing 2016 to 2016 was published this morning. Both new generations. Finally! It asked: "*Which green bestseller is right for you?*" I was intrigued by that title. Sadly, all it did was say both have improved over their predecessor, gave a little history, then provided a few details. That was it. Disappointingly, the same approach as in the past was taken... pretend there's no such thing as a plug-in Prius. In fact, there was even a bit that of greenwashing with: "*The conventional hybrid Prius doesn't plug in at all.*" Rereading what was written, this made it worse: "*For the first time, the Prius Liftback offers two different battery packs.*" Coming from a self-proclaimed green-car website, they should be called out. That's blatant misleading. The plug-in model obviously has a different battery-pack. They've written a number of article about the plug-in Prius. Heck, they even published one with this as the opening line: "*Today, why the next Toyota Prius Plug-In Hybrid could be a game changer...*" If anything, they're extremely vague. That's a major contributor to problems. It's what feeds the rhetoric... which we are now see a ramp up of.

- 1-29-2016 Diesel Mess.** Remember in the past how businesses did things for good will, taking an extra step simply for the sake of being nice? True, it did help their bottom-line in the end, but there was a very real up-front monetary cost to the gesture. They saw value in reputation. Strengthening that by taking unnecessary effort went a long way. With VW, we see them fighting the law to get us to accept their "good enough" claim through argument of detail. It's very clear that spirit of the law was violated. Whether that was intended or not doesn't matter. The violation happened. Now, they are making it worse by fighting instead of trying to negotiate an acceptable compromise. Being "legal" wouldn't make it right anyway. Even if they do get Europe to accept weaker standards, that doesn't address the growing emission problem. Air pollution must be fixed. Allowing dirty cars to contribute to smog issues is not helpful. We've had to tolerate that nonsense for far too long. Diesels just barely met minimum requirements. Hybrids like Prius are the opposite extreme, earning the highest emission-rating for any fossil-fueled vehicle. It's sad the problem could get so out of hand. It's disheartening to see some people defending those actions.
- 1-31-2016 First 2016 Reports.** It's exciting to read them. Here's my view of the situation: Gen-3 still doesn't get reported correctly, after all these years. There are too many circumstances to keep in mind when trying to kind posts simple. So, don't expect anything clearer for Gen-4. That's just the way it is. Fortunately, being a hybrid like Prius it doesn't matter anyway. Whether you are in fuel-cut mode or EV doesn't make a whole lot of difference at highway speeds, since the energy flow changes so frequently. The system is smart enough and flexible enough to exploit even the tiniest of efficiency opportunities. Gen-3 has a top EV speed of 100 km/h (62.1 mph). You won't see that unless you have the plug-in model though. The reason for that is a simple matter of battery power & capacity. Without plug-supplied electricity, there isn't much of an overall gain. Without the plug, EV is restricted to 40 km/h (25 mph). That's only available when the system is fully warmed up, but the advantage is you get more power than Stealth mode (the other EV mode). That has less power and the system still needs to be warm, but the top speed is 74 km/h (46 mph). Gen-4 is sad, since I don't have one yet. It's a new twist. I was a pioneer in 2000, 2003, 2009, and 2012. Each time, my purchase was among the first in the country. This time, I have to wait and live vicariously through others. Though, I can point out that leaks online indicated a top EV speed with the new generation for the plug increased to 110 km/h (68.35 mph). We also learned that both mechanical & electrical operation has been made more efficient. What this means for the regular Gen-4 is interesting to read about through the experiences of new owners. However, we really need someone with an aftermarket gauge to report actual RPM values. Anecdotal observations are only the first step. After all, we don't really know what "EV" truly represents. With the current plug-in model, miles driven with the engine off (0 RPM) while in HV mode are not counted as EV... despite the fact they are traveled using only electricity and with the engine motionless. Keep reporting to use what you find. Thanks.

2-01-2016 **Suggestions.** With the inevitable tax-credit end approaching, we do get a little bit of discussion about it now. It isn't necessarily constructive, but at least there's something. I particularly liked this comment: "*It doesn't seem fair to essentially punish GM or Tesla for being pioneers in the market.*" Naturally, my response didn't exactly get a warm welcome... despite providing an suggestion of a new approach: It doesn't seem fair to punish automakers striving for maximum penetration either. If the goal of tax-credits is to help the tech reach as many consumers as possible, why don't automakers get the choice to divide up the subsidies in terms of money rather than quantity? Everyone who purchases early on is a pioneer. \$3,750 would benefit twice as many people than \$7,500. The recommendation should be to allow current automaker subsidies to end. Focus new funding on infrastructure instead. Give new subsidies to those who will struggle to get a level-2 charger installed, those who wouldn't otherwise purchase a vehicle with a plug. In other words, the current subsidies are just the low-hanging fruit. What's really not fair is ignoring those who follow.

2-03-2016 **Explosive Reaction, shocking.** Within just 7 minutes of posting, I had already got 9 negative votes on my comment today. It was on that daily blog for Volt. Things are really falling apart with respect to sales and that's what the topic was today. That has been the expectation for awhile. So much hope had been deferred to gen-2, that they forgot how quickly things fell apart shortly after gen-1 was rolled out. Shortcomings are very difficult to overcome once the transition from anticipation to on-the-road takes place. The problem of not matching priorities becomes all too real. Want cannot compensate for need. They know it now too. I was shocked how quickly that was confirmed. Whoa!

- 2-03-2016 Explosive Reaction, choices.** My shock turned into this: Reading through the comments posted 2 days ago about the inevitable tax-credit expiration expected sometime mid-cycle for both Volt & Bolt, it's easy to see the signs of trouble apparent already. That discussion thread started with complaints about fairness. It then turned to flag waving. It was followed by the fuel-cell red-herring. How is any of that constructive? Over and over again, it has been posted that the true competition is traditional vehicles. Those cars and small SUVs sharing space on the showroom floor are what draw people away from the high-efficiency, low-emission choices. With gas prices so low and no expectation of them to rise much for years, there's a lot of pressure keeping things status quo. The market for change simply isn't there. That's why sales results of Cruze, Malibu, and Equinox get posted every month. They are what's holding Volt back, not other high-efficiency, low-emission choices. It's time to face that reality. No amount of advertising will change that either. What stirs interest on the showroom floor is quite different to what people find appealing while watching television or hearsay or online. We knew Volt sales would be inflated due to year-end rush for the tax-credits. We also know the 2017 model coming soon is only a minor upgrade and that winter sales are typically slow, but availability will increase. So, expectations have been a little screwy. January 2016 sales are especially interesting. Cruze did well with 14,362 sales. Malibu just beat that with 14,746 sales. Equinox was the strong seller. With 18,574 sales, there's no denying demand is hot for small SUVs. That's a particular problem for Volt, being a compact car. Bolt will offer more interior space, which reinforces market preference for more room. Ford had always hoped to capitalize on the opportunity to sell more small SUVs by offering a hybrid version. After years of struggle though, it was dropped. Toyota experimented with the large interior aspect in this market by offering Prius V, a wagon model. Results were a mix. Sales were much higher than Volt, even without any tax-credit or HOV incentives. But growth was flat. So, attention has been turned to the small SUV market. January is first month for RAV4 hybrid being offered. 1,973 were purchased, without incentives. Watch what happens with demand for it over the course of this year. That may be our best indicator of mainstream preference. Remember, the goal is to become business-sustaining. That means high-volume profitable sales. There cannot be reliance on tax-credits. There should not be a dependency on low gas prices either. For the vehicle to truly be competitive, it must be among the top-sellers on the showroom floor.
- 2-03-2016 Explosive Reaction, problems.** What more can be said: Personal attacks and an attempt to draw attention away to another topic. Wow! Clearly, sales are becoming a major concern. What I find as the biggest confirmation is how Prius was always used and continues to be the basis of comparison. That never made any sense. It was entirely new. GM already had a wide array of experience when Volt was rolled out... EV1, Two-Mode, and BAS all taught the GM engineers & executives a great deal about battery & motor technology. Now, there's suddenly a panic. Volt isn't measuring up to Prius either. At this point in gen-2 history, sales had already exceeded mainstream minimum... by quite a bit... and without a tax-credit. What should the outlook for Volt be? For that matter, what should we expect from the "Voltec" family?

- 2-03-2016 Explosive Reaction, growth.** Not wanting to deal with the issue is far from new. The usual reaction is to redirect attention. For example: *"I'm not sure why you specifically comment on GM all the time when Toyota is staring you in the face."* I was happy to take the bait from that defender (internal-troll), since there was a very real curiosity what kind of reply would come from it: Toyota's rollout of both the gen-4 Prius and introduction of RAV4 hybrid just happened within the past few weeks. Inventory is getting filled as quickly as possible. The approach to draw new interest has been discussed many times. How much more do you want? Toyota's heavy investment in hybrid technology is what will get them past the low-hanging fruit. That's what will get traditional buyers to purchase a high-efficiency, low-emission choice. The platform offers easy & profitable transition to plugging in. It's a strategy to reach the masses. That low-hanging fruit is rapidly disappearing. Volt will not be able to rely upon early-adopters and tax-credits for too much longer. Notice how that reality was brushed aside rather than discussed 2 days ago? How is that not staring you in the face? In other words, what strategy will GM be taking to grow sales?
- 2-03-2016 Explosive Reaction, next steps.** Having the low-hanging fruit situation pointed out was quite unwelcome. No one has ever stated it that way before. They were so obsessed with the "early adopter" excuse that no one took the time to consider when the next step would need to be addressed. An abrupt announcement of that time having arrived definitely stirred so emotion... in an already volatile situation. I pointed it out this way: The reality of there not being much low-hanging fruit left has clearly struck a nerve. Heavy bets were placed upon gen-2 of Volt delivering and neither an EV nor a plug-in hybrid being necessary. Yet, we see Bolt and CT6 are on the way. I suspect GM will move on, leaving Volt as a niche much like Camaro & Corvette have always been. Ironically though, it will have to shed a mainstream look to achieve that... which is the direction gen-4 Prius has already taken, but the expectation for that is high-volume sales. The upcoming expiration of tax-credits, continued low gas prices, and increasing choices mean something must happen in the near future to enable Volt sales to grow. They must reach a point of competitiveness soon. Reaction here is confirmation of both pressure & worry building. With so many choices on the way, it will only get worse. What should the next steps be?

- 2-03-2016** **Intent.** Overcoming blindness from having invested so much in a philosophy that proved unsuccessful is a challenge. That's why dealing with it head on today, facing it directly was a reasonable tactic. Out of that came this: "*Based on that criteria I'll just take a look at these *niche* vehicles.*" He was quite angry. I didn't care: This is pretty basic stuff. An automaker chooses which vehicles will provide business-sustaining profit and which will be favor some specialty criteria. The one type will be produced in high-volume, the other limited quantity. Both are perfectly reasonable, since they balance either other out. GM and supporters see how Volt's look was toned down and made to blend into the crowd. Looking very similar to other popular picks is fine, but the expectation is for it to sell the same way. You're working frantically to convince us that's not the case, telling us the opposite of what is so obvious. No amount of spin or distraction will mask intent. To be the "*game changer*" that Volt was to intended to be, it has to actually change the game. If ordinary people don't buy Volt, mission not accomplished. That's why "*mainstream*" is so important. High-Volume sales are essential. I've never encountered anyone so truly desperate to defend. You clearly don't understand the purpose of having a mainstream target, the reason why such a specific minimum was chosen.
- 2-04-2016** **We Knew.** The argument continued on to the next day. I just kept telling it like it is. No reason to dwell in the past. The goal is to move on to gen-2 offerings. A way of effectively doing that is to just summarize. So, that's exactly what I did: We knew from the beginning that Prius PHV was a mid-cycle upgrade intended for real-world data collection. Expectations were never beyond modest sales. Heck, the first full year had a planned quantity of just 13,000. That resembled the same thing Toyota did here with Prius back in 2000. Both quantity and availability were intentionally limited, it was also a mid-cycle upgrade. No one seems to remember any of that history or how successful that approach was. We'll end up with a second-generation model designed for mass-appeal, just like the transformation that regular model experienced. It might not look like the gen-4 Prius. It may not even be called Prius. What we do know is that it will be an improvement based upon what Toyota learned from the previous.
- 2-04-2016** **What do you see?** Attempts to get constructive dialog going can be a challenge. The personal attacks usually get ignored. But in this case, the desire to move on means addressing them directly. I was rather curious what the reaction to more information would be anyway. So, when that opportunity presented itself, I posted this about myself: I see a person who has and continues to support affordable choices for the masses. That's why tax-credit and profitability gets brought up on a regular basis. It's vital for the automaker to quickly find a way for their tech to become self-sustaining. We see all of the following plug-in hybrids on the way: Hyundai (Ioniq & Sonata), Kia (Niro & Optima), Mitsubishi (Outlander), Ford (C-Max & Fusion), Toyota (Prius), Honda (Accord), and Chrysler (Pacifica). Each is striving for sustainability. Heck, that's also the case for the EV offerings: Nissan (Leaf), Tesla (Model 3), and even GM (Bolt). Volt is the only standout, without a plan to be competitive. What do you see?

- 2-05-2016** **Bashing.** It's quite interesting to see just how desperate a person can be. How far can denial be taken? The point of gen-1 is to move on to gen-2 or whatever the successful trail ended up to be. Holding on to the past at the penalty of not progressing to the next is futile. Yet, there are a few who do. It's tiring. It's annoying. It's a waste. I still took the time to deal with it anyway: Spin of history by pretending the purpose was different, we're quite familiar with that. Volt did it a lot. Prius goals were very clear. So were those for Volt. Prius achieved them. Volt did not. Volt gen-1 was supposed to be a "*game changer*" that would out Prius the Prius. It didn't, not by a long shot. So, we ask purpose of Volt gen-2. But rather than get sensible feedback, some type of goal laid out with a timeline to show there is clarity of intent, we get more Prius bashing. It's really unfortunate. Notice how most have shifted over hope to Bolt now instead?
- 2-05-2016** **Misplaced Hope.** Seeing to this was unpleasant: "*With current Li/Ion prices, it almost seems like the pack is free after the tax credit.*" It's the equivalent of betting big that non-hybrid SUVs are the future. Just like low gas prices, we know the tax-credit will end. What then? How do you sell that inventory you were dependent upon when prices go up significantly? The dependence of that \$7,500 will be quite painful. Oh well, it's not like they weren't informed well in advance: Popularity would mean business suicide. Each automaker must carefully consider how to promote their plug-in technology. So when those tax-credits run out, they'll still be able to retain high-volume profit sales. The catch is, they must achieve that level of consumer interest prior to the expiration. Toyota gets mocked continuously for rolling out their gen-1 plug-in hybrid in such limited quantity, despite the fact that they were able to collect vital real-world data without using up a lot of tax-credit. That leaves them far better positioned than GM, who is facing an inevitable subsidy loss right in the middle of both Volt & Bolt product-cycles. What was learned? Turns out, people value seating & cargo space more than they do range. Knowing the preference, automakers are working to deliver exactly that. Heck, even GM is experimenting with that now too. Look no further than the upcoming CT6 plug-in hybrid for confirmation of that real-world data collecting. Volt worked out well for enthusiasts. It really is a nice car in that regard. It simply doesn't appeal to the masses. Heck, Prius doesn't either... but at least it sells at a much higher rate, doesn't depend upon tax-credits, and is profitable. The new generation will expand appeal as well, making it a true contender for drawing away interest from traditional purchases. RAV4 hybrid was rolled out to draw even more interest. It represents the very diversification Volt supporters have wanted for years. There is hope, but low lithium prices are only a piece of the puzzle. All the plug-in hybrids must find a way to become self-sustaining quickly. Because once those tax-credits are gone, that goal become much harder to achieve if there was a heavy dependency upon them.

2-05-2016 **Small SUVs.** The concern about "*too little, too slowly*" fell on deaf ears for so long, it was disturbing. The common-sense rules of business were simply ignored. The most obvious was resistance to diversification. When you'd point out something beside Volt was needed, it was taken as an attempt to label it a failure so it would be discontinued. That was paranoia at it's best. Enthusiasts would lash out any way they could to defend. The situation is finally changing: "*Bottom line is, GM should forget about making more plug-in cars and instead make a plug-in Equinox or something of the like. That's where the market is going.*" Of course, it took until the first hints of trouble with gen-2 to emerge before that attitude changed. Nonetheless, it is progress... though, painfully slow. Anywho, this was my reply: Equinox is GM's top-selling non-truck vehicle. 18,574 purchase last month provides good perspective. No matter how enthusiasts want to spin the 996 Volt purchases in comparison, true supporters know the need to diversify is now. GM really should focus the next plug-in hybrid effort on something in that category. RAV4 is Toyota's equivalent situation. Seeing strong potential for the small SUV market... especially with gas prices so low right now... they introduced a hybrid model. First month's sales were in January. Even without full availability (or any tax-credit incentives), the initial purchase count was encouraging. 1,973 is a good start. The jump from 25 MPG combined to 33 MPG combined without any sacrifice is proving to be a draw. Lithium battery improvements along the way will make adding capacity & plugs an easy transition. The catch is having a market with the base prior to that. Volt didn't, hence the stem of much of its struggle. Not having a hybrid counterpart of any sort is a lesson GM learned the hard way. Enthusiasts mocked Toyota & Ford to no end for their approach, only to find out later that would have been quite beneficial. Have you considered the position Ford is in now? They had Escape as a hybrid, a small SUV. They abandoned that in favor of the next-gen system being offered in a sedan & hatchback instead. That expanded to offering a capacity increase and a plug. Think about how much Ford must now be yearning to reintroduce a small SUV hybrid. The market is going in that direction, but there will still be a demand for the cars too. This is simply how growth will take place. The reach out to entirely new customers will be the taking advantage of the draw small SUVs offer.

2-05-2016 **Vue Hybrid.** Remember the Saturn Vue hybrid? Back in September of 2009, an article was published highlighting the 28 MPG no one will ever get. That's because the effort was canceled after getting an official EPA rating. It got that close to launch. Two-Mode was falling apart at that point. I continued to remind people to not forget the success GM had with the Two-Mode plug-in mule. The next step, adding a plug, got hyped quite a bit by GM... but never got anywhere. It was a constant source of news, since the story kept changing. In the end, Volt was chosen instead... a compact car rather than a small SUV. Now, we see the rise of small SUVs... some as hybrids... some even with plugs. The fact that GM is getting left behind, the supposed leader of the plug-in movement, is not rubbing enthusiasts the right way. That's why there's been an escalation of tension recently. That history both opens up old wounds and reveals new opportunity. Response has been mixed as a result... quite passionate though. I'm quite intrigued how this will play out over the next few months. New offerings in the need-to-improve-small-SUVs category from other automakers are on the way.

- 2-05-2016** **Compromise.** There was more lashing out. The very word "*compromise*" makes some people cringe. They don't see it as an effort to find balance. They see it as a loss. That's really unfortunate. In this case, it was worse. He was angry. Unwilling to allow the nonsense to continue, I turned it right around: Calling business accountability "*slanted*" perhaps does date back that far. Like it or not (obviously some definitely not), that's reality. As exciting as range & power may be, it's just plain not what wells in high-volume sustainability. It's been that way since before many of us were even born. Mainstream consumers focus on the practical nature of their purchase. Need wins out over want. That's why the small SUVs are such a hot item right now. Want is the desire for the massive guzzlers of a decade ago. Need is to downsize. Offering a hybrid system and a plug is a compromise many will accept. They like it.
- 2-05-2016** **Who?** It was interesting getting asked this question: "*Do you work for, or are you compensated by Toyota?*" Since it was from the moderator, I knew that was a sincere act of wanting to know more. Why would anyone be so persistent on a GM forum, especially someone who owns a Toyota? I answered with: Nope, I'm just a consumer with well-informed contacts and a devotion to supporting the masses... hence the continued push to get past this first stage of tax-credit dependency and catering to enthusiasts. With a strong business background and a career as an engineer, the spin here is a draw. Participating with the local plug-in owners group adds to the exposure, getting to interact with Volt owners quite different from certain particular ones here. It's been an interesting experience over the past 15 years. Back then, it was totally unheard of for anyone to make such an effort to help change along. Now, it pretty easy to find others wanting to overcome old barriers of the past... like cross-automaker cooperation, targeting the market itself instead.
- 2-05-2016** **Bumping Heads.** Sometimes, you can tell the tide is changing. Even with this, I still had a feeling: "*He is part of a PiP 'users group'; but PiP represents the trailing edge, not forefront, of PHEV progress.*" So, I posted this: Haven't you noticed that we sometimes actually agree? Your focus is on the fore-front, considering leadership a measure of technical achievement. My focus is on the trailing-edge, considering leadership a measure of mass acceptance. Those are two fundamentally different approaches both ultimately trying to achieve the same goal. It means we will always bump heads, opposing each other based on perspective but not on purpose. Progress will be made when you accept that and focus on what we have in common instead. Toyota isn't interested in breaking new ground all the time; instead, their primary focus is on how to get the technology out in large quantity inexpensively. Notice how drastically different that is from GM, whose long-term intent is the same but doesn't wait until the technology is affordable? Toyota upgrades as cost justifies, along the way. GM delivers the end-product immediately, hoping cost-reduction will follow. Notice what Ford & Hyundai have been doing? No, which is the point. They decided to lay low until something viable can be delivered. Why get involved with the bigger players attacking the problem from two very different perspectives. That is yet another approach, also with the same ultimate goal. See how this works?

2-05-2016 Chapter's End. The final battle in this chapter came to an end. I pushed to make it happen. Knowing the story wasn't over, it was easy for me. A small group of particular die-hard Volt enthusiasts didn't realize what was going on. They thought there was only a single chance, that failure meant death. It was their battle cry for 5 years... don't like Volt die. That was the reason why my purpose kept getting questioned and why I kept having to asked their goals. Seeing more was to come didn't happen until today. Fear based on assumption overwhelmed rational thought. I've see this before, hence taking a very different stance. The end of Two-Mode came about from the announcement of Volt. Supporters could let it go at that point. With Volt, it was the announcement of Bolt. That's easy to see now. Stages in between are too. Ford's rollout of Energi was a major set back. Recently, the same panic erupted from Hyundai stirring emotion with Ioniq. RAV4 hybrid's initial success made it worse. I took advantage of that to introduce a moment of reflection. Multi-Front battles often lead to a finale with online conflict, if pointed out properly. Sure enough, that worked this time. Thank goodness. In this case, a simple observation of what's available now and what's coming is all it took. GM has delivered what it originally promised back in 2010. It took as additional 5 years, plus a little more waiting. That's far longer than anyone imagined, but that "40 mile" range is realistic. Enthusiasts just plain didn't want to admit the extra 25% capacity required to achieve that in Winter. They didn't want to admit that it will still take a few more years for overall cost to come down enough to compensate for the upcoming loss of tax-credits either. Getting them to look far enough ahead to actually see future potential, instead of dwelling on all the lost opportunity, was quite a challenge. It got ugly, really ugly. Thankfully, that's over now. Phew! The story isn't complete though, only this chapter.

2-06-2016 **Suggestions.** Wanting to encourage & solidify this end, I went all out with the posting:

It's a well-proven practice in my career to review a project upon completion. You note what worked and what didn't. I see good reason to do that here.

Voting down facts was probably the most counter-productive activity. Rather than just trying to hide what isn't liked, a suggestion would be to address it as directly as possible. Don't leave any opportunity for the topic being brought up again. That means provide concise reasoning. Vague replies make it worse. Excuses validate a problem. Responses of dismissal only encourage reposts.

Anonymous posting was another major problem that never went away. What a pain. Sadly, replies without substance made it worse. Defenders become the source of further tangents by not making an effort to get back on-topic. The suggestion is to simply state purpose. Counter there disruption. Knowing what the desired outcome is makes those distractions easier to end.

Making it personal and diverting discussion with automaker attacks, that was a huge waste. Instinct compels us to discredit. We feel it works well as a deterrent. In reality, it doesn't accomplish anything. In fact, it tends to reduce effectiveness of following posts. Casual readers tend to lose interest and abandon the thread. The suggestion is to prevent is simple. Don't do it.

Identifying goals is among the most powerful tools for progress available to us. We've seen great things emerge from learning opportunities. You try something. If it works, great. If not, move on. Remember, the market itself changes as time advances. The best suggestion for dealing with that situation is to embrace shortcomings. Failure is an option. It's only an end of a chapter, not an end of the story.

Endorsement for both plugging in and lithium batteries went extremely well. Notice how successful the idea of using electricity became early on? Everyone was in agreement about that being a major objective. It allowed us to very effectively focus on how to best achieve that. We followed the suggestion of trying to deal with next-step barriers by focusing on the future, rather than dwelling on the present.

Bringing up history can be a powerful decision-maker for what to do next. If something was attempted repeatedly but resulted in disappointment each time, don't do it again. That seems like such a straight-forward suggestion; however, the trap of dismissal is very easy to fall into. As painful as it might be to address mistakes, those can be the key to success the next time around.

Celebrating success can be a source of renewal. You need something to keep the group engaged. But if you focus on that past achievement too much, that very thing becomes what holds you back. If you focus on what comes next too much, that hope becomes a liability when circumstances change prior to rollout. The approach should be to seek out a balance. Providing compliment with complaint can be a very effective means of advancement when a suggestion is included.

The need to acknowledge the market as a whole was a lesson learned the hard way. Far

too often, past rivalries interfere with attempts to overcome barriers simply by losing perspective. Focus solely on particular groups allows the bigger picture to be overlooked. Making an effort to redefine foes & allies based upon objectives goes a long way. That suggestion should not be taken lightly. It's a difficult change of mindset. We've been trained to not think that way.

Finally, the very concept that a single solution will solve all problems is fundamentally flawed. Yet, that is what we do... over and over again. Commonplace successes we've witnessed that support differences are easily forgotten, not even noticed or considered. Just look at how uncommon the vehicles we drive actually are. Sizes & Shapes vary dramatically. Heck, even our preferences change over time. Why can't what powers them be different too? We need to embrace diversity. It's a suggestion that will take us a long way.

That's what worked and what didn't. Let's make a big effort together to start out the next chapter on a good foot.

2-06-2016 **9 Years Later.** Remember back when gas prices were climbing into new territory? GM had given up the anti-hybrid "stop gap" campaign and revealed Volt to the world. It would be vastly superior to Prius in every way, the answer to our car problems. Ugh. The nonsense started immediately. It only took a day for vaporware talk to emerge, questions of how that could actually be accomplished. My initial thoughts were: *"I don't believe that is a cost-effective solution for the masses for many, many years still."* The explanations why angered supporters. What I saw as realistic, they saw as fighting words. Having experience in that area made no difference. I was the enemy, because that knowledge came from the supposed competition. Watching Toyota strive for affordability taught me a lot. They turned and were basically hostile ever since. Reading through that history I documented as it unfolded, writing down observations as they happened, sure provides an interesting perspective now. Looking back is quite different from preserved day-to-day thoughts. I was right... oh more accurately, I correctly sighted past events as being highly likely to reoccur. Sure enough, they did. Volt has been a disaster... not the car or the technology, it was the business aspect. This was a great example of a *"solution seeking a problem"*. We were told all about *"range anxiety"*. Capacity was too expensive. The approach Volt offered would overcome that. Catch was, if battery cost came down enough to make Volt affordable, why not just sell an EV to people instead? That type of plug-in hybrid made no sense. It required cost to remain high... but then couldn't be sold in large quantity because the cost would be too high for Volt too. It was a mindset doomed from the start. Augmenting a hybrid was a business model supporters wanted no part of... which ironically, would have addressed the issue well enough to make prices affordable. Other automakers see that potential and hope to capitalize on it now. GM sees battery cost having dropped so much, they're planning to offer an EV which will overcome the *"range anxiety"* problem. No need for Volt. We'll have Bolt instead. What a mess! So much time wasted. Oh well, at least that chapter has come to a close. GM is now planning to introduce a hybrid and an augmented model now too, just like what was suggested 9 years ago. Volt will remain an enthusiast vehicle. It didn't die after all. It just won't leapfrog either. This is yet another example of not understanding the difference between want & need.

2-07-2016 **Friendly Rivalry.** The hope was always to find one. When there were only two hybrids available, Prius & Insight, things were a mess. Honda had delivered something that wasn't competitive. Insight was a 2-seater with a manual transmission and an aluminum body. It had nothing in common with the 5-seat automatic sedan called Prius. Yet, the two were constantly compared. Being the only choices for purchase back then, it was all people understood. GM had the opportunity to avoid that with Volt. There weren't any other plug-in hybrids offered. That was it. Gas was expensive then too. Enthusiasts were smug though. GM didn't care. There was enough conquest potential to prove the technology viable. That's all GM cared about. Enthusiasts didn't want to see that reality. They saw their population growing. It didn't matter that money-losing leases and tax-credit dependency made it happen. They just to claim victory over Prius. That was disappointing... and frustrating. Now, we see Volt struggling for an audience. Almost all the low-hanging fruit is gone now and there's a rivalry growing between Toyota & Hyundai. It's looking to be friendly too. That was the very thing people like me had hoped for 9 years back with Toyota & GM. The situation got ugly quick. Ford entering the plug-in arena made it worse. The struggle grew more and more difficult. There's an unspoken fear growing that Toyota will "*leap frog*" what GM offers. That was the hope Volt enthusiasts taunted Prius supporters with, saying it with belittling attitude. I won't do that. In fact, it's the very reason I'm extending a hand in friendship. I'm putting my hope on the chance that we can establish a friendly rivalry instead. That should be just a matter of focusing on goals, what I had attempted to do countless times in the past. What's different now is rollout is in progress. The reality of low sales can get people to change. Someone offering to help is what they will seek, especially someone with extensive experience to share.

2-07-2016 **Influence.** The comment was made about now knowing how much we actually have. Could you really ever find out? I climbed up on the soapbox again to share some insight:

Realistically, it doesn't matter. The end result is the same. The benefit is they get confirmation of it being an acceptable decision much sooner. There's a lot at stake. That helps a great deal.

With Prius, we established a direct line for feedback with Toyota. They shared information with us directly, a few times with tidbits even before the dealers. We got confirmation the forums were being monitored for suggestions. The next-gen rollout included some of what had been discussed. It was a great exchange.

I was always baffled that this group wasn't able to achieve the same thing with GM... which is why I kept on pushing. There were several here who insisted we should just be patient and hope for the best. I'm not that type of person. I also know that reacting afterward is far more costly than being proactive. Interacting with users during the development is priceless.

25 years into a career as an information engineer (software developer) and having a father as a mechanical engineer taught me a great deal. I learned the value of feedback long ago. I established a group beta-testers, who gave candid and well thought out suggestions. It was a very productive relationship.

Way back in 2003, we knew the design of the hybrid system for Prius was able to deliver speeds of up to 100 km/h (62.1 mph) using only electricity. We also knew that would be incredibly expensive. Yet, there were some who experimented with added capacity anyway. When the next-gen rolled out in 2009, we could see the design continued to support that ability to take advantage of additional electricity. It was still too expensive. A few aftermarket providers didn't care. They tried attracting consumers, despite the high cost. Toyota saw that, but waited until a configuration actually affordable would be possible.

That approach had trouble from the start. It was exactly what enthusiasts had requested, but it wasn't what supporters saw as appealing to the masses. The reason was simple: Volt. It wasn't the configuration hoped for (since the engine ran often in the winter and the wheels were powered directly at times), yet it wasn't marketed as a plug-in hybrid. So, people focused solely on range rather than results. Toyota took advantage of the feedback early on, keeping availability limited to select markets. It gave them an opportunity to learn more about how widen appeal without trading off price. In the meantime, energy-density and production-cost of batteries would continue to fall. When Ford joined in offering their plug-in hybrid, there was no reason to expand. Observing their progress (which also had challenges), would provide a great deal of valuable information.

That history will, of course, be spun to make it look like goals weren't accomplished. But sales expectations were never set high in the first place for the plug-in Prius, quite unlike Volt. It was also a mid-cycle upgrade, rather than an entirely new vehicle requiring a full 5-year cycle. The cost & risk was profoundly lower for Toyota than it was for GM.

Reality is, few will care. Many here will deny that even happened anyway. So, there's little chance ordinary consumers will bother trying to figure any of it out.

The point is, what was set out to be achieved will be accomplished. So what if it was a round-about way of doing it. Taking an economics class will teach you what to expect. Market reactions are difficult to gauge. Both consumer & competitor will do everything they can to resist change and influence outcome. Still reaching the finish-line without having incurred great expense or done anything inappropriate is what counts.

2-07-2016 *The Real Question.* I was asked this: "*The real question is, what do we expect can be done beyond what has been done?*" It was a new twist on addressing goals. I was happy to contribute thoughts to that: Don't expect. Suggest. There's growing worry of the inevitable tax-credit expiration, right in the middle of Volt's product-cycle. Yet, notice how no one wants to actually address that? It's a sign of trouble on the way. We need to push for a solution. Don't let the opportunity now slip away. An example from Prius history is the improvement to the ride quality. It wasn't necessary for the audience Toyota had targeted. So, focus was put on diversification instead. We got a smaller and a larger model of Prius, along with a plug-in. We just got a small SUV as well. But with gen-4 Prius, the hope is increasing appeal to draw in a wider group of consumers. Stiffening the body by 60%, giving it much better suspension in the rear, lowering the center-of-gravity, and adding quite a bit of sound insulation will go a long way toward helping to achieve that. Those were all suggestions from current customers. Look at what people made discouraging remarks about. Would changing any of them draw in new customers? Ask what people commonly seek out when shopping for a vehicle. What doesn't Volt offer? Consider the rest of the market. Think about what sells well. Why haven't we got a small SUV variant?

2-07-2016 **The Challenge.** A former foe has accepted my effort to become a friend. We are trying to find some common ground. This my latest exchange in that effort:

Nice summary and good question. The past is what it is. Our focus is now 2016.

GM just delivered gen-2 Volt. How should it be marketed? Having an engine was a strong draw in the past, since it eliminated concern of range-anxiety. But with next-gen EV choices targeting 200-miles, that will become a much harder sell. A range of 53 miles simply doesn't compare. It does top other upcoming plug-in hybrids though.

Hyundai, Ford, Toyota, Mitsubishi, Honda, and Chrysler all see the appeal of 25-30 miles for plug-in hybrid range. Ask yourself: Why? People will still get an EV experience, but MPG high values will likely be the draw. Price has proven a major deterrent. Will consumers care if the engine runs from time to time if they can buy something competitively affordable?

Toyota has an advantage in place with respect to reaching affordability. The regular model of Prius brings about economies-of-scale benefit. Motors, controllers, and battery-cells all see cost-reduction as a result of high-volume production. The plug-in model will benefit as a result.

Toyota also has an advantage with respect to reputation. The hybrid system is known for its reliability. The hybrid system is also known for uninspired performance... until this evening's Super Bowl commercials. Toyota is taking advantage of Prius past to point out how much the newest generation has improved, emphasizing this upgrade changes how people will think of Prius.

Perhaps that is what GM should do... find something to revitalize Volt. What is the strength now to point out? Maybe range is the selling point. Oddly, offering the most capacity may not have a negative impact on other plug-in hybrids. It could serve as an endorsement for the category.

What do you think?

2-08-2016 **New Perspective.** The feeling is great when you can look at a situation from the other side. The fighting is over. Yeah! I finally have the ally which I sought for all those years ago. This was today's post: Gen-2 Volt ushers in a new perspective. Gas prices have plummeted, but so has battery cost. Audience has widened, no more early adopters. Competition has emerged, namely Bolt. It's a changed market. The worries (and greenwashing) of lithium fires has vanished. Impact of heater use in winter is well understood. New awareness of emissions (diesel cheats) has been raised. The situation is quite different from years back. Hybrids, Plug-In Hybrids, Electric-Only, each with its own take on how clean & efficient travel should be achieved makes understanding them a challenge. That all have battery & motor use in common though, which allows us to finally establish cross-automaker bonds. 2016 will introduce several more next-gen upgrades. That should make things easier. The catch is we must all make an effort to convey the new information. Don't let outdated data obscure the effort. Those next steps are worth it. We're all in it together now.

- 2-09-2016** **It Worked.** What an interesting conclusion. He recognized that I would never give up. I complimented him for having the strength to survive all that. We can now make an effort together, combining resources and perspectives to finally make some progress. One individual wasn't happy. You're not supposed to become friends with a former foe. Attempts to lash out failed. No one cared. It's his loss. Support for Volt has moved on the second generation. What happened in the first simply doesn't matter anymore. We all know several goals weren't met. The point was acknowledgement. Without any type of acceptance, there's no way to take the next step. Who knew it would take so darn long? Oh well. Being able to move on feels great. It's too bad so much effort was wasted. But then again, that was rather predictable. And what does it matter anyway? Failure is an option. You can't win them all. Learning what worked and what didn't is the point. Having to try again is just part of the life. It's unfortunate that certain mistakes cost so much, especially when parts could have been avoided. At least it's over... with all things, a reconciliation. Cool.
- 2-11-2016** **Niche Market.** The spin from some EV supporters is that hybrids never amounted to anything. We see that routinely. For example, this conclusion: "*...you must keep this in mind, HEV is still a tiny fraction of Toyota line-up and is much less profitable than ICE cars for Toyota.*" Just like any other greenwashing attempt, being vague is key. Do everything you can to avoid detail. I know that all too well. Providing actual numbers brings the argument to a screeching halt. That's exactly what I did. It did indeed achieve that outcome too: 10% isn't exactly tiny, especially when you look at the actual quantity. The question is, how profitable must hybrids be? Keep in mind that the gen-4 just introduced reduced production cost a little more. Here are the counts for 2015... United States sales = 452,152 hybrid of 2,499,313 total is 18.1%. Europe sales = 208,464 hybrid of 873,844 total is 23.9%. Japan Aqua (Prius C) = 215,525. Japan Prius (regular) = 127,403. Japan other hybrids = 50,000 (estimated). Worldwide = 10,150,000 sales total gives an estimated 10.4% hybrid.

2-11-2016 **The Catch.** I had fun with this one: *"GM will not lose much on the 2017 Chevy Bolt EV, as long as the Bolt EV gets sufficient national marketing, and the dealers cooperate with their own marketing, salesperson motivation, and customer test drives. People will not buy the Bolt EV or any new GM vehicle if there isn't any news or promotion about it."* (followed by) *"So, if GM pulls out all the stops and markets the Chevy Bolt EV as it should..."* It's a disaster in the making, just like we saw 5 years ago. What can you say? I posted: The catch is, GM must make a solid commitment right out the gate. Without an ample supply available, the rest won't simply happen. In other words, that's how they get dealers to cooperate and salespeople motivated. Seeing the inventory at a level capable of on-going sales is what drives the business. This is why that measurement of *"mainstream"* sales was deemed so important and continues to be a source of irritation for some. Contracts with suppliers to guarantee inventory all the way through is what helps to drive down costs. It's risky though, especially since those Bolt sales will take away from Volt tax-credit opportunity. All automakers face commitment issues like that. With the gen-4 Prius hatchback such an improvement over the previous generation, Toyota is faced with the dilemma of whether or not to upgrade the wagon model. Is the production effort worth it... especially in a market where gas here is just \$1.44 per gallon? We've been seeing sales of small SUVs climb. That loss of interest in MPG presents challenges for even a small hybrid SUV. That's why the gen-4 Prius took on such a standout look. Performance improvements alone aren't enough with such fickle buyers. We know gas prices will remain low for the next few of years still. We know the tax-credits will get used around mid-cycle for both Bolt & Volt. We know other automakers will stir the market in unpredictable ways. Difficult choices must be made. What should GM do?

2-12-2016 **Placing Blame.** Ugh. Change isn't easy. A mindset for such a long duration is difficult to overcome. Today, it was: *"If your football team is down 55-0 in the 4th qtr. and you call in a new assistant coach – does that mean if you lose the game, it's that assistant coach's fault?"* We need to focus on next steps... look forward. Asking who is at fault is looking backward. Here's my take: Considering who is to blame is the wrong question. Remember, just about everyone from both management & development had left the Volt project prior to it being rolled out. For that matter, many of the outspoken supporters vanished shortly afterward too. Placing blame is pointless. Listening to the message, on the other hand, is quite valuable. Things change anyway. What was learned from prior decisions? Look at the quandary of how to promote gen-2 Volt. Promoting a vehicle means focusing on strengths & unique qualities. The selling-point of Volt is said to be the 53-mile EV range. If you emphasize that too much by drawing focus the system only needing the engine 10% of the time, people will start questioning the worth of having such a large gas-engine & gas-tank. No one cares who made that size decision. It happened long ago. All we should ask is why that was chosen and if continuing on that way is best? After all, Prius PHV was mocked relentlessly for having a small battery-pack. The claim was it being wasteful carrying around so much extra weight for something not used often. Now, the tables have turned. What do you suggest for next steps? Shouldn't it be to juggle around the players on the team, rather than look for yet another coach? So what if the first game is lost. What about the next?

- 2-13-2016** **Range Minimum.** There are a handful of people, unfortunately all old-school Volt enthusiasts, who still push the belief that Prius PHV delivers only a 6-mile EV range. The refusal to accept video-evidence and to acknowledge battery-capacity just boggles the mind. What's the point? Well finally, we got this: "*But now all that seems mute because...*" That's the looking-forward attitude we've been hoping for, but the unconstructive nature of it rubs me the wrong way. How will range be measured if capacity is unacceptable? The highly misleading nature of the hard-acceleration at the 6-mile mark is quite arbitrary. It just as easily could have been at 5 miles or 7 miles or 2 miles. I chose to respond with: The actual reason is that "*range*" estimates hurt the industry. We saw everything from disappointment to greenwashing. When owners found out the impact heater use had, there was some backpedaling. It was made worse by discovering an automaker's estimates didn't correctly reflect results from standardized testing. Then to sour appeal even further, there were a few who intentionally misled by exploiting misunderstandings of terminology. That's why stating capacity in terms of KWH of electricity available is far more informative than miles that could possibly be driven under the right circumstances.
- 2-15-2016** **Kia Niro.** Crossover competition is what Kia (parent company Hyundai) is hoping for. Their upcoming Niro hybrid is supposedly targeted directly at Prius. It's really a small SUV with basic styling. Clearly, we have arrived at the end of a trend. Though appealing to consumers right at this very moment, it already looks dated. It will blend in well with many SUVs already on the road. That's the point. You'll be getting supposedly 50 MPG discreetly. The approach is interesting. People are resistant to change. This won't stir any attention. It's not ugly. It's not pretty. It simply doesn't draw attention. You're buying technology that offers reduced emissions & consumption, and that's it. With the advent of uniqueness being a draw, the situation is a matter of timing. Maybe consumers will jump on the opportunity with this as both a bridge to the future and a monument to the past. Personally, I couldn't imagine wanting something so plain. It looks quite ordinary. But then again, that's all some people want. They have desire to own a vehicle that's expressive. That's ok. It's just not me. Variety is important. Having a hybrid option for them to choose is great.

- 2-17-2016** **Cost.** Discussions are getting interesting. Barriers of the past, which prevented constructive posts, are gone. It's quite a different venue for posting now. I especially liked reading this: *"What I don't get...if the Chevy Volt early gen-1 was able to do 35 miles with a smaller body, why couldn't the PiP 2nd gen do at least that?"* The reason why was simple. It was an honest question. In the past, that same sentence wouldn't have been taken as sincere. That's typically because the attitude was to undermine. Things have changed. Hopefully, response to what I contribute will too: We'd all like a vehicle with a plug that's actually affordable. Rolling out a vehicle to the masses that's dependent upon a \$7,500 tax-credit isn't a good business choice. Once that subsidy is gone (each automaker gets 200,000 before phaseout begins), the challenge to grow sales and be profitable becomes even more difficult. GM is taking quite a gamble, especially with remaining credits available being divided between Volt & Bolt. Toyota held off and will strive to deliver something capable of standing on its own. That means larger quantity with lower cost. So, keeping the battery at a size reasonable enough to compete with other high-volume sellers is a big deal. Remember, the competition is vehicles on the same showroom floor, not those offered from other automakers. Keep in mind, Toyota sold 2,499,313 vehicles here in the United States last year. GM sold 3,082,366. That puts some perspective on just how few 200,000 really is.
- 2-18-2016** **No Response.** It wasn't worth the effort: *"Part of the reason hybrids and plug-in hybrids are so hard to sell is people think they are buying 2 cars instead of one....thus they are paying more up front to buy it and also have all the maintenance of a pure electric plus a gas car."* We endured years of Volt promotion which, ironically, emphasized the 2 car perspective. We got countless endorsements telling us the vehicle was an EV with a full hybrid system as a back following depletion of the plug-supplied electricity. The short-sightedness of that perspective never ceases to amaze me. It was an effort that ultimately highlighted the fact that Volt was the worst of both worlds. The range was too small to compete with an actual EV and the engine efficiency was too low to compete with hybrids. Ultimately, that is where some of the hate for Prius PHV came from. Even though it had a much smaller battery-pack, the EV range was impressive amount of electricity it had available. The resulting MPG afterward was obviously a strong point too. Since the smaller capacity was an effort to keep the system affordable and to not sacrifice cargo or seating-space, the augmentation was often looked upon as the best of both worlds. That polarity contributed to most of the online conflicts... in the past. Now, the hypocrisy of acknowledging that self-deprecating stance has quieted most. It's a sign of progress. That meant no reason to bother with a response. Yeah!

- 2-18-2016** **Lousy Job.** At times, it can be quite interesting to learn about other perspectives people have. Most often, they judge actions based on only recent history. Without background, it's easy to draw a different conclusion. Much of this comes about from thinking short term. It's the way our particular society works. So, it makes sense that the market responds according. It's why Toyota commonly gets misunderstood. They take a different approach. Reading this today was no surprise: *"Again, Toyota did a lousy job of advertising and communicating their vision for the car."* Seeing that point of view doesn't take much. Seeing another, or even acknowledging there could be another, is a different story. Though, I tried to point that out: The intent was to remain flexible, not revealing a mass-market plan until the initial data-collection phase completed. Since it was a mid-cycle rollout and the other plug-in offerings were facing unexpected barriers, it didn't make good business sense to commit yet. They chose to watch & learn about the emerging market. Waiting until gen-2 is still looks to be a wise move. That delay (lousy job) should make things easier in the long term. Toyota can start fresh, rather than have to backpedal as with certain others.
- 2-19-2016** **Credit, game.** We're seeing 2016 shape up to be a year for the history books. A big part of that is change being observed in discussions now: *"In my view, GM played the credit game properly, and Toyota is leaving massive amounts of money on the table. The tax-credit is limited to 200,000 vehicles per manufacturer, and the credit is pro-rated to the capacity of the battery. Toyota's PiP qualifies for the minimum tax-credit (\$2,500) while still counting toward their 200,000 vehicle limit..."* Remember how even the mere mention would result in hostility? This difference is welcome... and long overdue. I'm happy to see constructive dialog beginning. Here's my insertion into that: Toyota studied the market and was well aware how few 200,000 really is. When that subsidy expires, the vehicle must be able to sustain high-volume profitable sales. Notice how gen-1 PiP rollout was limited, saving credits for gen-2? GM will be facing that expiration, with 2 vehicles still depending upon that \$7,500 credit, mid-cycle. Being just 2 years into gen-2 Volt and the new Bolt will make sales in large quantity quite a challenge. Who cares about not getting more federal assistance if the vehicle becomes difficult to sell afterward. That is not a game you want to lose.
- 2-19-2016** **Credit 2, competition.** This is the reason the question of "Who?" was asked so often. Notice all the "if" conditionals: *"If I were thinking short-term, I would do exactly what Toyota did. However, if the long-term is increasing EV usage to meet ever increasing fuel economy and emissions regulations as well as customer demand, I would use the tax-credit to develop higher range EV technologies and logistics so that I have an edge on the competition for when the future inevitably becomes the present. GM appears to have the edge on the future."* Some people just plain don't want to commit. It's like the next level of vague. Keeping things uncertain is another warning, an indicator time is being wasted. Unfortunately, there's not much you can say. Those acting that way will just label you as argumentative. But hey, at least I try anyway: We know capacity will be increased for PiP. We've heard that power will top-speed could increase to 110 km/h (68.3 mph). So, there is a natural generational improvement. Toyota views the "competition" as traditional vehicles. GM views the "competition" as other plug-in vehicles. That fundamental difference has a profound influence on approach. In other words, priorities are different. Toyota has always considered cost to be paramount. Range isn't as important if the end-product isn't affordable.

- 2-19-2016** **Credit 3, sales.** Sometimes, you get lucky and discussions really do swing in a productive direction: *"Also, we get an indication of growth locally from clubs and organizations we are in contact, although this isn't as reliable as the actual sales numbers."* I was both pleased & stunned to read that. The topic of sales usually dies when tax-credit dependency is brought up. We really are moving forward: More important than sales is attitude, since that persists throughout ownership. The years of hate from *"vastly superior"* enthusiasts only existed online. When the plug-in owners club would meet, we were all friends together working toward a common cause. This *"leap frog the competition"* discussion thread highlights the problem. In the club, there's a diverse set of plug-in owners. We all recognize the competition as traditional vehicles. Only those smug few online, who unfortunately spoke as representatives for their peers, saw the competition as other plug-in vehicles. That head-butting caused a lot of trouble over the years and consequently impaired progress forward. Thankfully, the rollout of gen-2 offerings woke them up from their complacency. In fact, there are a few individuals who were former foes that are now friends. The nonsense of *"range anxiety"* has vanished with the advent of 200-mile potential. Part of that comes from the realization that those tax-credits which they were heavily dependent upon will quickly vanish as a result of delivering a truly popular vehicle. What I find most redeeming is the vindication of cost being the highest priority. It seemed so simple of a message: *"The design must be affordable for the masses to accept it."* Yet, that belief was met with fierce resistance. Costly approaches were justified with twisted excuses and the dismissal of facts. Sadly, despite finally getting recognition of importance, we'll be dealing with the collateral damage from that for years to come. Long story short, the plug-in options we endorse must be appealing to ordinary consumers. No matter how appealing certain aspects of performance are, selling those vehicles profitably in high-volume is the ultimate goal. That ability to provide business-sustaining revenue is vital.
- 2-22-2016** **Better.** There is still a little bit of smug, but it's quickly fading. This could be among the last examples: *"The crappy Prius took how many years to get where it is now, and it still sucks. In one design exercise GM came out with a much better car. #engineering."* Going down with a fight is normal. There's always someone who wants their message to be made quite clear before standing down. After reading other posts, which clearly didn't agree with him either, I posted: There is an essential balance. Too much of a good thing is a problem. It's really unfortunate the devotion to engineering prevented seeing business need. GM focused so heavily on delivering maximum EV that it sacrificed priorities of ordinary consumers, resulting in a really nice vehicle enthusiasts would praise. Consequences of that approach have become quite apparent now. Notice how much focus has shifted over to Bolt instead? Volt isn't considered a mass-market choice anymore. The newest Prius is, hence the obvious resentment. Sorry, but the reality is that *"better"* is not measured in terms of engineering praise. That success is determined by the count of sales. The better a vehicle is, the more it will be purchased. This isn't rocket science. It's ordinary business.

2-24-2016 **eAssist.** What else can you say other than: *OMG!* Never in my wildest dreams did I expect the mild hybrid approach to be tried for a third time. The prior two attempts were horrible failures. GM's first was called BAS. It went nowhere. The second fell apart too. This third is interesting, since it specifically targets the large pickups. That is a bit odd though. The system adds only 13 horsepower, so there really isn't much in terms of assist... especially for a truck. The power comes from a 0.45 kwh lithium-ion battery. So, it's small and light weight (about 100 pounds total). Cost wasn't mentioned. Efficiency gain is expected to be 2 MPG. Purpose is to gather information. Only 500 Silverado and 200 Sierra will be built in 2016. GM has learned the value of limited rollouts. Too bad Toyota supporters had to suffer by pointing out the benefit. Oh well. This is one that definitely needs real-world data. As an option, it would present sales challenges. But if this is being considered as a standard part of upcoming rollouts, a way to deliver an edge over the competition and to satisfy CAFE requirements, that's a different matter. We'll see.

2-25-2016 **Writer Provoke.** It never hurts to know your presenter. In fact, that can be even more important than knowing the audience. For example: *"Nissan has repeatedly said it has a fourth-generation battery waiting in the wings that could provide 200-plus real-world miles that would soon make "range anxiety" a non-issue, so why is it waiting?"* That quote was to be expected. It came from a writer whose job it is to stimulate discussion. He already knows the answer. It's cost. Rolling out a vehicle too expensive to compete simply doesn't make sense. Nissan could be facing tax-credit expiration sooner than all the other automakers too. Double the capacity of a battery-back isn't exactly easy either. There's physical space & weight challenges to deal with. Simply having the technology available doesn't make it practical. Even with delay, there is the benefit of that message of 200 miles being a selling-point continuing to get reinforced. Automakers are uniformly sighting that as a realistic threshold for mass adoption. Articles with statements like this writer provided today help too. I still don't like it when presented in the form of a provoke though, but that is the nature of online commentary. They have to do something to stimulate interest & participation.

2-26-2016 **Please.** We're seeing more and more progress. Barriers of the past are breaking down. New friendships are forming. That makes it hard to believe something like this could still get posted: *"FACT: The 2015 Toyota Prius PHV is EPA rated for only 6 miles all-electric range. The 11-mile figure is for blended gas-electric. Please stop spreading false information."* Even the moderator of that daily blog for Volt, which is where that was posted, got a bit irked. The discussion thread was about other plug-in hybrids coming out this year. Why in the world with a Volt supporter continuing fighting the advancement of the market. Obviously, I wasn't exactly thrilled to read that either... and was happy to fire back: Please make an effort to overcome confusion of the past. We all need to do our part to move on. That so-called fact has been used extensively for greenwashing, because it was extremely misleading. True, the EPA test does indeed trigger the engine to start at the 6-mile mark on the driving course. However, there is still 5 miles of electricity remaining. Following that hard-acceleration event, the engine shuts back off and EV resumes. The better information to share is battery-pack capacity. Take the time to do the calculations. Looking at EPA detail on the window-sticker, we see an electricity consumption-rate of 29 kWh/100 miles. That means 3.19 kWh is required to travel 11 miles. Knowing that Prius PHV utilizes 67% of the capacity available from its 4.4 kWh battery-pack, we can easily account for 10 miles. That's 2.95 kWh required to travel that distance using only electricity. The 11th is a blend, using that final 0.24 kWh of electricity still available combined with a small amount of gas. Proving only 6 miles total is all that's available cannot be done. Detail provided by EPA measurement clearly confirms it.

2-27-2016

Adding Insult. Someone else saw the opportunity to belittle: "*So most of these cars would get high single or low double digit battery miles in the winter. That's pretty awful.*" I jumped on that opportunity too: Since the point of augmentation with a larger battery and plug is boost MPG, using "*awful*" to describe outcome isn't accurate. For example, last weekend's Saturday morning blogging at the coffeeshop was a round trip of 8.9 miles. With the temperature in the low 20's, I made it back home with just a tiny bit of electricity still available. That's so far beyond the "*6 mile*" claim, it's quite frustrating to have to tolerate a source of such obvious confusion. While typing this, I'm at the coffeeshop again. The temperature is just barely over freezing. That extra warmth resulted in less electrical resistance. As a result, the battery-pack is currently sitting at 58% remaining (of useable EV capacity) rather than 50% like last week. When no-jacket weather returns, range will increase even more. The entire drive uses only electricity. About half the distance speed is 55 mph. It's very effective use of a gen-1 design. Another example is yesterday's commute. It was 37.8 miles round trip. There's a short stretch at 70 mph (though traffic doesn't always go that fast) and a mix of 45 to 55 mph the rest of the way. I plugged in at work, taking full advantage of the 85 kWh solar-array they have there. The resulting average for that driving was 117 MPG. In the summer, I tend to get between 135 and 150 MPG. Late this year with the upgrade to gen-2, there is an anticipated max EV speed increase (from 100 to 110 km/h, that's 68.3 mph) and a more than doubling of the battery-pack capacity. Those improvements are the result of cost dropping and the technology being refined. For my commute and running around town, that will offer a nice upgrade... so much so, it's far easier meeting others in the middle, rather than continuing to bump heads. In the past, there was quite a bit of misleading about how the system operated above the max EV speed. Certain individuals worked hard to feed the assumption that at faster speeds, there was no benefit from the plug-supplied electricity. It was amazing how much effort got expended to convince people that the vehicle reverted to just a hybrid then. Nowadays, most people understand there's a blending that occurs for fastest travel. The result is much higher MPG than with a no-plug hybrid. The hope now is to get past the same type of misunderstanding from "*all electric range*" values. You can see new friendships emerging among former foes. As we see the technology getting upgraded and expectations toward automakers changing, that's becoming much easier. True, there are uncertainties still... like public charging-stations and tax-credit expiration, but at least we're seeing progress. This discussion topic points out the wide variety of plug-in hybrid options coming this year. Even more are on the way. That array of choices will cause confusion among buyers unless we as plug-in owners find a way to convey a uniform message. Clashing amongst ourselves will spell our own doom. We need to find ways to overcome differences. The last thing we need is having to deal with new misconceptions. Don't forget, those not in favor of plugging in will work hard to create them and ordinary customers aren't anywhere near well informed. It's up to us what happens next.

2-27-2016 **Displeased.** I wasn't the slightest bit happy with the response: "*If someone says the PiP has more than 6 miles of all-electric range, I'll continue to correct them.*" That one particular individual is anti-EV, so it makes sense that he'll be a more difficult personality to overcome. The others simply want plug-in choices to prosper, which made it easier to meet them in the middle. He has no interest in compromise. It's weird too. Even the guy who had hate for Toyota was willing to call a truce. That's so refreshing too. I had always hoped for allies. Now, they are offering gestures of friendship... really trying to make it work. This person though, what a pain. I'm curious if he'll bother to reply. I expect silence. We'll see. This was my follow up: 8.9 miles to the coffeeshop and back this morning. About half the drive was at 55 mph. The temperature was just above freezing. When I got home, 5% of the EV capacity still remained. The engine never started. That entire drive was all electric. Range was well beyond just 6 miles. Our purpose is to promote plugging in. Even Toyota's initial affordable offering clearly contributes to that. What possible benefit is there to telling people the range is less?

2-28-2016 **Closure.** This recent statement from a past antagonist to now someone trying to help out is what I chose to climb on onto the soapbox for, attempting to sum up the situation as a form of closure:

"Remains to be seen where Toyota wants to go in terms of cars you can plug in. They seem to put virtually all those eggs in the hydrogen basket now (while still doing a large number of non-plug-in hybrids), but they've issued misleading statements in the past so I'm not sure I believe they won't do an all-electric or serious plug-in hybrid."

The business approach differs to such a degree, it's easy to wonder. Our culture here has focused heavily on the now. So, things like long-term projects and sustainability simply aren't given much consideration. Remember what things were like before the economy fell apart? Focus was almost entirely on quarterly returns. Getting over that mindset takes some work.

My all-time favorite "*misleading statement*" from Toyota was the comment about lithium batteries not being suitable for automotive use. There were a number of people who immediately took that verbatim, but didn't include everything. It quickly became a popular out-of-context statement. The reference to cost was omitted. The thought that stance would change later was overlooked. Our desire to draw conclusions right away contributed to that misleading. No one cared though. The damage was already done.

Another big part of the problem was the mentality that only a single solution is the best outcome. People see an interest in hydrogen being exhibited, then believe that means there is no interest in electricity. We've backed ourselves into a corner by thinking co-existence isn't an option. So, in the case of Toyota, most of the effort to establish a base for plug-in customers and reduce cost by introducing a modular production architecture has gone totally overlooked. There's a belief that hydrogen is the investment of choice, that all else has been abandoned.

This is nothing new. When the plug-in Prius was first rolled out, there was no acknowledgement of it being a mid-cycle rollout with a potential for adjusting plans based on what would be learned along the way. It was just an immediate push to compare it directly to Volt with fixed expectations, as if circumstances didn't matter. At the same time, rollouts of Prius C and Prius V were outright dismissed... even though those were helping to draw away people from traditional choices, making the enticement of plugging later less difficult.

Now, within a similar window of time, we're seeing rollout of the new Prius and a hybrid RAV4, while also discontinuing the entire Scion division and rebranding the upcoming C-HR hybrid as a Toyota. Again, this is more of that effort to pave the way for plugging. People also seem to forget the goal of offering a hybrid version of every Toyota passenger vehicle by 2020.

None of that would be a issue of dissension if it wasn't for GM doing similar things, but in a different manner. We heard strong statements in the past about GM having no interest in EV offerings, since Volt was the winning solution for all. Now, no one seems to remember that and Bolt is widely accepted. The same goes for regular hybrids; yet, GM will be rolling out 3 different varieties.

We need to focus on the goal of plugging in. The gen-1 models taught us a lot. We know the affordable, high-density batteries are coming. It's just a matter of thinking further out, not getting hung up on the now or dwelling on distractions.

2-29-2016 ***Happy Birthday!*** How about this for a message remarkably well timed: "*Prius Plug-in Hybrid has helped usher in a new era of efficiency, but we are temporarily pausing production after the 2015 model year. Rest assured, we remain committed to the continued progress of alternative-fuel vehicles. As was done with the previous generation, this next Prius Plug-in Hybrid vehicle will arrive later in 2016 after the launch of the all-new Prius liftback and will feature significant enhancements in performance, design and technology.*" Discovering that announcement on Toyota's website today was great... since today just happens to be my Prius PHV's first birthday. True, I bought it 4 years ago. But the papers were signed and the check was delivered on February 29. This is the first leap-day since then. So... happy birthday! The timing of the next plug-in hybrid has been interesting. There was a lot of spin. Greenwashers attempted to convince people that Toyota had abandoned the idea all together. Antagonists claimed Toyota wasn't taking the situation seriously, that leadership means delivering the most advanced technology possible... rather than striving to reach the masses. It's been quite an experience to witness firsthand, as a participant in this history. Fortunately, I know what's to come. After over 16 years of study, that's rather obvious. Too bad others are quite so confident. Oh well. They'll find out soon enough.

3-01-2016 **Diesel Downfall.** We're seeing postponements now. The new deadline for a revised fix from VW to submit to the EPA for approval is March 24. The original submitted in January was declined. It wasn't good enough. April 28 is now the new deadline for the release of VW's own internal investigation, rather than next week. The denials, mixed messages, interpretation excuses are only making the situation worse. All of this is being described as "self-inflicted wounds". I'm amazed the situation has become so bad. We knew pressure was growing on diesel. There's simply no way to compete with hybrids, even those without plugs. The upcoming option of inexpensive augmentation basically spells death anyway. The gen-2 Prius PHV will be so much cleaner and more efficient, what's the point? Then when you take into account how dramatically quieter & smoother the drive is, how could diesel even remotely compete? Then when you take into account the reputation damage, it just plain doesn't make sense anymore for personal consumer vehicles. What the cost of the damage truly is remains a complete mystery too. Current owners here in the United States are left wondering, despite heavy government pressure to deliver a fix. Their resale value has plummeted and there's frustration from the fix inevitably reducing performance... the very thing many owners found most appealing about their purchase. Needless to say, there is a very ugly situation. We're witnessing the downfall of diesel. The next few months here will be harsh. Who knows what the backlash in Europe will be. Over in Japan, new testing procedures will be introduced. There is much worry about the future of diesel already.

- 3-03-2016** **Repeating Mistakes.** Sales results for February were released. Both Prius and Volt were hampered by new rollout availability. Unlike Prius though, sales were quite low for Volt... so low, no one wanted to discuss the topic. It was literally just a mention in a completely unrelated daily topic. I found that quite telling, especially since that particulate topic was about GM's lobbying effort to restrict Tesla sales... a heated issue... which is an on-going trend. When there's bad news, post something else to distract. Ugh. From Bolt, you get the impression of a green outlook, that a heavy investment is being made in efforts to change the market with EV sales. For this, that doesn't seem the case. It's like only releasing a gen-2 offering in limited fashion. Perception clashed with reality. Oh well. This isn't anything new. We've seen it before. Sadly, that's been in the form of repeating the same mistakes.
- 3-04-2016** **Intentional Risk.** Speaking of repeating mistakes, it's not just some automakers. Some consumers don't have a grip on reality either... as this points out: *"Some Prius drivers play a silly game called, "How low can you go?", or "How many miles per tank?" These are useless metrics which serve only to increase the probability..."* Sadly, it's the same old story. Oh well. All you can do is point out facts and ask why: That capacity beyond the reserve wasn't as big with gen-1 and consequently, there were a number of reports of ordinary drivers running out of gas. It was a quite surprise to discover the American mindset was to routinely push extremes. Toyota adjusted accordingly. Very few run out of gas following that. A major contributor to the reason for such a buffer is battery well being. In normal operation, there's a buffer for it too. Never deeply discharging is how it is able to last so long. Unfortunately, owners would drain the battery well past that longevity threshold. Consequently, its life is shortened upon continuing to drive after there isn't any gas available. With such a long driving range anyway, why anyone would disregard the visual & audio refill warnings is beyond me. Why take the risk? What's the benefit?

3-05-2016 **Low Hanging Fruit.** What do you think after reading this: "*However, 90% of miles put on EVs are charged at home. Or in other words, 90% of the infrastructure is already in place. As range increases, the rate of home charging will also increase.*" It's a common greenwash problem, where the is oblivious to the fact that he or she isn't seeing the big picture. They'll see a statistic and assume it can be widely applied. This is yet another issue related to not understanding audience. Much of it will come from those in favor of EV as the only solution. They pushback on plug-in hybrids and outright deny any potential for fuel-cell vehicles. They figure a plug at home is the answer for everyone... not realizing, that's far from realistic. They see the initial success and don't realize the next steps are going to be far more challenging. That's call the "*low hanging fruit*" problem. Current owners were the easiest to reach. Anywho, this is how I replied: That 90% is highly misleading, since the value comes from owners with easily accommodating homes. In other words, they are the low-hanging fruit. Upgrading homes in old neighborhoods is a major effort not taken into account. Some people just plain don't have a good setup available. Wires are hanging from old-school poles still and garages don't have physical room or electrical capacity to support a level-2 charger... not to mention, a second charger for the other car. As much as I desire plugs for all, that's just plain not realistic. For that matter, it doesn't even acknowledge those who live in condos or apartments. Obviously, we can overcome those shortcomings. It's going to take a heck of a lot longer than enthusiasts hope though. It doesn't address the backlash we'll get from the oil industry either. They're going to fight back hard, extremely hard. It wouldn't be pretty if it wasn't for hydrogen. That's a alternative fuel they can invest in, reroute their future drilling money to support for fuel-cell vehicles instead. After all, they have the resources already. It's an infrastructure adaptation they'll endorse long before embracing the idea of plugging in. We're going to see a lot of arguments against hydrogen in the upcoming years. Watch for those which don't take all the issues into account. Focusing on just efficiency and sighting the cost of fuel-stations is a red-flag that the big picture wasn't considered. There is no one-size-fits-all solution. EV and FCV will end up co-existing.

3-05-2016 **Timing.** I found this recent quote encouraging: "*Chrysler introduced the new Pacifica at the Detroit Auto Show less than two months ago. Production started Monday, and units will be at dealers in four to six weeks.*" How could I not respond to that? The new plug-in hybrid option came quite unexpectedly and will be delivered right away. That means no hype to deal with in the meantime. A fundamental problem with GM was the mindset that early announcements were beneficial; consequently, it set them up with the "over promise, under deliver" problem. And despite over a decade of struggle with that, the problem persists. We continued to get a lot of grief from Volt enthusiasts about the gen-2 Prius plug-in. For quite awhile, they would spin the discontinuation of the gen-1 as an end to the entire endeavor. Toyota finally to say something to put an end to what became a greenwashing effort. Ironically, there was a ton of hype for gen-2 Volt, yet GM only rolled it out in limited quantity and only to 11 states. To make matters worse, they announced the rollout of Bolt nearly 2 years in advance of actual availability. In contrast, we will likely learn very little about the gen-2 Prius plug-in until shortly before rollout begins nationwide. Why rush? After all, it has proven a winning formula. The original (gen-0) model of Prius was revealed in October 1997 and sales began just 2 months later. That blew the minds of other automakers and proved to be effective. What good does it do to hype a rollout so long in advance? That forces the automaker to attempt to match what was promised much earlier, even if it means sacrifice due to market change. That's a hard lesson learned with gen-1 of Volt. How come GM continues to make that same mistake? Thankfully, we aren't seeing that with Chrysler. It will be intriguing to see how the market responds to that. It should provide a clue what we can expect with Toyota. In other words, there is much to say but little reason to... yet. The wait won't be long.

3-05-2016 **Range.** It's an interesting topic. There are many perspectives, with varying interpretations depending upon when judgment was made. That's because the market is changing quickly, as the technology advances and people learn about their own assumptions. Understanding purpose is an obvious change too. This is what caught me today: "*The range of PiP 1 is terrible. I think that PiP 2 needs 2x-3x the battery capacity and range as PiP 1.*" I jumped into the mix with: Range wasn't the point. People in this market had a very difficult time accepting the low-cost approach of augmentation though. So the next, will target that market shift. If nothing else, Toyota has shown the ability to adapt to change. Also, let's not forget that numbers don't mean the same thing to different audiences. The best example of this was the EPA measurements for MPG prior to the 2007 change. In the past, those numbers simply served as a basis of comparison. Standardized criteria was introduced for the sake of making comparisons amongst the wide array of vehicle choices easier. That's it. Those numbers did *NOT* represent a real-world expectation. But then when hybrids came along and the market started to give a crap about actual MPG results, the testing changed. The measurement approach changed to reflect the market shift. That's a reality most people are totally unaware of. Toyota's approach to delivering a MPG boost wasn't understood by the typical consumer, following rollout. Prior to that, purpose seemed obvious. But traditional greenwashing and new efforts to undermine, along with continued battery technology improvement, resulted in a pause. The market was actively readjusting, much of it having to do with perception. People are changing their view of plugging in. People are seeing the hybrid market expand & mature. People are finally paying attention to the dependency our economy has on oil. The audience has changed.

3-06-2016 **Want vs Need.** It's not just an issue buyers have to acknowledge. Automakers have similar tradeoffs to deal with. For example: "*The demand for the PiP was there, but the cars were not. Toyota just wouldn't build them.*" Why is there is presumed need to rush? Isn't that really a want? My choice of enlightenment was to draw attention to the importance of when: What's the point of building an older generation for early-adopters when a new one for a wider audience is on the way? Ask the typical consumers for information about Volt. All they know is that it was first. Many cannot correctly tell you how the system actually operates. They are unaware physical size and battery attributes as well. Toyota saved the opportunity to start fresh. Two-Thirds of the states still haven't seen them yet and far more tax-credits are available than with the other automakers. They still have the opportunity to be the first to offer wireless charging too, which is proving to be a major convenience for cell-phones. Look at it this way, a similar situation existed 13 years ago. Availability of the Classic model Prius was quite limited. We'll never know the true demand as a result of Toyota sticking to a strict quota; however, we do know that sales of the Iconic model which followed were very strong. Also, keep in mind how information from a previous generation become tools of greenwashing. Reports will be shared without context, leading people to believe what's written about is all that has ever been available. It's very easy for an ordinary consumer to be unaware of generational detail.

3-06-2016 **So Far.** It's interesting to watch the perception of plugging in change. Some would call it a double-standard. Some would call it hypocritical. Others would call it damage-control. I'm not sure what to call it yet... perhaps, back-pedaling. For over 5 years, there was a fierce campaign to differentiate Volt as a EREV and to patiently wait for gen-2 rollout. Now, there's an endeavor to identify Volt as a PHEV instead and to disparage Toyota for having been patient. Reality is, ordinary consumers haven't been paying attention anyway. All they know is the basics... there are plug-in vehicles available and they are not cost-competitive yet. That's pretty much it, so far. This is like trying to explain to someone the benefits of a smart-phone. They would have no clue how they would actually use one, until exposed directly to one. Even then, that's no guarantee by any means of a purchase. The price of that is trivial compared to a vehicle purchase, as is the expected service life. No amount of "*first*" or "*leader*" claims will change that either. It's the nature of how ordinary consumers react to change. In other words, achieving mainstreams sales is far more difficult than just appealing to enthusiasts. We haven't even come far enough for most to see that yet.

- 3-13-2016** **Wyoming Trip.** My wife and I took another long weekend to visit her sister out in Wyoming. That's a 1,500 round-trip drive, with much of it at 80 mph. It's a MPG killer. Both this time and back on New Year's the result was an entire MPG drop from my lifetime average. On this trip, there was a day-trip extra side excursion as well. Speed so fast for so long simply isn't efficient. True, even at that rate of travel, efficiency is still better than other vehicles. After all, Prius is extremely aerodynamic. MPG in the low 40's is hardly anything to complain about. It is great experience taking a trip like that too. The drive itself is surprisingly refreshing as well. Much of that has to do with having adaptive cruise-control. Without that radar-detection to automatically slow the car down it would be somewhat of a pain. With all that space on the wide open roads, people out there few compelled to get out of the left lane as fast as possible... resulting in them cutting you off at 80 mph. It's basic stupidity at play. Sometimes, people just don't think. Why put yourself and the other vehicle at risk for no reason whatsoever? Just stay in the lane to finish passing at a safe distance before merging. Geez! Needless to say, the adaptive feature is quite handy. That allows you to enjoy watching the country side... including Devil's Tower. That's always fascinating to see off the distance from the highway while on that trip. We pass by the Badlands too. It's quite scenic of a drive, once you get past the wide open flatlands.
- 3-14-2016** **One Week Later.** It's as if Volt doesn't even exist anymore. We went from hype & rhetoric to failed attempts to draw attention. The enthusiasts are out of ideas. Last week's highlight was an owner having reached 300,000 miles on the odometer. With a 110-mile drive each way of his commute, that number isn't a huge surprise. Being able to plug in at both ends didn't help as much as you'd think either. There were many comparison attempts to Prius. All fell apart. It still makes no sense whatsoever comparing a plug-in like Volt to a regular hybrid like Prius. That massive difference in battery-capacity and the one not even having a plug makes them such extremes, only a true act of desperation would anyone try to put them into the same category. Yet, that happened anyway. Funny part is someone pointed out that overall energy consumption was from the Volt. Having done the same thing with a Prius, only a small amount of additional gas would be needed.... without any plugged-supplied electricity. Needless to say, people have moved on. Nissan is rolling out an upgraded Leaf. This year's model with offer a 30 kWh capacity battery that actually fits into the housing for the original 24 kWh battery. That bumps EV range up to 107 miles. So, even without the doubling of capacity to come in the next year, Leaf continues to stay competitive... which is why focus on Prius was the choice. The enthusiasts thought they could flex the "vastly superior" muscle one last time. That's getting so old. We know that cost is a major purchase factor. No amount of attitude will conceal that's still a problem. The distractions don't work anymore.

- 3-16-2016** **Very, Very Different.** Yesterday brought an announcement that the gen-2 Prius PHV will be revealed in a week. Volt enthusiast hate for the first generation plug-in Prius made for genuine curiosity about how they'd respond to this. Long ago, they claimed competition was Leaf. The solution Volt delivered would be a cure for "*range anxiety*" an EV like that would supposedly cause. Well, turns out, it didn't. So, focus was shifted over to Prius instead. They knew it was an easy target to insult, belittle, and criticize. They didn't care about well-being of the automaker or relying upon tax-credits. It was an obsessive compulsion to brag, boast, and be smug. That trophy-mentality had clouded their judgment for years. That was the past though. Gen-2 of Volt is now available. Had the lesson of need verses want finally been learned? Turns out, that may actually be the case. I chimed in on that daily blog by pointing out how goals still remain fundamentally different, that Toyota is focused on cost and delivered a system capable of high-volume profitable sales without any dependencies. Oddly, they seemed to recognize targets are not the same. Competing head-on with traditional offerings requires taking an entirely different approach. GM's priorities & schedules are most definitely not the same. That's a profound change, a paradigm shift of enormous magnitude. The enthusiasts had felt threatened in the past. Now, they aren't fighting back. It makes you wonder why. Could it be that sales of the new Volt are proving to be a struggle? I keep mentioning the reality of low-hanging fruit. That's because it is a cliché which points out the situation well, reinforcing the prior excuse of "*early adopter*" audience. In other words, the answer to the "*Who?*" question is now overwhelmingly clear. The situation now is very, very different.
- 3-17-2016** **First Sighting!** Today it happened. I saw a 2016 on the road. It was pulling out of a parking spot, so I got to watch it from every angle. That was the first time I had seen the brake lights illuminate. It was difficult to tell how they would be integrated into the design of the long curvy lights. The result was really nice looking. Of course, the entire vehicle is that way. It's among the few on the road that don't conform to "*plain*" styling. Those traditional shapes of the past have got to the point of being "*blah*". Why would you want to drive something that looks just like all the other vehicles already on the road? Close resemblance to the majority only goes so far. People get tired of the being the same. We're approaching that point now, where everything appears so similar, people are beginning to seek out something different. It never ceases to amaze me how people don't see the pattern. We've witnessed market saturation in so many ways, you'd think the outspoken wouldn't fight against change so hard. But then again, it only takes a few loud voices to misrepresent. Anywho, it should be obvious that I find the new look appealing. Like in the past. Toyota is paving the way for others to follow. That's what leadership is all about. The obsession with technology alone is so short-sighted. There are many aspects to drawing sales. Watch what happens as more new Prius become available at dealers.

3-17-2016 **Scary.** I got a kick out of reading this: "*The biggest news here to me is the statement that they need to sell 500,000 to be profitable. That is a really scary business plan!*" It was about Tesla's approach. Supposedly, that's scary. True, it is a major endeavor, but success means fear for the automakers not aggressively pursuing sales. Ironically, the comment came from a Volt owner who hopes sales of Volt will dramatically increase... but hasn't expressed the same concern. Tesla's dedication and concise message of purpose is a dramatic difference from the wishy-washy mix of intent we hear from GM. It's an interesting situation... which, thankfully, is finally getting attention. Remember all those years of blowing off sales & profit concern? This is how I responded: There are plenty of investors who see the solution to overcoming tax-credit dependency as high-volume production & sales. That's a vital next step, something Nissan is also committed to dealing with in a big way. Scary is the position it puts GM in. Heavy investment in Bolt could push Volt out of the spotlight, a vehicle already too specialized for traditional buyers. 200-mile capacity is quite compelling, basically eliminating range-anxiety concerns. Would you really expect Tesla to not attempt to penetrate the mainstream, breaking out beyond initial expensive models? There's a large potential for ordinary consumers to be drawn to the 200-mile offerings. Why not capitalize on that, becoming well established as an EV automaker in the process? We see efforts to spread FUD and resistance from those unwilling to change. There's the on-going problem of climate issues, oil dependency, and polluted air to deal with too. Seeing serious plans to overcome all that is what we've wanted for a very long time. This is long overdue. Many will step up to help make it happen. In the grand scheme of things, that half-million is not a large amount. There were over 17 million new vehicles purchased in the United States alone last year.

3-18-2016 **Dieselgate.** That label for the VW disaster is set in stone. People will be referring to this dramatic end to passenger-vehicle use of diesel that way for decades to come. The scale of the damage caused is so far beyond comprehension, no one could have ever imagined it. Prius supporters always knew the push for diesel as a clean & efficient solution was irrational. It simply couldn't compete in honest tests. Even the side-by-side contests rigged to favor diesel struggled to actually deliver. And that was in the past too, prior to the gen-4 rollout. The most die-hard of diesel supporters were dishonest... with themselves. It didn't make any sense when you took the time to consider what was claimed. How could they possibly expect a "50-state" minimum rating to compete with PZEV emission levels? Those were opposite ends of the CARB scale. Hybrids like Prius were far cleaner in terms of smog-related pollution. So what if carbon was close? You can't just ignore what you don't like. Of course, 6 months later, we see the much improved Prius... which handles far better than the previous generation... delivers MPG way higher than any diesel can achieve. There's no contest. Even without the scandal, there's no aspect of being competitive. That's without taking into consideration the upcoming next-generation plug-in Prius... which coincidentally, just happens to have a reveal date the day before the final deadline for VW. In other words, next week will be historical. Diesel is a mess and there is no hope for any type of comeback. The expectation is that it will fade away from consumer interest... while causing a great deal of industry pain. The thought is VW will not be able to deliver an acceptable fix. That means buybacks and some type of goodwill are the only options available. That will be very expensive... a costly mistake which will bring about new restrictions, permanently souring the appeal for diesel as a consumer choice.

3-19-2016 **Why Not?** With the reveal of the next plug-in Prius just 4 days away, there's a growing anticipation... as well as some uncertainty. This particular comment caught my attention: *"And I doubt this would be called Prius Prime, Prius Plugin suits it ... come on!"* I couldn't help but to jump on that opportunity to sound off: Why not? Don't you think the technology is ready for prime time yet? We've seen plug-in hybrid struggle in the past. Volt was far too expensive (production cost). Ford's Energi required too much interior space compromise. Prius PHV attempted to strike a balance, but needed to wait for the battery technology to advance. Haven't we arrived at that tipping point now? Personally, I would like the *"prime"* label... since I was the first who suggested it as Prius identifier... back in 2009. There is a great deal of potential for plug-in hybrids. Remember 15 years ago when Prius was just starting to get recognition as a possible solution for the masses to reduce emissions & consumption? Some couldn't imagine how the added motor & battery would appeal to consumers. Yet, we are now seeing Toyota approach the 9-million sales milestone. Greater battery-capacity and the addition of a plug seems such a natural next step. It doesn't have to be enormous or powerful. The non-plug battery certainly didn't deliver that, yet it was a huge success anyway. People focus so much on extremes, they overlook the obvious. Simply consider the success of ubiquitous technologies. Things like touch-screens have become so common, we don't give their actual specifications a second thought... even though they are restrained much more than they would have to be. There's a balance of need & want. Toyota is striving to deliver that.

3-21-2016 **Lucky.** What gets posted just prior to a reveal is fascinating. I homed in on this today: *"I think all of us who are waiting for the rev II Pip are lucky that it's even being offered up, much less whether or not it will be delivered to every state."* That came from a frequent poster who's been very upset with Toyota, under the belief interest in plug-in vehicles has been abandoned entirely in favor of fuel-cells. It continues to baffle me how someone could be so pessimistic, basing expectations solely on anecdotal observations from limited sources and from only specific points in time. Whatever. Some of us do research, seeking out a wide variety of input. Of course, that has left me looking very unlucky. Much of my study has come from unfriendly forum participation. Those there can be rather hostile at times, personally insulting you for even just asking the tough questions. But then again, when I do get an answer from there, I feel quite lucky. Anywho, this is how I responded to that comment: Sounds like you've been reading too much into the rhetoric. We always knew battery advancement would bring about a new generation. We also knew they would focus elsewhere in the meantime. I saw no benefit from Toyota joining the former market with so many problems plug-in offerings were having to deal with. True, their distance was spun as anti-EV, but that has no connection to next-gen rollouts. We've seen many examples of that in the past. What makes us lucky is Toyota staying true to aiming a product directly at the masses, not giving into enthusiast misdirection. The true competition is traditional vehicles, not other plug-in vehicles.

- 3-22-2016** **Great Expectations.** The anticipation of what tomorrow will bring certainly has stirred discussion. Many who didn't say much in the past are now sounding off. Without much reasoning, were seeing posts like this: "*30-35 miles of range would do it for me.*" As great of an expectation that is, I don't see it as realistic. Where the heck would you put that much battery? It simply too much of a size, weight, and cost tradeoff. I just plain don't see Toyota doing that. A doubling of the existing capacity makes more sense. It may be a hard sell in terms of EV range. But then again, the new plug-in Prius will still be a Prius. I returned the hopeful post with: How many are willing to pay that cost and willing sacrifice that physical space? Toyota will strive to achieve a balance, something like 50km (Japan estimate) is a reasonable expectation. That capacity translating to real-world 22'ish here would be nice for ordinary consumers. There will naturally be disappointment & backlash from enthusiasts who's interest is pushing boundaries. But what difference does their opinion actually make? They won't be the targeted buyers anyway. They won't be contributing to the sales goal. They aren't even interested in choices for the masses. Everyone would like more. That's in our nature. But realistically, that isn't how we (as mainstream consumers) make purchase decisions.
- 3-22-2016** **Guesses.** I was quite intrigued to read this: "*Any guesses on PiP AER?*" It came from the moderator and content-provider of that daily blog for Volt. It was just a comment randomly interjected into a discussion thread about the upcoming Cadillac CT6 plug-in hybrid. I waited 5 hours waiting for a smart-ass response. I got it: "*Not enough.*" The hate for Prius from that particular individual runs very deep. Obsession with the most possible EV driving range has blinded him from accepting anything less than what Volt has to offer. All of the other plug-in hybrids are inferior to him, period. Of course, his hate for BMW's i3 isn't exactly a secret either. It's interesting to witness the behavior of someone dead set against everything else. Heck, he doesn't even acknowledge the existence of hybrids without plugs. They are a complete waste as far as he's concerned. Needless to say, I couldn't resist: Who is the market for Volt? That question was asked many, many times over the years gen-1 was offered. The reason was to point out that the target market was very, very different from that of the plug-in Prius. With gen-2, we expect the same thing. Volt offers a design that strongly appeals to enthusiasts. That's fine. There's nothing wrong with wanting to utilize plug-supplied electricity as much as possible. It serves the intended audience well. They are pleased with their purchase choice and consider it an excellent recommendation for anyone else seeking those same performance traits and willing to tradeoff a few of the traditional purchase priorities. Prius has a very different audience. The target market is ordinary consumers, those who will seriously consider purchasing a traditional vehicle. These are the people that would like some EV driving opportunity but are not going to accept cost & space penalties. They'll be happy with seeing +100 MPG results. That's enough.

3-22-2016 **Constructive Questions.** They are so refreshing. I was delighted to get this: *"Does your inside information give you an insight into the AER of the new PiP? Care to give us a SWAG? Who knows, you may win!"* Though some sarcasm following, I didn't mind entertaining the request: Here are some thoughts... Toyota has always kept low-cost a high priority. With the inevitable loss of tax-credits mid-cycle and advancement of EV choices confusing the market, it makes sense keeping the battery-capacity down to a practical size. We know compromising depleted efficiency would make sales more difficult, it must remain well about what traditional vehicles offer. Fortunately, the system itself has improved making hybrid performance even better. Battery technology has improved along the way too. Currently, only 65.1% of the capacity is used for the plug-in. That's from EV full to HV 2-bars remaining depletion range, a SOC from 83.5% to 18.4% for routine operation. We could reasonably expect a widened operating range. Energy density, as well as packaging, has advanced as well. So, more can be squeezed into limited space. Cost has obviously dropped significantly too. Rumor is that around 30 miles, based on the testing cycle used in Japan, is the range the new plug-in Prius may likely deliver. Knowing that our EPA measurement process results in lower values and a difficult to estimate real-world expectation, it will be a challenge to really understand whatever the kWh rating for the battery-pack will truly deliver. Estimates in terms of AER are even more screwy, now that MPG well above 100 face diminishing-return issues. At what point do higher values not appeal? My routine is to recharge at work, using the massive (85 kWh) solar-array they have available. That effectively doubles battery-capacity. But with a 38-mile commute, more would obviously be beneficial. The gen-2 system will be more efficient as well. But since my commute average is already 125 MPG, no one will really care. That's already well beyond what the typical consumer is accustomed to. We'll get some specs soon, less than 12 hours from now. You and I both know there will be lots of spin to deal with and a wide variety of perspectives as a result. Little of it will matter though. We don't represent the mainstream consumers targeted anyway. Our participation online to discuss design & approach makes that easy to see. We're well-informed supporters, not ordinary consumers. We'll be stuck waiting for sales to tell the real story.

3-22-2016 **Competition.** Who is it? How many times will that continue to be asked? Hopefully, tomorrow's reveal will bring an end to the mistake of dismissing traditional vehicles as competition. But for know, it's the simplistic view of only other plug-in vehicles mattering: *"They really need to start a "breakthrough" in the relatively small EV market. The only car this really competes with is the volt. The next Prius Plug-In needs to have (at least) close to the same EV only numbers as the G2 Volt."* Reading that was a bit annoying. I still took the time to respond though, secretly wanting it to be the last time... I know, that's not realistic: Volt isn't the competition though. Toyota's purpose is to draw interest away from customers interested in their own traditional offerings. Remember, the ultimate goal is to replace traditional vehicle production. That means delivering platforms compelling enough for people shopping for a Camry or Corolla or RAV4 or any other 20th century approach to purchase a hybrid option instead. Appealing to those perfectly content with getting a new Corolla when their old one finally needs replacement is quite a challenge. That won't be accomplished with lots of EV. It's not as simple as trying to deliver more EV as other automakers.

3-23-2016 **My Response.** The whole day, those Volt enthusiasts posted about me, wondering why I hadn't participated on their discussion thread about Prius Prime. My response wasn't going to happen until they all stated their stance. I was quite curious how the tables would turn. So much had instantly changed for them, it opened up the door for more cooperation. The days of "*vastly superior*" are long gone. But I knew there would still be some upset. So, I waited until just before midnight, then typed up and posted:

It has been interesting reading comments posted on the wide variety of websites today about Prius Prime. There's lots of spin, denial, and rhetoric. Fortunately, that's all easy to avoid. It's just an amplification of the usual greenwashing from the usual antagonists.

Trying to find genuinely constructive discussion was a challenge. The consistent message in that regard has been the battery-capacity should be greater. No one is willing to accept the space tradeoff though. Somehow, Toyota should have found a way to deliver more without facing the same barriers as all the other automakers. That's not realistic. I see things like cost, weight, handling, efficiency being carefully balanced with size & capacity. Let's not forget the hidden aspects of operation either, like cooling and accident resistance.

On the don't-want-to-acknowledge side, there's the enhancement of utilizing both electric-motors for propulsion power instead of just the one. That increased the EV maximum speed to 84 mph and allows for full-throttle acceleration without the engine. It's a big upgrade quite a number of people taunted Prius about for years. Now suddenly, they've all vanished. It's as if no one ever proclaimed that improvement was impossible.

There's an absurd new twist emerging too. Even though Volt has nothing but a tiny middle area for a child to sit without any legroom whatsoever, some are claiming it has a 5th seat anyway. That somehow makes it better than Prius Prime. How? And why would anyone even bring up the topic? The regular Prius offers more leg & head room than Volt, for both front & rear seating. So, the expectation is for that to also be the case for Prius Prime. That's much more of a selling feature than a 5th seat. And what happened to all those Volt supporters who told us over the years that 4 seats were enough?

I'm intrigued what comes next. Will others in favor of plugging in accept the new plug-in Prius or find some new way to belittle? It really doesn't matter. People researching a purchase will see the EV range offered, see the MPG delivered following depletion, and then take into consideration all the usual decision factors. They couldn't care less whatever the heck EREV means... especially since its confusing & arbitrary definition no longer makes any sense.

While we wait for delivery this fall, enthusiasts of Volt have an interesting new situation to consider. They already had Bolt on the way, dividing focus among GM supporters. Now, there's a new Prius that breaks apart gen-1 stances. The change gen-2 offerings bring about will be significant. Some will like it. Others will struggle. Consider next steps carefully...

3-24-2016 **We'll See.** Only one person got upset with my post. He refused to comment about the attitude of others though. Pretending no one else posted any type of disparaging message, despite overwhelming evidence to the contrary, is usually a sign of venting. He was really just seeking someone to blame for the change. So, I ignored it and continued the discussion with the few constructive individuals there. This was my contribution to that: The 5th seat is an example of a paradigm shift. We know most people don't ever use it, yet they consider that essential purchase requirement anyway. We've seen this before... especially with new technology which replace a long-standing expectation. Over time, people will refocus onto priorities that actually have an impact. In this circumstance, it's the amount of leg & head room you get. For that matter, ease of entry and visibility while seated come into play too. There's also aspects people typically don't notice, like whether you have a ceiling or just glass above your head. Think about how much value people place on having AWD. We hear remarks all the time about how important some feel it is. How often would it ever be necessary though? I haven't ever had it, despite dealing with Minnesota winter roads for decades. Heck, just yesterday was an snowy, icy, lumpy mess to commute home in. Reaction to having "only" 4 seats will be interesting. It will be a deal breaker for some. But then again, how does that compare to a vehicle being compact rather than midsize? We'll see. Prius Prime offers a significant increase in EV power and the range will satisfy many. For me, my commute will go from averaging around 125 to 999 MPG. I'll retain great efficiency following depletion and will still have a large area available for cargo.

3-24-2016 **Fans & Trolls.** A former foe who is now making a genuine effort to extend a hand in friendship asked: *"This all reminds me of the comments we faced at the beginnings of the Volt. Toyota fans and trolls grilled us unmercifully on the 4-seat issue (and many others). How does it feel?"* After giving that serious consideration, I replied with: It goes both ways. You realize I could easily spin that as others gloating. Some will claim that a victory. Others will try to convince us Volt has 5 seats. Think about all the intentional misleading about EV range. Whatever the case, I appreciate the effort on your part. The point is this is an ever-changing market. We need to work like a team, no more sparring. As a constructive next step, want to address the "EREV" issue? I'd love to get that over with. Remember how the definition changed from development to rollout, then changed again when Ford joined in, then changed again when BMW offered a plug-in, now again with Toyota? There will be Hyundai, Mitsubishi, and Chrysler choices this year too. Our goal is to promote plug-in vehicles. The key is properly identifying the differing purposes & buyers. We can show there's diversity available, demonstrating that all together they are an effective means of competing with traditional vehicles. The approach of placing Volt against Prius makes even less sense now with Prime. Can we agree they are all plug-in hybrids and move on?

3-24-2016 **Some Perspective.** Back on the big Prius forum, we got into statistics. Toyota specifically mentioned the EV range that Prime would deliver covers 51% of commuters here. I interjected some perspective (a bunch of numbers) into the discussion to see what response it would stir: Toyota sold 2,499,313 vehicles in the United States last year. Their top-selling car was Camry. 429,355 were purchased. That's a total of 17%. That in itself shows there's lots of opportunity available. Next, consider what the 51% commute value means to the 17,470,659 vehicles all the automakers combined sold in the United States last year. That's a great deal of potential for the seemingly small 22-mile EV range. Remember, this isn't a one-size-fits-all situation. There will be other vehicles with other configurations. Nonetheless, it should be easy to see there isn't tiny market as some are attempting to portray. Don't forget that the system will still deliver outstanding efficiency even when the engine does run. Averages over 100 MPG will appeal to some buyers. The industry target in this market (United States) for a vehicle to be considered mainstream, which means it is able to maintain consistent profitable sales without outside incentives (like, tax-credits & HOV privileges), is an annual rate of 60,000. So, the question we should focus on is how & when would this be realistic.

3-24-2016 **Market.** Certain people are curiously absent. They're the antagonists, those individuals who like to oppose... sometimes, simply for the sake of not wanting any type of agreement. After all, acceptance means no more discussion... even if it isn't constructive. Taking advantage of that absence, we've got a good dialog going on at the moment. Cheap gas makes EV driving expensive. That's a very real problem. How are we going to deal with the economics of that. Here were some of my thoughts on the current market: I look at it this way, we've encountered lots of people along the way who said Prius wasn't efficient enough, that higher MPG would be needed for it to really take hold. That didn't turn out to be the case. The balance Toyota strived for is what attracted lots of sales. The hope is that same will be true now with the plug-in model. It doesn't offer as much EV as detractors said it should, but it doesn't compromise shortage space to an extreme either. We'll lose roughly 3 inches of floor height for cargo, but a large open area for cargo will still be available. The leg & head room could end up being identical to the regular Prius. The efficiency without plugging in should be fairly close to the same. There's also hope it will be easier to sell than an EV or even another plug-in hybrid. It's a Prius. People are already familiar with the proven reputation for reliability. You can plug in using just an ordinary household outlet too. No need for a level-2 charger means a savings often overlooked by those thinking more is better. Gas prices do present serious challenges. But we know emission concerns will help the effort along. There's a growing spirit of cooperation among plug-in supporters too. Hopefully, all that will allow us to capture the available market.

3-24-2016 **Semantics.** Facing fallout in that form was inevitable. It came as: "*If one can't meet the original goals; change them!*" I got a kick out of that. Having been through the generation experience several times now, it was easy to see coming. Those Volt enthusiasts who caused so much trouble in the past didn't have that background; consequently, that meant seeing things from a different perspective. Only now are they getting the view we had years ago. Much can be learned from the first generation. You don't realize that until the second arrives though. With Prius itself on gen-4 (which is technically the fifth, if you study the original rollout in Japan), that knowledge was well earned by some of us through firsthand participation. I gained much from that history. Now, it's an attempt to share that with others. I wonder how this will be received: Goals for each generation change. That's a normal process. The upgrade is suppose to deliver adjustments & alterations based upon what was learned. The problem comes when people lose perspective or simply forget what the ultimate purpose was. The catch is when gen-1 rolls out. Nothing could have been learned yet, since nothing was available prior to it. So, original goals are quite important. Haven't you noticed Prius isn't just one vehicle anymore? 4 years following gen-1 rollout of the plug-in model, there are now 2 distinct designs. Each will offer several different trims. They are all still Prius; choice have expanded though. If you want to label that as moving the goal posts or arguing semantics, so be it. Personally, I called it adding a second goal. There's a gain from that addition. It's not a double-standard. It's not being hypocritical. Look at Volt for some perspective. It continues to be just one design upon gen-2 rollout. There simply isn't another Chevy offering. It's still the one-size-fits-all. How exactly does that achieve the "*leap frog*" claim? We could consider the upcoming CT6 variant. That truly will be another choice based upon Volt technology; however, adding 2 clutches and another planetary-gearset to deliver 449 horsepower clearly doesn't target the same group of consumers. The upcoming Malibu does seem a much better comparison, but that isn't in the same category either. It's a bigger vehicle. It's also a sedan, rather than a hatchback. Again, Toyota has branched out by offering another configuration based upon a shared design. Adding an entirely new choice like that, rather than it being a trim (package) option, is different. It's simply not the same situation. Implementing change based upon what was learned from gen-1 is a reasonable expectation. Some won't like that. Others will. With all the spin that resulted from the ending of gen-1 production, I'm really surprised anyone is willing to speak out now trying to stir comments of the past. That spin should get attention too then. It was meritless-speculation and talking-points confirmed recently to be false. Continue to look back or finally look forward?

3-25-2016 **Seats.** By far, the biggest topic of discussion about Prime is the matter of only offering seating for 4. Some of that is simply the fact that other issues have been put to rest. For example, the increase in top EV speed to 135 km/h (84 mph) along with engine-less full-throttle acceleration ended all posting about pretty much everything related to EREV. The topic is dead. So, it makes sense addressing the seat change. It's one of those strange ideas. That 5th seat in the middle does indeed get used by children. But for adults, basically never. It's tiny and that throws the maximum carry weight into a mess. In fact, extra reinforcement underneath is needed to accommodate. So, why bother? After all, Prime will most definitely not be the only plug-in hybrid Toyota offers. They have already pointed out the TNGA benefit (their new cost-reducing production approach). Anywho, it's reasonable to expect a degree of fallout to continue. Some will insist the 5th is vital. Of course, they'll continue to dismiss leg & head room in the process. That's a dead giveaway they haven't addressed all aspects of the decision. Heck, another is simply comfort. Those are clearly more appealing to our backsides. Wasn't that a major contributor to how the benches got eliminated? This is how I joined into the discussion, obviously taking a direct approach knowing the extensive history with the topic and how it will inevitably be brought up repeatedly for awhile still: The problem with support for Volt up until just a few days ago was the enabling. Those in favor would allow the 6-mile misleading to continue. That greenwashing effort to convince people the battery-pack only delivered 6 miles of total capacity for EV prevented any type of cooperative effort. Why listen to those who blatantly allow that undermining? Their reasoning for only 4 seats fell on deaf ears as a result. To make matters worse, there was an outright dismissal of leg & head room being important. Thankfully, that did change when gen-2 of Volt was revealed. Unfortunately, the 6-mile misleading continued. So, now, we are at a point of decision. Will they constructively address design or continue on with the same rhetoric? It sure would be nice to look forward. Features like seat-warmers for in back are possible with the bucket design. You'll never get that from old-school benches.

3-25-2016 **Somewhat Frustrating.** Over and over and over, I posted a reason why production of gen-1 Prius PHV came to an end early and why it wasn't rolled out to the other 35 states was the likelihood of gen-2 delivering major improvements. When you've got an upgrade that compelling, why in the world would you bother promoting the old version? It quite simply doesn't make any sense. Then when you consider the limited number of tax-credits available, it becomes counter-productive. An effort to expand rollout would educate the population on outdated specifications. That's self-deprecating, a step in the wrong direction. Why certain individuals chose to argue that wasn't the case is beyond me. But I remember that. It's somewhat frustrating to think about still... especially now that my hypothesis has been proven correct. In fact, I was so accurate on some counts, those naysayers have completely vanished. Not hearing even so much as a peep is quite redeeming. The same thing has happened in the past. Once they get confirmation of dismissing a vital clue, they disappear. There are a few who stay. They pretend none of what they claimed was ever said or that wasn't what they heck or that it was just devil's advocate posting. That's a crock, of course... simply by looking at their attitude. If they were rude & insulting, they weren't being constructive. Making it personal, rather than sticking to facts, is a rather obvious sign of emotion clouding judgment. That influence of belief over understanding is a difficult barrier to overcome. It's why I have to tolerate a level of frustration. A few of those antagonists actually pull through and admit their mistakes. Those are the ones who I want as friends. Even though they came to the wrong conclusion, their persistence of continuing to try and desire to keep digging for argument points shows a strength most people don't have. They are who you want as an ally... after the current chapter concludes. After all, their ultimate goal is usually quite similar. In this case, they want to end the dependency on oil and greatly reduce the damage we are doing to our environment.

3-26-2016 **Complaints.** The biggest complaint found online... which served as constructive criticism... ended up being battery-pack capacity. That's no surprise. The cost verses size verses weight verses efficiency, with respect to the wide variety of consumer need, made that a huge issue to tackle. Taking the end-product approach like GM wasn't an option for Toyota. That expense & risk just plain isn't worth it. GM learned that lesson the hard way. Toyota got a lot of grief for having avoided that dilemma with gen-1 by taking the upgrade approach instead. What does that mean for consumer perception? Doubling capacity seems the most sensible balance. Density & Packaging improvements, combined with system efficiency upgrades, made that a realistic expectation. Many goals could all be addresses at the same time, rather than sacrificing some for the sake of more EV. The top speed for EV was obviously the next issue frequently posted about. Adding a clutch to disengage the engine and allow both electric motor/generators to provide propulsion power at the same time was a logical reconfiguration. The design could support that without having to sacrifice hybrid efficiency. More EV power is what people wanted... and that's exactly what we got. Toyota listens to complaints. The variety of sources all sounding off really made a difference. It's too bad GM focused almost exclusively on enthusiast input. That's how they ended up with such a niche vehicle, one that still garners a great deal of praise from those enthusiasts. Unfortunately, that does very little to entice ordinary consumers. Not drawing them in to grow sales is a very big problem. Toyota is clearly taking that seriously. Another interesting outcome of complaints was simply what to call it. If you still want gen-2 to carry the Prius nameplate, yet be easily identified as unique in every venue, how do you do that? The decision was to call it "Prius Prime". That particular decision made me absolutely ecstatic. Way back in November 2008 (specifically on the 30th), the select group of us chosen to go to Detroit to participate in the gen-3 reveal were having a discussion about what to name the various generations. Having identified the 1998-2000/01 model of Prius as "*Original*" and the 2001-2003 model of Prius as "*Classic*", we saw the need to coin a name for the outgoing generation. I posted this, not realizing how forward-thinking or significant my suggestion would become: After searching and searching through the thesaurus. It just hit me, like a ton of bricks! Since the current model is the one that was adopted by the mainstream, I followed logic of words like "*established*", "*common*", and "*widespread*". The word "*mature*" has been used countless times in response to greenwashing attempts. All those took the mindset beyond "*historic*" and "*founding*". It was the "*familiar*" feel I was looking for, a sense "*base*" that was heavily "*celebrated*" among typical consumers, even "*renowned*" by some. Being "*well-known*" by a "*broad*" spectrum of people gives it reason to have the spotlight... and will continue to, even as the new model takes hold. See where I'm going with this? I suggest we call the 04-09 model: Prius **PRIME**

- 3-26-2016** **3.3 kW Recharging.** Toyota is quite pleased to point out that the recharge rate from a 120-volt connection (a standard household outlet) will be quite a bit faster. In fact, it will supposedly be faster than what Volt offers. But then again, with Volt's battery-pack so much larger, you pretty much need a 240-volt connection anyway. Not having to upgrade your wiring at home is an expense nice to avoid. Keeping the purchase process as easy as possible is a big deal. That upgrade is simple for some. For others, it requires some major rewiring. That extra cost could be a purchase deterrent... which is why being able to stick with the 120-volt is so nice. It depends upon where your electrical-box is and how much power is has available. Fortunately for me, it's in the garage and I already have 200 Amps available. Of course, I may not upgrade, especially since I'd like a smart-charger. Being able to connect it with Wi-Fi to track charging data would be great. Those devices are relatively new still. So, waiting is fine. In the meantime, I'd be watching the maximum rate jump from 2.2 kW with the Prius PHV to 3.3 kW for the Prime. That's a substantial increase in recharging speed without having to change anything at all in the garage. Cool.
- 3-26-2016** **1.8 Miles.** The drive out to the coffeeshop to start out my weekend with some blogging is an interesting drive as Winter melts away. With the temperature just above freezing, I can just barely make the drive there and back using only electricity. It's remarkably close sometimes. As I'm backing into the garage, I can see the EV range brush up against the minimum reading. I make it though, without doing anything special. Getting up to 55 mph and keeping it there for about two-thirds of the 4.5-mile drive really pushes it. In the Summer, no big deal. It's the cold. That causes electrical resistance to increase, which means EV driving range decreases. It doesn't help that air-resistance is greater then too. If the engine starts, it isn't the end of the world. But to be so close, it becomes an interesting experience to witness. Not trying to squeeze out more is what makes the experience worthwhile. You truly don't know what the outcome will be. That's over now though. I got smart and wondered... what if? Rather than taking the same route home, forcing the Prius up to 55 mph after having sat out in the cold for around 2 hours, I took a residential route. Speed only briefly gets up to 50 mph. The rest is slower and cuts through the area diagonally. That makes it both shortly and less demanding. I made it home with 1.8 miles still left, despite nearly identical conditions with last weekend's drive. I had no idea it would make that much of a difference. Sweet!
- 3-26-2016** **EV Fanatics.** This was an interesting comment: "*I don't think anyone but few EV fanatics know about that...*" I agreed and was delighted we are now discussing perspective. Far too often, people overlook others. They assume everyone else has the same background and same needs. That difference should be obvious. Often, it actually isn't though. So, I said: We understand scope all too well. In general, people don't pay close attention. They never get enough detail to be properly informed and they forget the few things they did know. To make matters worse, facts get blown out of proportion and dates get mixed up. It's an unfortunate reality we've had too deal with for years. I've blogged extensively over the past decade and a half. It's fascinating to read that history documented as it was happening. You get a very different perspective from those looking back well afterward. The EV stance is already quite distorted. Fortunately, a number of those who kept trying to stir the pot have grown silent. That's pretty sweet. I'm not going to let their efforts get in the way of what comes later this year.

- 3-27-2016** **Mid-Cycle Updates.** That's a topic getting unforeseen attention. In the past, any improvement to the system along the way was seen as an expectation, something that just naturally happened with new technology. We've grown so accustomed to it with computers, we don't even noticed model changes anymore. With vehicles though, that's a different story. Generational upgrades were always such a big deal, changes mid-cycle were simply looked upon as a refresh. There was never an expectation of anything worthy of drawing attention. When you've got a plug though, the story is different... and continues to change. Volt got minor tweaks to it's battery & system, allowing modest range increases. Leaf experienced the same, until just recently. This latest improvement wasn't modest. Combined chemistry & packaging improvements equate to a rather substantial update. It's not mid-cycle either. Nissan just offered what they could when they could. People are already speculating something similar could happen with Prius Prime. What if the raising of the false floor when away mid-cycle? That's entirely possible. No need to increase range, though that is an option too. The benefit of squeezing the 8.8 kWh capacity into a smaller area would stir interest. That's a great thing to have happen along the way, especially with the entire industry striving to reach mainstream consumers. Think about the timing. When automakers hit their tax-credit phaseout trigger, that will put pressure on the entire industry. Nissan, Tesla, and GM will all face that in roughly 2 years. Toyota positioning to deal with that seems rather sensible. The fact that some are seeing that already is rather surprising. Cool.
- 3-27-2016** **Electric Heating.** Hooray! The topic is finally getting some attention. I'm excited. It's hard to believe something so vital could have been neglected for so long. With the gen-1 plug-in offering though, it simply didn't get discussed. There was little to no detail available. All we ever really heard was that keeping yourself warm in the Winter meant a rather significant EV plenty. Range would just plummet and there wasn't a good solution available. But now with gen-2 models drawing attention, we are finally stirring some interest. Supporters are seeking out information for a better understanding. I'm getting to note key differences. It's exciting to know that Toyota will be including an industry-leading setup. It's much like the A/C system all those years ago. Not only what is fully electric, it also was the most efficient design available. Hearing that Toyota will do the same with Prime is great!
- 3-28-2016** **Why?** It's rather bizarre reading an article which compares a 2011 Prius to a 2016 Volt. Why not the newer generation Prius? Why not the plug-in model? Why not something from GM instead? Obviously, it was one of those filler articles with the hope of drawing attention to that publication. You can't really get anything constructive out of such a mismatch. Though, I was intrigued by the attempt. After all, it takes quite an effort to make them seem similar effort to compare, but you can if you gloss over certain facts... like production cost, price paid, seating & cargo size, carbon & smog emissions, and depleted efficiency. My response on the big Prius forum was: The underlying point of the article is rather impressive... You can actually compare a gen-3 Prius to a gen-2 Volt. It shouldn't make any sense to do that. One is 5 years older and doesn't even have a plug. We've heard all the rest before. But now with Prime on the way, this type of comparison comes off as just floundering to keep readership active. Why wouldn't there be any mention whatsoever of a plug-in Prius or any of the other plug-in hybrids being offered? For that matter, why not compare to GM's own hybrid... the upcoming Malibu?

- 3-28-2016** **Wrong.** What do you do when you encounter information where some is mixed up and some is totally incorrect. This really go me head scratching: *"The new electric motor is all the more commendable because it can achieve up to 95 kW or 127 horsepower compared to the previous one's 68kW or 91 horsepower. With this, the newly launched hybrid can run up to 22 miles at 82 mph..."* 95 is just plain wrong, as is the 127 value. That 68 isn't for the previous, neither is the 91. Both are for Prime instead. The 22 is wrong too. You'll get that under normal driving circumstances, like a 60 mph highway and through town. Getting that 82 mph isn't realistic. Aerodynamic drag increases significantly with faster driving. Where did that 82 come from anyway? The maximum EV threshold is 84 mph. Needless to say, all that was such a mess, I didn't bother to respond. It's simply not worth drawing attention to such a collection of potential greenwashing material.
- 3-28-2016** **Naming.** There are some who don't feel Prius Prime is properly named. That makes me wonder what they are thinking. Why do that feel that way? So far, responses have been quite vague. I jumped in with my thoughts on the topic: I couldn't imagine *"Prime"* not catching on. After all, there is only a small group of early adopters & enthusiast who ever used *"PiP"* anyway. The market for plug-in hybrids is still quite new. Most people know little beyond the basics and certainly aren't aware of the history. We want to make it clear which generation we're discussing. So, it is our best interest to intentionally differentiate the generations. Calling them each by a unique name makes it a heck of a lot easier, especially with respect to searches. Simply altering an unfamiliar abbreviation is not the way to go.
- 3-28-2016** **Lose-Lose.** That's an interesting situation, when no matter what is done the outcome will be a loss. I found this a concern: *"Granted all marketshares are kind of small, but the Prius Prime is reaching in all those directions while compromising what it was originally...a Prius family, eco friendly car!"* Some people seem to be spinning the purpose of Prius being a family oriented vehicle as one that caters to just the young. They aren't giving any consideration to what happens once the children begin to grow up. A family isn't just car-seats & elementary school. When the kids grow up, you still have to transport them. At that point, they are larger and have different comfort requirements. For that matter, some may be driving... putting you in back as a passenger. Doesn't it make sense that Toyota would recognize what happens over the years and want to retain those customers? I was annoyed by the absence of consideration for that, so I posted: Prius was a sedan for 5 years. For gen-2, it became a hatchback with midsize seating. With Prime, it is still a hatchback with midsize seating. True, it doesn't offer a place for a 5th person. But then again, families grow up. Isn't it trying to continue to appeal to an audience that's changing? Retaining all of the same aspects of the past means not attempting to adapt to not keep the existing or reaching out to appeal to the new. That sounds like a lose-lose scenario.

- 3-29-2016 Ioniq Compare, part 1.** Today's daily blog topic was all about Hyundai's upcoming offerings, all 3 of them. I'm obviously most curious about the plug-in hybrid. So, I dove into the discussion: With only a 0.1 kWh difference in battery-capacity compared to Prime, it will be interesting to see how the plug-in hybrid compares. Since Hyundai hasn't released specs on the electric-motor yet, knowing what to expect is a mystery. The guess is it won't use the same one as the EV model. Will it be what's in the hybrid model? If so, that's only 32 kW (43 hp) plus whatever boost the larger battery may be able to deliver. Toyota has released Prime detail. With the 2 electric-motors combined, the expected output is 68 kW (91 hp). That's quite a bump over the current 38 kW. Toyota will also be delivering electric warmth for the winter. It adds an interesting new twist for comparisons, especially since it will come from a heat-pump with vapor injection. That's an industry first, which increases efficiency of heating by roughly 20%. That will reduce the negative impact on EV range. Also, keep in mind that Ioniq is smaller inside than Prime.
- 3-29-2016 Ioniq Compare, part 2.** Turns out, that mystery detail is available. The electric-motor in the plug-in hybrid model of Ioniq will be 45 kW (60 hp). Seeing how much of the early market didn't understand the benefit of boosting MPG and was obsessed with EV power, that could be bad news for Ioniq... or maybe not. It's really hard to tell where the line will be drawn. It is more power than what the current Prius PHV offers, 38 kW (51 hp). Ioniq will be a smaller vehicle too. Heck, it may even deliver higher HV efficiency. Will that matter? What will people want? We have no idea. The only thing getting attention right now is the expectation of more EV miles. But that's only based on estimates. Toyota likes to keep their value low, under-representing expectations to avoid any possibility of disenchantment. Hyundai is an unknown. Their MPG estimates have been too high. But then again, will it matter. Price will likely be the greatest influence. Undercutting Toyota would be advantageous. Toyota treats cost as a factor of great importance. Prime could be quite competitive. After all, it will need to face traditional vehicles. That presents a huge pricing challenge. Whatever the case, we have to wait roughly another 5 months before we find out.
- 3-29-2016 It's Cost, Not Price.** Ugh. Good thing I haven't been counting the number of times must that same fact be pointed out. That had to be repeated yet again today. The discussion got off on a tangent about price. At least there's was an opportunity to address it. Topics having to deal with profit and automaker motivation typically die from quick, short deaths. People get so hung up on engineering and have such weak backgrounds in business, they just plain don't understand what I'm talking about. Who knew all those accounting, economics, and marketing classes in college would compliment my software engineering degree? Go figure. I jumped in with: Actually, it's COST that's everything. How much Toyota must spend to produce the vehicle is what determines its future. Because once those tax-credits expire, only the well planned out designs will be able to maintain high-volume profitable sales.

- 3-29-2016** **Flexible.** What comes to your mind upon reading this: *"Toyota did a poor job of explaining that the Prius Plug-In was meant to use even less gas than the Prius with the help of electricity from the grid, not to provide an EV driving experience."* Not filling in the all blanks is how you learn, since it results in feedback. Of course, being somewhat ambiguous and not responding when false beliefs emerge is an entirely different matter. That happened with Volt, prior to rollout. Toyota didn't do that until after Prius PHV was rollout out. Big difference. Prius PHV owners could answer questions, simply by trying. They'd report their own real-world observations. Since no one owned a Volt yet, real problems emerged for GM. Rather than serving as an educational means, like it did for Toyota, things escalated out of hands based on nothing but speculation. Put shortly, any *"poor"* judgment depends on when events take place. There's an added advantage of not providing what could potentially become false hope based upon speculation. It's flexibility. I put it this way: That was intentional. They wanted to study market response as a whole, rather than pushing any particular approach. No matter how many times it was pointed out that Toyota wanted to remain flexible, some people just plain didn't want to accept it. In fact, their response was usually to call people pointing that out defenders trying to spin the situation. That was annoying, but now we have confirmation of it being the case... which has rendered most of the naysayers silent. This is why gen-1 rollout expansion was postponed, then production ended entirely. Looking back, it should be fairly obvious the market was quite fickle and really not certain what it actually wanted. Remaining flexible offered opportunity.
- 3-30-2016** **Doubt.** Some people thrive on it, stirring discussion by raising some. Oddly this time, the situation is reversed: *"I think the shock about 4 seats is that there is no denying Toyota is trying to go for a different market than the Prius, which might be counter to what many think of the Prius family."* Who knew that this was come about? I certainly didn't expect it from that particular individual. His contributions typically draw out discussions and prevent conclusions. I wonder why this particular situation had a very different response. But then again, maybe it was some type of reverse provoke. So, I took it as bait. After all, that use of *"think"* was a little suspicious: Why raise any doubt? We already know Toyota is reaching out to new consumers. I suggest looking at Prime as another offering, not a plug-in version of Prius liftback.
- 3-30-2016** **Stats.** Eventually, we'll have real-world experiences to share. Until then, it's stuff like this: *"I'll be curious to see what the stats are for the Prime. For me, I'll be plugging in the Prime every other day (taking into account side trips to the supermarket and not strictly commuting)."* Driving circumstances & conditions vary so much, there isn't much realistic speculation possible. I still remember some posts prior to Prius PHV being rolled out. A few have left rather vivid memories. We simply didn't know. This time around, we have background with respect to plugging in available. Here's mine: I'll be going from a 125 MPG commute average to around 999 MPG. I plug in at work, taking advantage of the huge (85 kWh) solar-array for recharging. My commute is 38 miles round-trip.

3-30-2016 **Inferior.** The attacks never end. Having to deal with the rhetoric is a pain: "*We, as in Volt supporters, have always been fighting for plug-in acceptance. You argued against the Volt since day 1, saying it was inferior to the Prius hybrid.*" They look for scapegoats, then paint a picture for others to believe. It's always vague. It's always an extreme. It's always dishonest. In this case, I couldn't help but to chuckle, since this was included afterward: "*If sales are the measure of success...*" That bit of uncertainty is absurd. We've been talking about sales as exactly that since long before day 1. The specific count & timing was concise. There was never any doubt how success would be measured. But when the actual numbers began falling well short of those expectations, goals were changed. They said that wasn't important. Ugh. I kept my rebuttal fairly short, to force the bigger picture: No matter how many awards any particular technological achieve earns, that's just engineering if sales aren't accompanied too. Not agreeing on that point has been the basis of misunderstandings and disagreements for years. We've all given and acknowledged engineering achievements Volt delivered, then most of us moved onto the business part. That's sales. It's time to focus on getting mainstream consumers involved. The niche stage is over. The enthusiast engineering-only perspective isn't enough. Gen-2 is now available.

3-31-2016 **What They Thought.** Ironically, we're starting to see the situation that Prius faced and dealt with now arising for Volt... consumers not actually buying what they thought they wanted. For many years, there was a common call for added battery-capacity and a plug, to supplement the existing system. The purpose was to boost MPG. Aftermarket conversions proved the approach. Toyota ended up delivering a version improved upon that. Unfortunately, the idea wasn't embraced by the masses. Fortunately, it was a mid-cycle rollout to only limited areas. So, there was very little risk or fallout. That meant delay for wide-scale availability but also meant the opportunity to build upon real-world data collected in the meantime. Prime is the result of that. GM is still going under the assumption that maximum EV and minimum HV is what people will buy in large quantity. We've been told by enthusiasts that is the purchase priority. We've await to set that from ordinary consumers. That disassociation of saying & doing is nothing out of the ordinary. In fact, it is quite common. Problem is, this situation comes with a substantial penalty for the business upon assuming incorrectly. Put another way, Toyota altered design from only one of the two motors providing propulsion power to both. That allowed the system to offer more EV, but not tradeoff HV performance. This was due to the market revealing a lack of understanding of how plug-in hybrids work. Most people believed the vehicle would operate as an EV until depletion. The concept of blending wasn't understood. Since that's the way Volt always operated, there was much rejoicing among enthusiasts. It didn't translate to the massive success that had been anticipated though. Like with Prius, it addresses what people had been requesting. But interest from those ordinary consumers hasn't materialized yet. Will it be embraced by the masses or will some type of adjustment be needed? Consumers not actually buying what they thought they wanted is a very real problem.

3-31-2016 **Get Over It!** Ugh. Reading this in the past would have been frustrating: "...*buying tired-old HSD (it's good as a hybrid, but Voltec us just far better)*." Now, it serves as vindication. I see it as confirmation of having studied both the engineering & business need well. Seeing the explosive post as a result of pointing out that was a provoke really showed that well. It certainly was over the top. He went on and on. The rant was rather entertaining to read. My reaction was quite different: The extreme over-reaction to such an obvious provoke that didn't work was quite telling. Putting me on the defensive invites the opportunity to ask why. So, let's do that, starting with a look back at the history... Back when Volt first rolled out, there were a number of problems to deal with. Volt enthusiasts felt overwhelmed by a variety of unexpected barriers and ended up taking a defense stance. There was a very real belief Volt production would end. Fortunately, the consensus ended up being to promote gen-2 rather than dwell on what had become very difficult market issues. They believed GM would continue to invest in the technology, to make that next rollout the strong-seller they had hoped for. As that was happening, a great deal of effort was expended to make people believe the same could not be done by Toyota for the technology in Prius. It was a blatant double-standard. Volt enthusiasts disregarded facts and did what they could to belittle & mislead. That was astonishing to witness... and went on for many years. Last week, the next generation of plug-in Prius was revealed. It confirmed that Toyota could indeed upgrade the system. The technology was not old, tired, or obsolete. Right there, for the whole world to see, was a design improvement which exposed certain individuals as being hypocritical. That's an uncomfortable situation. It's understandable why some would lash out in anger. My suggestion to that situation: GET OVER IT! I've worked really hard to bridge the divide, to extend a hand in friendship. Ultimately, our goals are all the same. We want the plug-in technology we support to be purchased by large numbers of consumers. Look at what Toyota actually did. A clutch was added to the system, allowing the gas engine to disengage. The result is the ability to use both electricity motors for propulsion. Combined with a larger battery-pack, power from the system was significantly increased. This was something scores of stubborn Volt enthusiasts claimed was impossible. Perhaps that's why Toyota's promotion of the next generation Prius was titled: "*Beyond Possible*". That brings us to today. I'm tired of the nonsense and will continue to point out wasted effort of pretending the real competition isn't traditional vehicles. Look at the facts. Those gas-guzzlers are outselling the hybrid & plug choices by an extreme. Want to over-react? Do it in frustration from that.

4-02-2016 **Extreme Mistake.** The reaction to Tesla's recent enormous success has been interesting (Model 3 reservation count had already hit 115,000 by the time the reveal had concluded and continues to rapidly climb). This is what I get presented with: "*Obviously, Toyota thinks this is a fad. Toyota's senior leadership has stated that. That is an extreme mistake.*" Those saying things like that have already made of their mind. So, it's pointless to attempt some understanding. You can try though, as an exercise demonstrating the situation as a whole has been carefully considered: That's called drawing a conclusion based on anecdotal evidence. Don't get hung up on the first 4%. Stepping back to look at the bigger picture, this natural progression to the next stage should be relatively easy to see. Focusing on just those who participated so far means not seeing the other 96% of the market. What are the consequences of the supposed mistake anyway? First by no means equates to everyone else failing. For that matter, it doesn't guarantee success either. Just look at how horribly wrong both Two-Mode and Volt were for GM. Sales were a major struggle, despite being first and supposedly best. Tesla will most likely do well. Some of that simply comes as a result of being able to dedicate resources. They don't have any legacy technology to deal with, nor customers demanding to purchase it. Toyota does. Traditional production must continue while new territory is explored. They'll use that to seek out opportunities about to reach those other 96%. The market is enormous and there is a great deal of potential still. True, we will see pressure forcing approaches to change. But don't go writing up an obituary upon the first sign of another automaker's success. We only recently finished the first inning. Look at the entire market. The gen-2 rollouts have just begun. The mainstream consumer hasn't even been a participant yet. The attitude of pushing EV range accomplishes what? Sure, it captures interest. But how does that improve motor, controller, and battery technology. Any plug-in offering will deliver that needed data. In fact, the less there is to work with, the greater the engineering effort to compete. Go ahead and congratulate Tesla. Those orders are an amazing achievement. That recognition is well earned. But don't declare the other approaches to deal with emission & consumption issues until there's something actually showing high-volume profitable sales haven't happened. The low-hanging fruit doesn't represent what comes next.

4-03-2016 **2016 Prius Sightings.** I've spotted several on the road now. Woohoo! It's nice to know that, despite the nasty fire causing lots of damage at a steel production plant, the new Prius are finally becoming available. The timing of that was really unfortunate. Things like that mess up advertising campaigns. It makes you wonder how many people went into dealers hoping to take a close look at the new Prius were sent away in disappointment from there not being any. Not much could be done about that. It likely hurt initial interest in the RAV4 hybrid too. Oh well. At least a few people around here have been able to purchase. I was at my dealer a few weeks ago. They had 3 recent deliveries and none in the usual area. Seeing 20 in back and a half dozen in front is normal there. Shortages aren't good. Hopefully, that situation has changed quite a bit since then. I'll have to stop soon. I've been yearning to get an inside look. My first was at another dealer, where there were only 2 and that was after hours. I regular visit would be nice. I really look forward to the test drive.

- 4-04-2016** **Prius C Refresh.** This morning, my wife and I got a surprise. We spotted a new color of Prius C racing past us on the highway. Looking closer, we noticed some cosmetic differences. I hadn't realized Toyota would be doing a refresh of the model. That usually happens mid-cycle. But with the future of it uncertain due to the ever-changing market. That makes sense. There's a wait-and-see approach right now. RAV4 hybrid seems to be quite popular. The new Prius gives that impression too, but there haven't been enough available for purchase yet to really make any type of demand assessment. People like to gauge success based on small samples, limited time & area. I try to always point out the bigger picture. For example, Prius C in Japan (known as "Aqua" there) is no longer the top-selling vehicle for the country. The regular liftback Prius has surpassed it... by quite a bit. 21,036 versus 12,720 in January this year. In February, it was 19,010 versus 14,010. In March, sales were an impressive 21,434 versus 23,314. That shows there's a huge demand for the new Prius there, but the refreshed C is clearly hanging on to the second place title. Will there be a next-generation that resembles the C we become accustomed to or will there be some other smaller hybrid offering instead? After all, the ultimate goal is to phase out traditional choices. That means approach adjustments as the market grows is a reasonable expectation.
- 4-05-2016** **Sales Spin.** There's been an ongoing effort by some to make it appear as though the hybrid interest will not grow, that plug-in offerings will surpass the marketshare in both size & speed without any trouble. To do that, you have to disregard the tax-credit. Pretending that has no influence is important... and nuts. Yet, some continue to try anyway. We'll get concluding comments like this on a regular basis: "...the marketshare of hybrids has remained stagnant for years." In reply, I pointed out some marketing principles and mentioned the inevitable plateau that comes as a result of competitors not joining in yet. I also made it clear that sales of the gen-4 Prius only just began. This was the response to that today: "*The numbers I provided were for all manufacturers, but glad to see that you still found a way to spin this in a positive light.*" It came from someone who simply seems angry and doesn't want to support hybrids anymore, consequently turning against them... by misrepresentation. That's really unfortunate. It does happen though. Disenchantment is a very real problem. Oh well. What can you do? I posted this: GM, Chrysler, and Nissan are major automakers that don't offer any hybrids. There's smaller automakers too, like Mitsubishi. The number of hybrids coming from Honda, VW, and Subaru are almost non-existent. Look at the top-selling category, small SUVs. There is only the RAV4. There aren't any hybrid minivans here. For that matter, there's only one sub-compact available. The market is most definitely lacking choices still. Thinking that's representative of "all" is serious denial.

4-06-2016 **Observations & Expectations.** It's nice to get asked something actually constructive: *"Why did you buy a PiP? Are you happy or sad that Toyota manufactured it? Your discussion keeps coming across as Toyota was smart to make a car you wanted but even smarter to deny me the same car."* He is one of those supporters still quite upset by plans not meeting his expectations. Unlike GM being backed into a corner (committed to the original approach), Toyota has been willing to adjust based upon what it learned. In other words, the innovation pushes the two automakers in different directions. He prefers that of GM. I don't, since Toyota's is what targets the masses. My effort is to endorse what will be realistic for mainstream consumers. That will continue. These are my observations & expectations: I knew exactly what I was buying. Expectations of GEN-1 were quite clear. So, I have been very happy with that choice. Expectations of GEN-2 were very different. And based upon what's been revealed to us so far, Toyota will do well fulfilling them too. The problem with the availability has been adaptation to the changing market. Toyota included that in their plans. That annoyed the heck out of some supporters. They didn't expect the halting of rollout... even though that was always one of the potential choices. Running such a massive business requires a careful consideration to risk. Leveraging other aspects of HSD advancement while collecting real-world data from the limited PHV rollout, along with analysis of consumer perception seems to have resulted in a Prime that will reach out to a new audience. Expanding the market (penetrating deeper into the mainstream) is the ultimate goal. You can't please all the people all the time. You can widen appeal by responding with variety though. Those are my observations. What are yours?

4-06-2016 **Reality.** Quotes like this are quickly fading away: *"Toyota and Honda are late to the game, but I'm happy to see they are beginning to get it."* The attitude from GM enthusiasts was still someone coming from the *"vastly superior"* perspective. It was quite ironic how they'd poke fun at Prius owners, calling them *"smug"* and claiming their posts were condescending while being guilty of that very thing themselves. Thankfully, the major does of reality provided by Tesla has served as a wake-up call. Failing to look at the bigger market... mainstream consumers ...has always been a big mistake. It's hard to believe how they'd continue to make that same mistake over and over again. On the big Prius forum, I posted this about my observations of the situation: Posts on the big GM forum in response to Tesla Model 3 aren't painting a pretty picture. It's becoming easy to see that Bolt & Volt are facing a new set of circumstances, neither one of which is prepared to deal with. In other words, consumer interest for plugging in is changing much faster than the traditional vehicle model-cycle planning allows. Being prepared to make changes to plans along the way is a benefit, not a liability as the spin would have us believe. True, it does look bad in the short-term and could disenchant those with very specific expectations. But looking at the entire production of a vehicle for the next year or two, some will see the wisdom of choosing to adapt based upon what is learned along the way.

- 4-07-2016** **Gross Exaggerations.** Having to deal with them is a pain. They'll never go away. New ones like this are an expectation: *"In my Prius, yes I could travel 500 miles without using the restroom, but I was always very tired and worn out afterwards. You don't realize the cognitive load that's actually required to even cruise on the highway in an ICE vehicle. Yes, I do stop at Superchargers to charge while I use the restroom and get a snack."* He was arguing in favor of Tesla's supercharger network. I was not impressed and felt quite compelled to point out why: Having already taken two 1,500 mile trips this year and planning another (visiting my sister-in-law about to have twins), I can tell you that type of claim isn't helping anyone. I'm very much in favor of Tesla, but am not going to just allow such misrepresentation to take place. No one would ever drive 500 miles without using the restroom. Period. Roughly, every 2 hours you take some type of break. Someone always needs to use the restroom, food, beverage, or to just stretch. Other technology is what you'll find beneficial with respect to cognitive load. In my case, I find the adaptive-cruise absolutely wonderful. Why so many drivers cut you off when they pass is beyond me. Ugh. The fact that the Prius will automatically slow down to provide room for safety is great. That goes a long way toward relieving cognitive load.
- 4-08-2016** **Abandoned.** Posting this observation will likely stir some discussion. That's not my goal. In fact, it's an effort at closure. But nonetheless, someone inevitably will read this and think otherwise: Anyone else remember the claim that Volt was the answer to competing with Tesla? Since the reveal of Model 3, there has been an abandonment of Volt. Look at any of the GM forums & blogs. The posts are all about Bolt. It's as if Volt is just a memorable chapter in history and everyone has moved on. This further supports the approach Toyota has taken. Not only is it proving wise to have halted PiP rollout because Prime would offer so much more, but there's also the strategy of keeping a distance from the supposed competition... especially if ends up having trouble attracting customers. The claim all along that Volt is the EV solution for *"range anxiety"*. Based on initial market response, we're seeing the solution is actually just a big enough battery-pack. Volt is in an awkward position of not being able to compete with its intended target. That's where Prime comes in. For those wanting the EV experience, but also wanting extremely efficient MPG afterward, why not get a plug-in Prius? What would make the consumer purchase a Volt instead? Greater range seems like an easy draw, but why bother when you could just buy a Model 3, Bolt, or Leaf instead?

- 4-08-2016** **Bad Mouthing.** I get a lot of grief for speaking out, making sure people understand scope. Today it was: *"I was just quoting John's language. He's the one that said 'everyone has moved on'."* That was annoying. I clearly didn't say that. But he is one of those who only see the plug-in market and disregard all other vehicle purchases. Choosing to isolate like that does make it sound like I'm bad mouthing GM a lot. But that's due to claims not matching reality. Oh well, all I can do is post my part: That would be quoting out of context. The reference was to posts on forums & blogs. Those individuals are only a small part of the market as a whole. That online community isn't representative of ordinary consumers either. Again, just because Volt wasn't able to attract mainstream consumers doesn't mean GM is done. They will be offering Bolt, Malibu hybrid, and CT6 plug-in hybrid. How that observation can be considered bad-mouthing is beyond me. You try something. If it doesn't work, move on to the next thing. Here's another observation: Volt enthusiasts became staunch defenders, lashing out at anyone who criticized in any manor... even when a post was to compliment GM upon delivering a vehicle to be praised by the niche market. They just plain didn't want any type of *"failure"* label, even though it didn't attract the mainstream as hoped. So now, we point that history out and move on. Remember that this is the third try. Don't forget Two-Mode. That was an efficiency improvement venture as well. It didn't work out either. What can be done this time to avoid falling into the same traps again?
- 4-09-2016** **Diesel Desperation.** It's interesting to watch the end of diesel for personal vehicles unfold. Daimler now faces a class-action lawsuit claiming: *"The fact that Mercedes passed the dynamometer test in all tests, but failed the real world test, is suggestive that like VW, Mercedes is implementing a defeat device."* A former executive for Fiat says plug-in hybrids will be hurt by the VW emissions due to the upcoming requirement of real-world testing. On the road results are what revealed the diesel cheat. Supposedly, the same will be true for the competition. I'd call that desperate. We know that some owners drivers who don't drive as far get much better real-world results than the EPA test measurements. The same is true for those who get to plug in more often. The catch is that even when you don't plug in a plug-in hybrid like Prius, it still delivers cleaner emissions than the diesels currently on the road. The electricity added is a bonus, not a requirement. The PZEV rating is already achieved without. We most certainly haven't seen that from VW or Mercedes.
- 4-10-2016** **Bigger Obstacles.** We're seeing the *"vastly superior"* mindset emerge again. That's a reasonable expectation each time a new chapter begins. Repeating the same mistakes is a possible outcome. Some don't learn from previous efforts. In this case, we're going from gen-1 offerings from gen-2. It's especially interesting to have comments like this being made: *"Tesla has far bigger obstacles in their path."* Coming from someone angered with Toyota not pushing for the most from an EV, that was no surprise. He just plain isn't interested in the problems of reaching the masses. Concerns for mainstream consumers are just brushed aside. He's one of those who doesn't see leadership as anything other than break new ground. Pushing extremes is his only focus. So, replies just fall on deaf ears. Nonetheless, no harm in posting something anyway: They are different. Saying otherwise would be a move toward falling into the same trap GM did... twice. We don't want to see that mistake be repeated again and saying one is bigger than the other doesn't help anyone involved. The difficulty in changing existing legacy that's been in place and is extremely well established poses huge challenges too.

4-10-2016 **Too Little, Too Late.** The antagonists love to claim that, but never actually have anything of substance to back it... All we get is just a reference to EV range. At least in the past, there was the EV power aspect. There isn't anymore though. Yet, this is what's posted anyway: *"Despite after the fact creation of convoluted strategies that seek to explain Toyota's moves and make them seem like well-considered genius, the Prime is too little, too late."* I'd certainly like to address whatever perceived shortcomings there could potentially, but none have been provided so far. This is how I replied to that: That's one of the traps countless individuals with good intentions have fallen into. They get hung up on the current market and don't even notice the rest. Most consumers aren't part of this stage of electrification. For them, 0 miles of EV is perfectly fine. They have no interest to plug in. It's that simple. Not being drawn to EV driving, regardless of how impressive the experience can be, makes them a very difficult group of consumers to reach. Making compromise for the sake of a pure EV isn't worth it. Offering a decent amount of EV followed by impressive HV is what Toyota believes that audience will find appealing. Ironically, Volt has faced the *"too little, too slowly"* problem, a concern expressed by the group assigned to oversee the bankruptcy recovery. The outcome was an opportunity missed. Gas was \$4 per gallon, yet sales of Volt were never able to reach beyond niche. There wasn't any competition back then either. It had the entire category of plug-in hybrid to capitalize on, but didn't. Now in 2016, we enter a new chapter. The effort this time is to reach beyond that niche. This new group of consumers have different requirements. Since these are people who have yet to begin their search for a plug-in choice, offering an EV capacity with enough to cover some commutes entirely and others provide triple-digit MPG averages will draw interest. What's little or late about that?

- 4-11-2016** **Playing Catch-Up.** Today on the daily blog (which now only features Volt from time to time), there was a well written article about Prime. Some operational aspects were pointed out along with some detail explaining the why & how of that design choice. Unfortunately, this was posted: "*Toyota is playing catch up to GM and Ford in the Prius Prime.*" That non-constructive comment was to be expected. What was not was something to actually support that. Upon asking for it, incorrect information was posted instead. False facts was a bit of a surprise. That's so easy to debunk nowadays. Oh well. I chose to respond with: I'd like to find out more. Please tell. In the past, there was a strong belief Toyota wouldn't be able to upgrade the system, that it was an obsolete approach. In fact, that's where the EREV verses PHEV head-butting came from. Those distinct categories were drawn based upon what was assumed not possible. What actually happened was a generational update. Researching need was key. Finding out how much battery-capacity and how much EV power would be beneficial is helpful. We're all subject to falling into the trap that more is better. There are tradeoffs. Somewhere in the middle is the right balance for mass acceptance. While that research was in process (especially the collecting of real-world data and following online comments), advancement in lithium chemistry, motor production, controller efficiency, and software enhancements all took place. So, it's not like that wasn't planned anyway and didn't address a variety of different improvements. Toyota already had more powerful electric motors. Toyota already had an AWD option. Toyota already had an EV platform. Toyota already offered advanced features like LED lighting and adaptive cruise-control with automatic braking. We see that Toyota has jumped ahead of GM by offering vapor-injected heat-pump for heating rather than using the less efficient resistance type too. Caught up would be the most constructive way of putting it. The gen-2 will be delivered this fall. What else is there?
- 4-11-2016** **Smug.** Almost immediately, the blog fell apart and lost pretty much any hope of being useful: "*Too little too late. But they are getting closer, each day, to a 2010 Volt, LOL.*" The attitude of GM being better than Toyota runs deep. There is no spirit of cooperation from some. Certain individuals see the competition as other plug-in vehicles, not mainstream offerings. As far as they are concerned, the rest of the market simply doesn't matter. Wouldn't it be great to live in your own little world like that? Ugh. Fortunately, others take the situation seriously. I posted: The rest of us have moved on, recognizing that low-hanging fruit has been picked and reaching mainstream consumers is a much greater challenge. Keep living in 2010 if you want. In the meantime, we'll be working toward support of plug-in vehicles as an effort to bring traditional vehicle interest to a close.

4-11-2016 **Pessimism.** There's an underlying belief that the niche group currently seeking plug-in choices are all that matter. This is why there had been a fundamental problem of disregarding the mainstream. Ordinary consumers didn't matter, as far as the enthusiasts were concerned. Thankfully, there's a growing group of supporter who don't share that sentiment. Some, including me, believe gen-2 rollouts have potential to reach the ordinary person. Prius has been able to attract customers shopping on the dealer's showroom floor. Why couldn't Prime do the same thing? Needless to say, all of them don't share the same opportunity. The configuration of Volt currently pushes some limits, hence what I suspect this came from: "*We ain't there yet and continuing to remind everyone is getting tedious.*" He went on from there to rant about pickups and long-range EVs not being available yet either. It's always some type of distraction, rather than addressing the actual issue. Oh well, at least I get to say my piece: So, your claim is that none of the gen-2 offerings will reach mainstream consumers? We've already seen reductions of size, weight, and cost of batteries over the years. Look at how both Leaf and Volt were able to use the advancement as an opportunity to lower prices and offer mid-cycle improvements. Why wouldn't you think Prime could take advantage of that too? I see it as a platform designed to capitalize on technology upgrades, without needing to wait for a next generation rollout.

4-11-2016 **You're doing it again.** I was informed that was my the nature of my posts today. That's an easy impression to get. It was a great opportunity to point out that wasn't actually the case: Read the posts again. Notice the effort to focus plug-in choices against the competition of traditional vehicles? Certain individuals are clearly not happy about treating Prime as a player on the same team. That's their loss. They don't like the EREV verses PHEV battle to having come to an end. Again, that's their loss. We are now attempting to unite by having open discussions about design attributes. That's what we do in person on a regular basis with the plug-in owners club here. Tesla, Leaf, Volt, i3, Prius PHV, i-MiEV, Energi, and a few others all get together and share ownership experiences. It's no big deal. The conflicts here come from a few unwilling to accept change. Reality is, the gen-2 rollouts are bringing about change. What was argued as not possible is happening. The variety presents challenges, but the goal is the same. We want to see traditional vehicle production come to an end. The statement of "*doing it again*" serves as a nice reminder of purpose. Those claims of "*catching up*" and "*too little, too late*" clearly weren't efforts to help reach the goal. Their posts were not with the intent of being constructive. I shouldn't have to be the only one pointing that out. Others have a responsibility to not just be enablers.

- 4-11-2016** **Grades.** It's nice to see a discussion come about with respect to level of performance rather than the all-or-nothing attitude of the past. Unfortunately, people seem to be trying to reinvent the wheel rather than looking back to the past for ideas. I jumped in right away to interject that history: The system that has worked exceptionally well for the past 15 years is what will ultimately end up being the choice of the ordinary consumer is what we all grew up with... grades... A, B, C, D, F. It's an elegantly system we are already familiar with. No need to come up with anything new. Use of that ended many battles over the span hybrids have been around. It's very easy to point out how a vehicle doesn't earn an "A" grade. There is no confusion what the value means either. Grades make the evaluation of worth easy to understand. The analogy of homework works exceptionally well too. Some enthusiasts like to gloat about an ability their preferred vehicle offers (want), while completely disregarding what was actually assigned (need). A teacher will see right through that deception, giving a lower grade for not delivering what was asked for.
- 4-12-2016** **Smug.** There's some really nasty bragging taking place now, attempts to take credit were none is deserved. That type of self-validation is what those antagonists often accuse others of. The irony is not wasted. I see it as validating. He even twisted that: *"I'm more than happy that Toyota just validated the Gen1 Volt by making their version of it."* We expected this. Way back in 2010 it was made quite clear that Toyota would upgrading as time proceeded and GM would reduce cost as time proceeded. Those are fundamentally different approaches. GM's approach was much higher risk, starting at an end-state with the hope that they guessed market want & need correctly. Toyota's approach allowed for flexibility, providing the option of making changes along the way. So naturally, any type of change would be spun as GM being right all along. The attitude is annoying. Volt needs change too. Trouble comes from disregarding that, claiming Volt is just fine the way it is. Why not just acknowledge what hits the target market and what doesn't? It's moving anyway, as more consumers learn about vehicle electrification. We're supposed to be on the same team, all working together to figure out how to compete directly with traditional vehicles. The smug most definitely doesn't help.
- 4-12-2016** **Polarizing.** Buried within the greenwashing efforts, there is some truly constructive discussion. It's unfortunate certain individuals do what they can to suppress that progress. I responded to this to help the thread from getting overwhelmed with distractions: *"I believe the GEN 4 Prius will not sell well because the design is too visually polarizing..."* I was curious to learn about his perspective. They may not happen, but at least I had the chance to say: That's a reasonable assessment; however, many people eventually seek out something that no longer fits the mold. It's in our nature to grow tired of the same after awhile. Toyota is gambling that point has been reached. Looking around, it's easy to see how the most popular selling vehicles... small SUVs ...have become very similar in appearance. They don't stand out anymore. That could be considered boring. LED lighting ushers in a new era of styling. Some people just plain won't like it. Some people will. Not some many will be indifferent. That's the definition of polarization. There is no correlation to popularity though. Sales could swing either way. We'll find out together.

- 4-12-2016** **Even Better.** Having former foes receptive to new ideas is great. This helped that process along: "...at this point the Prius fails to generate any buzz. We're past the point when getting 50 MPG will get anyone that excited." Coming from someone who was an intense vastly-superior warrior, it feels good seeing a glimmer of recognition that we're moving on. Being stuck in the past was really a problem. Now, it's all about what new market draws the gen-2 plug-in offerings will help bring about. I jumped in to keep the perspective with gen-4 hybrids (specifically, Prius) will help bring about: That's an expectation in economics. You want to eventually reach that point, since becoming common (high-volume sales) requires the loss of certain technology draws. The transition from engineering to business isn't what groups like this tend to consider; it's when interest is lost and the label of "*boring*" begins to be used. Ordinary people see that as confirmation of a technology now being accepted as the next standard. It's the "*proven*" stage. First thing that must happen is the early rollout incentives vanish and sales finding a way to continue to grow without the help. Prius achieved that. Second is for others to join in. We're seeing them strive for same... with Honda, now Hyundai, next will be Ford. We may see GM join as well. In other words, there will be a tipping point when the 50 MPG vehicle is considered the most obvious choice for purchase. That's not exciting by any means. There's no buzz, just business-sustaining profit for the automaker.
- 4-12-2016** **Antagonist Taunting.** That seems to be the best term for an internal troll. There are a few who just plain don't want to accept compromise. They'll do everything they can to claim superiority. That's annoying. The trophy mentality blinds those individuals. That's troubling. Posts end up becoming a major problem. They turn to greenwashing, intentionally misleading to avoid having to acknowledge making a mistake. That's sad. Their underlying effort is to provoke. It's a distraction to not have to deal with reality. That's happening... yet again. I'm doing what I can to address it: Notice how certain individuals continue to be extremely vague? For example, the continuous suggestion of "*add more kwh*" doesn't tell us anything at all. It's just an antagonistic taunt to stir posts, because there's no effort to actually address the reasoning; we get a condescending comment instead. That complete absence of detail and attitude isn't constructive. In fact, it hurts the reputation of the group. On the big GM forum, they cracked down on that type of activity. Others here need to join in to help stop that, rather than watch it repeat and blame the person pointing it out. So what if it ruffles a few feathers? That's how you get those taunts to stop. You need to break a few eggs to make the cake.

- 4-12-2016** **Intentional Misleading.** The greenwashing effort is well underway. We knew there would be spin. It's a twisted acknowledgement of change... which is better than denial. The stubborn nature of certain individuals have a difficult time accepting the next stage. In this case, the transition from gen-1 to gen-2 has been painful. This particular Volt owner never bothered to actually read what was posted. There was always a misguided belief that Prius couldn't ever be upgraded. He was wrong and will do everything possible to conceal it. Ugh. Oh well. All I can do is try to push beyond the greenwashing being used as a diversion from revealing the truth: We all knew battery-capacity would increase with the next generation. We also all knew the increased battery-capacity would provide an increase in power. Lastly, we knew gen-2 would be right on time, since gen-1 offering had much ground to break before mainstream interest could be stirred. Toyota did their homework during initial development and decided to take the approach of delivering more as cost justified. That would provide them the opportunity to build up a profitable vehicle without heavy dependency on tax-credits. Being able to continue to grow sales without that help is a very big deal. When the opportunity presents itself again, the offering will be upgraded. Perhaps that will be mid-cycle. After all, the first plug-in itself was mid-cycle. It served to show updates without a generation change are quite realistic.
- 4-12-2016** **More Greenwashing.** There's some blatant lies being posted. Those I don't even bother with. Something like this though gets some attention: "*Many people seem to forget that the Prius went on sale in 1997, and initial sales were low.*" He's obviously misleading us by not pointing out sales here didn't actually start until 3 years later in 2000, but that can be overlooked. It still gives me an opportunity to raise attention to the fact that supply was intentionally limited and to state why: Actually, demand was surprisingly high. The sales were limited to quotas. People had to wait anywhere from 6 to 9 months for delivery those first 2.5 years Prius was available here. That was without a tax credit. Incentive was nothing but a tiny deduction, providing \$300 to \$400 for the typical person. There was little reason to actually push sales. The goal of that gen-1 was the same as the gen-1 for the plug-in... to gather real-world data to deliver a much improved gen-2. That approach worked well in the past. It looks like it will again too.
- 4-13-2016** **Diversity.** That's the goal of all mainstream products. If it can reach a wide variety of people, mission accomplished. How else will it achieve sustainable high-volume profitable sales without? Confirming that is a big deal. In the big forum for Prius, we have been able to. That's especially difficult online, since most discussion groups aren't able to draw that many people. Looking at the current member count, the number is now at: 122,976. That's amazing, even more so is the number of discussions: 153,010. What blows my mind is that there have been this many messages posted: 2,292,152. I clearly remember when it was founded. That memory is still quite vivid. Anywho, in a discussion today, there was a reference back to the original poster... who went missing. That happens from time to time. They'll post a few things, then vanish. We sometimes don't find out why. This was my insight to contribution to this particular thread dealing with that situation: Some seek out a venue to vent frustration from not having studied well before purchasing. Some make an abrupt discovery upon joining about something they had overlooked. Some post for the sake of exchanging information and learning more. We see all kinds here. It serves as validation of Prius reaching a diverse range of people.

4-13-2016 **The Push.** Ever since the reveal of Prime, I've been pushing that group of bloggers to move on. They really want to hold on to the past, where lines were clearly drawn. The best example of that is the "EREV" definition. Even though parts of it had fallen apart over the years, there was enough left to keep Volt in that category of its own. The goal was to promote it as superior to the "PHEV" choices. Prime brought that to an end. No argument to hold up to this new generation. That chapter in history is over. Another example was being vague. That was relatively easy to do without any information about what Toyota would offer next. I milked the opportunity recent, asking what the antagonists meant. No detail provided meant anything could be said in reply. I pushed to something, anything. It ended up being nothing but rhetoric posts. They had nothing. That means I can now just relentlessly post facts. They hate actual constructive information. That's really difficult to push. I have a lot at my disposal. The goal is to bring their nonsense to a close. Our purpose is to endorse choices that offer compelling reasons to not purchase a traditional vehicle anymore. Tell shoppers why, not fight amongst ourselves. First and foremost, that means properly identifying audience. The gen-1 Volt clearly didn't target mainstream consumers. They didn't want to accept that, which made taking the next step impossible. Prime clearly targets the mainstream. Ordinary people will give it a look. There's a nice balance of power, capacity, and style without trading too much of anything. It's not a specialty vehicle like Volt. It attempts to deliver some EV, just like the Ford Energi models and Honda Accord plug-in did, but still retain appealing hybrid traits. That's what Hyundai's Ioniq is pursuing too. Pushing to make that clear is a gain for everyone, even if the antagonists continue to refuse to play along with the rest of us on the same team. Ugh. There's always someone...

- 4-13-2016** **Cooperation.** There's an obvious effort to be constructive. Some who would have presented challenges in the past are now giving a sincere try at learning more. That really makes this fun. I got this: "*Quite right. My mistake. I made a broad observation...*" Which provided the opportunity to proceed with: Looking at Volt's history, we see that it was intended to be the direct competition for Tesla's lower cost offering. So, from the start, it was designed to be an EV. That approach of using an engine still allowed the battery-pack to be much smaller. The tradeoff was cost & complexity. GM realized this wasn't going to work as the rollout of Volt approached and bits of info from Tesla were shared. That's how Bolt emerged. Bolt was an abandonment of all that GM had preached. The anti-EV sentiment it had fought so much for was suddenly embraced. Resources would be heavily invested in it instead, to the point where Volt rollout would be delayed & reduced. Then here comes Toyota with Prime, targeting a completely different audience with a very different approach. It never made any sense to compare the plug-in Prius to Volt and it still doesn't with Prime. GM is pursuing those interested in the pure EV experience now. Toyota is targeting its own customers, hoping they will chose to purchase a hybrid rather than a traditional vehicle. Prime will expand upon the same type of appeal Prius did. More EV is nice, but by no means necessary. In other words, the targeted customers won't be looking for a 100% gas-free driving experience anyway. So whatever Volt is or will become doesn't even matter, no label necessary. This is why the question "*Who is the market for Volt?*" was asked so many times over the past 6 years. The difference of audience was profoundly important, yet that kept getting lost in the "*more EV is needed*" claim. If Volt wasn't to compete with Tesla anymore and wouldn't draw interest from GM own customers, what is its purpose? Understand why? No harm done. Taking the time to discuss perspectives is helpful to everyone. The rapidly evolving market deserves a fresh relook at everything.
- 4-13-2016** **Follow Up.** He stated it this way: "*I guess we'll find out next year.*" I really didn't want to leave such a cooperative exchange hanging, so I posted this as my close: That brings us back to the topic of this thread... waiting. Circumstances will be very different a year from now. Look no further than what happened 2 weeks ago for confirmation of that. Tesla's new pressure on GM will push so hard, something will end up giving. Expect some sort of plan change. If Bolt volume really is ramped up for the sake of getting ahead of Model 3, it very well could come at the sacrifice of Volt. There's the consideration of both battery-pack production capacity and tax-credit availability. There's also the range-anxiety conflict about how to promote. It could leave Prime outside of the realm of all that.

4-13-2016 **Caught Greenwashing.** The one absolutely desperate Volt enthusiast still remaining, after having got caught being smug, lashed out at Prius with this: "*After 3 years in Japan, and 4 in the US, Toyota was only selling 24,600 Prius in the US. GM sold 23,500 Volts in the 2nd year they were available.*" I was shocked to see that. It provided a great opportunity to post back with lots of facts revealing his greenwashing effort: Wow! There are so many misleading claims in that statement, I don't know where to begin... First and foremost, Prius was limited to a strict quota. That meant there was no way to actually measure true demand. Those who did manage place orders had to wait 6 to 9 months for delivery due to the limited supply. Second, Prius was not available for purchase from Toyota dealers. You had to place an order through an online process and wait for regional to get it within their limited allocation. They were not carried in dealer inventory until 2.5 years after initial rollout, which at that point gen-2 had been announced. Third, there wasn't a tax-credit available. Only a \$2,000 deduction could be taken, which calculated to between \$300 to \$400 for the typical owner. That's a drastic difference from the \$7,500 people get for the purchase of a Volt. Fourth, the 4th year of availability for Prius was the gen-2 model, which began late October 2003. (gen-1 was late August 2000). This was the first year sales which were not limited to a quota. Those sales came to 54,000. The following year, still without any tax-credit incentive, the sales climbed to 107,900. Fifth, there were fierce market campaigns against hybrids back then, gas was cheap (no one ever even imagined \$2.00 per gallon), there wasn't concern about oil dependency, (in fact) we were encouraged to drive larger vehicles to "*help the economy*" recover from the war, climate change wasn't on anyone's minds yet, and misconceptions about battery-packs for automotive use were abundant. Sixth, the supposed diluting of the plug-in market now is really spin on the fact that other automakers are endorsing the idea. That support from them is a valuable benefit, something Prius certainly didn't have back then. Seventh, GM already had extensive knowledge of motor & battery production & sales by the time Volt was rolled out. EV1, Two-Mode, and BAS all provided very helpful experience that Toyota didn't have back when Prius sales began. Lastly, that 2nd year of Volt sales was the best on record (specifically 23,461). Each which followed had decreasingly lower demand and the expectation for this year (the 6th) isn't any higher.

4-14-2016 **Pushing New Territory.** Using new terminology can bring about unforeseen circumstances: *"It's more difficult to 'push into new territory' if your vehicle doesn't have standard utility. This is their second plug-in and it should have been as mainstream as the previous."* I joined into today's discussion by responding to that. The hope was to get the exchange to attract others. That push reference provided a fresh look. The risk is pointing out an attractive feature Toyota offers that GM doesn't or the fundamentally different approach with design. Toyota provides upgrades. GM reduces cost. I prefer Toyota's, since it offers flexibility and doesn't take the massive risk of correctly guessing what the market will actually want & need. GM backed itself into a corner with Volt and now struggles with it as a result. My attempt to get constructive feedback was: Toyota has been taking the flexible approach. That's why the mid-cycle rollout of the plug-in came with a "subject to change" note. Few paid attention to that plan to adjust based upon market observations, but that was the intent even before rollout began. Another obvious, but often overlooked, part of the plan was to increase battery-capacity as cost justified. After all, it would only be a few years, rather than having to wait an entire product-cycle. So, we always knew that the next generation wouldn't take long and would bring about a range & power increase. As for direct "mainstream" targeting right away, we could see that wasn't realistic as the 200-mile race heated up. The bump in price that would carry meant some more flexibility for Toyota. Tesla, GM, and Nissan would all be in the mid-30's. Why not add a couple of luxuries onto Prime, since it would be the premiere plug-in for Toyota? That's how the goodies like the 11.6" screen and the LED lights came about. Reaching that new territory (consumers who haven't shown any interest in hybrids or plug-ins yet) requires new approaches. Notice how even Model 3 is breaking new ground by placing all dashboard interfaces onto a single screen? (That had been exclusive to only the high-priced luxury offerings.) More EV alone won't be enough. The hope would be that around mid-cycle, we'll get either some new packages for Prime or a second plug-in choice. It all depends how the rest of the plug-in market plays out in the meantime.

4-15-2016

Sad Reality. This came from a disenchanted supporter: "*GM management and GM dealers are not interested in selling EV's. Plain and simple. Tesla is.*" The new of Model 3 interest taking the market by storm, it's not just Volt struggling. There are concerns Bolt will face issues as well. I tried to help, or at least be empathetic: That's a sad reality. Prius supporters had to endure quite a bit of grief over the years trying to point out that great engineering alone was far from enough for Volt to be successful. Every different approach tried ended up getting twisted into the scared belief that it was really an effort to show Toyota was superior to GM. Thank goodness that is over! Only a handful of stubborn individuals still believe it and they simply are not worth bothering to help. They are grossly outnumbered; all the rest of us have moved on. There is a growing group of plug-in owners trying to figure out how the heck to get dealers interested. The local club here has begun by creating an online expert-list. We identify those few very well informed salespeople who really work to sell plug-in vehicles. We figure sending more business directly to them is a win for everyone. Realistically, it is up to us as supporters to provide the education. Salespeople getting asked lots of questions they know little to nothing about for a vehicle that will provide a small commission and will require more work to get is of no appeal. Most don't even bother. As a result, dealers see no reason to carry more than just a few (if any) in stock. It's really unfortunate. Tesla's approach is facing criticism now. Yet, the effort continues anyway. Toyota is pushing ahead too. Their increase in lithium battery production along refinement to the motor, control, and software is still just brushed aside, claiming not enough AER indicates no interest in EV propulsion. That's nothing but a bunch of antagonist bull and I thank everyone helping to show that. Yesterday's heat-pump discussion provided a wonderful example of working together. Thank you! As the gen-2 offerings rollout, we learn more about what's new & refined, then share that information. It's a win-win situation. It is not an effort to undermine other automakers. The competition is traditional vehicles. For proof of that, look no further than the dealer's showroom floor.

4-15-2016 **Wrap Up, summary.** There's no debate, the market is moving on. We're seeing the competition between Tesla and GM really heat up. Count of reservations for Model 3 hasn't been published in awhile. The last report stated 325,000. That was more than enough to fuel the fire for Bolt. The stance taken by GM is to remind us their EV will be available for purchase this Fall and no deposit to reserve one will be necessary. It's providing Bolt with an unbelievable amount of attention, so much so; no one is giving regard to Volt anymore. Hope surrounding the second-generation model has vanished. The only expectation for buyers are enthusiast & supporters who have long endured the wait for rollout. The anticipated purchase by those outside of that realm are absent from any discussion. Nothing. None. Zip. Zero. The gen-2 delivery was expected to be met with a fire storm of excitement, creating demand well in excess of what Toyota had to deal with upon the gen-2 delivery of Prius. So far, it's been upset after upset. Rather than be available nationwide right away, only CARB states got any last year. The rest of the nation had to wait until the second month of this year. That wouldn't have been much of a big it, if certain assumed upgrades would be available upon the delay's end. The biggest one was the hope for adaptive-cruise control with automatic-braking. Since I've had that on my Prius PHV for 4 years now, it made sense would offer it for Volt too. That didn't happen. To make matters worse, leg & head room issues again for Volt. That's the result of not having a 5th seat in Prime... which enthusiasts for many years have stated isn't needed for Volt anyway. After all, there was belief that a radical new design would be taken for gen-2, just like Toyota did for Prius. That seemed reasonable, since technology for moving large battery-packs from upward locations to buried under the floor has been the desired approach. Long story short, this rollout has been a fizzle.

4-15-2016 **Wrap Up, history.** Discussion of Volt's struggle has become a popular topic on the big Prius forum. This is what inspired me to write up a history of how it got to this point: *"I'm baffled as to why the Volt wasn't more of a success, when it had the plug-in market to itself, in such favorable market conditions..."* Needless to say, I had much to contribute on that:

I have literally thousands of blog entries documenting that history as it was unfolding, noting many forgotten influential events as they took place, with no way of knowing what would come next. They offer perspective unlike what looking back long afterward can reveal. There is much detail a summary cannot address, but we can at least give it a try...

The problem with Volt that immediately comes to mind was the setting of expectations. GM fed the hype leading up to rollout, allowing it to spread excitement through vague statements then not providing clarification as assumptions grew. The most obvious resulting from that was the impact heater use in the winter caused, reducing EV range far below what was hoped. People had been led to believe 40 miles was what GM would deliver. Real-World driving revealed cabin-comfort in freezing temperatures dropped EV range to the 20's.

The second biggest factor was likely marketing. Support completely fell apart. There simply wasn't any uniform message. Enthusiasts took over, sending out a chaotic flurry of supposed goals... many conflicting with the intent of Volt. That's how the *"Who is the market for Volt?"* question came about. It was originally targeted at mainstream consumers. What got delivered was being promoted as something entirely different though, a vehicle for those who would appreciate paying a premium for superior performance.

From the automaker perspective, production cost was a serious issue. GM decided to gamble, hoping they'd achieve mainstream sales level (minimum rate of 60,000 annual here) by the end of the second sales-year. That turned into a disaster. Inventory piled up, despite the rollout of Cadillac ELR. Purchase interest continued to be a struggle. So, the third model-year came with a \$5,000 price drop, with the continued hope that economics-of-scale would bring down production cost. Despite that, sales still didn't increase.

Falling gas prices, recovery of the economy, and growing demand for Leaf & Tesla made the bad situation for GM even worse. No one really knew what to expect for the second-generation design, yet focus had almost entirely shifted over to it. Hope was blinded by desperation. The first-generation model was left to struggle on its own. Nothing was able to ignite excitement for the technology in Volt. Viewed upon as a small, complex, expensive plug-in vehicle with hybrid MPG well below Prius, it just plain couldn't find an audience.

Problems continued to mount as Volt leases began to expire. The original deals were deeply discounted, making the choice very compelling to take advantage of. Unfortunately, 3 years later, the resale values for those older Volts had plummeted. Growing competition from Nissan, Ford, and Tesla along with the \$5,000 price reduction left little reason for lease holders to stay loyal to GM. Those conquest sales which enthusiasts had flaunted were turning into large abandonment

numbers. Even the original audience was being lost.

Evidence of GM changing course emerged in 2014, when we started to hear about an EV that would be offered. By late summer, confirmation of Chevy Bolt being revealed at the Detroit autoshow in January ended any doubt. The fundamental strength of Volt had completely fallen apart. The solution for "*range anxiety*" had become a battery-pack large enough to provide 200 miles of electric-only travel, no engine necessary. At that point, the success became even more uncertain. Supporters were being drawn to Bolt.

Most people are familiar with what happened from that point. Details of the second-generation Volt were revealed. Promise of a design able to compete directly with other GM vehicles on dealer's showroom floors was lost. When rollout finally began, only a small number of states received delivery. The rest of the nation would have to wait another 6 months. By the time that happened, the production version of Bolt was revealed. 3 months later, Tesla revealed Model 3 and began taking reservations.

2 weeks later (that's today) we have no clue what GM has planned for Volt. It appears as though resources will be spent primarily on Bolt instead, to take advantage of the delay Tesla will have prior to Model 3 production.

- 4-15-2016** **Wrap Up, brief.** The want for a quick & easy understanding of the situation was requested. The history, even just those highlights, was too much to follow. So, I added this: Volt did not reach mainstream consumers, it ended up being a niche. There's nothing wrong with a specialty vehicle though. That left us wondering if gen-2 would change radically, like gen-2 did for Prius or another vehicle would be offered.
- 4-15-2016** **Wrap Up, elsewhere.** It went well, on the big Prius forum. On that daily blog for Volt (which now only rarely gets mentioned), there were issues. Almost all of the trouble comes from a single individual not. Pretty much everyone besides him has welcomed change. He continues to stay hung up on the past, desperately holding onto it as long as possible. That's too bad. But his actions have become so obvious now, it's easy to get rather terse without upsetting others. They seem to be tired of his rhetoric and have been allowing the attempts to bring that to an end a layer of forgiveness. So, I poked: The endless nit-picks of wording, the dismissals, the distractions, the parroting, it's all so telling. That serves as strong confirmation of being on the right track. We all knew what was meant. We all know the goal is to deliver something affordable for mainstream consumers which makes a profit and will be able to sustain high-volume sales. Absolutely refusing to join in with others and instead taking the stance of superiority by belittling others is so childish. It's quite refreshing being able to point out such terrible behavior.

- 4-16-2016** **Wrap Up, perspective.** Oddly, I got a little bit of a let-us-give-it-a-try opportunity from him. Without high hopes, I did: I understand the perspective. It could seem to be that. It's not though. Take another look. I'm striving to find a middle ground, where there isn't an absolute polarizing every topic. You interpret the back-step to achieve that as a change of stance, a contradiction. That's unfortunate. It's really an effort to let some things go. Watch for that. Using the term nit-pick was an attempt to point out that there's no reason to take every little detail so literally. After all, the market isn't that exact anyway, as we have witnessed. Remember, there are many purchases influenced heavily by emotion. That's reality, but should not be accepted. Sales are essential. Losing them is a major problem. Whether we like it or not, the fact is that automakers are running a business; they must make a profit to continue. There was an obsession with gen-1 engineering, always the desire be to the best was underlying reason to keep trying. That doesn't pay the bills. So, it can be that way anymore. As 2016 progresses, it's becoming clear that much of low-hanging fruit has already been picked. There isn't a group of early-adopter consumers remaining... hence the change. We're dealing with a totally new situation. Think about that. We have a different market to address. Do we continue to butt heads or try something new? After all, it doesn't make sense comparing choices of the past to vehicles of the future.
- 4-17-2016** **Wrap Up, dismissal.** It didn't work. No surprise there. He simply entirely dismissed what I had posted and attempted to change the topic: *"That was a lot of words about nothing. Back on topic, how does Toyota make a plug-in that will appeal to mainstream consumers to compete with the Corollas & Camrys? Does Toyota even want to?"* That topic he had chosen was intriguing. I got the impression it was that subject matter which irritated him most. So, why not ask me the same thing. I didn't bother. What a waste. I have been asking that same thing since way back when Saturn Aura was the most people of GM's sedans. That was long before the bankruptcy was settled. It was before the gen-1 Volt was rolled out too. Disappointed that he still remained so stubborn and unwilling to even try, I replied with: Like I said, you simply enjoy the discussion. Since I've been asking that very same question of GM about Cruze and Malibu for years, you go first.
- 4-17-2016** **Wrap Up, resentment.** You'd think I've have some... for it to take nearly a decade until the message was finally understood. Geez! Who knew that way back in the days of Two-Mode that it wouldn't be until the successor of its successor rolled out before that importance of reaching mainstream consumer could be discussed constructively. There was obviously a lot of barriers to overcome. The scale of which overwhelms. Toyota's approach of being flexible helped it weather the storm. That really upset some. They saw that "after thoughts" rather than being responsive to the market. It's too bad the proactive measures were dismissed as nonsense. True, not all of those ideas paid off. Capturing the hearts of the masses means dealing with the fickle. They are incredibly misleading, saying one thing but doing another. To complicate matters, they abruptly change their mind along the way. When you are stuck on a course like GM, lacking that ability to adjust quickly, there isn't much hope. So naturally, pretty much all constructive criticism offered is brushed aside, believed to be a clever way to undermine. That sets up an atmosphere of suspicion & panic... a recipe for disaster they cannot see. The resulting behavior is quite predictable... hence all this blogging about it over the years. Witnessing the entire cycle would be worth the effort... which is why I'm not resentful about all the crap the enthusiasts put me through.

4-18-2016 **Wrap Up, change.** Phew! It actually worked. I was delighted this morning to read this: *"So for once you have nothing to say (can we keep it this way?). And I guess Toyota is SOL. I don't think they are serious about plug-ins anyway as they will let everyone else do all the heavy lifting."* That response from the weekend craziness was quite a relief. I had my doubts it would work. Accomplishing such an odd goal take a lot of patience and reading between the lines. I wanted to see change... some indication of progress, even if it's only slight. Going from an absolute of never, to *"I don't think"* is progress. As always, it needs to be pointed out that reaches the masses is leadership. That's *"light lifting"*, a lot of it. The product offering the most of something is what gets the attention. Offering a lot of something smaller is what goes unnoticed, hence not getting credit, despite being an essential contributor to change. Anywho, this is how I replied: It was obvious you wouldn't bother actually answering that question from the past. I was surprised you even brought it up though. It was great confirmation that you have indeed heard the message, but have repeatedly chosen to ignore it. Going after Toyota instead for the same thing was an interesting move... since it has revealed something new. You had been saying Toyota gave up on the idea of supporting anything with a plug. That's why you were so harsh about all of the regular hybrids they offer. But now that GM is about to rollout Malibu hybrid and Toyota has revealed Prime, you changed. That's the *"middle ground"* I've been striving for. It worked! You took that step. True, it was masked with quite a bit of attitude, but that still counts. I'm more than happy to give credit where it is due. So... thank you. It may have been a painful journey, but the goal of letting go of that absolute has been achieved. As for the *"heavy lifting"*, that's worthy of giving praise upon GM pulling it off. The measure of success with Bolt will be volume, since there's nothing to prove anymore. Volt already took care of the technology part. It's all about reaching the next wave of customers now.

4-18-2016

1.5 Years Later. There's a thread on the big Prius forum that was started 2 years ago. It was about how the next Volt would *"leap frog the competition"*. As you could imagine, I was all over that. Much has happened since then. Volt has fallen by the wayside in favor of Bolt. In fact, the entire topic of *"range anxiety"* has completely fallen apart. The odd position Volt occupies isn't being taken by any other mainstream automaker. Either you have an augmented hybrid, offering a larger battery and a plug, or you go full electric. There's also the BMW approach, but the much larger pack and much smaller engine makes it a full EV with just an emergency backup. Volt's stance of being in-between... with both EV range too low and HV efficiency too low... we're all wondering what future it holds. My guess it will remain a niche, that a Malibu plug-in will take over its role & purpose instead. Anywho, this is what the originator of that thread 1.5 years ago had to say now: *"Tesla has had great sales because of their EV capacity and fast charging ability, in spite of the high price of the Model S and X. So, sometimes higher capacity does change the market. I think the Volt, with 2.5x the range of other plug-in hybrids, will fill a role of transitioning drivers to BEVs. GM could easily sell a somewhat cheaper me-too 20-something plug-in hybrid if they want to. That may be a saturated market at this point."* It was that saturation mention that caught me. That's clear evidence of change. The expectation had been gen-2 Volt would take the market by storm. We're not seeing that. In fact, attention has almost entirely shifted over to Bolt instead. I added to the discussion: Tesla has done an outstanding job with S and X. Stage 1 = mission accomplished. Tesla has embarked upon the challenge of delivering an affordable choice now. Stage 2 = off to a great start. GM attempted to deliver an affordable choice, able to *"leap frog the competition"* by achieving a mainstream sales rate by the end of the 2nd year. Remember, GM had even announced the ability to ramp production all the up to 120,000 if demand called for it within the 3rd year? That just plain didn't happen. Fine. Whatever. We move on to gen-2 instead. After all, we were told to be patient. This next Volt would surpass the popularity of the gen-2 Prius. So, we waited. The time has arrived. It is available. Sincerely, what should we expect now? I truly don't understand how the market could be saturated if the point was to use this technology to phase out the production of traditional vehicles. True, GM makes you wonder if all will be invested in Bolt now to compete directly with Tesla, in the process leaving Volt as a highly regarded niche... kind of like the plug-in version of a Camaro. No one has been willing to address that either. It gives the impression of that being an undesired outcome. But the reality is, only so many tax-credits are available and time to react is limited. GM could regard EV as the only reasonable next step. They tried Volt. It obviously works. But that approach didn't result in mainstream sales. Since that is what Toyota also seeks, it is reasonable to continue to ask what was learned from Volt. Why the thought that there could be a saturated market? Prime will be offering less EV range, but the EV power will be increased considerably. The smaller battery-pack keeps costs down, while still covering the needs of a number of potential buyers. It also establishes a base to build up. It doesn't sacrifice HV efficiency either.

- 4-19-2016** **Childhood Stories.** I enjoyed posting this, on the big Prius forum: They are supposed to teach us about life. Some don't learn the lesson though. I think we are watching "*the tortoise and the hare*" story play out in the automotive world. GM has exhibited much of that same behavior about getting to market sooner and racing well ahead. Toyota has been taking its time, at a pace so slow it gets mocked every step of the way... yet always paying attention and very carefully planning ahead before taking any action. Years later, we likely will see that Toyota has been quietly preparing to win. After all, the work to refine battery chemistry, motor efficiency, control software, and cabin-comfort technology will be beneficial to any plug-in vehicle. Meanwhile, production of the cells for the packs would have continued to get optimized. So, when the time comes, we very well could see that GM already ran out of tax-credits and Toyota is taking advantage of the full amount still available to them and is very well positioned to deliver high-volume during the phase-out stage.
- 4-20-2016** **That's it.** There are some who get so hung up on blame & shame that they don't see the big picture. For example: "*So it's GM spin being the GM fault, not anything to do with the Volt itself?*" That was actually an interesting question. It shows we're moving beyond problems of the past, finally addressing what's important instead. Anywho, I hope I did a good job of explaining the situation with: Setting of false expectations has consequences. GM created challenges for itself that could have been avoided. It's not rocket science. It's simply business. Understanding how accounting, economics, and marketing interact isn't easy, but it is necessary. Fortunately, you do sometimes get lucky and notice a pattern. In this case, the expectations played a major role. That put Volt in an awkward position right out the gate. Not everything that had been anticipated was actually what they got. Why does GM set expectations that could present major problems later if the challenge to deliver becomes too great? Notice how certain announcements stand out? There's almost no detail, yet lots of praise is given anyway for somehow overcoming a problem no other automaker could. That spotlight is the first sign the risk may be too much. Attempting to apply the same logic to Prime, what do we see? The highest requested upgrade was more EV power. Next was more EV range. Since neither had any set target, reaching the goal was much easier. In other words, it was just like any other generational change. People simply expect the successor to be improved. That's it.

- 4-21-2016** **Red Herrings.** They come up a lot in discussions. It's a great way to derail threads online. Both trolls & defenders thrive on the distractive damage they cause to constructive posting. That's unfortunate. Worse is that you cannot ignore them. The only effective way of dealing with them is to reduce their effectiveness. Real-World data does a great job of that. Unfortunately, very little is available for gen-2 offerings yet. So, we're stuck trying to do it with just design detail. That helps, but squashing the attempts to undermine that way isn't easy. Oh well. You keep trying anyway. I did: With HFC (hydrogen fuel-cells) being a long-term project, very different scope and very different audience, it's really a red-herring... especially since they won't be mutually exclusive to EV anyway. Look at the other automakers also investing in them. Why not similar scrutiny? For that matter, shouldn't there be the same expectations for hybrids & plug-ins? Toyota's current work to refine battery chemistry, motor efficiency, control software, and cabin-comfort technology will be beneficial to any plug-in vehicle. Meanwhile, production of the cells for the packs will continue to be optimized. It's easy to get the impression of tepid. But taking that detail and the bigger picture into consider, it looks more like preparation for high-volume profitable sales not dependent upon any incentives.
- 4-21-2016** **Much Ado.** Lack of background is a common problem. We certainly saw that play out with Volt. There was fierce pushback whenever Two-Mode was mentioned. Enthusiasts believed that was a totally unrelated project and in no way could share any of the same challenges. Thinking mistakes couldn't be repeated is a difficult lesson to learn. Once you do though, it leaves you apprehensive. Could the same assumptions leading to poor choices happen again? It is almost incomprehensible at times to determine what's important and what isn't. We have seen real problems have real consequences. We have also seen non-issues stir up a massive amount of controversy. How do you determine which is what? There's a group of us attempting that with the 5th seat topic. My post today on that was a reminder of the past: Most here have no clue how major of a "*much ado about nothing*" situation there was for the Classic Prius (2001-2003) with the shifter. OMG! People went nuts over the fact that you had to pull it toward you rather than downward. The lash out was incredible. Yet, almost no one remembers that now.
- 4-21-2016** **Competition.** New questions about the change we're witnessing are great. I especially liked this one: "*I wonder what Toyota thinks about Tesla's 400,000+ deposits for Model 3 reservations? Does Toyota not consider Tesla an automaker?*" It's interesting how my same response as in the past now gets a very different reception. That gave this post lots of anticipation & wonder about how it could be replied: The competition is traditional vehicles, not automakers pursuing plug-in options. That fundamental misunderstanding of approach is a major impairment to progress. The goal now (this stage is quite different than with gen-1 offerings) is to get interest up high enough to sustain profitable high-volume sales once the tax-credits expire. That means each automaker using the technology at their disposal to help achieve that paradigm shift in the market. In others, Toyota welcomes the effort.

- 4-21-2016** **More Plugs.** Lack of personal patience. Lack of business foresight. Lack of consumer understanding. We get this as a result: *"Why is Toyota not putting more plugs on their top selling hybrids?"* I turned it around with this: The better question is: WHICH HYBRIDS SHOULD PLUGS BE OFFERED ON? All the automakers have the issue of what to consider. They face the same challenges overcoming their own legacy constraints. Look at the explosive popularity of the small SUV lately. Some have been suggesting for years to GM that Equinox should get the Voltec treatment. We're still waiting & wondering. Initial success of the new RAV4 hybrid seems to put it on the short list for which vehicle Toyota should consider for the Prime treatment.
- 4-21-2016** **Buy Back.** It looks like TDI owner here with *"clean diesel"* vehicles will be getting the opportunity to sell it back to the automaker. The proposed price will be the book value as of right before the scandal was uncovered, along with an additional \$5,000. That's the first sensible thing to come out of this mess. Retrofitting an existing vehicle is a difficult & expensive process. It presented a major challenge of proving the fix actually worked. And the owner would have to deal with decreased engine performance, reduced efficiency, and the inconvenience of reduced truck space. Of course, not everyone is happy with the proposal: *"This is an EPA problem, not a VW problem. Regulation are destroying the diesel industry."* That's called denial. There was no way traditional diesel could possibly compete with plug-in hybrids. The efficiency difference is massive. Had this cheat not happened, diesel would have already begun to wide down production for passenger vehicles. Instead, VW was dishonest and got caught... revealing other automakers had attempted to circumvent emission regulations too. What a interesting way to be destroyed. Who would have ever dreamed they'd do it to themselves? Our air cannot handle pollution like that. Over in Europe, the situation is much worse. Taking action to slow the damage is necessary. Regulatory entities given the task of preventing air-quality from getting worse are not the problem.
- 4-21-2016** **Moving On.** The very last of the gen-1 holdouts has accepted fate. There is now a tepid spirit of cooperation. It's awkward laying down arms with someone who fought so intensely against you, celebrating victorious battles but ultimately losing the war. We're trying to meet in the middle. One individual has protested the effort. That's it! What a relief. It's over. Now, the constructive discussions can begin. His question to me today was: *"Toyota should put it on the Camry & Rav4. Call it the Camry Prime and Rav 4 Prime. Or make a unique plug-in car for the mid-size sedan and CUV."* My thoughts on the topic were: That's the water Toyota will be testing soon. How far from other offerings could or should the plug option be? With Prime, we'll be find out if the breaking the status quo, with respect to design, is what some will be attracted to. The bucket seats in back and the bubbled rear windshield is new territory to explore.. possibly new opportunity. How will customers shopping the showroom floor react? We all remember seeing vehicles of the future featuring unique design like that. Heck, anyone have any memory of the concept shown back in the 80's at Epcot center? The difference now is you can actually buy it, right there at that moment. Will seeing it, combined with a test-drive, compel them to drive away with a Prime? Having a battery small enough to easily work in any garage offering a 120-volt outlet will help to overcome complexity fear. It also eliminate equipment cost concern. Heck, even 2 of them staggered with a timer could both recharge overnight from the same line. It's a matter of testing the waters before going all out. With such a fickle market and most of the early adopters already spoken for, we need to find out what the next wave of consumers will actually buy.

- 4-21-2016** **Facing Reality.** It's not easy. There's still some lingering resentment. We are making progress. Rather than rhetoric of the past being repeated, we can see some willingness to address certain once taboo topics: *"That's the too little too slowly. With Toyota's fanbase, they shouldn't be timid."* I totally embraced that opportunity to stir interest and ask questions: Those customers are the target market. It's that *"mainstream"* term we've been tossing around for years. The more we see, the more this looks like the tortoise & hare story. Focusing on final outcome verses celebrating having raced to specific points was lesson learned the hard way. In this case, reaching those who would otherwise be perfectly content just driving off the lot with the newest traditional is the win. When you have buyers who think 35 MPG is enough and still haven't decided about climate change, you know they won't be willing to spend much on clean & efficient technology. So, how do you appeal to that group of people? The tradeoff of size, weight, and cost is a delicate balance. Toyota will be delivering a system with more electric-only power & speed along with a modest range increase. That should make it somewhat cost-competitive while not trading too much. There's nothing providing any indication of what EV range they are willing to pay for. More doesn't necessarily make it better. That only way to find out is to actually try. Customers will vote with their purchases.
- 4-22-2016** **Volt/Prius Review.** It was the usual this and that. Prius came out on top. That's still a strange situation though. In what world does it make sense to compare a hybrid to that of one with a plug? Knowing there is a plug-in model, why not include it? The answer is simple, the publication provides information for immediate purpose. Again, this is another know-your-audience situation. It's not like an enthusiasts magazine publishing statistics from circumstances you'll never actually ever encounter. That unrealistic nature is annoying, but not as much as the idealistic we get from enthusiasts online. There's also the business media that takes an entirely different spin on the market. This particular review made it clear these findings observed firsthand, gathered specifically for the review. Knowing that, this was easy to credibly draw attention to: *"The Prius clearly has the roomier back seat. It's open and airy by comparison, with wide seats, better foot space, a livable amount of head room, and a relatively hospitable middle seat."* Naturally, certain individuals didn't like that. Well, too bad. We're trying to be constructive now. That means addressing issues directly. Why GM didn't make the rear seating area larger remains a mystery. With so many people pointing that out as a shortcoming, it doesn't make sense. Feeling cramped in back is a difficult turnoff to overcome.

4-22-2016 **Good Enough, message.** In the past, it was a flurry of mixed messages. We had no clue who was being targeted and what the goals were. That uncertainty of audience & purpose made understanding scope & timeline impossible. We're starting to see progress on that front. This revealed some: "*The EV drive experience and ownership experience is much better than the alternative.*" Rather than the explosive reaction to that as in the past, it is now quite different. There are mutterings of saturation. My pointing out of that by continuous referring to it as "*low hanging fruit*" is obviously helping us move forward. Enthusiasts are coming to the realization that all the early adopters are gone. Overnight (literally), Tesla gobbled up the last of them. Appealing to a new mindset from the consumers remaining is no where near as straight forward as the "*experience*" promotion suggest. It's nice recognition of that is beginning. Next is acknowledgement with suggestions. We are starting with: Problem is, that isn't a priority for that group of buyers. They simply aren't interested. Their "*good enough*" perspective presents very tough challenges to overcome. I know that "*good enough*" is a response Volt enthusiasts don't like to hear. But after 5 years of that better being well proven, yet not drawing interest anyway, it's time to accept those differing priorities. Reality is, mainstream consumers are much more difficult to appeal to.

4-23-2016 **Good Enough, superior.** Looking for sympathy won't take you far: "*You've got to be kidding me. GM is the red-headed step-child of the auto industry. Everything they do gets scrutinized more than any other company.*" I was rather curious where that comment would take the new effort to work side-by-side rather than butting heads. So, I posted a bunch of exposition to set the stage: What do you suggest to break out beyond that reputation? Sincerely. It would be helpful to find out what next steps will take them far enough to shake off problems of the past. GM got there from a number of terrible business practices... some of which Prius owners were complaining about, back when GM was flaunting fuel-cell technology and working aggressively against hybrids. Remember the "*stop gap*" and "*go yellow*" campaigns? When GM finally started taking emission & efficiency concerns seriously, it turned into an "*over promise, under deliver*" nightmare. Rather than joining in with the other automakers, we had to endure relentless bragging about what Two-Mode would be. The claim was it would be far better of a system than what Toyota offered and would quickly be spread across the fleet. That effort became a publicity disaster. Overcoming that is what contributed heavily to Volt. After all, we know that gen-1 was really improvements originating from Two-Mode. That wasn't too much of a stretch to recognize, since we had been shown a Saturn prototype with a plug. But for some reason, that past was disregarded and a "*vastly superior*" campaign emerged instead. It was history repeating. Needless to say, that didn't go well either. Hope shifted over to gen-2. We waited. It rolled out with a frustrating delivery delay. Fine. Waiting a little longer wasn't the end of the world. But when the new Volt arrived nationwide, it entered a market of disinterest. Attention had shifted over to 200-mile EV choices instead. The long believed "*range anxiety*" solution wasn't a problem anymore. Those wanting to end their gasoline consumption spoke out... resulting in about 400,000 reservations. Dealing with that situation leaves GM in quite a pickle. Heavy investment in Bolt to help end the scrutiny of the automaker could prevent Volt from leaving of the specialty category. There are many automakers working to also deliver a competitive plug-in hybrid. Not only will they fulfill their purpose of getting traditional buyers to choose some form of electricity instead, they also put pressure on each other... until mainstream penetration becomes a reality. That requires waiting though. Profitable sales at that scale will have to survive without tax-credits. Long story short, we still have much story to go. There's lots of waiting still. The end of 2016 only marks a significant page in the next chapter of this history. We'll be in this one for awhile.

- 4-24-2016** **History.** When a chapter in history closes is rather obvious. You abruptly reach a point of recognition. That came today. It was with an attempt to consider what was learned from events & actions leading up to that point. The post stated this: "*You have a weird version of history and the current situation.*" The dead giveaway of problems to come was nothing else was said. There was no alternative viewpoint provided. That's a form of denial. They just dismiss what they don't like, rather than correct you. If a fact is overlooked or misunderstood, that information is conveyed... which didn't happen. So, my reply was: Weird is a interesting way of describing the perspective of someone who was an active participant in that history and heavily documented it as those events played out. No one had any idea what would happen next. Looking back so many years later from the viewpoint of the market which changed as a result of that history gives a very different impression. In fact, that difference is what provides the basis for repeating mistakes. Recognition of what led to challenges of the past helps to avoid falling into the same trap. It's surprisingly easy to allow the opportunity to prevent by changing direction to slip by. Whether there's agreement or not, it doesn't matter. We now see measures taking place to change direction.
- 4-25-2016** **Superiority.** There had to be one last bout with that nonsense of the past. Some people just cannot let it go. I'm more than happy to point out their behavior and remind them of the past: You don't see the history repeating? "*...show the stark superiority of Volt.*" is literally the same old nonsense posted by enthusiasts as 6 years ago. Yet, the spotlight is shined on me instead. People are allowing the cycle to restart. Enable rather than speak up. That's amazing. Volt was put on a pedestal, declared as better than everything else. No one made an effort to find some common ground. It was just GM against the other automakers. The very idea of competing with traditional vehicles continues to get shunned. The concern of cost verses price just get tossed by the wayside. It's exactly what we saw in the past. Seeing the same red-flags again and not doing anything about them means we have a good idea how this will play out.
- 4-26-2016** **Better.** Could this be the very last snippet of spite: "*...trying to prove the Prius is better...*" I remember how predominant of a belief that was in the past. Enthusiasts just plain didn't bother to read posts related to Prius at one point. They'd freak out, declaring anything with the "P" word an attempt to disrupt and stir trouble. Ironically, a few became antagonists... doing the very thing they accused me of. Guilty of what you proclaim others have done is what? Personally, I don't care about the retort. It's all about confirming they are not being sincere. That lack of good faith is a sign of trouble. Fortunately, virtually all of that type of behavior is gone now. That was among the very last. I couldn't help but to point out such a momentous point: There it is. No matter how hard I try to find common ground, there is always someone who believes it is really an effort to prove superiority. That is the mistake being repeated.

4-26-2016 **Approach.** There is still a little bit of resentment from some: "*GM will continue to improve on its electrified vehicles, while you constantly berate them. In the meantime Toyota will drag its feet, but you will bite your tongue, even when they make huge mistakes, yet creep ever closer to GM's designs.*" The particular individual who pointed that out clearly doesn't like the fact that my predictions were correct. I'm turning that back on him by attempting to get some useful dialog from his continued provokes:

Please tell me what "*berate*" refers to. Seriously. I'd appreciate the clarification. People freaked out when I mentioned sales, in the past. So now, we try to avoid that topic, instead focusing on the technology.

But then when I point out actual tech detail, the immediate fallback is the childish obsession with more EV being better... preventing virtually any discussion about the engineering itself.

I'm not sure how Toyota could be looked upon as dragging. We've clearly seen wide-scale adoption of lithium batteries. The regular Prius uses it in all but the Eco model. Prime will obviously be exclusive to lithium. That's a lot of cells being produced. We've also seen refinements to the motors, controllers, and software. There will be an industry leading vapor-injected heat-pump as well. How could that possibly be considered huge mistakes?

As for creeping, we always knew cost & battery improvements would bring all automakers to a similar place. GM took the low-volume, high-cost route. Toyota is taking the high-volume, low-cost route. Hyundai will be attempting to pass Toyota on the same route. Ford, Honda, Chrysler, and VW are working for something in the middle. It's a mix of approaches.

4-27-2016 **Seems Like.** Perspectives are changing. There is still a bit of attitude though: *"Hybrids have been around a long time, particularly with Toyota in the Highlander, while good, totally seems like OLD TECH at this point when compared to a plug in that can potentially virtually eliminate most gas usage."* Fortunately, dealing with it without ruffling feathers has been surprisingly effective:

That "seems like" is the greenwashing mindset being passed around. Until recently, it was difficult to prove otherwise. Now, it's pretty easy. The upcoming Prius Prime shows that the supposed "old tech" is really a market-ready platform to support plugging in. Toyota added a clutch to the existing system, allowing it to completely disengage the gas-engine for pure EV driving while at the same time increasing power output by allowing the 2 electric-motors to work in tandem.

The initial popularity of the RAV4 hybrid rolled out just a few months ago provides a good indication that Toyota is positioning to be able to quickly join the plug-in hybrid market for small SUVs as the other automakers begin their rollouts. For now, there are just many announcements... all with the same question of how much will people have to pay to get one.

It's a slow process. We've seen how popular Outlander has been in Europe, yet still hasn't been made available here. Both battery cost & capacity are major hurdles to deal with. Having a good hybrid already drawing interest and proving HV efficiency (for when the plug-supplied electricity runs out) is a good place to be when the sales opportunity finally arrives.

4-27-2016 **Looking Better.** Today's discussion topic was about upcoming high-efficiency SUV choices. I saw the opportunity to point out some history on the topic. Since it was on what had been the daily blog for Volt, there was an audience with strong favor for GM. My providing of a half-dozen links to articles of the past got a positive reception. No more butting heads! They are actually reading what I share. Supposedly, it has to do with the way in which I present the information now. You be the judge of that: GM began plug-in hybrid research for the small SUV (specifically with Saturn Vue) before Volt. It was the next logical step with the large Two-Mode system. We even got prototypes. When the bankruptcy hit and Saturn was disbanded, focus was turned to Equinox instead... but fell on deaf ears due to the gen-1 Volt struggle. Seeing that gen-2 of Volt isn't taking the market by storm as hoped either, finally looking at Equinox as a diversification opportunity would be great. It's the technology Volt enthusiasts praise, rather than an attachment to the vehicle itself, right? Pushing GM for Equinox as the next Voltec offering makes a lot of sense.

- 4-28-2016** **200-Mile Choices.** Today, got an announcement from Ford stating intentions to deliver an EV offering a 200-mile range within the next few years. Yesterday, we got the same from Hyundai. It's interesting to read those. There's little to no value in what they claim. We've seen broken promises and long delays in the past. What makes this any different? I'm curious because Toyota doesn't play that game. Withholding information about plans is their approach. Just look at what happened with Prius PHV. When production of it ended, some attempted to greenwash by saying the program had come to an end entirely. Toyota kept quiet anyway. A few people, like me, pointed out that pattern and stated how a much nicer plug-in hybrid coming later would be reason for those actions. They dismissed what I said. When Prime was revealed, I was vindicated. It's hard to believe people would just make up stuff and disregard observations of the past. Oh well. Even though there is little in the form of realistic expectations, the excitement stirred from such announcements at least helps to change the mindset. It helps push the market along. People will hear about the shift away from gas and toward electricity. That's enough when they aren't even looking to purchase a new vehicle anytime soon.
- 4-29-2016** **Surprise.** I was able to post a correct and not have to deal with backlash. In fact, I didn't even get any negative votes. They were actually positive! This is what got me going: *"Your math is wrong, because 400,000 reservations will not be the same in sales. There were over 150,000 sign-ins (not "reservations") interested for the Volt, but less than than in sales after the 2011 Chevy Volt arrived."* There's a natural sense of defensiveness toward Tesla. The strong interest in Model 3 has put Bolt in a very awkward position. Seeing a rather blatant lie being posted in response got me wondering. Did he make up that number in his mind to soften the blow? Impact from such an event can really hurt. After all, Volt has failed to draw interest twice. This particular enthusiast has put his third hope from GM on Bolt. That's isn't going well. I did some searches. The final count came up over and over again. Those old cached pages easily confirmed the final tally I had remembered. So, I posted a reply: 55,819 was the official number at the time of rollout, which was reasonably close to the annual goal of 60,000 sales. Not sure where that supposed higher count came from. But what needs to be pointed out is many of those reservations were placed long before details of the vehicle itself were actually released. Many became disenchanted upon finding EV range was lower, HV efficiency was lower, and price was much higher than anticipated. There was no way to remove your name from the count either. But since it was a no obligation sign-up anyway (no money down, no dealer contact) it didn't matter anyway. The point is, math has nothing to do with the situation. Recalling the past accurately is. Sorry, but I get a lot of grief for not including detail. So, turn-around is fair play. We're all trying to make plugging in work. That means learning from the past. To be totally fair, it can be pointed out that Volt had limited availability that first year. This is why the sales rate (5,000 monthly) was targeted for the end of the second year. It allowed time for ramping up production, educating dealers & salespeople, along with informing consumers.

4-29-2016 **Change.** It sure is nice reading stuff like this now: "*Hopefully GM's strategy to use Voltec components for non-plug-in hybrids is part of getting the economy of scale where it needs to be for a much broader rollout of Voltec-based hybrids and EREVs.*" I actually get positive votes from my responses too:

That would seem reasonable. Though, I still get a lot of pushback from pointing out the very same thing for Toyota. That double-standard is quite annoying... but not deterring.

I will continue to point out the benefits of the no-plug hybrids helping to ramp up production of lithium battery cells. It's hard to believe how incredibly smug some people were last year about Prius using "*outdated*" battery tech, even though they had advanced. Disregarding the fact that the larger Prius (7-seat model) and Prius PHV (plug-in model) already used lithium could have been considered greenwashing. It was most definitely misleading, especially since we all knew the gen-4 reveal was only a few weeks away. And sure enough, we found out it use lithium too. The "*outdated*" commercial abruptly halted as a result.

We need to be constructive in our discussions. Improvements to motor efficiency, control software, and cabin-comfort technology will be beneficial to for any vehicle using a battery. We'll see the chemistry in the battery itself continue to be refined too. Ordinary hybrids help that process along. Hybrids will plugs benefit from it.

Looking back, I find it astounding that so many fought against diversification. They truly believed that call for more choices was actually an effort to undermine, that somehow additional models would dilute Volt interest. Ugh. Thank goodness we've moved beyond such a fearful belief.

I'm really looking forward to what this next year brings. Prime is obviously where my strongest endorsement will go, since its smaller capacity is an obvious effort to keep costs low enough for reaching mainstream consumers without tax-credit help.

I'm all for the long-range EV offerings (very large battery-packs) too. Being able to drive from the cities here all the way up to our vacation destination in the north with just a single charge would be great. I can envision people feeling comfortable with that in the not-too-distant future. So, hearing about Hyundai & Ford planning to join in with 200-mile offerings is very encouraging news.

4-29-2016 **Denial.** I'm enjoying this chapter's end. There are attempts at rewriting history. It's all that's left. There no reason to bother pointing out what actually happened. I started to, then saw it was just a waste of time. No one else would care. No one is listening anymore. It's over. Comments made at this point only support the denial. Those few are quite alone. So, I didn't actually post a response to this: "*Nobody fought diversification. They just didn't want a PiP version of the Volt, one with only 6/11 electric miles.*" My for confirmation didn't turn up anything. I hadn't ever heard that before... but wondered if there had been a misunderstanding blown so far out of proportion, it took until now to find out he had been fighting a false belief all these years. Nothing supported his claim though. He's been irrational before. But rather than be hypocritical, he was likely just trying to make up an excuse to justify his behavior. I didn't want to contribute to that, so my comments never made it to the thread: I just did some searches. From 2008 to 2014, there were fierce battles against a Volt offering anything less than a "40 mile" range. Following that, the topic of a "lite" model finally started to get some traction. The discussions sighted 25 to 30 miles of EV range. At no time was there any mention of 6/11 miles. It was brought up many, many times how the next PiP would offer increased for EV driving (due to lithium cost dropping). In fact, the resulting power increase due to the larger capacity was even discussed. Your claim has no merit.

4-30-2016 **Constructive Discussion.** The sense of moving on is becoming easier to see. There was from an interview with a Toyota executive about Prime. It was article published by an automotive enthusiast magazine. This came about today in response to that: *"If someone was looking for a commuter only car, wouldn't a BEV be a better fit? Sure it won't likely work for those occasional trips, but if a person wants a PHEV for that, they probably want more space for luggage and passengers."* It was constructive! I was happy to join into that discussion:

What's been confirmed long ago and has continued to stand true for years is there's no such thing as an *"only"* car. It was absurd to claim that the sole purpose for purchasing a Prius was just for the sake of MPG. Yet, countless people have tried and continue to. Thankfully, their arguments always fall apart in the end. It's like trying to justify the purchase of a SUV for commuting.

Prius strikes a balance, striving to be a good all-around vehicle... which is why so many have purchased it. Prime will be attempting to deliver the same thing, but with a plug. You'll get the full EV experience for a limited duration, enough to cover some commutes and to cover running errands nearby. You'll still get the large cargo area. You'll still get the outstanding MPG.

So far, the range comments coming from Volt enthusiasts have had a childish approach. That *"more is better"* claim has resulted in a smug attitude and an unwillingness to actually address detail. They set a terrible precedent, tarnishing the work genuine supporters worked so hard to establish. That's really unfortunate when having a goal of getting people to choose a vehicle with a plug.

As for the spin about more passengers, I particularly like this question from the article: *"Did the fact that General Motors reached the opposite conclusion with the Chevrolet Volt, adding a fifth seat to the new generation, give you any pause?"* It was an obvious provoke for comment, not real journalism. Anyone who has seen the gen-2 Volt knows it really doesn't offer a fifth seat. Only a young child could actually fit in that legless spot. Yet, we hear defenders vaguely claim Volt has seating for 5 and Prime only 4. Ugh. The nonsense we have to deal with...

At the end of the day, it doesn't matter. We've seen an abandonment of Volt recently. Those enthusiasts have turned attention to Bolt and rapid interest growth toward 200-mile EV offerings. That opens up opportunity for plug-in hybrids designed to target ordinary consumers. Prime clearly has a goal of mainstream sales. It may take a few tweaks along the way, but that's the nature of attempting to draw interest from an emerging market.

We've seen this before. Remember the size emphasis with Two-Mode? Remember the power emphasis with Accord? How is an emphasis on range any different? There's a careful balance required to attract buyers. Cost & Efficiency tradeoffs hurt. With range, the additional EV capacity requires a sacrifice of size & weight. Toyota is attempting to deliver the right amount. After all, there are millions of Prius owner who have been pleased with roughly 2 miles of EV. Giving them roughly 10 times more is quite an upgrade.

4-30-2016 **Frenzy.** I particularly liked this question: "*They'd love to have Tesla-like frenzy for the Volt and Bolt.*" With GM fighting legislative efforts to prevent direct sales in Connecticut and 5 other states already requiring franchise dealerships, you know the situation isn't going to be pretty. With Volt basically having been abandoned in favor of ramping up both Bolt interest and actual production, we need to ask what GM actually intends. What kind of sales should we expect? Seeing I actually get somewhat constructive answers to questions now, I asked: What would stimulate that level of interest? The major hurdle to overcome is battery-cost. Seeing a substantial drop means a benefit for all automakers. That is likely what will happen too. Looking for distinct advantage for high-volume sustainability means the ability to earn profit without the help of tax-credits. Because when they are gone, the competition of traditional vehicles reaching out to attract the same consumers becomes a very real problem. That's why pack-size and battery-chemistry is such a big deal. Automakers like Nissan & Toyota have been working hard to not require liquid cooling. That's a cost, weight, and size expense with potential to be able to avoid. Tesla has worked hard to reduce packing overhead, by combining cells in a more compact manner to avoid those expenses. Notice how new topics, use of aluminum & carbon-fiber and heater efficiency, are now being discussed? In other words, we are beginning to see next-generation upgrades aimed at addressing how to still draw sales once all the low-hanging fruit (early adopters purchases) have been picked. It won't be as simple as listing EV range and MPG values going forward.

5-01-2016 **Who 2016?** It's exciting to see how the question is still applies so well after all this time. It's becoming more relevant as people begin to grasp the magnitude of scope beyond what the gen-1 models targeted... actual, not rhetoric. This was the latest: "*With the Prime, Toyota seems to be saying that PHEVs aren't for families.*" Prior to 2016, we couldn't even address the topic. Nobody cared. But then again, the audience for Prius PHV was far smaller than what GM had attempted to entice for Volt. Things are different now... and I'm pleased to point out why: Apparently, you missed that there were several different discussions all talking about Prime being an option for the families who grew up with a Prius. Their children are older and a middle faux seat wouldn't serve any purpose anyway. The bucket seats, storage area with USB, convenient cupholders, and possibly heated seats would be far more appealing to the older children. Why do you think I got on enthusiasts so hard asking the "*Who is the market for Volt?*" question. There was a lesson to be learned for all of us going forward. GM made a colossal mistake of not knowing their audience and those Volt enthusiasts made that worse by endorsing it. The early adopters were assumed to be representative of ordinary mainstream consumers. They couldn't have been more wrong. A group of us tried to show how Prius success came from Toyota not giving in to emphasis on any particular trait, instead working really hard to find a balance... which was a clear effort to match consumer interest. Understanding the difference between want & need is a challenge in ordinary conditions. The crazy, rapidly changing, demand for clean & efficiency vehicles we currently face makes it even more difficult. I see Toyota's willingness to try new approaches by diversifying the Prius options even more as a genuine effort to push deeper into a stubborn market perfectly content sticking with traditional guzzlers. Change doesn't come easy. Taking some level of risk, without sacrificing cost, is required.

5-02-2016 **After All This Time.** It truly amazes me how much certain individuals just plain don't understand the difference between want & need. You'd think after all this time, they'd finally figure it out. The problem typical comes down to not being able to distinguish between their own perspective and what's required of the point community. They'll over-generalize, pointing out factors of appeal and provide examples of extremes. Today, it was all about the need to drive at 85 mph and climb up mountains at highway speeds. That just plain is not realistic for some of us. Where is the legal limit that fast? My guess is select areas around the United States. That's it. Same goes for mountains. Here in Minnesota, we have neither. The fastest speed is 70 mph and there are only 2 high-speed climbs, one in the north and one along the south-east border. In other words, some owners would never encounter those situations. Heck, the drives out to Wyoming this year were at 80 mph and had some small, steep climbs... neither of which were a big deal. Why is there a supposed need for more? The excuse is: "*Cars aren't sold based on need. Most cars are sold based on want.*" That's a crock. True, there is a portion of the population that desires more and have the ability to actually purchase it. For the majority (that's the mainstream) though, it's not the case. Most people carefully weigh options, choosing a few luxuries to features... but rarely actually just giving in to want. There isn't an indulgence. We seek out reliable, affordable, practical transportation. The reason for the false belief about want is simply not seeing. Those reliable, affordable, practical vehicles aren't even acknowledged. That's why enthusiast magazines pretty much never review ordinary vehicles... like Corolla or Camry. They dismiss them as boring appliances... which is why they aren't accounted for by the antagonists online either. See how confusing matters get? It should be simple. We should all recognize the necessity for clean & efficient vehicles. Unfortunately, some don't. Some call that a want. They don't see the need to end oil dependency, reduce smog-related emissions, or face climate-change. That's too. Fortunately for me, I don't need to waste time on them anymore. The next chapter has begun!

5-02-2016 **Bottom Line.** This is definitive proof of having started the next chapter: "*Issue is the bottom line. Hype, innovation, buzz, perception are GREAT, but profit keeps the lights on.*" That's clear confirmation of things having changed. With gen-1 of Volt being stuck as just a niche, any discussion of business was quickly subdued. That's why even a mere mention of Prius set enthusiasts into a tizzy. The complete absence of objectivity was a dead giveaway of challenges to come. Now that we've arrived at that point, things are getting rather interesting. That greenwashing claims of Toyota not being interested in EV support have come to an abrupt stop. It shows how childish & petty some will be when focus is so narrow. Of course, there's still the reality of the tax-credit limitation not being addressed. At least there's some progress. The bottom line is very important.

- 5-02-2016** **BMW i3.** I still remember the hostility that erupted upon the rollout of Ford's first Energi offering. It was the C-Max plug-in. That wrecked all arguments, making many look guilty of mindless defensive posts. The behavior is typical. That's one of the stage of grief, what you have to deal with upon being faced with major change. Anywho, the claim that I was simply a Toyota fanboi, promoting Prius by any manner possible. Giving an endorsement to Ford proved that wasn't true. That group of antagonists had been exposed and they didn't like it at all. Ford's new addition to the market damaged much of what had been claimed about Volt to make it unique. There wasn't a distinctiveness anymore. Fast-Forward a number years, the situation becomes profoundly worse. BMW's rollout of i3 was everything Volt strived to be, but failed to actually deliver... which hurts... so much so, that no matter how the information presented, they won't like it. I remember why GM set those specific goals. There's nothing wrong with changing them. After all, the point is to remain flexible. But if that change doesn't achieve improved results, you've got a very real problem. In fact, you're even worse off at that point. That's where Volt is today with the announcement of a mid-cycle upgrade from BMW. The improvement to i3 will increase EV range from 81 miles to 114 miles. That's a huge improvement. It leaves Volt in a very awkward position too. Enthusiasts belittle Prime for offering less than half the range of Volt. Now, they find themselves at the other end of such a comment. i3 delivers twice the range. That forces the issue of what's actually needed. If you have enough capacity to cover all your daily driving, why the heck carry around a full-power gas-engine? It simply makes no such for supposed "EREV" purpose. That engine had been promoted as a backup, just in case. BMW delivered precisely that. (Note that the i3 gas tank was 1.9 gallons; this upgrade will increase it to 2.4 gallons.) In other words, it's very easy to argue that Volt is carrying around a lot of unnecessary weight... the same argument Volt enthusiasts had used against Prius PHV in the past. So basically, the market is beginning to settle by pushing out the designs that don't work well for the masses. That's why we continue to ask: *Who?*
- 5-03-2016** **Not Yet.** Sales results for April sure did raise a hubbub. You'd think the rose-colored glasses would come off. Clearly, not yet. The best thing to do when reality hasn't come crashing down, but it inevitably will, is to finally just acknowledge it. If some don't want to, post a provoke. There's nothing like wasting resources on a futile endeavor. Get it over with. Geez! Sadly, that means having to recognize the fact that there's still a superiority complex at play. Rather than unite the effort of plug-in vehicles as a common cause against the reign of traditional vehicles, a few still absolutely insist Volt is better than all else. Ugh. That's why it gets so much attention. Why an opposing force would come about and be so counter-productive is beyond me. Most failed attempts are simply written off and the next tried. Toyota faced challenges with Prius PHV. Even though the market said they needed a "*plug-in hybrid*", that isn't actually wanted. So with the increase in power as a result of the growing battery-pack (a normal expectation for a generational improvement) came a simply enhancement to the system to make it deliver more EV. Again, this is yet another denial issue from Volt enthusiasts. (They claimed this would be possible.) So... I let them have it with some cold hard facts: It will leap-frog... the competition. Not yet. 21,763 - Malibu. 20,607 - Equinox. 14,153 - Cruze. 1,983 - Volt. With gen-1 offerings, the argument could be made that "*competition*" meant other plug-in vehicles. Not so with gen-2. They need to find a way to draw sales from the showroom floor during their product-cycle. Looking at those results for April, much needs to be achieved in the next few years.

- 5-04-2016** **The Point.** I asked this: Wasn't the point of gen-2 Volt to overcome that barrier? You don't even need to know what I was referring to when you read the response: "*No. The point of the Gen II Volt was (in addition to turning in sales at least commensurate with the previous Gen), to showcase the new drive system which could be adapted to many other models as Plug In, EREV and Hybrid; the Volt representing it's ultimate expression.*" It was a question of sales. The slow growth is becoming a disappointing reality. That's why so many have shifted focus over to Bolt instead. That's also why I push for answers... like, who? It's maddening to think so much time was wasted and so much damage to the market occurred as a result of the floundering. Oh well. At least it's over now.
- 5-04-2016** **Competitive Sales.** The pattern is repeating. Those same old excuses for flat sales are emerging again. There's no sense addressing them. That didn't work in the past, why would it now? Sales of Volt continue to struggle. That's a fact. Heck, it's a fact with Prius too. Those sales are flat as well; however, they are considerably higher. 8,923 is clearly more than 1,983. The interesting peek into the bigger picture is looking at RAV4 hybrid sales. 3,807 for the first month of full availability is a strong showing. Anywho, I needed a new way to present some perspective. This is what I used: "*The Leaf (and the new longer range BMW i3) are in trouble with the Bolt EV and Model 3 out in the public eye now. When you can get a 200 mile range BEV for \$30-something, who is going to spend it on a 100 mile BEV instead?*" His arbitrary dismissal of BMW's offering is what got my attention. Eliminating i3 but not Volt simply doesn't make sense. I wondered why... and really wanted to know what kind of response I'd get with this new way of looking at sales. So, I asked: What will happen to Volt? Remember, it's not just the other automaker offerings attempting to attract buyers. There is also the reality of showroom floors diverting GM customers elsewhere. That's how so many opportunities for Volt have been lost to Malibu, Cruze, and Equinox. Also, don't forget that the phase-out of tax-credits will have an impact a year or two later, putting a lot of pressure on dealing with high-cost quickly to remain competitive.

5-05-2016 **Shoppers.** I wonder how long this will have to be dealt with: "*Just pointing out that the Prime will be successful because of brand loyalty is not something to count on with it comes to plug-in shoppers.*" The thought is we'll be at the mercy of spin for several months still. The craziness with Model 3 will die down at some point. For now, we're getting a lot of hype from Bolt as a result. That's to be expected. I find it odd that 2 such profoundly different vehicles are considered to be competitors anyway. The only thing they really have in common is the 200-mile range; otherwise, each EV is quite unique. Whatever the case, it's a distraction. Toyota will wait it out. Patience is a requirement anyway. Prime will offer only a little more than one-tenth that range, but it will come with an engine that will deliver remarkable efficiency for when you use up the plug-supplied electricity. It's a great bridge away from traditional vehicles, offering a step beyond just getting a hybrid, but not requiring a full commitment. You'd think those online now would understand that. Unfortunately, many either don't understand or refuse to accept the fact that audience won't be the same. This gen-2 will target a new market. These buyers won't be the same... regardless of how convinced they are that goals this time have changes. Whatever. All I can do is try to point that out: Plug-In shoppers aren't the target market of Prime. That stage is over. Those early adopters have made their purchases already. The chapter in history just starting is the reach out to mainstream consumers. That's why Prime is configured differently, not following the gen-1 approach.

5-05-2016 **Misguided.** Understanding change isn't coming easy for some: "*Targeting mainstream buyers with a less-mainstream configuration (four seat), however, seems rather misguided, even if it will work fine for many.*" True, it is challenging to alter perspective. But why wouldn't you believe that things won't be the same over time? We've witnessed the popularity of vehicle styles come and go. Why is it so difficult to accept that the middle seat isn't practical? Heck, even I eventually accepted the arguments of Volt supporters claiming the middle wasn't necessary. Of course, I get labeled as a hypocrite for doing that. But then again, I'd get labeled as a Toyota fanboi for not. It's a no-win situation. To make matters worse, quotes are taken out of context. They don't care that you also included the need for increased leg & head room. They don't care that endorsed the technology for a second model either. All the antagonists care about is winning an argument. That sacrifice the war for the sake of a battle is preposterous. Yet, it happens on a regular basis. All I can say is: Prius taught us that following the status quo can be misguided. It was literally the only midsize hatchback available back in 2003. Look at how many followed suit as a result of not following traditional expectations.

- 5-05-2016** **Only Hearing.** It's the old problem of only hearing what you want: "*I think you have missed Toyota's claims that the four seats in the Mirai and Prime are to take the cars more 'upscale', 'luxurious', and 'distinctive', not about them being the next family car.*" I'm tired of dealing with this one particular individual on the big Prius forum. His perspective is that of absolutes & extremes. There's no sense of balance. That contributes to lots of conflict. Others feed his desire to discuss. After all, he is well informed. But then again, he choose to only respond to what brings about more posts. Allowing the means to find an end simply doesn't happen. Combine that with some newbies, the threads can go on forever. I dealt with today's problem this way: No, I heard & understood the rest of what was said. You can't just refer to part of it. When a family grows up (no more car-seats or juice-boxes), that's what they'll purchase. Why not transport the kids to soccer practice in a nicer vehicle?
- 5-05-2016** **Potential.** It's refreshing to read this for a change: "*The Prime has a potential market for folks who want a Toyota class reliable car and a PHEV. Toyota may not be wowing folks with EV range, but quite a few buyers want reliability first, whether it is EV or ICE providing the assurance of getting there.*" Too bad ordinary consumers don't participant in online discussions. Yes, I realize that's a direct conflict. You cannot be ordinary, yet do out of the ordinary stuff. Think about the over 14 million new vehicle purchases here alone each year. How many of those buyers ever post even a single message in an online forum or blog about their intended purchase? We're clearly not representative of the mainstream. I suspect many of the Prime buyers will come from in-person shopping, based upon a few mentions they came across prior to going to the dealer. Some will stumble across an article. Some will search online for reviews. Some will make the discovery at a dealer. Some will hear about it via word of mouth. Some will encounter one on the road or in a parking lot. There is potential for Prime. Prius is already known enough to have a reputation of being a good buy. It's reputation and practical nature tends to sell itself. Just imagine what the test-drive experience will do. This is the common person's plug-in hybrid we've been waiting and waiting and waiting for. Yes. I know. All good things...

5-05-2016 Quick Sale. I couldn't resist added more to this post: *"Just pointing out that the Prime will be successful because of brand loyalty is not something to count on with it comes to plug-in shoppers."* This had to be said: It will be successful, but not for the reason you presume. For that matter, it won't be who you presume either. Plug-In shoppers are not the focus of Prime. True, the configuration will be appealing, but they aren't who it was designed for. Those shoppers will carefully weigh a variety of traits & specs of the vehicle, researching in great detail and calculating performance expectations. Since they are determined to purchase a plug-in vehicle one way or another, they are far more willing to accept greater expense & tradeoff. That's an elite group. In no way do they represent the majority. Ordinary consumers don't participate in online discussions, download resource material, or even read automotive publications. They go to the dealer and look around. They succumb to the "endearment effect" from the salesperson convincing them to touch & drive, often resulting in an impulse purchase. That's the way mainstream buyers do business. No matter how much an enthusiast praises a vehicle, it means nothing loyal customer simply shopping the showroom floor. Salespeople want a quick sale, without having to answer many questions or convince... For example, the ability for Prime to completely recharge in 5.5 hours using just an ordinary 120-volt household outlet is easy to understand & embrace. Think about how much of a challenge the sale will be for Volt in comparison. It takes 13 hours. If you have to leave for work at 7:30 in the morning, charging must start at 6:30 the evening before. If you have any night life whatsoever, you're screwed. Explaining to the customer what it takes and how much it will cost to get a level-2 charger won't be simple. That lack of intimidation is quite powerful. It's enough to get the customer walking around at the dealer to take a closer look. That's where those 'upscale', 'luxurious', and 'distinctive' features come in. No amount of enthusiast scoff at the supposed limited range will change that. In fact, those customers won't even be aware of any of that rhetoric. The salesperson will offer a test-drive opportunity. They'll take a spin around the block in EV, then ask where to sign. Quick sale achieved. Put another way, Toyota's target audience for Prime is not plug-in shoppers.

5-05-2016 Average Consumer. What do you say when a friend posts this: *"Prime has no shot at being successful. But it depends on how you define success. It might be a player in the PHEV market, but will never capture the average consumer."* Obviously, I wanted clarification and insight. What brought about that opinion? So, I gave this a try: Let's discuss who the "average consumer" is. I would suspect pretty much everyone assumes the same thing, a person looking to purchase a Toyota car... like Camry or Corolla. We keep ignoring the truck market, the pickups and SUVs. Do you really think Toyota will never do anything to attempt to draw those who went from a car to a truck back to a car? Saying they will "never capture" is a bit of a stretch. Why did they switch to a truck in the first place. With Prius Prime, there's a chance of coming back. It's a vehicle that doesn't represent what they tried to get a way from years ago. Think about it. Offering something completely unique has potential. These are customers who would be paying more for their new vehicle purchase anyway. Prime provides a means to switch back to a more efficient means of transport. It's also a heck of an effective way to lower impact to the environment, without requiring a paradigm shift. Addressing the fleet as a whole can't just be with the expectation of people purchase a plug-in version of the vehicle they currently drive. The hope is it will be a relatively easy jump from Camry or Corolla, but how do you get people to take the bigger step away from the big guzzlers?

- 5-06-2016** **Ironically.** You gotta love reading this: "*Given Toyota's hesitancy to promote EVs, I don't have high hopes they will put much effort into this.*" It came from an EV owner who's been really, really hard on Toyota under the belief they are only in favor of hybrids & hydrogen. No matter how much evidence I'd provide to the contrary, he just plain didn't see anything beyond a polarized outlook. One extreme or the other was his stance, no in between. That was annoying. I attempted many times to point out the middle target, Toyota's quest for balance. He just plain wouldn't acknowledge it. In his mind, unless Toyota delivers something to compete with Tesla, the automaker wasn't interested in anything offering a plug. So, when the end of PHV production happened, his anger blinded any sense of reason remaining. It was unfortunate. Now, there's the reveal of Prime to deal with. That confirms what I've been saying all along... which obviously wasn't enough. So, I conveyed the message yet again... but this time with a little attitude: Ironically, the reason for being hesitant to promote was due to Prime. Why promote EV when you are busy developing a PHEV with the hope that will stir mainstream consumer interest?
- 5-06-2016** **Some.** What other response can you give to this other than, ugh: "*Do you honestly expect truck/SUV drivers to convert to the Prime??*" It was from another of those who likes to stir the pot. He asks the same questions over and over again. That's annoying, since he clearly doesn't like the answers and hopes for something different. He also enjoys the discussions. He's polite and doesn't try to provoke. He just won't accept what you say either. I did anyway: Your perspective of absolutes continues to make discussion challenging. I'll give it a try though. Yes, I expect **SOME** will. It's human nature to seek out something different eventually. Financial, Family, and Work circumstances change over time. Having something new to choose from is what Toyota will be offering. Don't forget, not everyone has truck/luxury money to use indefinitely. We've already heard Prime being referred to as the "*common man's Tesla*". Think about how Toyota will adapt packages based upon how buyer preference patterns emerge.
- 5-06-2016** **Test Drive.** Sometimes, it's easy. All I had to do was agree and suggest a new thought: Yes, there are a large number who don't have the need for transporting more than 4 people. There is also the group of people who shop based on the test-drive experience. Think about how little the salesperson has to do if they are smart enough to keep the battery-pack topped off.

- 5-07-2016** **Anti-EV.** I reposted the "*hesitancy to promote EVs*" comment again, requesting a response. In other words, I provided a polite advanced warning that I'm about to turn on him... quite hard, if he doesn't speak up. All that impatience we had to deal with... for what? He absolutely refuse to acknowledge the possibility that Toyota's indifference was really smart marketing. Why in the world would Toyota undermine itself by revealing intentions well in advance, knowing that it will cause trouble as a result? My guess is he's old school, where the belief is no harm can come from promoting well in advance. Trouble is, with the market evolving so fast, it is now more important than ever to remain flexible. What still leaves me wondering is how he fell into the trap of not seeing it as necessary. He's not alone. Like many of the others I have butted heads with, they understand the engineering well. It's just when it comes to the business aspect, that comes up short. Perhaps more of the big picture will sink in over time. I'm hoping to accelerate that progress. Having been able to become friends with other foes of the past, there is a reasonable hope that could happen with him too. His anti-EV belief sure will be a problem going forward otherwise.
- 5-07-2016** **Setting Expectations.** I did: We'll see the building of a foundation (awareness, education, reputation) within the first 2 years, then a big ramp up for the 3rd along with announcements of what comes next. That's the precedent already set. Prime should be no different. The timing works out especially well when the market as a whole is taken into consideration. Like you said, there is fear of the unknown. That's more of a problem than ever with ordinary consumers. We're past the early adopter stage now. That chapter in history is over. Gen-2 plug-in offerings (both PHEV & EV) are what will bridge the gap to mainstream acceptance, when plugging in is a consideration when making purchase decisions. Think about how there is rarely any mention of battery concern now. When it comes to hybrids, the belief of needing to replace the pack at some point is pretty much gone. These gen-2 vehicles will demonstrate the batteries are up to the chore. We'll get to some tipping point with consumer confidence. That takes awhile. In the meantime, there must be a scramble to figure out how to reduce cost enough to make the design capable of high-volume profitable sales without tax-credit help. It must be able to compete with traditional vehicles directly. That is absolutely vital... and still not being taken seriously by some. We can help with the awareness, education, and reputation. Lots of real-world data and focusing on the true competition is what it will take.

5-07-2016 **What Prevented?** Is it worth the bother answer this, yet again: "*What prevented Toyota from doing so with the PiP?*" It came from a well known antagonist. He's quite open about his provokes too. That's quite irritating. It does provide an invitation to post certain things though. So, I took advantage of the opportunity, one last time: Ugh. We've been over this literally dozens of times already... It simply made no sense spending time & resources on a platform to be replaced by a much improved next generation. Do you have any idea how much work that is in the first place? Then, you'd have to spend extra time & resources afterward to re-educate. We all know how outdated information gets used for greenwashing too. Intentionally contributing to that makes a challenging effort even harder. The answer to the question should be obvious: PRIME What's sad is the answer was provided way back when PHV production ended. Those who didn't believe that to be the case made up some other reason. Heck, some even shot the messenger. The catch is, that still doesn't change the answer. From Toyota's standpoint, they were well into finalizing the design. There was nothing to gain, but much to risk & waste, by saying anything. So, they didn't. Toyota was well aware of what Prime would deliver. They gathered as much data as possible from the initial limited PHV rollout, just like they did with the Classic model. They then took what they learned and prepared to capture the hearts (and wallets) of ordinary consumers. This isn't rocket science. It's basic accounting, marketing, and economics. We'll see this Fall how well that preparation was. In the meantime, if the same questions of why get asked anymore, I'll post a bookmark to this message. Repeating the same thing over and over is getting old.

5-08-2016 **Sobering Facts.** How much is big enough? The difference between want and need is quite vast when asking that question. That's what we've been doing. It was best put with: "*As long as we are crying in our beer (or wine or water), here are some sobering facts...*" We were discussing the reality of the entire market. That big picture can be very disenchanting. To think of how little got accomplished in terms of count alone. Sigh. Thankfully, some of the biggest hurdles are among the first. It really does get easier as things progress. We're not there yet, but there is reason for encouragement. I explained the situation with: That's why I have confidence in Toyota's approach. It seems disappointing to take the perceived slower route (by offering just 8.8 kWh), but the reason for that approach in the past has been with the intent to keep cost in check. How is this time any different? The wait for battery tech to improve takes generations. We don't have that kind of time (or patience). Keeping the pack small is how to reach more customers. After all, we've seen that business-model be extremely successful in the computer industry with respect to expanding reach of new technology, why not with the automotive industry too? As the EV owners have stated, you want more once you've experienced it. That just plain isn't realistic for many budgets. Some people don't need mega-capacity either. I've been recharging at work... which provides a simulation of what a 38-mile commute would deliver with the new battery-pack charged only at home. My average is around 125 MPG. What new owner wouldn't be thrilled with results like that? Isn't that what we've been looking forward to since many years ago when the idea of plugging in was limited to just aftermarket upgrades? Upgrading from the PHV to a Prime, just commute average will climb to around 999 MPG. On long trips, I'll get a solid 50 MPG. At a reasonably competitive price, why wouldn't that sell at a decent volume... like half the mainstream minimum to begin with?

- 5-08-2016** **Why?** I had a responsive audience and was on the soapbox already. Time for some more exposition: Speaking of history, a major issue rarely addressed is WHY it was decided to not expand rollout of Prius PHV beyond the initial 15 states. Sure, there are some who bring up the topic, but it's always to complain rather than actually be constructive. They absolutely refuse to acknowledge what the cost was for lithium batteries and how modest the reception was to other plug-in offerings. Why do more in a market not ready yet? It made good business sense to just stick with the existing customer base, watching those others attempt to overcome their obstacles before joining in and continuing with their own research & development. That provides a great basis for learning, to be better off when rollout resumes. We'll see that next step taken with Prime. In the meantime, consider the struggle Volt and Leaf are currently facing. GM's next generation offering has not taken the market by storm. In fact, it still hasn't even reached the sales rate hoped for years ago. Nissan faces growing competition and is watching sale of the outdated generation slip. Toyota's offering will provide a modest EV range, but with competitive EV power. We think the price will be reasonably competitive too. The hybrid efficiency will be top-grade. Seating will be comfortable, for 4. Cargo will be much greater than any sedan. Tech options will be compelling. It's a good mix for this time in this market. The hope is having studied history and responded accordingly will show favor. After all, how well are the others doing?
- 5-09-2016** **Raising Doubt.** It's a challenge to figure out why particular people continue to prevent progress. Inattentiveness and the unwillingness to accept is what I see as the most common reason. Whatever the case, stuff like this is annoying: *"I am still trying to figure out how..."* No one else has any trouble understanding, especially after having literally years of the same discussion. It just repeats over and over. I got tired of the nonsense. So, my reply was in the form of questions that ended with some attitude. Whether he likes the answers or not, that's the way it is: How many broken promises have we witnessed over the years? What's wrong with waiting until there's actually something substantial can be delivered? Notice how all the *"Toyota doesn't support lithium"* naysayers have suddenly vanished? There's an obvious desire to keep the discussions going. I've noticed the pattern of the same question being asked by several individuals over and over again. Reality is, Toyota has invested heavily in lithium battery production as well as advancing motor & controller efficiency. They've also introduced an industry-leading heat system. So what if there isn't an EV right away to utilize that. Their other offerings will and they'll be well positioned to rollout when the market is ready. Too bad if you don't like that approach. It's still an investment in electrification.

- 5-10-2016** **Denial.** To my surprise, I got my answer: "*You are delusional. Nobody ever accused Toyota of not supporting lithium.*" There were years and years of posts complaining about how Toyota wanted nothing to do with lithium. The spin was claiming was they were too dangerous for automotive use. Countless times I pointed back to that original presentation that pointed out the reason for disinterest was production cost, the technology was simply too expensive for the vehicle to be profitable. It was frustrating how the contents of that presentation were taken out of context and twisted to make it look like Toyota was afraid. And for him to call me delusional, exclaiming that none of those debates ever too place... Grrr! Needless to say, I was quite upset. His behavior is quite typical. It was clearly an unwillingness to accept change. He discovered he made a mistake and that was his effort to cover it up. Saying that never happened is the expected defense. This is why I like having these personal logs so much. They document what actually happened. Denial like this is how history ends up repeating itself. People convince themselves it simply wasn't possible, that the person pointing it out is incorrect... or in this situation, delusional. Ugh.
- 5-11-2016** **Think About.** It's annoying to read posts starting with this: "*So Toyota was myopic and could only see as far as...*" then going on to end with this: "*That would have really affected sales.*" That came from the other big criticism of the upcoming Prius Prime, the 22-mile EV capacity. Arguments have been that Toyota should have designed a platform able to carry more battery. There's a strong belief of more being better, that twice as much would result in huge demand. It's the very same trap GM fell into with Volt. Fulfilling the daily commute (with complete disregard for any driving other than to & from work) using only electricity is supposedly a necessity. That means it is acceptable for a great deal to be sacrificed to achieve that supposed requirement. I think the pressure to deliver more originates from the feeling of being left behind. It's our polarizing belief that there can only be winners & losers. Simply running a sustainable business is so boring & unappealing, it's not even considered an option. That's why enthusiast publications don't pay any attention to ordinary vehicles like Camry & Corolla, even though those are what a lot of people purchase. Building something for the middle, something that won't stand out isn't given the attention it deserves. Sadly, there isn't much to do about that other than point out the thinks to consider: It would be short-sighted to deliver a design unable to be sold profitably without the tax-credit. I see the effort to share a common platform as attempting to strike a balance to achieve high-volume sustainable sales. Think about the limited number of tax-credits remaining. Think about what happens in just a year or two when the plug-in boom hits. Think about what happens to those dependent upon the subsidy.

5-12-2016 **Family Car.** There's a demographic being overlooked still, those who want a Prius but don't really want a *family* car. That's a lot of people to forget about. I've tried to point out that omission. You'd think such a massive exclusive would get noticed. Turns out, it hasn't been. There has been an obsession online with Prime's lack of a middle seat in back. So far, that's been great publicity for Toyota to draw attention to the fact that a new Prius is on the way. Simply remaining unknown could be a major problem. Volt suffered miserably from that. Enthusiasts desperately cried for GM to promote Volt more, to the point of continuously complaining about the lack of advertisements. They too got obsession... with the wrong thing. Do we really need the 5th seat? That's been thought of as a necessity for purchasing, but all the reasoning has been presented as a want. Having a small spot for squeezing in an extra passenger for short drives is handy. No doubt there. Problem is, that distorts the "*family*" car reach. It implies only families will buy it. That stereotype is harmful. Toyota knows this. They are well aware that DINKS (dual income, no kids) households, people who are single, and people who are retired have interest in a vehicle like Prius too... but don't want the associated reputation for hauling children. Think about how stigmatized the minivan became. Prius was beginning to fall into that same type-casting trap. It should be easy to see that Prime is an effort to diversify. So far, that hasn't been the case... or has it? Offering bucket seating in back rather than the generic bench of a "*family*" car highlights an obvious difference. I've struggled a lot with outspoken daily posters having little to no business backgrounds. That was my minor in college. Besides the accounting classes, I also took economic & marketing classes. No my surprise, those was quite enjoyable. Little did I know back then that the analysis & design studies for my major to become a software developer would be complimented so well. I learned decades ago that engineering skill alone was no where near enough to achieve success. Business is more than just important, it's vital. Know your audience. Recognize the benefits being different can offer. Find a way of offering it without compromising the balance. That's exactly what Toyota is striving for with Prime.

- 5-13-2016** **Change.** If you push, you get labeled as a "troll". If you accept, you get labeled as a "hypocrite". It's a lose-lose situation. No matter what you do, there's no way to win. The situation can be very frustrating. I went through that quite a number of times. What kept me going was the opportunity to witness "*lashing out*" events, those times when an enthusiast is proven to have made an error, then become desperate to justify their position. Rather than join the rest of us, we watch excuse after excuse getting posted. When that eventually fails to get them out of the corner they backed themselves into, the messages turn from reasoning to attacks. They make it personal, posting anything they can think of to draw attention away from them onto you. That fails after awhile too. It gets to the point where we have arrived recently with Volt. The years of personal logs documenting the inevitable downfall have revealed the "*that was the plan all along*" attitude. You must choose to accept the obvious misrepresentation or accept the consequences of staring new pointless battles. The war is over. Nothing can be gained from further engagement... except... learning from that history to prevent it from happening again, again. Remember Two-Mode? They didn't. It's why I could proclaim the inevitability so long ago. I simply recognized the pattern. I look back, reading through my own documentation of what happened in those years long past. I've been able to recognize true change and distinguish it from false hope through seeing those similarities. Notice the complete abandonment of Volt in favor of Bolt? That's exactly what happened with Two-Mode when Volt was introduced. A major effort to "*out Prius*" the competition, at the expense of alienating partners, failed miserably... twice! That's why there was so much resentment toward me. I didn't ever need to say "*I told you this would happen*" for them to act as if I did. Just my presence alone was a painful reminder. Change isn't easy. Hearing about its need can be inspirational for some and painful challenge for others. The key in both is a persistent effort and a clear understanding of goals.
- 5-14-2016** **Yeah!** It's so rewarding to come across an ordinary post like this: "*I drive 100% in the NORMAL mode now. There was no difference between the first month in ECO, and the second month in Normal. And my car seems to perform better in NORMAL.*" It was from new owner trying to figure out what his new Prius has to offer. I joined into the discussion with: ECO provides a gain for temperatures on both ends, not in the middle as you have been experiencing. In the north, during true winter driving (daily highs under freezing), there's a noticeable improvement. ECO alters the coolant threshold, directly affecting when the engine runs for the sake of providing occupant warming heat. ECO also has an influence over the A/C system for occupant cooling. Keep in mind with a new vehicle, there's an efficiency influence caused by break-in. Your observation of ECO first, then NORMAL, could have had a cancel-out effect. In other words, anecdotal observations present challenges. If you want to learn detail about how the hybrid system operates, purchase an aftermarket device. There's a wealth of information available through the OBD-II port. You can watch a wide variety of quantitative data using your smart-phone or a dedicated reader. Simple things like RPM and temperature of the coolant can tell you quite a bit about how Prius achieves such great efficiency while also maintaining an impressive level of emission-reduction.

- 5-14-2016** **Caught Greenwashing.** This particular individual comes on the big Prius forum to promote Volt. That purpose is obvious. He freely admits his loyalty. The catch is, his messages are posted with the intent to mislead. I caught him greenwashing today with this: "*The Volt hasn't suffered the same range degradation as the Leaf, I think largely because it's liquid cooled as opposed to air cooled that the Leaf uses.*" I was pleased to respond to his deception. My guess is he won't, instead, choosing to just ignore it and hope the attempt is buried by other posts. I won't forget. It's easy to look up those quotes later. That's handy when you want to reveal the greenwashing. The pattern of attempts without responses upon being caught speaks for itself. My post was: That's a misrepresentation of battery-management. Cooling is only part of the equation. A factor that's actually more significant is the SOC (state-of-charge) usage limits. Avoiding recharge levels too high and depletion levels too low really makes a difference. GM set Volt's at 87% for the high and 22% for the low. Nissan set Leaf's at 95% for the high and 2% for the low. That choice to push the battery so much harder has proven to have significant consequence... something you failed to mention. We really need to make an effort to not spread incomplete information like that. By the way, the choice for Toyota with Prius PHV was to set the high at 85% and the low at 23.1%.
- 5-14-2016** **New Approach.** The topic of style is interesting. It hasn't been given much attention in the past. Prius was so different, it stood out. That was the end of discussion. No depth ever came about. Style posts were brief, drawing conclusions with very little consideration. The reveal of Prime has changed that. Rather than just a plug-in model coming about as a package option, Toyota took the next step. That's a cost-reduction not taken advantage of. But this plan for national rollout is 5 years later. The market has changed quite a bit since the first generation. This second generation will offer new twists, which bring about new comments like: "*I can't get excited by the carbon fibre or curved rear window, but who knows, maybe that will attract...*" New is what we want, as I explained: Toyota wants to draw in buyers outside of the usual Prius interest. Making Prime different enough to stand out, yet still deliver on the Prius fundamentals, is the point. With a goal of phasing out traditional vehicles, you can't just keep following the traditional approach. This isn't a matter of conquest sales from other automated. It's trying to figure out how to get Toyota's own traditional customers to now choose their hybrids.

5-15-2016 Gas Prices. They are really low. We're seeing a struggle with sales of clean & efficient vehicles as a result. A recent article published stirred a new discussion. I took advantage of that opportunity to climb up on the soapbox:

The business choice of not rolling out Prius PHV further, limiting it to just the 15 initial states, then ending production without any word of future plans caused quite a stir. Some people absolutely refused to accept the reality that a much-improved successor would follow, labeling Toyota as unwilling to support anything with a plug. Their greenwashing efforts, based on nothing but anecdotal evidence, was relentless. It was a sign of industry change and the inability to deal with it. They made up excuses to feel better.

Since then, we have got confirmation that there was indeed a much-improved successor on the way. The conclusions drawn based on just observations of the automaker alone were proven incorrect. The problem was as stated, the market has changed. That new audience would be even more difficult to reach. This article about some hybrid owners switching back to traditional vehicles highlights the problem isn't just how to get people out of traditional vehicles. There's a step backwards occurring.

Personally, I'm really annoyed that so many Volt enthusiasts fought against me, claiming traditional vehicles were not the competition. They were wrong, very wrong. So much time & effort was wasted trying to prove they wouldn't impair sales. They claimed battery technology would improve to such a degree, sales would grow. Nothing else mattered. They'd dismiss evidence to the contrary. Heavy dependence on tax-credit subsidies and the hope of higher gas prices was what they focused on.

They why I focused on Toyota's goal of cost-competitiveness. They never gave into GM's approach of striving to deliver more EV by making tradeoffs. Wandering too far from the purchase priorities of mainstream consumers means a struggle to sell... which is exactly what we've seen with Volt. Low gas prices and the effect that has had on the hybrid market make that rather obvious.

Think about how Toyota was able to share the Prius platform with Prime to keep cost low. How much battery-capacity could be added without raising the floor and having to find a location for the charger without using the middle seat? You wouldn't get much, but we've all seen how much of a space penalty there is for offering a lot more.

Toyota's choice to use a little more space, but require major inconvenience is what we'll be getting. It will be something to entice buyers to take a closer look. That little bit of compromise provides a reinforcing effect, reminding the owner of their choice to not just succumb to low gas prices. It's basically a tiny ego stroke... which is exactly what Prius has provided for the past 16 years.

Something new was needed in this market now facing a saturation issue. Traditional vehicles offering interior features that had once been exclusive to Prius means offering a new draw. 22 miles of EV is just enough to satisfy without increasing cost substantially. It's just enough to make those considering the purchase of a traditional vehicle to take a closer look.

- 5-16-2016** **Surprise.** What comes to mind when you read this: "*Ordering sight unseen can be a surprise.*" I was intrigued. What did he actually mean? Unfortunately, my post didn't result in anything. It was essentially ignored. Knowing the poster well, I knew that point made was received. He didn't have anything noteworthy. It was just a gut reaction. People often do that. It's often the nature of online comments. Constructive exchanges are much more of a challenge. Though, I continue to try: Nowadays, a great deal of research can be done online. Heck, consider how much video footage is available, filmed by owners, supporters, and enthusiasts. There's a wealth of articles & reviews that are easy to find too. I would think just about everything, except what the test-drive experience reveals, can be learned unseen (not in person). Of course, even knowledge of some aspects like acceleration, handling, and comfort can be obtained vicariously. What would you anticipate as potentially a surprise factor?
- 5-17-2016** **2,000,000 Problems.** This is a really big oops.... or was it? Supposedly, there was a clerical error of some sort that resulted in the window-stickers for the 2016 model-year of 3 large GM vehicles to state MPG incorrectly. The mistake showed much greater efficiency than the vehicle actually delivered. In other words, customers didn't get what they paid for. That left a number of watchdogs suspicious. How could that have happened? It was especially perplexing by the fact that nothing had changed between the 2015 and 2016 production. Things just plain didn't add up. Well, turns out, the previous years were wrong too. So, whether or not the resulting information was intentionally wrong or it was accidental really doesn't matter anymore. There are roughly 2 million customers who will be expecting some form of compensation. Think about how many gallons just a few MPG difference makes when you're driving a monster-size guzzler. That's a lot of problems to deal with.
- 5-18-2016** **Anti-Hybrid.** My frustration hit a tipping point. I'm tired of this particular individual. He's an EV owner (a purist) who turned antagonist. This is what pushed me too far: "*The reason Tesla, and other EVs will continue to grow market share while hybrids remain stagnant is hybrids are a one trick pony. The only unique advantage they have is fuel efficiency.*" Post after post has been denial, contradiction, and pessimism. I let him have it, intentionally making it personal: Your dismissal of hybrids in favor of EV never ceases to fascinate. You simply refuse to acknowledge change. Toyota just rolled out a much-improved Prius and will be rolling out a new plug-in model later this year. That alone is a wake-up to the market. They just entered the small SUV hybrid market too. What about that? Then there's the fact that VW diesel owners thrive on efficiency (and supposedly being clean) who will be looking for replacement vehicles. We have new players joining in too. Hyundai, Chrysler, Mitsubishi all offering new hybrid market choices. There is also the economic factor of EV providing an endorsement effect for hybrids. Those who still believed rechargeable batteries weren't good enough for automotive use will finally see they are. In other words, stop being so anti-hybrid. You're not doing any good by disregarding so much recent change.

- 5-18-2016** **Acceptance.** He fired back, attempting a counter-attack by implying I was being hypocritical: "*As for refusing to acknowledge change, that is a very interesting charge from the person who lambasted GM for making a 4 seater, yet applauds it when Toyota does it.*" I found his cherry-picking an dead-giveaway. After having been through this very thing with him several times already, it was quite clear he wasn't going to accept anything presented. So, I just posted what I felt others would learn from this exchange: Ironically, I changed my stance and you continue to refuse to acknowledge why. I accepted the 4-seat reasoning, then moved on to leg & head room. Portraying me as hypocritical for actually accepting the arguments of others is not constructive. I changed. Why can't you accept that? Why stay stuck in the past? The misrepresentation does not advance discussions. You learn something, then accept the change.
- 5-19-2016** **Get Over It!** His choice to make it personal, calling me out but not wanting to accept the facts presented left me at the podium. So, I kept on posting: Another thing you are refusing to acknowledge is the fact that Volt's audience has changed. It was originally marketed as a mainstream vehicle, something for families of all types. As the years progressed, the market changed. It became a specialty vehicle, targeting a more narrow audience... one that 4 seats is fine for... which is why my "*lambasting*" ended. Toyota is targeting that 4-seat audience with Prime right from the start. It's a vehicle different from Prius, not just a plug-in model as PHV was. Heck, Toyota even stated it was for the grown up family, who's children are not older. Those children will be driving sometimes, no longer in a carseat or bringing along a friend to squeeze in back. That comfort and the extra tech-features are not what you'll find in a regular Prius. Again, I tired of getting labeled as hypocritical by omitting detail which shows that's not actually the case. Things change. Look at how different the audience is no compared to back when the gen-1 vehicles were first rolled out. Get over it!

5-20-2016 **42 Miles.** I had a lot of driving around to do. So, I figured... why not do some "*stacking*" last night. That's something I had only done while on vacation, when there's no opportunity to plug the Prius in. It's something not encouraged, since not doing it properly will cause MPG to drop. The technique is simple, you push the EV button whenever you are slowing down. The purpose is simple, to recharge the battery pack. That same recharging would happen anyway, regardless of whether or not you take advantage of the button. The difference is, the electricity generated while still in HV mode is later consumed in HV mode. While in EV mode, the electricity is saved for when you designate it should be used. That comes in handy if you know for certain you will be in a situation that is best served by EV. If not, you actually miss out from the opportunity to have the engine join in. Consequently, overall efficiency will be lower. Remember, Prius PHV is a plug-in hybrid. The engine is there for a reason... to reduce emissions & consumption. It's goal is not to eliminate gas use entirely. Only-Electric has tradeoffs. Balance is better. That's why Toyota only reports EV miles driven as EV values. The HV values include electric-only driving. (We've been calling that "*stealth*" mode for the past 15.5 years.) Anywho, that's what I did today. The results certainly were interesting. From the 2 charges for the day, the result was 88 MPG. Total distance traveled was 86.8 miles. EV miles was 42. For HV, it was 43. You add those up, it only comes to 85. The reason is simple, Toyota truncates the value. That EV was literally only 100 feet or so short of the incrementing. I was carefully watching the odometer. But I wanted to reach my garage with 0.1 EV still remaining, I could take photos without outside glare. Also, my camera was in the house. Needless to say, 42 is well above the expected 22 miles. That's 21 miles of EV between plugging in. It confirms design can deliver, it used well. Of course, the 88 MPG speaks for itself anyway. Heck, even with mindless driving, an average of 70 MPG would still be far better than any traditional hybrid could deliver.

5-21-2016 **Who?** I decided to ask that question of GM about Toyota, clearly showing favorites are not being played. To make that point stand out, I made it in the form of a rant: Why have Volt sales been such a struggle? What makes the particular capacity of 53 miles a draw? Why have both enthusiasts and GM itself moved attention to Bolt instead? There are an abundant number of simple excuses available as answers to those questions. We've seen countless debates over the years. All provide reasoning. None reach beyond enthusiasts though. Appeal to ordinary consumers isn't a matter of logic. For that matter, it isn't a decision based upon emotion either. There's a very real problem of stirring interest. Desire from dealers to offer plug-in choices is extremely low. Why? Not even being able to overcome that hurdle means the customer base will remain enthusiasts only. For a mainstream consumer to even consider a purchase, the vehicle must be readily available. Seeing it on the showroom floor, then being able to immediately go for a test-drive is priceless. That's how sales to ordinary people happen. This thread claiming DOA doesn't address that. Why is such a fundamental principle like that still being overlooked? Toyota's decision to deliver a system "*only*" offering 22 miles actually addresses the issue. You'll get full EV performance that's easy to understand, but won't have to bother discussing EV support. With a pack that size, there's simply no need for a level-2 charger at home. Salespeople can simply point out that faster charging is available, but the 120-volt outlet in their garage is already enough. Nothing else needs to be said. Intimidation, Anxiety, Uncertainty, Skepticism, Concern... they are all dealt with entirely. It's a no-worry sales pitch the customer won't have any reason to question. Prime won't be a plug-in model of Prius either. There are obvious stand-out features, extras no available with Prius. That makes it even more of a draw. True, that will obviously compel some interested in Prius to purchase a Prime instead. However, Prime will also stir interest in some who aren't interested in Prius. It's complimentary product, rather than competing. I wonder why some people don't see those qualities of Prime. My guess is they are quick to judge, unaware of all the factors actually at play. Since many were not paying close attention to the market until recently, that seems a reason thought. After all, if you aren't interested in a purchase soon, why would you participate in discussions? You'd have to be a supporter of the technology... which means you aren't an ordinary consumer. Who is the market for Prime?

- 5-21-2016** **Downplaying Chargers.** This is a very real growing problem: *"Installing a 240v outlet and buying a L2 EVSE is easy for the consumer when they contract out the work. The cost is relatively low compared to the cost of a new vehicle."* Those deeply involved with the EV market forget what it's like to be part of the mainstream. That ordinary consumer perspective is lost. It's really unfortunate. The reminders of that doesn't always go over well either. Today's attempt may or may not. I'm really not sure what the response to this will be: Know your audience. Mainstream consumers will not in any way consider that easy. It's an expense with a very uncertain price (house wiring varies dramatically) and requires the effort to choose which 240-volt charger to actually purchase. That option will not interest KISS buyers. Think about how difficult just the decision of which vehicle to buy is. The last thing we want to do is add an intimidation factor by introducing plug complexity. We have much to do to get ordinary people interested in L2 charging. It's just not realistic for the masses yet. That's the reality of the situation now. Hopefully with Gen-3 offerings, the audience would have changed. Currently, we're stuck with the idea of plugging being far too new still. Starting with 120-volt is a simplicity Toyota plans to take advantage of. Think about how routine daily plugging in was 5 years ago. People would go days between charging their phones. Not anymore, the big screens and data services drain the battery quickly. Plugging in not only has become an ordinary thing to do each night, many people now are taking advantage of wireless pads to recharge during the day too. Patience.
- 5-22-2016** **Exploring Options.** Hopefully, this will stir some constructive messages to be posted: It will have been 19 years for Prius since introduction. Prime will provide a means of the trying something new, finding out what this new "battery centric" market will buy. You want practical? You want a 5th seat? You want a plug-in hybrid? Purchase a Prime version of Camry. Think about the full-size market. What will other automakers offer? The business must expand. Sales will come from a variety of buyers. The configuration of Prime is an effort to explore options.
- 5-23-2016** **9,000,000 Hybrids.** What else needs to be said? I summarize it with one word: *"remarkable"*. Toyota shocked the world back in October 1997 when it revealed Prius, telling everyone that was a production model that would be ready to begin sales late that same year. The other automakers were working to deliver prototype high-efficiency vehicles in 2000. Toyota beat them to market by such an extreme, they were left baffled. Sales did indeed begin in December 1997. The first upgrade was rolled out last August 2000, again beating the other automakers to market... all except Honda... who struggled. Ford did too. GM gave it several tries. Others joined in eventually. Nothing has compared to the success of Toyota though. Today, it was revealed that 9 million of Toyota's hybrid systems have been sold worldwide. Think about how many that truly is, especially the number of models. So many choices. Heck, just Prius alone offered quite the variety. But that pails to the upcoming potential. The system is well-proven already in larger vehicles. Highlander is the premiere platform for power. RAV4 is smaller and sales are starting out really strong. Someday, a Prime model may compliment it. Think about how popular the Mitsubishi Outlander has been over in Europe. Imagine something of that nature here. The improvement of adding a plug & clutch along with a larger battery-pack will be demonstrated later this year. The expectation of growth in the hybrid segment is quite promising... well, for Toyota anyway.

- 5-23-2016** **135,000 Payments.** Strangely, only 135,000 of the 2 million GM customers with incorrect window-stickers will be getting compensation. That sounds wrong. How could so few be the only ones? Whatever the case, the payments going out will range from \$400 to \$1,500 each. Will that be acceptable? I suspect owners will just accept that money without question, since gas prices are still low. Later on, the vehicle could become painful to fill. It's hard to tell what the future holds. Resale value dropped. This will just turn out to be another note in our history of guzzling. We've seen other automakers with similar misrepresentation problems. Hyundai, Mitsubishi, and Ford examples would be significant... if it wasn't for VW with the diesel not only misstating MPG, but also being much dirtier. I guess we can be grateful none of the others had that problem. It's too bad stuff like this happens. No wonder Toyota understates. It's better for customers to discover MPG averages are actually higher rather than lower what's stated on the window-stickers.
- 5-23-2016** **Stop & Slow.** It was a refreshing change to discussion commutes today: *"I hated driving the miata in stop and go traffic. Leg pain unbearable after a while. Prius is a pleasure in that department."* Contributing to that was a pleasure: The unfortunate greenwashing effort currently at play, attempting to undermine the success of Prime, is to disregard the benefit in stop & slow commuting. They spin it to make people believe EV range must cover the entire commute to be effective. In reality, there's a huge payoff where highways intersect and where bridges cross. It's a nice perk to have EV for full drive. But the 50 MPG without plug-supplied electricity is far more than what others get when cruising. And the 999 MPG when stuck in that heavy traffic from intersections & crossings is fantastic. My commute includes recharging at work. That makes my capacity now in the PHV equal to what it will be with a single charge in the Prime. Averaging 125 MPG currently is great. How can that not be a selling point for Prime? Of course, I'll continue charging at work. The 85 kWh solar-array is great for that. It will bump my entire commute to that 999 MPG.
- 5-24-2016** **That New Look.** This was exciting to post: I saw my first commercial use of a gen-4 today. It was white, wrapped with the business's logo. That looked nice. It certainly wasn't the plain business car you'd usually see. Think about how *"not normal"* the regard for Prius has been over the past +15 years anyway. Why not push the styling further into the unique category. That's where the industry is going. Notice how front & rear lights are rapidly taking on distinct looks? Heck, the EV will no longer have a grille, which was only cosmetic to make it look like other vehicles. Think about how boring the SUV has become. The small ones all basically look the same now. What's the draw to that? The age of *"normal"* is coming to an end. Hooray! I miss decades ago, when we saw the same cycle from blah to whoa. This time around though, there's fancy technology too.

- 5-25-2016** **Great News?** This was addressed with mixed feelings: *"The Toyota Prius has just netted the best gas mileage of any car in Consumer Reports' history. The influential product testing magazine netted 52 mpg overall on its test cycle, a huge improvement over the last generation's already parsimonious 44 mpg."* How their testing could result in such low MPG over the years had us scratching our heads. The thought was they did a lot of hard-accelerations and braking too hard to allow regenerating. The system wastes gas when you drop the pedal to the floor to get going and goes straight to the discs when stopping abruptly. True, that is proper validation of system potential, but in no way representative of actual driving conditions. An owner simply wouldn't experience those conditions... which is why they observe so much high MPG. With this newest generation of Prius, that still holds true. However, results from testing aren't as low anymore. Toyota took that type of driving into account too. The report published today clearly confirmed that. 52 MPG is still rather misleading. But knowing owners will get even better is nice and the published value is appealing to those not as well informed. However you look at it, you'll see the news all over. It was a very popular topic online today.
- 5-26-2016** **Cost.** I'm tired of the nonsense. This should speak for itself: The shortcoming with most EV promoters is they aren't able to focus on COST, yet... which forces them to just accept current PRICE with heavy dependency on tax-credits instead. COST determines successful sustainable sales that actually delivers a profit. That's vital and certainly not taken seriously, yet. Take a look at the COST numbers. Best case scenario is \$145 per kWh. Most realistic efficiency is 4 miles per kWh. That works out to \$3,625 for the cells delivering 100 of range, with no longevity buffer. Accounting for a usable capacity of 80% means adding another \$900 to the COST. There's also the need to add COST for the casing, connectors, controllers, and cooling. Who knows what that comes to; lets say roughly \$500. In other words, the COST of 100 miles is somewhere in the neighborhood of \$5,000. That COST makes the 200-mile EV unrealistic for reaching those without disposable income available. The 100-mile EV has a market. Those without the long-distance requirement would choose to pay less.
- 5-26-2016** **Window Sticker.** Ugh. Knowledge from the past sometime isn't passed on. The means of doing that can be a challenge. Of course, if you read blogs like this, there's a chance of preventing mistakes from being repeated. The other hope is to not waste time on ineffective attempts to educate. Sadly, we've learned that mainstream consumers do very little research and are prone to quick decisions with important matters... like purchasing a vehicle. The good intentions of those online often fall apart upon first attempts to share. The short attention-spans and lack of background-knowledge prevent much progress. In other words, the selling of a vehicle like Prius to an ordinary run-of-the-mill buyer is a touchy matter that's prone to failure. That showroom experience should not be ignored. Salespeople have little opportunity and little incentive. At least with Prime, there's a chance of enticement by suggesting a test-drive. We know that Prius often wins the heart of uncertain buyers once behind the wheel. EV should make it easier to stimulate interest. In other words, don't expect much searching or study to take place. I pointed out the problem this way: Know your audience. People don't read the fine print on the window stickers. It already points out results vary based on driving conditions. What would get them look at more information? A major contributor to the problem is they don't understand the factors at play, so providing additional data won't accomplish anything.

- 5-27-2016** **Core Functionality.** I really like reading posts with comments like this: "*...the Prime is giving us a bit more (and better) AER, but at the expense of doing exactly what the PiP didn't - compromising core functionality.*" In other words, some don't deal with change as well as others. It seems a confusing mess. That often comes from groupthink. You fail to see the bigger picture as a result. That narrowing of scope comes about from the need for clarity. Unfortunately, that can me purpose is forgotten as a result of getting side-tracked by smaller goals. That's why stepping back to consider things like core functionality are so important. However, those can be forgotten too. I provided a reminder: That's called not understanding purpose... which is interesting, since the problem is usually not understanding audience. Anywho, availability of short-term middle seating was never on the priority list. That higher & harder cushion wasn't sighted as necessary. It was a "nice to have" though. Prius focused on need. The fact that it also delivered a few wants is what pushed it into the mainstream and kept it there... profitably, without any special incentives. Core functionality was: Reliability, Affordability, Clean Emissions, and Great Efficiency. Later came the ability to transport cargo much larger inside than you could using a vehicle with a trunk. All that still holds true.
- 5-28-2016** **Garbage.** Sometimes, you just have to call it like it is. Upon reading this, I felt empowered: "*Considering how far the Volt has come in terms of battery size, packaging, and cost, what we were shown at the unveiling of the Prime was disappointing. For a battery pack of less than half of the capacity of the gen2 Volt's, the Prime appears to have the same level of compromises.*" As usual, it boils down to who. The consumer may see a great deal in the short-term, but once those incentives, how will it sell? I jumped at the opportunity to sound off: What kind of load of garbage is that? Volt doesn't stand any chance of competing against traditional vehicles without tax-credit help. Profitability from a vehicle offering a battery-pack that size just plain isn't realistic. Volt is smaller on the inside and doesn't get as gas depleted efficiency either. Prime's configuration will allow consumers even with a long commute to take full advantage of the power & capacity its battery-pack will offer. And for out on the open road, depleted efficiency will be outstanding. 8.8 kWh pack will cost much less than the 18.4 with liquid-cooling. The Prime hybrid system will benefit from a number of components shared with Prius. It's a formula with business sustainability in mind. You can spin "*disappointing*" all you want. Consumers shopping the showroom aren't going to bite. In fact, they won't even know about the claims of much greater capacity expectations even existed. Some of us hoped all along Toyota would stay true to principle, not sacrificing affordability for the sake of catering to a want. Toyota's fulfillment of need has been a principle approach for decades. We've seen that with Camry, Corolla, and Prius. Why should Prime be any different?

5-28-2016 **Hurt.** Disenchantment comes in a variety of forms: *"It's obvious prime is intended to attack a new audience, one that is unfamiliar with pip hatch space and rear seat. it's just disappointing to long time prius/pip buyers who have supported Toyota's effort. Ah well, you always hurt the one you love."* That's an effort to remain constructive, but an expression of expectations not having been met. My reply was: Having been a supporter of Prius prior to the United States rollout, back when original model evaluations from survey families and media reviewers was all that we had available (that's 1999 for those unfamiliar with the history), I had very different expectations. I studied the market in great detail and actively interacted with the influencing factors as it progressed. This will be the 6th major upgrade to the platform, with respect to the battery. It started with the D-cell batteries (gen-0). Then came along the prismatic packaging upgrade (gen-1). A much improved cell & pack arrangement (gen-2). Toyota then figured out how to do even more with less, by reducing voltage and introducing a booster (gen-3). Following that was switching to lithium (gen-4). Then, capacity was increased and a plug added (gen-5). With this rollout in the fall (gen-6), capacity will be increased even more, allowing much more power to be delivered for propulsion. Each upgrade always strived to keep cost down. It was a top priority. I never had an expectation of the dramatic increase in EV range others had recently hoped for. The history simply didn't support such a change in approach. Cost would be prohibitive. Does a parent expect a child who as always put a great deal of emphasis on being financially responsible to abandon those principles at some point? Even when they grow up, look much different, and perhaps not be as practical as in the past, there isn't a belief that change will alter purpose. That may *"hurt"* to see the change, but the ultimate goal remains the same. Prime is designed to attract mainstream buyers. It's not a Prius with a larger battery-pack and plug like PHV was. It's that child venturing out on their own after having completed his or her education. Some old friends will remain. Some new friends will be made. The next step is being taken away from *"home"*. Love hurts, eh?

5-28-2016 **Safety.** This was particularly exciting to post: Read through all the posts of this thread again. At some point, a factor of consideration still not taken into account should be noticed: * * SAFETY * * How so many for so long could neglect such an important aspect of vehicle design boggles the mind. Think about the number of decades it took before automakers were required to add a shoulder-restraint for the middle passenger in the back seat. For that matter, how long did it take before even just lap-belts were required? It's really sad that safety is rarely considered. The topic of safety is sometimes fought too. Anyone remember all the hoopla there was with the resistance to providing airbags? With the case of Prime, it makes sense that it is testing consumer reception to the idea of not providing any type of seating in the middle anymore. The possibility of upcoming new regulations from NHTSA requiring safety features for all in sitting back could really add cost to the vehicle, especially with the unique problems a seat in the middle introduces. A low rating hurts sales too. Personally, I cringe at the idea of a side-impact where the middle passenger is crushed up against the other 2 sitting in back. It's unfortunate some will think of this as a scare-tactic for the sake of justifying an approach, but nonetheless, the topic is something to consider. Until now, no one has. This thread serves as some proof of that. Avoiding safety issues & costs by sticking with 4 seats makes sense. It puts Toyota ahead of the rest by embracing the idea early on too.

- 5-30-2016** **Being Competitive.** I posted the following sentence in response to an antagonist who absolutely refuses to acknowledge the true competition: Not liking Toyota's goal of delivering a design capable of competing directly with traditional vehicles once the tax-credits expire... which will be mid-cycle... is no excuse for not accepting it. He's one of those who still holding onto the gen-1 banter. He thrived in those discussions and this new market doesn't support that same outlook. Change doesn't come easy for some. It's also more difficult to see, sometimes. For example: *"Comments from Toyota on the elimination of the fifth seat were for keeping weight down and efficiency up. The required structural and suspension changes for that fifth seat would be a small cost compared to the battery and charger."* He's so fixated the immediate issues, understanding new challenges isn't being taken into consideration. I gave him a gentle nudge: Did you miss the post about safety? NHTSA has been considering the introduction of rating measures to indicate the safety of rear occupants. Squeezing 3 adults in back is far from just a rare event when it comes to services like UBER. Those passengers are touching hips & shoulders and have a good chance of smacking heads in the event of an accident. Who's liable then? Insurance companies want to know the level of exposure each vehicle poses. This new topic of rear safety is something Toyota would already be well aware of and could very well be using Prime as the vehicle to test out consumer reaction to elimination of the sub-standard middle seating we've all become accustomed to. Think about the cost of that safety. Is it really worth it in a non-fullsize vehicle?
- 5-30-2016** **Audience & Goal.** It's becoming easier to respond. Reasons for choices are obvious, at first. Given time and an open mind, they can be seen though. I found this interesting: *"If you listened carefully to the launch event comments, it seems the Prime is a Prius intended for well-heeled Toyota hybrid fans who want to set themselves apart from both the rabble in the C, v, and LB on the one hand, and the fogeys driving Avalon Hybrids on the other hand. I can see how marketers might have talked themselves into this, but can anyone really think all that's going to translate into a big win in the marketplace?"* Coming from a hybrid fan whose expectations were not met, I was intrigued to find out what kind of reaction I'd get from this: Simple, Prime is not for hybrid fans. The launch event was for hybrid fans. Misunderstanding market is easy when you don't take audience into account. Expansion means reaching out to new buyers. The ordinary mainstream consumer hasn't said anything yet, since Prime isn't available. Their opinions won't emerge until after rollout. When pricing and test-drives are available, then their judgment will begin. Repeating the same formula for Prime as Prius or any of the other hybrids won't result in growth. Being able to appeal to new customers requires trying something different. Remember, the ultimate goal is to replace traditional vehicles with clean, high-efficiency choices.

5-30-2016 Hybrid Fans. The latest spin is to make claims of disappointment, but evade any type of audience identification. The who is stated in terms of a stereotype, rather than any particular individuals. It's the generalization we've seen with all the other generations: *"Compared to the Gen4 LB, the Prime absolutely delivers less of everything that today's conventional car buyers want in a car (passenger space, cargo space, likely affordability), and more of what today's "hybrid fans" crave (MPG, true AER, techno whizbangery)." Change doesn't come easy. This is yet another example. Oh well. What can you do? I deal with it this way: Simple, again. You're falling into the same trap countless other have done over the many years Prius has been available. You're assuming buyers are unwilling to accept any type of change whatsoever, that the word "compromise" means giving up something rather than seeking a balance. There are quite a few consumers who expressed interest in a plug-in Prius, but didn't find the first offering compelling enough. They wanted more power and more capacity. That's it. There was no request for jaw-dropping acceleration or anything that could cover their entire daily driving needs under all conditions. They just wanted a souped-up Prius. In other words, they weren't really a "hybrid fan", since the purchase step was never taken. They were interested. Not becoming an owner left them as a traditional supporter though. They chose to remain status quo until something better came along. Prime is that something better.*

5-30-2016 Better. We got another ranting session from a gen-1 Volt enthusiast. Thank goodness the gen-2 enthusiasts don't act that way. In fact, most are quite civil and often work really hard to keep discussion constructive. As for this rant today: *"Still, the Volt, not being a traditional PHEV – does much better. Floor it at the stoplight on those short trips, and the gas engine doesn't ignite. As long as you have charge in the pack, you can drive worry-free that the gas engine will stay dormant."* I was beside myself about all else that had been posted. It was blatant greenwashing, surprisingly worse than some of the nonsense of the past. That goes to show how things have changed. Anywho, this is how I chose to respond: The rest of that post was loaded with misleading & outdated information... not worth the time to bother addressing. So, I selected just the one statement above to ask about: What is a *"traditional PHEV"* ? It simply appears to be just another way of referring to gen-1 offerings. The upcoming Prime matches that *"better"* criteria listed. What does that make it? The lack of clarity begs the question of purpose. What is it? Wasn't the goal originally to alleviate range-anxiety? If so, the 200-mile EV offerings have overcome that. So... what is the purpose now?

5-31-2016 **Greenwashing.** The effort emerged again. It was pretty intense too. There was an attempt yesterday to belittle the supposed Volt competition by calling them "*traditional PHEV*" offerings. In other words, Ford's Energi plug-in technology is making the news again. Remember how intense the initial rollout was? That brought out the worst in some enthusiasts, separating any of their activity from genuine supporters... since they turned to greenwashing. Subtle misleading turned into outright lies. The example today was: "*Plug-in Prius.....it didn't even have an EV-only mode, so conversation stops there.*" This followed: "*Prius Prime? Toyota decided to slap on an "EV mode" button, but it'll be limited similar to the current Ford Energi twins.*" From that point, it was hopeless. The message degraded into a vastly superior declaration, which concluded with: "*Consider yourself educated.*" It never ceases to amaze me how blatant some people become. They just plain don't care. Spreading information intended to deceive is just what they do. There's no moral basis for that choice anymore. They just do it. That's really sad. Oh well. At least it provides the opportunity to share detail about what the situation actually is. I posted: Huh? That's loaded with inaccuracies, claims that aren't the slightest bit correct. Way back in 2009, the EV-only mode was introduced for Prius. When you pushed the button, you'd get an increase in power over HV mode electric-only. It was limited to 25 mph though, since 1.25 kWh battery-pack had a very limited amount of power to offer. When the plug-in model Prius was rolled out in 2012, battery-pack size was increased to 4.4 kWh. That extra capacity provided extra amps, which resulted in a EV-only mode speed increase to 62 mph. When Prius Prime is rolled out this fall, even more power will be available from the 8.8 kWh battery-pack and a clutch to disconnect the gas-engine will be introduced. You'll be able to drop the pedal to the floor to accelerate using only electricity and the EV top-speed will increase to 84 mph.

6-02-2016 **No More.** There was quite a bit of trolling bait dropped today. That daily blog for Volt has become a discussion source for everything but Volt. Even so, there is still the constant belittling of Prius. That never ceases to amaze me how some people absolutely refuse to be constructive. So many others have moved on. Only a few stubborn antagonists remain. No more arguing. Debates when no where. I let them have it with this: Reality is, the market has come to an impasse. The 100-mile EV offerings have been eclipsed by the upcoming 200-mile EV offerings. All attention has shifted over to the longer range potential. That doesn't mean the 100-mile EV will vanish. It just means sales will only happen if they can be affordably priced. Right now, even with \$7,500 of tax-credit and HOV incentives, that looks to be quite a challenge. That situation puts the supposed EV competition in a very difficult position. If Volt really is to be the more desirable choice, it somehow must have a cost advantage. Current pricing hasn't proven to be a compelling draw. Sales of gen-2 are only modestly better than the average for gen-1. Enough battery-capacity to make Volt perform as an EV most of the time is expensive, both in terms of cost and physical tradeoff. Even if GM can demonstrate that 53 miles is enough and the size & weight aren't a penalty, the range needed combined with a full gas-engine and transmission sacrifices any competitive edge. Owners would have to drive with the pack depleted routinely to justify that premium. Why carry so much extra if it is rarely ever used? Other automakers are keeping plug-in hybrid battery-capacity lower to keep cost lower. You'll end up using the gas-engine more often as a result. But if the MPG is quite a bit higher than traditional vehicles anyway, the advantage is not lost. It's still competitive. Like it or not, Toyota is taking that approach with Prius Prime. It's not intended to compete with EV choices, despite offering full EV driving. Owners will see the battery-capacity being depleted entirely (no waste, since all is used), then watch the system switch to delivering 50 MPG. It's a business formula for survival after the tax-credits are gone. Think about how easy it would be to use that same approach for RAV4 hybrid, which is seeing strong initial sales. Notice how GM is attempting something similar?

6-03-2016 **Burning Desire.** Witnessing the change of attitude has been interesting. Loyalty to Volt has become a long, forgotten memory at this point. Even the most stubborn have abandoned it in favor of Bolt. They still like that plug-in hybrid, but it is now referred to as a great engineering achievement from GM proving electric-only is the way to go. The very idea of "*range anxiety*" is a distant memory of the past. There's no point of having such an elaborate approach when affordable 200-mile EV choices are no too far away. In fact, the wait is only 6 months now. Interestingly, it leaves Toyota well positioned. Understanding the purpose of Prius Prime will be so obvious, it will be a much easier sale than when Volt was confusing the market. Prius Prime will deliver 22 miles of strong EV performance, then revert over to a highly-efficiency hybrid after that plug-supplied electricity is used up. Looking to GM for comparison will result in comments like this: "*GM doesn't have a burning desire to sell that many Volts. The Bolt EV gets more ZEV credits and the tax credits are an issue. I'm not saying that GM wouldn't sell more Volts if the orders came in, but at this point there are downsides to higher sales. If the tax credit changes I think we'll see a different approach.*" That was from a former antagonist. Things certainly have changed.

- 6-04-2016** **Grocery Store.** I thoroughly enjoyed the opportunity to post this today: In less than 3 weeks, a giant new grocery store just 0.6 mile from my house will be opening. It already has 4 chargers available. I'll be taking full advantage of that, stopping on the way to work for a quick top-off of the battery-pack while picking up something fresh for lunch. That opportunity to plug in for free while shopping is a nice draw for people like me. Others will see there are plug-in vehicles in their own neighborhood. That sounds like a great way to promote the technology and attract business.
- 6-05-2016** **Step Back.** I provided some encouragement to give it a try: Realistically, just about here has the wrong perspective. They look at what they think is the big-picture by identifying the gen-0 thru gen-4 Prius models, Prius PHV, and Prius Prime. Then they compare to what other automakers offer. That overlooks a vital aspect of the market. Step back even further. What do you see? Most people have no experience at that scale. You need to have the type of career that involves projects which take a decade or more to really get established for you to understand all that's involved. For me as a senior software developer, I have to deal with many cycles of upgrades before finally reaching the intended audience. There simply is no way to go any faster with such an incredibly diverse and change-resistant set of users. In other words, the market is really at the "*just getting started stage*". Heavy reliance on tax-credits and the continued emphasis toward HOV privileges should make that obvious. Unfortunately, there's the "*criticism from within*" that's preventing the bigger big-picture from actually being seen. It's the belief of "*more is better*" that muddles thinking. Consider how long it took for most consumers to finally abandon desktop computers. The next step to portable devices seems so obvious. Yet, there was a major effort to remain status quo for a very long time. Think about just one aspect, hard-drives: spinning verses solid-state. Mainstream acceptance really isn't determined by just having enough capacity. In other words, more is not necessarily being better. Toyota has worked really hard over the past decade and a half to deliver a system that addresses the wide array of consumer preferences, attempting to strike the right balance rather than emphasizing any specific trait. Remember, mainstream buyers have little in common with those of us here.
- 6-06-2016** **Avoid or Acknowledge?** I tried to get the situation out in the open. It didn't work. The post was diverted, as usual. However, there is the reality of a new audience emerging. It's been interesting to witness the change. That daily blog for Volt has been everything but for almost a year now. The reveal of the new generation ushered in change. Whether they liked it or not, membership online would never be the same. Just like with Prius, new owners means some old owners don't participate anymore. In other words, I should stand a change of getting a different response from those remaining. It didn't work. The avoidance we saw in the past continues on. Ugh. Oh well. At least it's well documented of what was witnessed as the events were unfolding. Looking back at this unwillingness later certainly will be interesting. History is often seen as "*obvious*" when looking back long afterward. But as it's happening, the outlook is from anything resembling acknowledgement. There is some flat out denial still... despite the writing on the wall already. I returned to the discussion with: That has nothing to do with 2017 model production. The reason you're obviously avoiding is the limitation being heavily influenced by the number of tax-credits remaining. We've all seen how 200-mile EV offerings wrecked the "*range anxiety*" selling point. That puts Volt in an awkward position. The hope is to discuss next steps and proper setting of expectations. That won't happen without acknowledgement.

- 6-09-2016** **Clueless Salespeople.** It rather frustrating to find out that a salespeople has absolutely no idea what they're talking about. Rather than research how something works, they just make assumptions based on anecdotal evidence. They don't even bother observing it firsthand. Some literally just make up stuff based upon hearsay. Finding that out is quite disturbing. Here's an example of one such encounter: *"When we test drove the dealer cautioned me that using the adaptive-cruise-control in town that it will stop for the car in front of you, but if there is no car, it will drive you thorough a red light if you aren't paying attention! Do'h!"* Talking about not understanding how the system actually works. Ugh. Annoyed, I injected this into the conversation: That's an interesting misunderstanding of how the system actually works. I wonder if that assumption will turn into a misconception... The safety part (radar detection to prevent collisions) is always active, even when you aren't using the cruise-control. You do not have to turn anything on, ever. When you are driving around with the normal accelerator & brake pedal use through town, that protection feature is running. It's disturbing to hear about stories where salespeople don't have correct information. Spreading false beliefs, especially with a feature that's been available for years, is not a good sign. I've had mine, in my 2012 Prius PHV triggered several times from ordinary driving without using cruise. I remember the first in-town experience, when someone abruptly decided to hit the brakes to make a left turn. Another time was when a turkey jumped out in front of the car. In both instances, the system sounded an audible alarm, flashed a message on the screen, retracted the shoulder restraints, and applied the brakes. It was impressive to experience.
- 6-10-2016** **It Finally Happened.** The enthusiasts are now saying what I posted years ago. It's an agreement without acknowledgement. The problems I pointed out that Volt would have to deal with came to be. They weren't any profound prediction. They were just pattern recognition. Knowing that history repeats itself and seeing the same thing beginning again made that easy... to point out. To get any type of constructive discussion... not a chance. It was they didn't want to hear. So, I got everything from undermining to hostility in response. That's all over now. Phew! They see it now too. I posted the situation in today's daily discussion as: Remember all the warnings about focusing solely on great engineering? We all know we can create & build incredible vehicles. That doesn't mean they will actually sell well though. The continued struggle to achieve sales is further proof that the business aspect should not have been so neglected. It's amazing how negative the response was back when that same message was posted. Sure glad that perspective has changed. The underlying problem still exists though... how to sell more. I see Volt trapped in a niche. People simply aren't interested in a small, sporty car. We see the high demand for compact SUVs. Wouldn't it make sense to just leave Volt as is and focus new resources on delivering a plug-in Equinox using the tech Volt established?
- 6-10-2016** **Next Steps.** The response to my post was civil. How about that !?! Seeing the opportunity to capitalize on a seemingly constructive audience, I followed up with: 4,185 of the RAV4 hybrid were purchased last month. Even with many awards, reduced price from tax-credits, and HOV incentives, sales of Volt haven't been able to compete with that. It should be overwhelmingly clear what GM's next step should be.

- 6-11-2016** **Progress.** The response wasn't quite as anticipated, but it wasn't bad either: *"Articles have popped up around the web saying Rav4 Hybrid has taken lots of sales from the Prius V. If economy and efficiency is your goal, and you want more room for a family hauler, Prius V makes more sense than Rav4 Hybrid..."* There was an obvious effort to evade with distraction. Nonetheless, it was something somewhat on topic. There are some who feel let down by Volt falling away in favor of a vehicle inspired by its technology. Others welcome it. I see that advancement as the goal. Being a software developer, I'm quite accustomed to having some things accepted and other things not. It's how you find what works and what doesn't. Don't be afraid of failing. Volt enthusiasts were and let pride get in the way. Thankfully, those having lost the most are finally embracing change. Phew! I put it this way: That's called progress. You find what works, they go with it. If something is discontinued in the process, that's fine. Prius Prime will become the plug-in variant of Prius. RAV4 Prime could do the very same thing... exactly what Volt supporters have been absolutely begging GM to do for years. Small SUVs are popular. One offering a substantial improvement over traditional versions, because it is a hybrid system with a plug, is clearly an effort to fulfill those goals.
- 6-11-2016** **Growth.** The attitude from a certain few goes way beyond smug: *"Hi all, been a while since I have checked in, now that I have the Leaf, but here I am! Maybe I have been detoxed of the Prius Kool Aid, but I did find this thread very interesting, until....!"* That was quite an opening statement. I was befuddled. It was a former chat member who came back to the big Prius forum for the sake of attacking. It was the concluding sentences of the post that really got me riled up: *"So I would estimate that the new Prius PHEV would actually have about 23'ish real miles! That's sad, just sad! I was at first quite interested, but those EV miles killed it for me! I bet the price will rival a Volt too, if so, as stated, why bother!"* He clearly was yet another one of those who wanted to gloat about having upgraded to a full EV. That's the type of person the plug-in owner's group here really worries about. When you are working to grow the market, then are confronted with someone intentionally belittling the effort to reach out, what do you do? My choice was direct confrontation: Clueless? Uncaring? Smug? We have to ask why some EV owners are turning their backs on the mainstream market by being so unsupportive. How does such an attitude help? More isn't necessarily better. Look no further than Volt sales to see that a longer EV range does not equate increased sales. A smaller pack is what will reach ordinary buyers, attracting showroom shoppers. That's an appeal problem with EV choices currently. Ask how will the market grow beyond enthusiasts. Toyota is attempting to reach those interested in EV driving but unwilling to take a major step yet. They'll get an extremely clean & efficient choice offering a plug that's capable of directly competing with traditional vehicles. Think about the challenges faced at dealerships. Think about inventory, commission, and profit. Think about the knowledge required.

6-12-2016 **Realistic.** Ugh. He claimed to be the voice of reason: *"No, realistic, realistic, and ever more, realistic! Shoving this piece of crap on the world is what further reduces common folks from walking the EV path! I at least have a knowledge of what the real world of EV is..."* That level of smug never ceases to amaze me. It's the trophy-mentality I warned out all those years ago. Seeing it emerge over and over again is disheartening, but no surprise. Being blinded by engineering or simply having no background in business is a common problem. My post back to this growing problem thread was: Rather than support a plug-in with the potential of actually reaching ordinary consumers and being cost-competitive in this generation (that means selling at mainstream levels without tax-credit help), you just want to stick with an ideal and hope gas prices go up? That's not realistic. It's a careless disregard for the past. Attracting sales from the showroom floor is far more difficult than simply offering a generous amount of EV capacity. Look at how GM misunderstood their audience with Volt. The first-generation struggle with sales... despite shockingly low lease prices, large subsidies, and HOV privileges. It was hoped to be a product for the masses, but was clearly probably it wasn't. Now, the second-generation seems to have fallen into the same trap. It's very appealing to enthusiasts but offers little draw for the typical driver. The *"why bother"* attitude certainly puts you at odds with history and the current state of the market. How will *"the real world of EV"* achieve sustainable high-volume profitable sales in this newest generation now being rolled out? There continues to be growing pressure from traditional vehicles. Think about how well the compact SUV hybrids with a plug would do. It doesn't take much to imagine an Equinox using the Volt system or a Prime version of RAV4. What EV will be able to affordably be able to compete with that?

6-12-2016 **Introduction.** I was difficult to see whether or not I was actually making any progress: *"You really think it's going to be introduced to people that haven't already been introduced to the Volt or Leaf?"* I kept at it though: Introduction means very little. It provides only the most basic information, by no means what's needed to make a purchase decision. People will hear about them and will stumble across tidbits online. They may end up doing some searches to find out more. Just a raising of awareness is nowhere near enough. We've already learned that selling "green" doesn't attract many buyers. Gas prices are low and the mindset is that efficiency & emissions are sufficient. The reasons for switching over to electricity fall on deaf ears. There simply isn't anything compelling to make most people switch. Nothing compares to the showroom experience. Being able to see the vehicle in-person and take a test-drive is priceless. Many, many Prius purchases were the result of discovery at the dealer. Prius Prime will take advantage of those opportunities. Rather than push the "green" aspect, let the technology draw them in. Sorry if some don't like the approach, but that is reality. Being realistic means finding a way to accept the situation. Change doesn't come from forcing an idea. The consumer must be part of the transition. Skipping a step by offering only an end-state doesn't work.

- 6-12-2016** **Obvious.** There's been a lot of looking back as a result of the EV owner attack. Thankfully, much of it has actually be worthwhile. I jumped in with: It should have been obvious, but clearly wasn't, that Toyota's effort to make the best use of plug-supplied electricity exceeded consumer understanding. Expectations were stuck on keeping the engine off as long as possible... even if it meant sacrificing efficiency. So, Toyota made the choice to delay. Notice what that gets us? Besides the obvious larger capacity due to continued cost reductions with lithium battery technology, we also get an electric heating system much more efficient than the gen-1 plug-in offerings. Combine that with the added power from the bigger battery (there's enough power to accelerate to 84 mph using only electricity), you've got a system much easier to sell to those consumers. Waiting for something better frustrated some. Others felt let down. There were even a few who believed the idea of plugging in had been abandoned entirely. At least we all know why that there was good reason. Reaching out to consumers beyond just enthusiasts was turning out to be much more difficult than anyone had anticipated... for any vehicle with a plug.
- 6-12-2016** **Expectations.** Well, not all goes as hoped. There are some who still express bitterness: *"All I am saying, is that in 2011/2012, Toyota was expecting PiP to go nationwide as well. It didn't."* That unending resentment is a pain. Fortunately, more regular posters are noticing. The pattern of negativity becomes easier to recognize given enough time. I poked back at him with: And you're going to continue *"just saying"* it for years to come... That's really unfortunate. The rest of the story is quite telling. For those who don't know, Toyota rolled out 3 new models of Prius within just a few months of each other. Prius v in December 2011. Prius c in January 2012. Prius PHV in February 2012. That was a major undertaking in a very difficult market. It was a diversification effort in 3 different categories, all at the same time. Toyota carefully watched the market. The 2 new hybrids did really well. The plug-in struggled with the rest of the battery-centric offerings. Deciding to invest more in the rollout of v and c made much more sense. Let the automakers with the big batteries figure out how to penetrate such a stubborn market. In the meantime, continue to invest in research & development of the technology. That worked out well too. Toyota has lots of tax-credits available to help promote rollout of their latest tech (Prius Prime) and the newest hybrid (RAV4) is proving to be popular.

6-15-2016 **Insightful.** The attacks from within have begun: "*When I first joined PriusChat, I've had insightful discussions with him, but since the release of the plug-ins, he has gotten obtuse and heavy on Toyota support.*" It's confirm of change. With this particular individual, he's a well known antagonist who simply enjoys debate. So, the expectation of contradicting posts is the norm. But that was always content related. Now, focus is shifting to shooting the messenger. That doesn't happen much on the big Prius forum. In this case though, there is little conflict. The purpose of Prius Prime is clear. He doesn't like clarity. It prevents endless online exchanges... which I work hard to prevent. So, frustration with approach to provide concise information for people to use for drawing conclusions rubs him the wrong way. Acceptance means no one to respond to his tempting provokes. I replied to his mild attack with: It's the reverse. Other automakers have wandered away from the affordability and offering something for the mainstream. Toyota always held true to that goal. There are many who don't give any importance to business, focusing solely on engineering instead. In other words, they see little value in high-volume sales and profitability. The heavy dependence on tax-credits is an obvious sign of that.

6-15-2016 **Too Bad.** Sometimes, you just get tired of dealing with nonsense like this: "*The thing about high fuel economy is that the 2 to 3 mpg the Prime might have...*" Rather than accept the well-balanced approach, it's a constant claim of shortcomings. In this case, it's the lack of a fifth seat. Even though it rarely ever gets used, isn't as comfortable, and doesn't offer as much room, there's still the portrayal of it being a major issue. If it was actually was a major selling-point, that would be a different story. It's not. The tradeoff of more comfortable seating as a result not being addressed is the first clue that they aren't being constructive. Remember all the reasoning from Volt supporters? Do we really just ignore that? It's why focus shifted to leg & head room instead. We accepted and moved on. Some just plain don't want to. I ended up following that with this: That's a long line of reasoning which doesn't explain what we have actually seen. Think about the sales of RAV4 hybrid. You'd be much better off with a Prius. It's futile to get ordinary people to agree with your logic though. Don't waste your time. They simply aren't interested. It amazes me how that is so hard to accept. That's reality though. People will find an excuse to justify their choice. The switch from wagon & minivan to SUV happened. Like it or not, that's the way it is. We must endorse technology & approach that brings about change. Too bad if it isn't the way you want it.

- 6-15-2016** **Desperation.** I wonder how long nonsense like this will continue: "*Face it - Toyota just hates plug-ins, and they desperately want to believe they will fail...*" Growing tired of the nonsense, this was my stance: Falling for greenwash spin requires the necessity to disregard certain facts. The most obvious is that batteries are still expensive. Why would a top automaker sell a vehicle at a substantial loss? It just plain doesn't make any sense. Yet, some truly believe a miracle will happen and competing directly against traditional offerings without tax-credits is realistic. The other blatant denial is believing electricity is clean & abundant everywhere. It's a cold, hard fact that we still have very dirty energy sources thriving. It's also a harsh reality to accept the fact that there are many who don't have plugs available. Claims that Toyota's approach of offering a modest-sized pluggable battery in a vehicle which seems like more of a hybrid are greenwashing attempts. You have to ignore the EV acceleration, the EV top speed, the EV heating & cooling system for that to be effective. Complete disregard of those attributes with an argument of just short EV range borders on desperation. At least those trying to figure out packaging choice are looking at the approach decision with reasonable assessment.
- 6-15-2016** **The Point.** Not seeing the big picture makes comments like this easy to post: "*My disappointment in Toyota over the Prius Prime has nothing to do with the way I want things. It is because they slacked off, and choose to build a PHEV that competes with the competition of the past.*" That comes from over-simplification. The disbelievers tend to focus solely on the battery-related market, totally disregarding the rest of the vehicles still being produced. That blindness leads to all kinds of problems. Mine should be quite obvious. I don't know how many times the point must be repeated before it finally sinks in: What part of TRADITIONAL VEHICLES is so difficult to accept? They are the true competition, not other plug-in choices. It's blatant denial & dismissal of that which is putting pressure on the adoption of plugging. Focusing on the wrong thing results in a holding back progress. It absolutely amazes me how something seemingly so obvious continues to be a problem.
- 6-16-2016** **No More.** I climbed up on the soapbox again: We have problems attracting ordinary consumers. Dealers are a major contributor to that. Most simply aren't interested in selling a plug-in vehicle. Why? Because it requires a lot of extra effort for very little in return. The lame automaker excuses and constant bickering about supposed deal-breakers isn't accomplishing anything. And yes, we're aware that a few individuals do everything they can to prevent conclusions from being drawn for the sake of keeping the discussions going. No more. Thankfully, the local plug-in owners club here has a very different attitude than some online. They don't see the claim of 22 miles of EV not being enough. They see a system fully capable of delivering an EV drive experience. Then even if the engine fires up afterward, that resulting +100 MPG average in the end is a compelling sales point. It's very easy to stir interest. Potential buyers won't care what we say. They'll be discovering Prius Prime right there at the dealer. Being able to plug in using the outlet already available in their garage and being able to activate EV drive when they want is all they'll need to settle any uncertainty. No intimidation. Unmatched hybrid performance, rock solid Toyota reliability, and a few technical goodies... that will appeal to both consumer & dealer.

- 6-17-2016 Minnesota.** There are no state incentives. It's very unlikely to ever have HOV access. That special privilege isn't something I supported for hybrids or EVs anyway. The goal of mass acceptance means becoming common. You certainly don't want lanes on the highway intended for carpooling to be used for that instead. There's a list of 10 states that offer generous credits of their own to stimulate purchases. That's better, but we certainly don't have that here. Instead, we have brutal Winter to deal with. A vehicle proving its worth in those conditions is rewarding in itself. I get irritated by some who say that money is needed everywhere. We're money progressive. Ethanol was locally researched, locally produced, and locally consumed. It was all within our power to help reduce oil dependency and we did. That's just the way we are. It's too bad that was twisted into something else in other places. Oh well. All I can do is tell it like it is: Here in MN, we haven't ever expected state money. That's way I come across as pushing harder. It was always going to be more of a challenge without incentives like that... and we have real winters to deal with too.
- 6-17-2016 Patience.** What else can be said about waiting for Prius Prime: We hear the same thing every time and others rushing never seem to exhibit any benefit. I went through this in 2000 then 2003 then 2009 then 2012. It's how Toyota operates. Set realistic expectations. Patience.
- 6-17-2016 Cargo Perspective.** There are very few counterpoints remaining. Here's one: *"The loss of trunk space hampers their hybrid sales, and the loss of cargo space will hamper the Prime's."* The fact that it persists surprises me, since it is only in online forums. No one else is stating any concern. So, you lose a little height in back for tall objects. You still get more than some sedan trunks in that regard and dramatically more in length. Width is roughly the same, but diagonal gets you a little bit more play room too. I put the rapidly fading topic (now obvious with the vague nature of the claims) to rest by asking: Sounds like a loss of perspective. The hatchback area is Prius Prime is dramatically larger than a sedan's trunk. Bulky items can easily be transported. What's the supposed problem? Don't give cubic-foot data either. That's clearly a red-herring. What actual real-world cargo are you referring to?
- 6-17-2016 Audience.** I enjoyed seeing this pop up in the now very active thread: *"But pretending that the missing fifth seat and raised cargo floor of the Prius Prime that potential buyers in a dealership can see and touch, and compare to a Prius on the lot, won't have any bearing on their decision is delusional."* It gave me the opportunity to dive into the discussion to poke the antagonist. Like always, the argument comes down to audience. So, it shouldn't take much. Misleading claims are fairly easily exposed simply by stating the situation, as I did: Why are you continuing to state the situation as an absolute? Of course it will have a bearing. The point of a Prime model is not to replace Prius. Stop portraying the situation as if that was the goal. This is the very problem Volt enthusiasts failed to overcome. They refused to acknowledge who the audience actually was.

- 6-17-2016** **Balance.** Sometimes, you feel like the person is clueless. When they keep drawing the same conclusion without reasoning to explain how the different factors end with the same result, what else can you think? Clearly, the very idea of balance eludes some people. The win or lose mentality, with nothing in between, contributes heavily to thinking all situations are polarized. That's annoying. But... I'm willing to put up with it. After all, the term "*spin*" came about for a reason. Some people do it intentionally. In this case, it wasn't. He was having a misunderstanding and I was hoping to be helpful: You did it again! By what other means would you like the situation explained? Clearly, this approach isn't working. I'm open to suggestions... Here's the most simple alternate way I can state it: The past has taught us that people will consider the plug-in when shopping, but will not view it as an "*upgrade*" model. It will stand alone, sharing only certain traits of Prius. The differences will be viewed as tradeoffs, a clear acknowledgment of pros & cons. That overall balance will be the selling point.
- 6-17-2016** **Repetition.** I needed it. The point still wasn't coming across; however, there was a glimmer of hope. "*I understand where you're coming from now... but it still misses the point... not the same audience.*" That was my own comments in response. It didn't work. So, I tried again: In reply to myself, I will quote myself: "*Who is the market for Volt?*" That question was asked scores of times over the years for a very specific reason... to learn about audience. Clearly, some still haven't figured out the underlying purpose of Prius Prime, despite it having been stated many times. It's to grow the market. Simply appealing to prospective Prius buyers won't achieve that. Drawing in new customers, rather than achieving sales through conquest is a terrible business plan. Yet, that's what Volt thrived on. The aspect of drawing in those shopping on the showroom floor was outright dismissed by enthusiasts. They just plain didn't care about those lost opportunities. So, GM kept on catering to them. Toyota isn't following that same approach... since it clearly didn't work. Achieving mainstream sales still hasn't happened. Instead, they will be offering a plug-in Prius that really isn't a Prius. It's different enough to draw the attention of shopper who were just looking around and hadn't ever considered Prius a choice for them. That ability to plug in. The distinct visual appeal. Those enticing tech features. See how some not interested in Prius would give it test-drive? It's an audience who wasn't even looking for an EV driving experience in the first place. That's the ultimate prize. You don't expand the market by appealing to those already interesting in being green. You find a way to entice buyers away from traditional vehicles.
- 6-18-2016** **Corolla Hybrid.** The market in Australia will be getting a hybrid version of Corolla. It's a hatchback model, sharing a resemblance to the discontinued Matrix. It's quite a bit more efficient than the traditional model, 4.1L/100km compared to 6.1L/100km. But it still doesn't match the 3.4L/100km the new Prius delivers. It looks nice. I suspect it will be a candidate for replacing Prius c here. Toyota will be faced with a decision about replacing that smaller model of Prius anyway, why not try a Corolla hybrid here? Though, it wouldn't be a hatchback. That's much like the decision coming up about replacing Prius v too. The hybrid version of RAV4 is a larger cargo-carrying alternative. True, it doesn't deliver the same level of MPG, but the market here for small SUVs is huge. Selling wagons is quite a challenge. Whatever the case, we know choices are being explored. This time, it's in Australia. We've known about others in Japan and Europe for many years now. After all, there have been 9 million Toyota and Lexus hybrids sold now. Only 5.5 million of them have been Prius.

6-19-2016 **Conquest & Cannibalization.**

Back in 2012, Toyota delivered what supporters of Prius had been asking for. It took many years. Toyota simply wasn't interested in delivering a configuration which would allow a plug to be taken advantage of. The reason was simple. Cost of batteries for that was prohibitively high and the source of much of our electricity was dirty.

A tipping point still hadn't been reached yet, but the time had come to prove the system design was capable of what supporters though consumers wanted... a hybrid with significantly improved efficiency. Increased electric-only driving was an expectation, but there was never any priority set on having a full EV experience.

The only supposed "competition" was struggling. Volt had the industry spotlight. GM wasn't able to draw in its own customers though. Sales came primarily from conquests & early-adopters. That was confirmed as the shockingly low lease-prices were phased out. That was followed by dramatically lowered PRICE with no correlation to COST having been reduced. It didn't anyway. Sales continued flat. Now in 2015, we see GM struggling with flat sales of gen-2 Volt and the new problem of cannibalization. Bolt will be stealing away potential Volt buyers.

Toyota is working really hard to avoid falling into the same trap. Rather than trying to conquest or cannibalize, they configured Prius Prime to be different from Prius. The true competition is traditional vehicles. How do you entice a customer who's been absolutely delighted with their Camry or Corolla to consider the purchase of a vehicle offering a plug?

Squeezing a battery-pack large enough into a sedan just plain isn't realistic. Ford has only had modest success with Fusion Energi. The loss of trunk space is so extreme, most potential buyers abandon the idea upon seeing it. Prius Prime doesn't have that limitation. Even with the slightly raised floor (less than the height of a smart phone), the area available for cargo still significantly exceeds that of what Camry or Corolla offer.

The 22-mile range for EV easily covers traffic congestion spans for long work-commutes and the entire distance for short work-commutes. That also covers errand-running around the suburbs in the evening. In other words, it's enough to make selling the idea very easy. Sales people don't even have to bother with any discussion of level-2 chargers. The customer can simply use the standard 120-volt electrical outlet they already have in their garage for recharging.

Think about the test-drive. When someone who was shopping the showroom floor is offered the opportunity and suddenly finds themselves behind the wheel experience the full-power EV drive, what do you think their thoughts will be? They'll be trying to remember when the last time was that they actually had more than 2 people in their Camry or Corolla. They'll wonder if any are available for immediate purchase and what colors are offered. They'll consider what their MPG average will be.

In other words, it's a carefully considered approach to overcome barriers of the past. Toyota did their homework, studying every bit of data the limited Prius PHV availability could provide. The rollout of Prius Prime will be to 35 states which will see

this plug-in as Toyota's first offering. The others will see a greatly improved version. The nation as a whole will see it as an undeniable step away from traditional vehicles.

6-19-2016 **Group Think Problem.** Ramping up for Prius Prime rollout has begun. My push is growing. Some won't like it. Some will be thrilled by leaders emerging in the effort to promote. I thoroughly enjoy doing it. This will be the fifth major release to participate in. Each was very exciting and very fulfilling. I'm looking forward to this Fall. Can you tell from this post: I'm somewhat surprised by how deeply entrenched the group-think problem has become. True, a large chunk of that will fade away as the rollout of Prius Prime progresses. Real-World data can be a very effective tool. But prior to even knowing what the price will be, some have dominated discussions with what could be looked upon as rhetoric. That should be easy to see too, simply because the market-attitude toward plugging in has changed yet the perceived audience has not. In other words, there's still an perspective of us & them. Either you're in the market for a plug-in vehicle or you are not. It's an approach that intentionally limits scope. Rather than take on the monumental problem of traditional vehicles, you choose to stay within the realm of those who won't settle for anything without a plug. It's a head-in-the-sand stance that no one seems to notice. How can so many be so naïve? I'm beyond frustrated with the pig-headed nature of this outlook. It may not be intentional, but it sure is predominant... so much so, it's getting in the way of progress. You've heard of "*being your own worst enemy*" used as a reason for getting stuck. Seemingly harmless habits lead to years of struggle. This group-think problem is becoming the very barrier we've been trying to overcome. It's a self-inflicted situation which prevents goals from being achieved. Don't expect me to stop pointing out the true competition or the reasons for Toyota's approach. Knowing audience & purpose is absolutely vital. Acknowledgement of that is a necessity; otherwise, we'll continue to argue amongst ourselves rather than actually make any progress.

- 6-19-2016** **Time.** Constructive discussion can be quite fulfilling. I enjoyed answering this: *"You keep asking the same question, but your answers fall short in my mind. I can't prove you wrong until the car hits the street. I hope i'm wrong, but I just don't see the attraction of prime for people buying ice vehicles at todays gas prices."* Not having all the information you need, but asking questions rather than making assumption is great. So, I provided: That's because you left something out of the equation. It's a very common oversight. You're in large company. So, no worries. The missing element is time. It will take 2 years following rollout for Prius Prime to become established. Anyone who thinks the distribution, education, and real-world data sharing can be achieved in a shorter duration clearly hasn't studied history. Think about where the industry will be at that point. Many tax-credits would have expired and EV sightings will have become routine. At that point, the MARKET WOULD HAVE CHANGED. It's that upcoming audience is what Prius Prime is targeted at, not what we'll in just 6 months. Think about what their perspective will be. Low gas prices won't have as much of an influence since battery-tech will be affordable. Parking spots with charging-stations becoming common by then is a realistic expectation. Reputation for reliability would be established. Uncertainty of industry intent will have diminished. 8.8 kWh may be thought of as *"too small"* by some now. 2.5 years from now is an entirely different story. That will be entry-level for plugging in, much like around 1.2 kWh became for hybrids. Rather than being treated as insufficient, it will have become an expectation for mainstream competing with traditional vehicles. In other words, a platform like Camry and Corolla still won't be realistic for plug-in hybrid offerings. Prius Prime will. It's configured to become competitive within this generation, even with cheap gas and expired tax-credits. It has the potential to bring about a RAV4 Prime offering as well. What other approach has that going for it, being able to survive as a high-volume profitable vehicle in a market so different from the one it is currently being judged against? Remember, Toyota will still be producing traditional vehicles. That presence on showroom floors represents a serious barrier to overcome in the minds of ordinary consumers.
- 6-21-2016** **14.3 Miles.** That's the highest EV range estimate I have ever seen. It's just a calculation based on prior driving history. Actual EV will obviously vary. Nonetheless, it is interesting to see. That makes me wonder what people will think when Prius Prime becomes available. My videos of driving to work and around town will go from showing really impressive MPG to all-electric in some cases. The further driving examples, when the hybrid system really shines, will be difficult to film. I'd have to have the camera on time-lapse. The complex setup for lighting would be even more of a challenge to sustain for long distances. I'll have to come up with some new approach. In the meantime, I'm enjoying Summer with the Prius PHV. It's still delivering that solid 11 miles of EV... despite what the antagonists claim. That's after over 4 years of driving & recharging too. Toyota clearly designed a nice system aimed at the mass market. There's no doubt about that. The catch is getting the right balance of battery & cost to deliver that electricity use, whether it be EV or EV-BOOST (that's HV with plug-supplied electricity).

- 6-22-2016** **Misdirecting.** This was the spin I got today: "*You do anything to misdirect attention away from Prius.*" It was the result of accepting bluffs from 2 antagonists. They were desperately attempting to disparage the upcoming new plug-in Prius, but didn't actually present any substance. They simply concluded it was a pointless endeavor. Being well aware that detail exposes false claims, I was more than happy to welcome whatever supposed fact they wanted to provide. Neither one delivered. It was nothing but another day of meritless rhetoric. When they have nothing but propaganda to spread, that's a good sign. I'm very much looking forward to rollout this Fall. In the meantime, I'll keep responding to attempts to distract & discredit with stuff like this: Asking directly for feedback about Prius repeatedly is misdirecting? No. We know all too well that they've got nothing to support the failure and do a claims looking forward. As much as they want to dismiss Prius Prime from attention, it simply won't work. There are a number of traits shared with the other plug-in hybrids.
- 6-23-2016** **\$10.2 Billion.** That's what the cost to VW appears to be for the United States. The end of next week, it will be official. Supposedly, two-thirds of that money will go toward upgrading the diesel system to make it clean enough to pass the emission criteria it violated and the other third will be used for paying state & federal fines. Diesel is obviously dead now. There's no point of it for consumer vehicles. The gen-4 Prius outperforms by such a large margin, competing is impossible. To that effect, plans are to drop their only hybrid offering next year. The expectation is that major investment will be made toward offering a variety of EV choices. It's a massive commitment, but what other option is available? Without diesel and having hybrid that doesn't provide a large MPG gain leaves them with only that. The consequence of sticking with diesel until the bitter end was clearly a terrible decision. We always anticipated the emissions & efficiency of hybrids would widen the gap enough to simply draw sales away from diesel, enough to slowly sour the milk. We had no idea it would come in such an abrupt manner. Corruption certainly wasn't expected... though, some of the attitudes did support theorizing that. Some were dishonest. They'd cherry-pick data, showing you only results to show favor. Some were dismissive. They'd state how much cleaner diesel had become, ignoring the fact that it was still among the dirtiest vehicles on the road. Those new "clean diesel" offerings were always suspicious. How could they possibly achieve what was claimed. It just didn't add up. Of course, now we find out the real math. The total is \$10.2 Billion. And that's just here in the United States. Think about the impact in Europe. Think about how much investment it will take to aggressively switch over to electric-only offerings.

6-24-2016 **Compliance Vehicles.** We get long, elaborate posts sometimes. The conclusions are often what set me off. In this case, it was the use of the term "*compliance*" vehicle. I wanted to know what that actually meant to him, especially since the definition has changed over the years. It had become a means of identifying token efforts, where the automaker makes just a minimum to satisfy some type of compliance criteria. Only problem is, we had no idea for what or for who or how many anymore. The term is so generic now, it is used to belittle & degrade rather than actually be informative. So, I asked and got this: *"A car designed primarily with the goal of meeting legal mandates to sell EVs, rather than as a good car. Which is evident in some of the packaging compromises that Toyota made when designing the Prime, rather than redesigning the unibody to maintain most of the versatility of the Liftback."* Notice how no detail was provided... nothing whatsoever. Heck, it wasn't even specified what "*good*" means. I find that quite irritating. It's the rhetoric we have to deal with on a regular basis. Not responding allows it to become propaganda. Obviously, I wasn't going to just watch that happen. This was my response, which almost immediately got 3 likes: Toyota did retain **most** of the design! You still get the great new handling of the improved suspension. You still get the great emissions & efficiency from the hybrid system. You still get the same head & leg room of the hybrid model. You still get a cargo area much larger than competing sedans. Expecting no tradeoffs whatsoever is neither constructive nor realistic.

6-25-2016 **Incentive Problem, part 1.** This conclusion came from an antagonist absolutely obsessed with keeping discussions active. Drawing a conclusion early with weak evidence is a way to stir new responses. It certainly worked on me: *"...but the rest of the competition has battery packs close to the size of the Prime, which leaves the Prime about the same price as them."* Seeing that, I was pleased about him giving up on the square-foot arguments, but frustrated for a new reason. His insistence on more being better was rather desperate. If the dimensions are accommodating, it makes no sense. The most simple of examples kept getting dismissed though: length. No sedan can carry a long object of any substance. Have you seen how small pass-throughs actually are? There's just a tiny hole in an clumsy location. My frustration offer becomes opportunity. I see the benefit of pushing the incentive problem into everyday discussion on the big Prius forum. Doing that on the daily blog for Volt with gen-1 was a disaster. They attacked me relentlessly, claiming a well-engineered vehicle would sell itself. They expressed no concern about dealer or salespeople incentive. That problem has since come back to haunt them. Sales of gen-2 are struggling the very same way. They thought an even more refined system without compromise is all that it would take. In fact, some still mock the tradeoffs Toyota will be making with Prius Prime. I'll start by addressing those on the bit Prius forum about the problem.

- 6-25-2016 Incentive Problem, part 2.** This is what I ended up posting on the big Prius forum: That logic is clouded by audience identification. You are focused solely on the consumer perspective, which in itself is problematic. That's not the only barrier to overcome though. Another must be fulfilled to achieve sales growth. How profitable do you believe the other automakers platforms are? Prius has been around much longer, upgraded aggressively for COST reduction. The resulting PRICE will provide far more incentive for dealers & salespeople to actually carry & sell the car. That's absolutely vital to attract the other audience. Those other automakers don't have that much of an advantage. This is a major concern the Volt enthusiasts dismissed for years. They now realize how wrong it was to not acknowledge such a business fundamental. No matter how appealing a technology may be to prospective buyers, it won't be purchased in large numbers if it is difficult to acquire. Sales have suffered as a result. The plug-in owners group here addresses complaints routinely about how much of a problem is simply trying to find vehicles for purchase. The pig-headed individuals here who complained about Toyota halting the rollout of Prius PHV have grown silent as they learned of this incentive problem. It's not a just matter of the automaker producing & offering inventory. Dealers have to actually want to carry them on the lot. Salespeople must have the desire to show them to customers. That interest comes about when COST is reduced enough to earn the dealer a decent profit and the salesperson an appealing commission. That may mean PRICE doesn't come down much. But it should be easier to see how much more likely a purchase will be.
- 6-25-2016 Incentive Problem, part 3.** Posts on the daily blog for Volt are pretty much dead. They just chat about this & that now. The days of attack, belittle, and insult are gone. Yeah! Like with most gen-2 rollouts, it's either a make or break situation. The uncertainty & discomfort is what stimulates discussions prior to the big day. Afterward, much changes. In this case, no more of the rhetoric. Heck, there isn't even any propaganda anymore either. They've pretty much all moved on to electric-only vehicles. No engine at all is what they really wanted all along anyway. Volt was really just a "*stop gap*" that couldn't be agreed upon for range, price, and audience. Prius Prime, on the other hand, has a much clearer purpose. Yes, there are a few "*vastly superior*" troublemakers, but some have actually turned. We're seeing antagonists of the past admitting that it will likely outsell Volt by a wide margin. Despite the smaller range, the remarkable reliability along with the fantastic depleted efficiency makes a compelling draw that many will not be able to resist. When you see former attitudes fade away prior to rollout, that's a very good sign. It means effort to focus on the incentive problem now should be fairly effective.

- 6-26-2016** **Strange Comments.** This one certainly stirred some posting: "*What was Toyota thinking?*" It came from someone shopping for a plug-in vehicle, but then ended up buying a regular Prius. Huh? If he was so excited about the consideration of a Prius Prime, why didn't he get something else from the disappointment of not enough EV capacity? It makes no sense at all to choose 0 miles. 22 is far more than none at all. I wanted to know more upon seeing an explanation of how it should have been more like a Volt, but then hearing how he purchased a Prius anyway. My guess is brand loyalty kept him from choosing GM. That strong sense of not choosing another automaker is what Volt has struggled so much lately. It doesn't appeal to GM's own customers, so they just purchase a Malibu or Cruze instead. I responded to that with: They saw how Volt has failed to gain market, despite gen-2 improvements and greater range, then decided to take a different approach. The topic has been beaten to death already. You want to appeal to ordinary consumers, you cannot cater to EV enthusiasts. This isn't rocket science; it's just routine business. Sustaining sales in high-volume at a profit without government incentives requires a thoughtful balance of all involved. Looking at the situation from just a consumer perspective will leave you wondering. There's much more to the equation. Think about everything it takes to actually produce & sell a vehicle that way. You purchased a gen-4 Prius, rather than something with a plug. Why?
- 6-28-2016** **\$14.7 Billion.** It looks like VW is in far more trouble than anticipated. That expectation of around \$10 Billion ended up being just the consumer part. Paying for repair or replacement is very important, but there is also the damage to the environment that has already taken place to consider. Money will be needed for that too. It will come in the form of federal & state penalties, which will be reinvested into betterment programs. An obvious gain from this money will be funding to expand the public recharging infrastructure. Now that diesel for consumer vehicles is essentially dead, there is growing interest in the alternative... plugging in. So, that makes sense. I'm still in dismay that the death was so painful. All those greenwashing efforts made it easy to see diesel was struggling already. But when you've got a plug-in hybrid like my Prius PHV, delivering efficiency quite a bit higher and emissions undeniably lower, where's the competition? There was no aspect of challenge already and the second-generation was destined to devastate. Needless to say, we are saying goodbye to that clutter of compression-engines being used for commuting in favor of ever-increasing electricity use.
- 6-30-2016** **Meritless Claims, part 1.** I was absolutely delighted upon reading this today: "*I think GM has a significant edge over the other manufacturers with their Voltec system.*" Nothing has come from claims like that in the past. They had a little merit to them back then too. But since then, the cost, efficiency, and appeal has proven that's not the case. We're seeing other automakers strive to reach the goal GM couldn't as well. I really wanted to know what edge that poster was talking about. So, I asked: Ford, Toyota, and Honda all have plug-in hybrid systems. What makes GM's stand out?

- 6-30-2016** **Meritless Claims, part 2.** I followed up right away, with a separate post to emphasize how meritless I found the claim to be. It's really annoying to get brainless cheerleading like that. It only serves to undermine too. Rather than providing support for the overall goal of reducing emissions & consumption, it just turns into trying to deliver the best niche product. What good is that? It's why I asked: "*Who is the market for Volt?*" Knowing GM wasn't targeting ordinary consumers, that their intent to deliver a mainstream vehicle went horribly wrong, made it imperative to get supporters back on track. They didn't like it at all. In fact, many hated me as a result. I didn't care. Their disregard for the masses ruined their credibility. When their best efforts were obviously insincere, I was encouraged. My own efforts would ultimately reveal what needed to be done. They'd have to suck up their pride and join in to build a partnership. This was yet another post to that effect: Isn't the minivan coming from Chrysler part of the old partnership that GM had with the development of Two-Mode plug-in tech... which ultimately led to Volt? Also, we'll be seeing Hyundai and Mitsubishi rolling out plug-in hybrids. Then, there's BMW now and Nissan planning serial-extendors.
- 7-01-2016** **July Sales.** What a sad situation. June was a mess for the industry anyway. The approach of year-end model clearance puts uncertainty on the market. Slowed sales of everything due to economic pressure adds to that. The shockingly low price for a gallon of gas makes it even worse. Why even consider a hybrid? Fortunately, Toyota really did as some of us had anticipated. The expiration of NiMH patents allowed for new opportunity. That's what provided such a low cost difference for RAV4. The AWD XLE model has a \$28,570 MSRP. The hybrid version of the XLE model has a \$29,270 MSRP. That's only \$700 more. Talking about a sweet deal. It explains the 3,751 sales, despite so many factors working against that type of success. Toyota is clearly capitalizing on the demand for small SUVs. We haven't seen growth for the new Prius either. Sales are basically flat, all things considered. One glimmer of hope is the buybacks of VW cheater diesels present a strong probability for contributing to hybrid growth. It's hard to imagine owners who took pride in high MPG going back to guzzlers. Why not restore some pride by purchasing a hybrid as a replacement vehicle?

- 7-07-2016** **Prius Prime Is Better, comparing.** I rarely start new threads. But when you see this title on an article, then discover why, you must: "*3 Reasons Toyota Expects the Prius Prime to Be a Huge Success*". The reasoning was greenwash material. I was frustrated: It's pretty easy to mislead about past hybrid system characteristics with an audience unfamiliar with the history. We've seen this type of misleading in the past with the regular model of Prius. So, it was pretty much inevitable when the next generation of plug-in model rolled out. It started with this statement about Prius PHV (the first generation of plug-in hybrid): "*It's hard to argue with Toyota executives on this point. The first Prius plug-in was rated by the EPA at 11 EV miles, but a look at fuelconomy.gov reveals it could only go 6 miles on electric power alone.*" That's blatant misleading. The capacity of plug-supplied electricity clearly isn't consumed entirely at the 6-mile mark in the EPA testing cycle. That topic was beaten to death over the first few years following rollout. Greenwash attempts were plentiful, but all fell short when actual kWh capacity was considered. There really is 11 miles of EV available. Driving without a hard-acceleration, like the EPA test has, easily confirms that. The next was frustrating to read: "*Imagine finding a Level 2 (240v) charger and hanging out for 1.5 hours every time you wanted to get the old Prius PHEV fully charged. It sounds ridiculous when you only get 6 electric miles out of the deal, but that's how long it took on a 240v connection. On a standard household outlet (110v), it would take between three and four hours to fill the battery.*" Not only was there that same misleading point about EV range, it also included an outright lie. On a standard household outlet, it only takes 2.5 hours to fully recharge. That attempt to claim it's 3 to 4 hours is so wrong and blatantly incorrect, I can't help but to get angered from reading it. Sadly, the reasons for those statements was to convince us that Prius Prime (the second generation of plug-in hybrid) will be much more successful. That's not the slightest bit constructive. Omitting vital detail and including information that is clearly not right really frustrates, to say the least. Why do some people do that?
- 7-08-2016** **Prius Prime Is Better, real-world data.** Being an entirely new topic to discuss, it was easy to draw interest. An effective way of rallying the troops is to interject real-world data. So, I did: 12.0 miles exactly for EV on the commute home yesterday. All were consecutive. I simply drove and stopped when 0.1 miles of range was left and shut off the Prius for a summary photo. It said 11.9 miles had been traveled with just electricity. I had 2 quick jaunts on the highway at 55 mph and there were 2 big hills to climb. No big deal... and twice the distance claimed. Overall efficiency for the round-trip, with a recharge at work, was 145 MPG. That's great for 39.9 miles of driving with the Prius PHV. Just think what the Prius Prime will be able to do on that same route driven the same way.
- 7-08-2016** **Prius Prime Is Better, tangents.** Inevitably, someone will derail the topic by mentioning fuel-cell vehicles. It's annoying, but understandable. I just simply respond with some perspective to get the discussion back on track: Effective greenwashing has led many to believe fuel-cell and electric-only vehicles are mutually exclusive. In reality, they will coexist. It is a means of getting uninformed readers to undermine discussion threads and discredit Toyota. Ultimately, the goal is to divert attention and prevent awareness of cost & profit importance. Prius Prime taking advantage of Toyota's new production approach aged keeping the pack relatively small helps to establish it as a high-volume vehicle capable of actually competing directly with the true competition without tax-credits traditional vehicles. What other plug-in hybrid is positioned for that?

- 7-08-2016** **Prius Prime Is Better, official FAQ.** It's nice when truly constructive questions pop up in a discussion. In this case, it was to ask what information had been released about charging times from Toyota. Turns out, some people find it challenging to actually find that. After all, online searches return an overwhelming number of links. The act of determining which has what you need and if that source can be trusted isn't easy. Fortunately, I save detail like that. You never know when it could be handy to have readily available. In this case, I was able to share... This is Toyota's official FAQ on recharge time for Prius Prime: *Prius Prime's battery can be charged in 5.5 hours by plugging the included charge cable into a standard household outlet. When using a public charging station (240V), Prius Prime can be fully charged in just under 2.5 hours.*
- 7-08-2016** **Prius Prime Is Better, no value.** It has always been a frustration to read posts with calculations that don't assign any monetary worth to having cleaner emissions and reduced oil-dependency. Sadly, almost all are nothing but MPG numbers. Their focus is to justify the "hybrid premium" based solely on the cost-savings from using less gas. They set the expectation of the "free lunch" scenario virtually every time. Rather than promote the benefit by speaking of its value, they exclude it entirely. That's as absurd as expecting a premium upgrade feature without paying for it. No one ever does that when choosing the larger engine for a vehicle. They are more than willing to pay for the increased power. But when it comes to increased efficiency (and the resulting decreased pollution), they are not. That goes way beyond double-standard. But expression of emotion toward the topic doesn't achieve anything. So, I settle for posting to-the-point comments like this: Applying no value whatsoever to the substitution of electricity in place of gas is the same sales challenge the regular Prius has had since the beginning. That perspective is a major problem for anything green. For that matter, you're far better off financially sticking with your old car.
- 7-08-2016** **Prius Prime Is Better, more is better.** Sometimes, you just plain can't get the message across. There's always someone who falls into the "more is better" trap. That problem coming up in this new topic was inevitable. It can't be avoided. It can't be prevented. It can only be responded to. The ultimate problem is their response is a gut reaction with little actual thought. Rather than joining them by responding with numerical exchanges, the best way to respond to that is to give them something to ponder. Remember how senseless the acceleration-speed arguments were well over a decade ago? Most people have no clue how much of a supposed issue that was. The greenwashing (both unintentional and deliberate) came about from the same belief... numbers. In that case, smaller was supposedly better. No one could prove way though. That's because real-world data proved it was overkill. That's the same in this situation too. More simply isn't necessary. The goal of significantly reduced emissions & consumption is easily achieved with a 22-mile EV capacity. In other words, stop thinking about "range" and start thinking about results. I put it this way: That belief of more EV being better hasn't proven the case so far and continues without substance. It's not so simplistic. The true competition isn't other plug-in vehicles either. Consider audience and production cost. Then think about dealer inventory and salesperson incentive.

7-09-2016 **Prius Prime Is Better, the challenge.** It continued: The themes of "*never enough*" and "*true competition*" come up over and over again. Each new thread may touch the topic, but none really actually address it well. That's the challenge to overcome. Volt just plain didn't attract the attention of the masses, even when gas was really expensive. It was those countless other factors of influence discussion struggle to get into. So, it tends to just fall back on more EV is better. Interestingly, the topic of Tesla popped up today at the barber shop. Even with the 200-mile range, that simply wasn't enough. They just dismissed the idea of electric-only travel and moved on. At least with some focus on 4 or 5 seats, we are seeing some movement beyond the trapped mindset of the past. Will people dismiss Prius Prime just as easily as Tesla was today? The supposed mass-market choices, like Volt and Leaf, certainly aren't coming up in conversations. Heck, we barely here mention of them here anymore. Signs of change are finally emerging. The old daily blog for Volt has been void of Volt topics for quite awhile now. It has transformed into another venue for plug-in support discussions. Posts no longer find Prius a competitor. Reality is finally sinking in that traditional vehicles are really the true competition. Consider how unappealing a plug-in vehicle is to a traditional salesperson. When you can get a commission that's larger and much easier, why bother? Selling a guzzler takes so little effort in comparison. That's where Prius Prime comes in. Even though some here don't like the approach, the lower production-cost (equating to higher commission) and obvious appeal of EV make a compelling reason for salespeople to actually try. A simple test-drive will be enough to get potential buyers to consider the purchase. That's hard to do with a regular Prius when you encounter a loyal Toyota customer on the showroom floor. But with the plug-in offering a new twist on being green, but not requiring significant compromise, there's opportunity.

- 7-10-2016** **Prius Prime Is Better, great example.** As supporters, we have much to share: For ordinary consumers, the topic of PHV verses Prime really doesn't make any difference. Today provided a great example. At that new grocery store, just 0.6 mile from our house, there are 4 charging stations... free and in high traffic locations. (It's a pretty sweet setup.) That draws attention to the Prius PHV. I've had people stop to ask about what I think of owning a car with a plug. They aren't obsessed with detail like many of us here in the forum. They simply want to know about convenience & reliability. Oddly, price isn't asked about. It really is just a matter of having confidence in the technology. That's the key. That's what will help sell it. Today, my wife just stepped back and let me engage in a quick conversation with a passer-by. I answered a series of questions. Range wasn't even asked about. I eventually just mentioned my 72 MPG average and that the newer version coming out this Fall would do even better. Her curiosity, there in the parking lot, looked very much like what I anticipate at the dealership later with Prius Prime. Ordinary people will simply want to know more and the basics are all easy to convey. We learned from Volt that attracting attention of customers wandering around on the showroom floor, just randomly shopping with the hope of stumbling across something to excite them, is vital. GM still hasn't achieved that. Sales for Volt come from conquest. Rather than appealing to their own base, buyers are from other automakers. That's a major opportunity lost and a sign of hard times to come. The goal is to transition from traditional vehicles to cleaner more efficient choices. Not being able to appeal to your own loyal customers is a very big problem. Toyota is attempting to overcome that, trying to avoid falling into the same trap as GM. That's why Prius Prime doesn't fit the profile we've come to expect. Change is challenging. I'm quite optimistic this approach will break out beyond current barriers. 22 miles seems small to us. But to the them, the resulting MPG will blow their minds. It's easy to understand and will be effortless to achieve. That's a winning formula for drawing in the masses.
- 7-11-2016** **Prius Prime Is Better, think about.** When you read this, what do you think: "*Honestly, I have a feeling Toyota will cripple sales of the Prius Prime to try to prove that people don't want to but plug-in's (between lack of 5th seat, price which we don't know yet, and nationwide availability which we'll see if actually happens).*" This is what I posted: That's a terrible way of setting expectations. By that, I don't mean the negative attitude. You're entitled to your opinion. That's fine. It's the vague nature of price & availability doesn't actually tell us anything. In other words, what goals have you set for the measure of success or failure? Keep in mind that not knowing is what crippled other vehicles in the past. People will just spin results without clear expectations having been stated. Think about the state of the market... mandates, credits, automakers, dealers, consumers, and battery technology.

7-11-2016 **Prius Prime Is Better, expectations.**

Setting them key. Prius PHV had a purpose. Remember what it was? That begs the same question of Prius Prime.

When Toyota rolled out their first plug-in hybrid, the design had a clear focus of augmenting the existing design. Give it a larger battery and means of supplying electricity that wasn't derived from gas. Since the design already had untapped abilities, like a more powerful traction motor than what the smaller battery could support, that extra boost was easy to exploit. The engineers had already taken the future into account. It was basically just a matter of waiting for cost to drop.

Turns out though, the market expectation was pushed in another direction following rollout. Volt was directly responsible for that. GM provided proof that power beyond the existing thresholds for Prius were desirable... but wasn't actually able to capitalize on it. GM wasn't able to capture interest from mainstream consumers as hoped. So, Toyota halted rollout plans and instead decided to focus on the limited established markets instead. The question became a matter of how to learn from GM's struggle and their own success with Prius.

What should the next-generation design deliver?

Toyota's approach of platform refinement & reuse has always been the key to sales & profitability. With a plug-in model, much of the design would need to be shared to have that advantage. The 4th generation Prius would become the first to use TNGA, a modular approach to vehicle production. The next PHV (known as "Prime") would follow using it.

Turns out, adding a clutch to disengage the gas-engine allows both electric-motors to deliver propulsion power. No need to alter much else. Switching from a traction/generator relation in the regular Prius to a traction/traction approach for the plug-in really was that simple. The increased battery-capacity could be exploited with little extra cost. More power could be delivered.

The question now is how can Toyota succeed where GM continues to struggle. Toyota will deliver the improvements claimed to be vital to advance gen-1 to gen-2. Like the PHV model, Prime will deliver industry-top efficiency following depletion of plug-supplied electricity. Prior to that, you'll get full EV driving experience, which includes an industry-top cabin heating system.

It boils down to initial reaction. Will ordinary consumers find the 22-mile rating acceptable enough to take a closer look? Since all the expectations are fulfilled, there isn't much else to ask.

- 7-12-2016** **The Point.** There was a new discussion on one of those all-audience blogs for green cars. I couldn't resist diving in upon reading this: "*The Prius Prime would not work for many commuters in the Minneapolis/St. Paul metro area as a commuter vehicle, even if you exclude winter.*" It seemed as though I would be dealing with someone who just plain didn't know how the system actually works. Sadly, I may never find out either. Those venues have threads with short lives and participants are quite random. Oh well. At least I could join in: That misses the point. AER to cover your entire commute isn't necessary. My recharging at work is to replenish the current 4.4 kWh battery. With the new 8.8 kWh, I wouldn't need to since the total round-trip capacity is doubled. Overall MPG will be outstanding, even without recharging at work. You still get the benefits of the hybrid system. You still get the benefit from plug-supplied electricity.
- 7-12-2016** **Wrong Audience.** I actually got a response: "*Necessary, and it being what the vast majority of people purchasing plug-ins expect are two different things. From my experience you are in the minority in not caring.*" He acknowledged the outstanding MPG, but just plain didn't care. Focus was entirely on AER. If that "*All Electric Range*" isn't far enough, he considers the configuration a failure. It's that all-or-none mindset. The purity nonsense went nowhere for 5.5 years. The niche perspective simply doesn't work. Ordinary people don't purchase an absolute; instead, they seek out a balance. Oh well. Some people never learn. For the rest: Those early adopters are not representative of the masses. Mainstream consumers are quite different. They will go for an augmented hybrid. They are not expecting electric-only drive 100% of the time. The 5.5 million Prius owners never had that expectation, but would be willing to pay more for more electric-only driving but still want a hybrid... which is exactly what Prius Prime delivers.
- 7-13-2016** **Reducing Dependency.** This simple message got a few likes: 89 MPG from my commute and evening driving today with my Prius PHV. 65.7 miles total. 2 full charges used. That's 4.4 kWh twice. In other words... it's a representation of what Prius Prime could deliver with a single charge. Keep in mind, the newer will have a more efficient electrical system. That certainly reduces our dependency on oil.
- 7-13-2016** **Purity Obsession.** Some people really don't learn: "*The point being gas is still being used when it might not have to use any at all.*" You sometimes have to wonder just how far someone would take that. Pushing a principle doesn't accomplish much. It's far more effective to lead by example. We see many stepping up to wait for the purchase of an EV. The wait is painful. Many actually will follow through. They are who post comments like that though. That unfortunate "do as I say, not do as I do" approach is annoying. That's why I push for detail. It reveals true intent. I also just push back, like today: No. That is not the point. It is to reduce gas consumption, not eliminate it. You want electric-only, you buy something that offers far more capacity. The effort to focus solely on commute distance is insincere... since most people have a life... meaning they drive somewhere else after work. That means using some gas on a regular basis.

7-15-2016 Prius Prime Is Better, annoyed. He tried to turn it back on me. I was annoyed and wouldn't allow that, especially from such a memorable antagonist. So, I pushed back. This is what ultimately did it: *"Agreed but I was only responding to your posts which in a full circle sort of way gets back to your OP concerning dealing with misleading statements or uninformed opinions."* And I was happy to reply with...

When I provided the opportunity to present some data, you chose to spin instead. That's a letdown and the same waste we had to deal with back when you owned a Volt. Why not try to help everyone move beyond that? Here's an example of what you should have posted:

Prius PHV cuts off EV depletion at 23.5% of total battery-capacity. If the engine is cold, up to 5.5% of the remaining capacity (down to 18.0%) may be used for warm-up. The purpose of consuming that electricity with a high-draw is reduce emissions by limiting the amount of propulsion power demand on the engine by keeping it at a low RPM. The traction-motor handles that burden instead.

Your supposed claim is that Prius Prime should consume that electricity for EV driving, preventing the engine from ever starting due to being close to your destination. This would mode would automatically be activated based upon current GPS location being compared to saved driving history.

In theory, that sounds simple. Looking at the actual data, not so much. Just under 0.25 kWh is available. Using the standard measure of 4 miles per 1 kWh, that electricity is enough to take you 1 mile under favorable driving conditions. With the heater or A/C running, highway speeds, acceleration from a stop, or having to climb a large hill, that distance available is reduced. Those factors will not be apparent to drivers.

In other words, a vague statement of *"like EV+"* only serves to feed assumptions and establish false expectations. By far, the better approach is to present information so discussions can take place about it and other detail & experiences can be shared. I requested that, but didn't get it.

7-15-2016 Support Material. I especially enjoyed sharing this today: Speaking of information sharing, I have been collecting Prius Prime support material from my Prius PHV for over 4 years now. By recharging the 4.4 kWh battery-pack each day at work, that resulting real-world detail provides a basis of expectations for the 8.8 kWh battery-pack with only a single charge. It was reasonable to believe Toyota would attempt to deliver double the current capacity. Little did I know that was exactly what would happen. Fortunately, it did. Now we have something to build upon, even before rollout begins. We know that Toyota has worked hard to increase efficiency of the electrical system too. So, results from Prius Prime should be better just recharging once per day. In my case, the 38-mile commute easily falls within the 22-mile capacity. So, recharging at work will put me into the 999 MPG category when I upgrade. I'm quite curious how the vapor-injected heat-pump will operate in Minnesota Winter driving. I'm also quite excited about the heated steering-wheel and the ability to pre-warm the vehicle using plug-supplied electricity. There's much to look forward to. Hopefully, my wait to upgrade will be less than 5 months.

- 7-15-2016** **More Misleading.** Sometimes, you simply have to blog about to... because some won't believe later that it actually happened: Here's another example of promoting by misleading: *"In 2012, just as other carmakers seduced these buyers with all-electric cars and plug-in hybrids boasting ranges of about 20 miles, Toyota finally offered them a Prius that had a charging port. But it was capable of just 6 miles of electric range—and that was only when it was driven as if an egg were under your right foot."* Not only did a supposedly reputable publisher claim just 6 miles total capacity, they also implied many carmakers were offering plug-in hybrids back then. In reality, capacity was 11 miles and it was only Ford. Another bit of misleading that got my goat was: *"Top speed in EV mode is 84 mph, which makes it more usable than the former Prius Plug-In's (mostly theoretical) 62-mph top end in EV mode."* Since when is the 62 mph EV speed theoretical? I see that routinely. What is the basis of their claim? Why does it matter anyway? Posted highway speeds around here are 55, 60, 65, and 70. There is no need to sustain travel at 62 mph. Needless to say, we're going to see a lot more of this misleading for awhile. That's unfortunate.
- 7-16-2016** **Diesel Is Dead.** Much worse news emerged this week. The hope of supporters to save the consumer market for diesel completely fell apart as a result. European penalties are now expected. Simply ignoring the environmental damage and impairment of hybrid potential isn't appropriate. Outcome from the United States has stirred the need to enforce fines in some way. To deepen wounds even more, the state of California has deemed the proposed fix for the larger (3.0) diesel engine unacceptable. What even more bad news, how about the information that a research group found the proposed fix for European diesel vehicles actually increases emissions by as much as 25 percent in some cases. Needless to say, there is nothing to look forward to anymore. It's time to give up the fight. With so many plug-in hybrids and electric-only vehicles on the way, why bother? Want even more bad news for diesel, consider what Germany just did. They are now offering \$4,000 toward EV purchases. The result has been an abrupt spike in sales of the BMW i3. How about that for declaring diesel for passenger vehicles dead?
- 7-17-2016** **47 MPG.** We took the kayaks to the lake. It was a beautiful Summer day. Spending it outside on the water was perfect. That 30-mile round trip with such a massive load on the roof wouldn't exactly be efficient. Adding a detour to pick up pizza on the way home would only make the situation worse. Yet, we did it anyway. The warm season is too short for such an opportunity on the weekend to be missed. To our surprise, MPG didn't take much of a hit. The result for all that driving with the awkward cargo was 47. It would have been somewhere around 39 without having plugged in. That's my guess anyway. With the other car, I'd see as low as 36 from dragging so much airflow-interrupting recreational equipment. Of course, even that is still impressive. Many vehicles can't get that at their best. My Prius delivered much more. That sad part is, that park actually has 2 charging-stations right there where we park after launching the kayaks. Unfortunately, they were having some type of electrical issue at the time. So, no plugging in this time. Perhaps in a few weeks we'll get to repeat the experience, but head back home afterward with a full battery. That data sure would be interesting to compare with today's.

7-18-2016 **\$2.21 per gallon.** That's the national average now. The prediction is that gas here will drop below \$2 in a few days... since the cost for a barrel of oil just dropped. It's amazing how cheap it has become. The boom was taken advantage of... pushing supply well beyond demand. Traditional suppliers kept pumping oil at the same rate they had been for years. The new sources here in the United States, as well as Canada, continued to introduce new supply. The market became saturated. Pushing high-profit guzzlers became very easy. Oddly, that has brought about an end to the monster-size SUV offerings. There isn't a stigma downsizing to a smaller SUV anymore. So, that's what people are doing in large numbers. Unfortunately, there are likely some who are replacing their cars with them too. Fortunately, Toyota saw this coming. I'm seeing a surprising number of hybrid RAV4 now. Having taken advantage of the low cost for NiMH batteries, the design choice is proving wise. It's becoming a "*right place at the right time*" situation. Why not upgrade from traditional to hybrid for just \$800? That decision is an easy one... which clearly many customers are choosing. Cool.

7-19-2016 **Small Steps.** Comments like this make you think: "*Ultimately we don't want to lose space, we like the PiP - it was the step in the right direction in terms of versatility and EV awareness.*" What was the intended reaction to that? Should I point out that we don't really "lose" anything, since there is a gain of affordability & capacity. Will that idea of trading something for something else make a difference? Are there certain absolutes which are not negotiable? If so, why? This is why there are updates. We get both generation & mid-cycle changes. Some are true upgrades. Others are adjustments to the market to meet changing expectations. Gauging how much to do is a very real problem. That's why taking small steps is so appealing... to the business. Some consumers disagree, wanting more right away instead. I stated my observations: Don't overlook the fact that 4 seats was too. Awareness of Prius Prime was stirred by the prototype revealing such a difference. It demonstrates change and helps to gauge interest. Toyota took advantage of that opportunity. It's brilliant move prior to rollout. Well played. Also, don't forget that mid-cycle updates were nothing but minor tweaks and some cosmetic alterations with traditional vehicles. Most people completely miss the paradigm-shift coming from vehicles taking advantage of battery-packs. They get mid-cycle updates offering much more. We could see the 5th seat return then. We could also see either a lowering of the floor or an increase in EV miles. That's another effort to seek balance. The initial Prius Prime sales will provide wisdom about what the market will actually desire. Remember, Prius PHV initial rollout did the same thing. The market claimed they wanted an augmented hybrid. But as the plug-in market struggled with sales, it became clear what they really didn't want that. Toyota took note and used that knowledge to build Prius Prime. Don't forget, Prius PHV itself was a mid-cycle update. True, the system was designed from the start to handle augmentation, but battery cost and battery density didn't make it practical. In fact, we're only seeing that just now in 2016. Small steps irritate some. Others see the importance when trying to appeal to the masses.

7-20-2016 **Change Considerations.** What do you think of this: *"The 5 passenger hatchback/sedan is ubiquitous and expected- especially when the standard is set in previous iterations. It seems a bad compromise to limit seating to 4 in a car that has a history..."* How important is that history? Think about the cars from 20 years ago. They weren't that wide. They weren't that tall. Sure, everyone knew someone with a larger vehicle. But those weren't plentiful during the 80's or 90's. Many of us grew up with smaller vehicles. Remember how small Camry actually was? I bet you don't. You likely remember the bench seat though. What a pain. If the passenger & driver were different sizes, someone had to make a sacrifice. There were no seat-heaters back then. Heck, where did you put your beverage? Of course, you didn't have a phone then and certainly didn't need to plug it in for recharging. I like the idea of individual seating in back with a center console. The middle seat was always narrow and less comfortable anyway. I sounded off about the situation now with: Sounds like the arguments long ago for keeping a bench seat in front... and you know how that went. Some people wouldn't give up what the buckets brought for anything nowadays. For example, think about how much of a deal breaker it is for some to not have a heated seat. You really think cold seats in back is preferred? That's an important consideration when you are using electricity to warm the car too. Would you really want to crank the heater when all that's necessary is just turning on a seat warmer? That's an easily avoided large draw on the battery-pack.

7-21-2016 **Diversification.** Some people just don't get it: *"I think inadequate seat capacity is a more essential disincentive than the option of heated seats to up gas mileage or power conservation or to accommodate the cold of a passenger that cannot be present, although I can imagine for some childless couples or singles the relative luxury or alternate technology (and those in northern climates with urgent heater needs) are more critical issues than basic practicality of what I imagine is the majority demographic for the Prius."* Getting stuck in a mindset is nothing new. People tend to seek out similarities. In fact, that's what attracts Prius owners to participate online in a forum dedicated to Prius. So naturally, posts counter to the status quo will get challenged. The differences in Prius Prime are causing more of a sour than with generation upgrades. That's likely not a problem. When gen-3 rolled out, a majority of the gen-2 owners didn't engage in discussions anymore. Aspects of the driving experience varied too much. They couldn't relate. It wasn't a bad thing though. Gen-4 is most likely going to do the same thing. We didn't see that with Prius PHV, but a large part of that was due to the extremely limited availability. Prius Prime won't be like that. It wasn't configured to appeal to potential Gen-4 buyers either. It is a true effort to diversify. Some obviously won't like that. I do. I look forward to the new audience. I look forward to more owners replacing their guzzler with a choice that offers a plug, then becomes an impressively efficient hybrid after that electricity is used up. These were my thoughts on the topic: Prius Prime targets a different audience. The point is to grow the market. That means appealing to a new demographic, rather than the existing. That assumption of it being intended to get current Prius owners to upgrade is quite understandable, but not what Toyota has conveyed. Their purpose is the expand hybrid system use, not cannibalize their own sales. Remember, the overall goal is to phaseout traditional vehicles. Doing that requires delivering diverse choices, not just providing a larger battery with plug option.

7-21-2016 **Paradigm Shift.** Change is slow. People are quick to dismiss. Not much consideration is given. It makes the acceptance of a technology a matter of perception, rather than any particular date you can pinpoint. That's how the "*overnight success*" comes about. Someone will work on something for a decade or two, the all of a sudden they get a massive amount of attention. Few cared all those years before. It's unfortunate. That's what is about to happen with the plug-in hybrid technology. It will go from obscure to "*ready*" in a remarkably short amount of time. We can see Toyota preparing for it. The 200-mile EV offerings simply aren't realistic yet. And of course, we haven't seen any sign of gen-2 Volt sales reaching that mainstream level yet. It's never quick anyway. But a key to success is being affordable. Just look around. We've had smart-phones and solid-state drives for years. When did the masses finally embrace them? Why did that happen? Once the hardware has proven reliable, you still have to wait for cost to come down. Ordinary consumers don't look for maximum capacity either. Even notice that? They are perfectly content getting something in the "*enough*" category. They aren't like enthusiasts who absolutely insist on the best & most available. People in general simply want a good buy. To be brief and stir new discussion online, I posted all those thoughts into this summary: Anyone else notice the recent paradigm shift? There are no longer any posts related to the technology itself anymore. That's a profound change. We have collectively moved on to the next stage.

7-22-2016 **The Catch.** Don't you love how people complain, yet don't actually consider what they are asking for? We keep hearing from a small group of people online who really wish Toyota had retained 5 seats and didn't raise the floor in the cargo area for Prius. How exactly would that have been achieved without costs becoming too high? What about the compromises it would require, like lower depleted efficiency and the loss of higher speed recharging? There's issues of complexity too. Keeping it simple tends to contribute to reliability. That also opens up opportunity for reusability. It never ceases to amaze me how some people never consider detail like that. They just respond with emotion, not thinking through what is actually required. Ugh. Needless to say, that's what the whole debacle with gen-1 Volt was all about. There was a surprisingly large group of people who had no concern for how or when or why. They just insisted their way was best. More ugh. Needless to say, we have new examples of the same problem emerging. This time though, I don't believe the situation will get so far out of hand. The niche will remain a niche. It was the promises of mainstream that were unrealistic. That isn't the case with this, as I pointed out: CT6 phev is what many here complaining really want... larger battery-pack that's flattened, much more electric capacity, and seating for 5 adults. The catch is, it will be extremely expensive... not in any way affordable to this audience.

7-23-2016 Exactly What We Want.

I really enjoyed responding to this today: *"Imagine if Toyota hadn't cut corners, spend all that R&D money on converting a Prius into a Prime (using a Prius and its GVWR and replace cargo weight with battery weight) and go straight into R & D a proper 5 seat PHEV with flat trunk floors, they would have save millions and give its target audiences exactly what we want instead of second guessing and hoping we would accept a 4 seat Prius with a raised floor."*

Prius PHV delivered exactly what we want. Clearly, the lesson of what had been learned in the past still isn't well understood yet.

Toyota observed the third-party augmentation efforts and monitored results closely. We knew a top electric-only speed of 100 km/h (62.1 mph) was realistic. We knew the traction-motor could deliver more if the battery possessed more power. We knew enough room existed in the cargo-area to hold increased capacity. Enhancement to the existing hybrid system is what people were demanding... and that's what was delivered.

Turns out, the consumers shifted priorities. Fallout from the early plug-in vehicles made that obvious. Sales struggled. Some of us noticed and were thankful Toyota halted rollout plans, choosing to further study usage in established markets instead. Others made up their own excuses based on anecdotal evidence... most of which have now been disproven. Using that time to stay true to the affordable goal.

You claim 5 seats and a flat floor is vital. How can you just dismiss what we get in the effort to achieve balance and affordability? Think about what the first 2 years of sales will reveal. That feedback is priceless. When the mid-cycle update comes and higher energy-density is available, will Toyota lower the floor or use that extra space to offer more EV miles? So far, the overwhelming request is more EV miles... not a flat floor.

Additionally, how do you know that consumers won't prefer the faster 3.3 kWh charging rate? Being able to replenish the battery-pack in a shorter amount time is very nice. Getting more electricity from plugging in while at the grocery is a really big deal. You can't just disregard such an advantage. To achieve that though, space under the middle back seat was needed for the larger hardware.

In other words, how do you know exactly what we want?

Lastly, how do you know Toyota isn't developing a dedicated plug-in hybrid? After all, they mentioned it in the past and even showed a prototype model.

- 7-23-2016** **Think About It.** This sure got me going: *"Yes - i get it the whole incremental philosophy - perhaps the reason why incremental is frustrating - is because the plugin Mitsu SUV is so staggeringly popular worldwide. That project (a sort-of 'hail Mary' pass - as they say in football) shows the huge benefit of pushing boundaries far beyond incremental ... you end up owning the market - ah la genII prius."* I enjoyed replying: What if Toyota actually did more than anyone has yet to notice? There hasn't been a close inspection of the 8.8 kWh battery-pack. Perhaps the seemingly clumsy size & shape for Prius Prime is actually an effort to speed up *"Prime"* rollouts. Think about it. With battery-pack production refined for rapid volume increase along with accompanying cost reduction, would it be a surprise to find out that same equipment also works with RAV4 hybrid? Think about it. Toyota would have collected extremely valuable real-world operational data in the meantime. That would greatly reduce risk as well as make it easier to market. That's an approach to reach the masses. Think about it.
- 7-23-2016** **Dedicated Platform.** We're hearing this kind of rhetoric a lot now: *"Prius won out because it was the most complete package of them all. It's not perfect but it had the rooms, the reliabilities in both the engine and batteries. It was a dedicated platform and not a converted platform like the civic or the accord..."* It comes from the lack of a small, cramped middle seat in back and a raised floor in the cargo area. I'm finding each new post interesting. The lack of substance is beginning to reveal itself. Rather than arguments growing stronger, weaknesses are emerging. That's the result of constructive discussion. Yeah! Such an outcome is rare. I appreciate the devil's advocate approach some are providing to foster that. This was my say on the comment today: Ironically, Toyota is doing the same thing now and that fact continues to be overlooked. The hatchback model of Prius is almost 13 years old. Any type of interior or exterior match would put it in the same *"converted platform"* category, especially with that being 3 generations. Making Prime stand out as different was an important goal. Yes, it shares some of the hybrid system, but clearly there's a very easy to see difference... the seating... the battery... the body. If it hadn't been given the *"Prius"* prefix, many would think of it as a distinct vehicle. If Prime gets a 5th seat later, unique identification would have already been achieved at that point anyway. Goal fulfilled. People like standout traits, even if it means a tradeoff. RAV4 hybrid is selling well. Why? Efficiency is quite a bit less. Remember how many people in the past said they'd be willing to give up some cargo room for the sake of more EV miles? Also, keep in mind that winning formulas of the past don't necessarily deliver another success when repeated later. Think about how little competition Prius had back then. Having Prime standout from the regular Prius makes sense in this crowded market with a wide variety of choices.

7-25-2016 **Spreadsheets.** I'm finally getting caught up on the number-crunching part of my data sharing. I never stopped collecting all the detail. There simply wasn't time to analyze & summarize. Now, there is. Some of the results are fascinating too. The ultimate goal was determine that value a certain antagonist from over 4 years ago hated. His upset over my insistence upon real-world data was intense. Yes, he was an early Volt owner who pushed absolutes and despised Prius. The balance from blending and the smaller battery-pack to make it affordable enraged him. So, naturally, he resorted to greenwashing. The intentional misleading efforts were annoying. I just kept collecting data. Now, all this time later, I have it. His fighting to prevent this new measurement is how his resentment became obvious. I simply suggested stating how many KWH and GALLONS it took to travel 100 miles. He wanted to hide behind MPG, supporting his objection to tracking electricity consumption. All that mattered to him was using less gas. That's just plain wrong. Guzzling electricity is not appropriate. Agreeing to that point though meant unknowing Prius PHV could compete directly with Volt in certain circumstances. He also knew that Prius PHV was only a mid-cycle release with limited scope. The next generation would be more competitive. And sure enough, that's exactly what Prius Prime will deliver. So... after all that being said... the value after 73,663 miles of driving came to **8.3 kWh + 1.41 Gallons** for every **100 miles** of travel. That's an intriguing result... especially since so few people actually have similar data to share. I documented every single time I plugged in and every time I filled the tank. Those are measured number, not rough estimates. The spreadsheets noting all that are quite extensive. I think it was totally worth doing.

7-26-2016 **Trolling.** I really getting tired of nonsense like this: *"And with a similar number of 3 or less households, 4 seats was a major detractor for the first Volt. Besides, households have extended family, friends, and coworkers. Along no middle seat for a child seat, the lack of the fifth seat meant taking a less efficient car for short outings, lunch with coworkers, when there is 5 people going."* He's been posting vague & misleading statements a lot lately. Omissions is what crossed the line. I wonder how much longer I'll tolerate it. He knows I switch to ignore too: Leaving out vital information paints a misleading picture. Only 4 seats was a major detractor of Volt for the initial rollout. After people discovered the other seating shortcomings (leg & head room in back, along with the low windows), it shifted to minor... and stayed that way... which is why gen-2 of Volt still doesn't offer seating for 5 people. The arguments about family & friends fell short anyway. People simply don't like cramming 3 across. It doesn't work for adults in vehicles of that size... which is why larger vehicles like Camry remain popular. In other words, it's not the big deal you make it out to be.

- 7-27-2016** **Taking The Risk.** I climbed up on the soapbox. The time to sound off was well overdue: We get a lot of spin. Many times, that isn't even intended. It's just a perspective people aren't aware they are stuck in. They have a set of expectations and don't realize what else is available. Over and over, we hear the glass is half empty. They are taking away a seat that rarely gets used for most and used occasionally by others. Why hasn't anyone noticed the other view? The glass can be considered half full too. Why not improve seating in back, starting with the introduction of a center console and bucket seats? We also get the sensors that detect where passengers are and directs the air-circulation accordingly. How come that isn't acknowledged as an effort to offer improvement for back seating? I'm tired of the nonsense and know after so many years of close study that the typical consumer won't raise such a huff. Family dynamics change anyway. What will work with the children while they are young will alter as the years pass. What do you do with the car then? People naturally seek out different after a while too. Toyota is hoping to capitalize on the opportunity... and getting grief for taking the risk... despite breaking out and not playing it safe being the very thing they were told to do. Take a chance, get criticized. Geez!
- 7-29-2016** **Ignore.** This is what did it: "*The EV range, which is increasing a tad for the 2017 model.*" My growing anger hit tolerance. He was clearly attempting to prevent conclusions from being draw. That's why he's considered a troll. Though, when you've been a daily poster for years, that label is seldom associated... despite the obvious behavior. In this case, he was making a comparison to BMW's i3. I was not happy. Rather than just presenting numbers for others to decide, he was drawing conclusions for everyone. That blatant effort to avoid being constructive, seen on a very regular basis, is intolerable. So, I called him out making reference to the quote: Excluding detail, yet again. Makes you wonder... Who would ever call the jump from 81 miles to 114 miles just a tad?
- 7-29-2016** **Exposed.** My effort to reveal the trolling did not go unnoticed. He knew he had been caught. The frustration in the response was obvious. He knew I'd be ignoring him from this point on too... the ultimate defeat, not taking the bait. So, he couldn't even address me. I was refusing to play his game. Phew! Yet another antagonist exposed. Each time something like this happens, it becomes easier to notice. New people attempting to do the same thing get called out sooner. Becoming aware of what to look for is key. This was a nice example to share with the group. On a big forum like that, such activity can go unchecked for a surprisingly long time. People just get caught up in the participation... not taking the time to think about what's happening. The engagement draws them into those pointless discussions. It becomes a huge waste of time that ultimately undermines. Progress is prevented. That's the trolls goal. They thrive on the status quo.

7-31-2016 Truly Desperate, undermining. It has been quite quiet over the last week. Inventory clearances have begun. With the shortage of Prius caused by supplier & production complications in Japan, along with low gas prices here, the situation is a rather odd. We're seeing markdowns on Prius that had only until recently been difficult to find. I expect a decent increase when the new model-year becomes available in a few months. The reality of cheap gas makes the idea of using less a challenging sale though. But then again, the entire industry is struggling. Anywho, while that has been playing out, I've been watching an entirely new problem emerge. Over the course of the last week, a lawsuit against Prius PHV has made the media rounds. The claim is the system doesn't deliver 13 miles of EV as promised and the engine runs whenever the temperature outside is below 55 F degrees. What kind of nonsense is that? I never heard such a promise. And where the heck did that temperature limitation come from? It's so absurd, I just ignored the online comments... until today. A well-known antagonist re-emerged, seeing that as a new opportunity to spread his same old rhetoric again. Ugh. Oh well, it gave me an opportunity to present facts. So, I did.

7-31-2016 Truly Desperate, the post. I was very happy to post this:

Prius PHV was rolled out and promoted as a PLUG-IN HYBRID. Everybody knew back then that it was a Prius augmented with a larger battery and a plug. That gave it the ability to deliver much higher efficiency. At lower speeds, the engine would remain off for longer durations than with the no-plug model. On the highway, it would gain a MPG boost from the plug-supplied electricity.

The claims of AER (All Electric Range) came about after, as a effort to undermine. That intentional misleading got pretty bad too. There was a group of Volt owners who grew quite irritated by the high MPG some Prius PHV owners reported. But rather than compete honesty, they chose to greenwash

Looking at the window-sticker's stated efficiency of 29 kWh per 100 miles, the deception was easy to reveal. It shows that you need 3.19 kWh of electricity to travel 11 miles. Being able to get that from the 4.4 kWh battery-pack should be obvious.

It never ceased to amaze me how desperate some became, pushing the belief that when the hard-acceleration point on the EPA test was reached (the 6-mile mark) there was no plug-supplied electricity remaining the battery-pack. In other words, they were hoping you'd be gullible enough to not check facts.

From my experience owning one, I routinely see at least 11 miles of EV in the warm months. In the coldest here in Minnesota, when it's well below the freezing point, I have seen as much as 9. With the heater on, it's less. But maintaining a lifetime average of over 70 MPG, even when dealing with snow & ice for months, is the point.

I'm not at all surprised to see the undermining effort continue. That seems to be a sign that the upcoming Prius Prime scares some. A clutch will be added, allowing the generator-motor to contribute propulsion-power to the traction-motor. The battery-pack capacity will be doubled. The system itself will be more efficient, requiring less electricity to travel the same distance. Delivering a solid 22 miles of EV with very high MPG following depletion is quite realistic.

To add fuel to the fire, Prius Prime will deliver industry-leading heating for high-efficiency EV operation in Winter driving. It will use a vapor-injected electric heat-pump. How will those desperate to undermine end up spinning that information?

- 7-31-2016** **Truly Desperate, easy as pie.** With my follow up, I got clever putting it this way: Keep in mind, the goal of all start-of-the-art technologies is for them to mature, so mass adoption will take place. The 4th generation Prius brings about cost reductions to the point of being competitive with the true competition... traditional vehicles... even with gas so cheap now. The 2nd generation plug-in Prius will be striving to achieve the same thing. Think about the smaller battery-pack. The size makes it affordable. The size also allows it to be used elsewhere, like in a RAV4 hybrid. That's what some are scared of. The ability to easily scale is an important aspect of business. Specialty vehicles, for example Volt, don't offer that advantage. The seemingly less capable system Toyota has designed is what will be able to reach mainstream buyers in a timing and cost-effective manner. Look at all the other top-selling vehicles. Cars like Camry and Corolla certainly don't carry any "*advanced tech*" type labels, yet that's what sells in high volume. That's what ultimately pays automaker bills and populates our streets. Watch Prius Prime reach an audience none of the other plug-in vehicles have been able to capture. They'll be the ones confident in the reliability & value reputation Prius has earned, looking for an "*easy as pie*" way to also experience some EV driving.
- 8-01-2016** **New Observations.** Having something truly new to discuss is quite rare. It happens though. I was lucky enough to introduce the topic too. It came about from this: "*As the traction packs age, and are less & less capable of holding capacity, in essence, they become a smaller sized pack.*" Few have enough detail to make observations relevant to that statement. I do. In fact, I have a massive amount of detail. I've been populating spreadsheets with my activity for a very, very long time. There's lots to notice patterns with. I started the discussion this way: However, as the battery ages, it would appear as though the chemistry responds differently. My observations over the past 4.5 years is that the internal electrical resistance has become lower. So even though the recharge quantity has dropped from 3.1 kWh to just 2.5 kWh of electricity, the distance I am able to travel with EV has remained consistent. There's also the fact that the vehicle loosens up over time and consequently becomes more efficient. For example, today's commute to work delivered 14 miles of EV driving. 80,000 miles and 2,400 recharges later, that's still right on par for what I got when the Prius was new. In other words, the net result is showing no loss.
- 8-01-2016** **Unanticipated Results.** I sure wish I had been filming today. It was one of those ideal condition days. Traffic was lighter than usual and the weather was quite pleasant. Heck, even the construction delay I've been having to deal with routinely was gone. That made for a very nice drive. It was reflected in the results too. 257 MPG from my 18.6 mile commute. I am clearly not see any degradation from the battery-pack... despite all the miles and the number of charges. Such a timely example of 4.5 years of aging certainly was nice. I definitely reinforces the 150 to 175 MPG that same commute has continued to deliver. People assume there would be a massive drop after enough time. That's not happening... yet. It still could at some point. But what car retains performance later in life? We know for a fact that cylinders in combustion engines lose compression over time. That reduced pressure available results in lost power. More gas is required to achieve the same thing as a result. How come that isn't ever brought up in discussions? Traditional vehicles suffer from that. A plug-in hybrid like Prius won't, since it's engine gets used far less over the same number of miles. I look forward to more unanticipated results like this. Of course, they'll be anticipated... so... um... not sure what to call them.

- 8-03-2016** **Blatant Lies.** The attacks have begun. Any article now posted about Prius Prime results in attempts to undermine from Volt enthusiasts. They clearly see it as a threat. With so much pressure coming from GM in the form of Bolt favor, it's no wonder the support for Volt is falling apart. The fact that we're getting rhetoric in the form of blatant lies is a bit of a surprise though. I hadn't anticipated so desperation to drag on this long. Today, it was: *"With the Volt, it's much colder when the engine needs to run (as cold as 15 degrees) but even then it cycles; with the Prius, it is always on."* I've pointed out how the heater actually works quite a few times now. He knows what he said isn't true, yet posted it anyway. Prius cycles too. I've even provided detail on how, pointing out the coolant temperature threshold triggers and the durations. To pretend to not have ever been told any of that is clearly an act of denial... and a confirmation of being desperate. That's sad.
- 8-03-2016** **Try.** How would you respond to this: *"I'm just not seeing the vision Toyota is seeing in the Prime. Who knows, maybe it'll be a big hit. I'm excited."* It doesn't really tell us much. The vague references are both negative & positive. It gives the impression of missed opportunity, but they suggests a great potential. I asked: How is *"big hit"* defined? What is considered **"vision"** for a plug-in? Most people feel pushing limits is how sales are achieved. Why? In reality, high-volume volume acceptance from the masses comes from making a product affordable. In other words, it won't offer amazing capacity. Notice how the most popular sellers, Camry and Corolla, are just good all-around vehicles. They really don't have any standout traits, yet they sell in great quantity. Positioning to capture a new market is quite a challenge. None of the plug-in offerings so far have reached the mainstream yet. Toyota is giving a new approach a try.
- 8-04-2016** **More Miles.** It doesn't take much to imagine how often stuff like this comes up: *"If folks have a choice for purchasing more EV miles versus less - chances are their dollars will vote for more miles - ah la volt. GM has kept their price reasonable, yet uped the ev range by 18 miles (gm secured a very low production cost per kWh from their battery supplier). Time will tell."* Today's response was: That seems reasonable; however, the market doesn't concur. Volt is not the *"leap frog"* solution it had been hoped to be. The second-generation is floundering like the first. The recent spike of 2,406 sales for July is likely due to model-year clearance pricing. If that could be sustained, it would meet the half mark for mainstream minimum (60K annual). That quantity is very important, since it positions the vehicle to be able to sustain profitable sales without tax-credit dependency. The clock is ticking. Toyota is delivering a package with greater potential to reach that sustaining level in time. The smaller EV range doesn't stir much excitement from the enthusiast perspective, but it should be much easier for dealers to embrace... who play a pivotal roll it the sales process. Also, keep in mind how consumers don't purchase the largest capacity available. We see that with phones, tablets, and computers. More memory is clearly beneficial, but not required. The same is true for Prius Prime.

- 8-04-2016** **Right Now.** We're seeing a lot of interesting perspectives emerge: *"Definitely I welcome Toyota back to the game with the Prius Prime, but there is lots of competition in blended right now."* Most of vague and give the impression Toyota had given up, rather than just waiting for the technology to be realistic for the masses. That implies they weren't doing any research & development in the meantime, which just plain isn't true. But you know how it is. The *"overnight"* success is always the result of decades of unnoticed effort. A bit annoyed, I kept it brief: Right now is a red herring. Consider the entire product cycle. The generation being rolled out must be able to sustain profitable sales for 5 to 6 years.
- 8-05-2016** **Understanding Change.** Coming from a person well known for doing everything in his power to keep conclusions from being draw so discussion won't end, I wasn't the least surprised to read: *"I don't understand this. Plug-ins are strategic products. Toyota certainly has said publicly they expect to lose billions on the mirai, and bleeding will last at least a decade. Why would they need to be profitable in the next 5 years with the Prime. Certainly the market has much higher competition than when toyota initially announced their first gen prius plug-in."* He knows all too well what the situation is. How many times can the same facts & concerns be posted? Anywho, I addressed it this way this time: Thinking the competition is only other plug-in vehicles sets the bar horribly low, pushing mainstream expectations out to the next generation. Why that perspective? Why such a pessimistic outlook? Traditional vehicles are absolutely crushing sales of plug-in vehicles. Simply watching that continue while also remaining dependent upon tax-credits for the next 5 years is absurd. To overcome this, mainstream volume must be reached in the next few years, by mid-cycle. It simply makes no sense taking a niche approach now that the battery-tech has finally reached a point of being affordable and offering enough energy-density to compete with other vehicles in the dealer's lot and on the showroom floor.
- 8-05-2016** **Fence Sitters.** I saw this coming: *"There's nothing about the prime that suggests anyone will switch to it from a gas guzzler, at least until gas goes back over \$4. It's a completely niche vehicle with 4 seats, and little storage. That's the reason for all the negativity, nothing about the lift back is exciting non prius drivers, and prime offers nothing more."* This is where the smaller battery-pack and high-efficiency hybrid system comes into play. Toyota isn't repeating GM's mistake. Remember how Volt remained a niche product, regardless of how much arguing there was that it was intended for the mainstream? It's why I kept asking the *"Who?"* question so often. That was a sincere effort to recognize & understand audience. The experience from that tells me there is far more than nothing. There is just enough to entice, but without going overboard... the mistake. More is not a good thing. Too much is bad. GM learned that the hard way. Toyota is attempting to avoid it. That's difficult to see though. I attempt to provide some clarity though: You're over-thinking the situation... a very common problem with online discussions. Some people are simply looking for an entry-level plug-in vehicle. They're the ones with a some extra \$\$\$ to get something nice that doesn't necessarily have to be 100% practical. I encounter that type of interest on a regular basis now with that new grocery store so close that offers the free charging spots. In other words, Toyota is going after those fence-sitters... who are more abundant than you think.

8-05-2016 **First Review.** Price isn't available, yet people complained about that having been left out of the review. The review itself stated Volt had a "*3rd rear seat*" without any disclaimer of it not offering any space for legs. There's a double cupholder instead. How is that considered proper seating? Ugh. Needless to say, there is very little to work with still. This first basically only revealed the observed EV miles. The total was 28. That's way over the initial estimate of 22. But then again, the pack is 8.8 kWh. The pack from Hyundai is 8.9 kWh, yet it got a rating of 31 in its domestic market. So, my original comments about Toyota targeting double (from 20 to 40 km) is dead on. 25 miles is looking pretty realistic. Looking to the comments, the first posted was advice to just buy a Volt instead. It was the same brain-dead advice you could expect to hear... more EV is better. I pointed out that mistake with: Prius Prime will offer some improvements over Volt. Most significant will be the vapor-injected heat-pump, which should provide much more efficient electric heating in the winter. Efficiency in hybrid mode will be notably higher (expected mid 50's rather than low 40's). And the head room for the rear seating will be greater (expected 37.4 inches rather than 35.8 inches). I don't believe Volt offers a driving recharge mode either.

8-06-2016 **Intended Audience.** Here's more from another antagonist: "*Could it be that Toyota rally screwed up the hatchback and the Prime?*" I jumped on that immediately:

Wow! That reminds me a lot of the anecdotal comment made last year, when the production of Prius PHV ended. Many of the comments were just plain wrong too. Having virtually no data to work with and disregarding certain facts is a dead giveaway the discussion is not constructive...

Start with the inventory shortage. Availability of the gen-4 Prius was severely hampered by a third-party supplier suffering from a major fire at a production facility. Without those needed parts, there's simply no way to deliver the vehicle. That's not speculation. That's not rocket science. That's not spin. It's basic business fundamentals. No parts. No product.

Next is the reality of a very confusing market. To expect the gen-4 Prius to be an instant success upon rollout is not realistic. Consumers are becoming overwhelmed by all the information now being spread. Look no further than the auto-show circuit this Spring. Notice the wide variety of green choices being promoted? How the heck is an ordinary person supposed to figure out that mess quickly?

The most telling though is the comparisons to Volt capacity. Since when is it appropriate to compare EV miles to a vehicle struggling with sales? Prius was always the basis of comparison due to its strong demand. That's not the outcome from GM's offering. Why in the world would you say Toyota should follow the same course when it hasn't been successful?

As for the supposed "delay" belief, since when does a rollout early-summer make any sense? That's when production ends for retooling and clearance takes place. Having a rollout occur then simply makes no sense. The cycle has been for that to take place at the close of the calendar year. Think about how long it takes to begin production, then ship the vehicles here.

Remember, the goal is to appeal to the masses. That means delivering an affordable vehicle which won't stir excitement among enthusiasts. Prius Prime will be an entry-level choice for plug-in hybrids... a very compelling one, different enough to stand out, but the technology not intimidating.

Expecting more reveals a misunderstanding of intended audience.

8-06-2016 **Driving Recharge Mode.** Much like the brain-dead advice of "more is better" with the EV dismissal, there's that of recharging the battery-pack using gas. Overall efficiency is completely disregarded. They don't think about how the engine & motors are being used, they just assume outcome. This is that "know your audience" problem I have to deal with on a regular basis in blogs & forums. They don't understand the perspective of ordinary consumers. That fundamental oversight messes up discussions. They build a mental image of the situation that's inaccurate. I find that so annoying. My efforts to convey clarity typically don't go well either. Lack of a business background on their part means engineering is the only consideration. There's no balance. Normally, that's bad. But in the case of trying to figure out driving recharge mode, you'd think they'd figure it out. That's all about engineering. Unfortunately, assumptions are made rather than calculations. Long story short, the use of the engine to recharge the battery requires gas. That's viewed upon as wasteful. Why? Prius Prime should deliver around 55 MPG from hybrid driving. My Prius PHV delivers over 50 MPG that way. So what if the penalty for recharging the battery-pack caused around 10 MPG to be lost. 45 MPG is still great. The resulting end of your highway cruise with a full capacity is fantastic. The driving to follow will be in EV, where it is most beneficial. Overall efficiency will be higher because of that. It's basically the hybrid system taken to a new level. How come these engineering-oriented people can't see that?

8-06-2016 **Constructive Discussion.** The challenge to have it continues. In response to an on-going thread about Prius Prime, I posted:

Then consider yourself informed now. The internet is loaded with intentionally misleading information. There's is also a lot of speculation that turns into "*fact*" simply through the act of passing it along. Squashing that as soon as detected is what some of us make an effort to do.

The case with Prius Prime is especially noteworthy... because Toyota is attempting to expand the market by reaching new customers through the reputation of Prius, but not taking a cannibalizing approach. Just think if they made it too much like Prius. There wouldn't be any growth. Buyers would simply shift from a 55 MPG hybrid to a 120 MPGe plug-in hybrid. That's not the desired outcome.

It upsets & dismays some supporters of Prius that such an approach would be taken. That's to be expected. Diversification means appealing to another group, not just more of the same.

Gen-1 offerings of plug-in vehicles consisted primarily of conquest sales which depended heavily upon tax-credit & HOV incentives. The expectation by our readers is for that trend to continue with Gen-2 offerings. After all, gas is cheap and business-sustaining high-volume production of large-capacity battery-packs is still years away.

Toyota is attempting to try something different, hoping to gain new interest as a result. Delivering a configuration with seemingly too little capacity and making too great of a cargo tradeoff is what many enthusiasts & antagonists focus on... rather than recognizing the goal of growth... and what it takes to achieve that.

The topic of profitability isn't interesting to most people. That prevents constructive discussion. Risk taking is often perceived as making a mistake. That prevents constructive discussion. Historical choices are often referred later to as obvious. That also prevents constructive discussion.

In other words, there is much to discuss and it is quite a challenge when there isn't even clarity about what was said and what goals are.

8-07-2016 **Mid-Engine Corvette.** This has been a high-performance vehicle with low-performance results. Efficiency has been disregarded since it's inception. Thankfully, upcoming efficiency standards will force a change. Moving the engine back will not only open up the opportunity to introduce motors and a battery-pack, it will also improve handling. Notice how a majority of the truly high-performance guzzlers didn't have an engine in the front? This change seems long overdue. How will enthusiasts respond to the news announced today? Think about how well a Tesla Model S performs. That's a family car. Shouldn't a sports car like Corvette be able to accelerate like that too?

- 8-07-2016** **Topic Drift.** Seeing the bigger picture as a result of topic drift, that's constructive discussion tangents, can be revealing... as I pointed out today: Drift can be revealing though. In this case, we're seeing a pattern emerge. The "5 seat" complaints are beginning to resemble the "full size" complaints. Full-Size prospective buyers would post their disappointment about not fitting comfortably in a mid-size car. The advice was always to consider the purchase of a full-size hybrid instead. How is this any different? If you have a full-size family, why are you considering the purchase of a mid-size car? And for that matter, why are you insisting that those of us who don't need that room should tradeoff back seat comfort/convenience (buckets with center-console are nicer) to accommodate a middle position that won't ever be used? This is why consideration of the bigger picture is so important. Focusing on just a single offering makes points like that easy to overlook.
- 8-07-2016** **Summer Filming.** Hooray! I'm seeing things settle down now. Getting married and moving was a much a higher priority than providing educational material for Prius. It just happened to be a good time for more personal activities anyway. Interest in gen-3 Prius dropped significantly and real-world data from gen-4 Prius would be available for awhile. That left even more of an opportunity for the plug-in model. Lots of time gave me the chance to relax & plan. Today, I put that plan into action. I bought a new video camera and had been experimenting with it. The imagine stabilization it provided along with a new method of mounting it in the car meant capturing even higher quality footage. I also tried out a newer OBD-II reader. But sadly, that didn't resolve the buffering issue due to the want to capture so much data. Anywho, it was a beautiful Summer morning. The temperature was extremely comfortable and traffic light. I still had to contend with all the stoplights and hills on that new commute route, but it was a nice drive nonetheless. The footage came out great too, both the instrument display as well as the road activity. I'll combine, render, and publish that... hopefully soon. I also filmed the commute from work too... arriving at home with equally pleasing results. Yeah! It's great having such comprehensive captures like that available, especially when we all know the comparisons which will come when Prius Prime is rolled out. Prius PHV performs much better than what people claim. This helps to prove it.

8-08-2016 **Who?** The topic came up, yet again. This time though, it was on a general green blog. No more Volt-only rhetoric. Phew! That sure got old. Virtually all who pushed the impossible-to-achieve promises have vanished. It's just a really bad memory. Now, we address how most customers are totally clueless. The very idea of plugging is overwhelming for them. They have nothing basis of comparison. Being a totally new subject matter, it's hard to know where to start. That's where I come in. With 16 years of study and active participation, it has left me well prepped to begin the process of addressing mainstream buyers directly. No more enthusiasts. Those interested in actual change for the masses are dominating discussions. Here's a contribution to that:

Understanding audience has been a fundamental problem. Think about how confusing MPG values were. Each report was different. Who found how much appealing?

GM made the mistake of targeting Volt enthusiasts... which wasn't a huge problem with gen-1, but the approach continues with gen-2. There's little to draw in their loyal customers. Those buyers of Malibu & Cruze will just replace them with new ones later, not even considering Volt.

Ford had the idea of augmenting their Fusion hybrid. That overcame some of the reluctance to change to another vehicle entirely, but introduced the problem of trunk room loss. C-Max had that hump in the cargo area to deal with, so that wasn't a help either.

Toyota has been the other player... but held back upon confirming the very problem mentioned here. Rather than rolling out beyond the 15 initial states, they decided to study the existing markets and adapt accordingly with gen-2... hoping to strike a balance that draws in new interest... those who didn't give Prius any consideration.

Prius Prime will fulfill that role. For the 35 states that never saw Prius PHV, it's an opportunity to start fresh too... an advantage neither GM nor Ford have anymore. The "*to the floor*" EV power will obviously be an easy characteristic to appeal to potential buyers with. There's a vapor-injected heat-pump and a driving recharge mode, both which each out the other plug-in hybrids, won't mean squat to them. However, owners will spread the word, which is far more effective than advertising or even salespeople.

That's the key. Like with Prius way back, well over a decade ago, it was endorsements from owners that played a major role in acceptance. It makes identifying audience easier. It's how a unifying message of purpose emerges too. Watch for it. Note what is favored and what is not by actual buyers, not enthusiasts. Knowing that is how market growth will be achieved.

For all, it should be easier this time around. In the past, promoting wildly varying MPG results only served to confuse. None handled that well. Lesson learned. Drives with EV miles, even if they are short or segmented, are what the typical car shopper will pick up on quickly. They'll understand the benefits of that engine-off experience.

Even small steps are still progress forward. With a market so complicated, so many choices, and gas so cheap, that's a really be deal.

- 8-11-2016** **Battery Degradation.** You can't do much more than share experiences, hypothesize about outcomes, and ask lots of questions. That's what is happening now... as a result of yet another vague press release from GM. The stated "fact" is that no battery-pack in Volt has ever been replaced due to degradation. The catch is, the state of degradation is never actually defined. The references to aging are so vague, they could be anything. That's the typical propaganda we've come to expect. They tell you something without really telling you anything usual. Oh well. This is what I had to say about that topic, on the big Prius forum: So... how does it work with Prius PHV degradation? Today's random errand running resulted in 11.2 miles of consecutive EV driving. Since the system supposedly only delivered 6 miles of EV in the first place, according to quite a few Volt owners, the opposite must have happened. The battery improved as it got older! (And yes, I'm quite pleased to have real-world data proving the naysayers were just spreading FUD.) I am actually seeing results that reveal an unexpected aspect of aging. According to the data from my recharges of the last 4.5 years, the amount of electricity to reach "*full*" has declined. Yet, I'm consistently experiencing the same EV distance as when still new. The thought behind that is the car itself is well broken in now (after 80,000 miles, along with 2,400 recharges) and the electrical resistance inside the battery itself has dropped. In other words, I'm not seeing a net change. Perhaps I would later, when the miles are doubled. But wouldn't I have already got my money's worth by then? And what if a new battery-pack was purchased? How much would that actually cost then? It would bring the car back to a near new status at that point too. Just think of how many more miles it could be driven still. Brushless electric motors keep going and going and going...
- 8-12-2016** **Safety.** We got detail today about Toyota's safety intentions. The price of Prius will go up a little bit. In return, some formerly optional safety features will become standard. That's great. Unfortunately, things like that go unnoticed by the typical consumer and exploited by those hoping to undermine. Specifically, the "Safety Sense P" package will now be included on all models. That consists of: adaptive cruise-control, pre-collision warning with pedestrian detection, automatic high-beam headlights, and a lane-departure alert system. The pricing increase ranges from \$45 to \$515, depending upon the model. That's really nice. It falls well into the category of delivering a well-balanced vehicle. Safety is clearly not being compromised for the sake of efficiency. Don't forget, we also get a major suspension upgrade too. That improvement to handling didn't contribute to an efficiency increase. In fact, the extra weight resulted in a minor penalty. Other aspects of design, like top-rated safety, are important too.

- 8-12-2016** **Adaptation, success.** It has been interesting to see where the "5 seat" discussions take us. A few believe Toyota made a serious mistake and will correct that in a few years by changing Prius Prime to accommodate a 5th person inside. I personally don't envision the many wanting a cramped, less comfortable spot in the middle. I consider the trade for buckets with a center-console an upgrade. Doesn't anyone ever think about their comfort? The shape of the seat along with a padded armrest is nice. Anywho, the most thought-provoking comment are coming from current Prius PHV owners. They look at Prius Prime as a gen-2 offering, rather than the fresh new approach Toyota has stated. Things change. Success means being able to adapt. I started with posting: Prius Prime is different than Prius PHV in a variety of ways, including who it will draw interest from. Most people don't remember the goals prior to rollout, back in 2010 when config had not be finalized. Things have changed since then. The market has shifted and Toyota is pursuing a new target. Adaption is a key to success.
- 8-13-2016** **Adaptation, luxuries.** His response to my post was: *"...and I'll say it again, but if someone is in the rear of my car, they are getting a free ride. I'm uninterested in how luxurious the rear of my vehicle is for those getting a free ride."* So much for the comfort consideration. He clearly see a different audience. I wonder what this will stir: That's why you are not the intended market. Know the audience. Some people do want that. Some also see the value in a large screen, heads-up display, LED lights, and a double-wave window. All are luxuries. For that matter, so are the larger battery & plug.
- 8-13-2016** **Adaptation, growth.** I didn't wait for a reply. I followed up shortly by adding: Speaking of adaptation, that was a grudge I always held against gen-1 Volt. There was no willingness to meet in the middle. That attitude of sacrificing all for the sake of EV didn't prove a draw. Loyal GM customers simply weren't interested. Oddly, gen-2 Volt retained many of the same hold backs. So, there's naturally a bit of a "compared to what" problem with many of the recent discussions. That's why we need to ask the "Who?" question. Having learned from Volt, it's absolute essential to understand audience. GM targeted enthusiasts... and did a great job appealing to them. Unfortunately, that wasn't the goal. Mainstream sales were never achieved and they still remain a struggle. Once the clearance inventory is sold in a few months, we'll be looking at a new market. Bolt will become available. Oddly, that 200-mile EV doesn't seem to be targeted at the mainstream either. To provide a large seating area, both cargo-capacity & aerodynamics were sacrificed. Who will be interested in a vehicle like that? In other words, what do the current owners of Malibu & Cruze really want from their vehicle? Same question for that of Toyota cars. Will Prius Prime appeal to Camry & Corolla owners looking for a replacement? For those who continue to complain here, their perspective is that Prius Prime is targeted at Prius owners. I disagree. I see greater appeal and potential. I see Scion owners having become older now looking for a Toyota to purchase. I see those who grew up with Celica looking for something modern with that draw from the past. I see those who like the perks of Avalon but don't want a car that large. Notice how Toyota is trying something new? Why insist that they retain a design aspect so few actually seek? Is it so bad to want a choice that doesn't resemble all the others? They are making an effort to adapt to the changing market.

8-13-2016 **Adaptation, reset.** Prius has matured to the point where it is so well proven and well refined, the word "hybrid" has become synonymous with it. In other words, it is just an ordinary mainstream vehicle at this point. Every few years, people expect a variety of smaller improvements... but nothing amazing anymore. It delivers well on specific goals. Gen-4 has nailed it. Done.

So, no matter how much some supporters push to retain the status quo, it's ultimately going to fail. Progress cannot be made that way. The established technology alone simply isn't enough. My technology observations over the past few decades tells of bigger change to draw new interest. In other words, the current market is saturated. To grow, something new must be tried.

Prius Prime is that... not a fifth-generation Prius or a second-generation PHV model. True, it builds upon existing technology... but that's the case for pretty much every combustion vehicle. They all take advantage of the past. But that's all hidden. Seeing that Prime different is a step out from beyond the box.

Sales from the first 2 years will indicate what is needed next. That's the opportunity mid-cycle updates provide. We won't know what those new customers really want (not need) until they are given a chance to decide. Most comments from existing PHV owners don't have the perspective required. They don't have "*to the floor*" EV acceleration. They don't have a vapor-injected heat-pump. They don't have a battery-capacity large enough entire commutes. We won't know the true value of those things until people actually experience them.

For me, I'll be going from impressive MPG to an all EV commute. That's new, no comparison available. The electric heater will be quite a treat. I can't imagine what it will be like approaching a car that's sat outside all day, yet is warm inside. And of course, I can't wait to find out what interest those on-the-fence about getting one will think of the stories I share.

It should be clear that the purpose of Prius PHV and Prius Prime are not the same, they do not target the same buyers, they don't even have the same scope. Like other well-proven technology, the time for a reset has come. Think of how desktop computers became smart-phones. That process was long, complex, and came with a few unexpected changes along the way.

8-14-2016 **Adaptation, opposition.** That previous entry was my rant post. I was annoyed by having received a reply so reminiscent of the past. Of course, the confrontations now on the big Prius forum were anticipated. That's one of the big benefits of having done the same on the daily blog for Volt. That was practice, to identify all the argument-points there we'd inevitably see here later. The pattern repeats. GM failed to recognize that reality. The same disaster Two-Mode has become is what they allowed Volt to become as well. To be so naive as to think history wouldn't repeat without making any effort to prevent it... ugh. Anywho, I'm not going to allow that to happen with Toyota. Watching for the signs, then addressing them as early as possible is key. Enthusiasts of Volt absolutely refused to acknowledge Two-Mode's past. They figured that technology and those executive decisions has nothing in common. They were wrong, very wrong. We now have those experiences to learn from. Building upon successes, even with the knowledge of what not to do, can be quite a challenge though. Scaling up isn't as simple as refining a design, then making more. There's where diversification comes in. People need choices. Opposition emerges when decisions about what to offer don't appeal. Not everyone will be pleased. That's all too clear with the seating for 4 choice. Oddly though, we aren't with the raised floor anymore. Seats down cargo room is still quite large. It's not as tall, but that isn't often what owners will need anyway. And if it is, there's still the extra height available closer to the front. Long story short, there are opposing views. Some will not be happy. Point is, they don't need to be. As long as one of the choices appeal to them, goal achieved.

8-14-2016 **Adaptation, mistake.** Pre-Rollout banter continues. That's expected. We want to shake out concerns and address them thoroughly, prior to sales actually beginning. Most consumers won't take notice of any detail until early next year. Now is the time to take advantage, considering this a practice opportunity to refine rebuttals with well thought out points to reply with. Here's more to that end:

What I find telling is those who label the attempt for Toyota to expand reach as a "*mistake*".

We went through this exercise already with GM. The outcome wasn't adding an actual 5th seat; instead, they choose to deliver other configurations... which is what they needed to do anyway. How many here actually remember all those fights? Someone would call for diversification and it would get interpreted as an effort to kill Volt? It was absolutely absurd. Enthusiasts were in a panic state for years, fearing any suggestion of change was really undermining. They seriously believed another offering would dilute, rather than strengthen.

You recognize the early signs of that here?

It starts innocently enough. There are legitimate claims to use of that middle spot; however, scope is quite limited. Most owners never use it. On the rare occasion they actually do, it comes with an apology for the discomfort. That's why the option simply isn't realize for the masses in Prius Prime. Why not offer it elsewhere instead? After all, the effort of developing the technology is to use it.

Look at how Prius v has progressed. Sales have always been respectable. 30,000 per year is sustainable, but not desired. How will Toyota stir more interest? What if it becomes the Prius model to offer the 5th seat? After all, it offers a larger cargo area. That's the better family car. Wouldn't it make sense for Toyota to capitalize on that, recategorizing the regular model Prius in the process. After all, it now offers much nicer suspension... something that clearly wasn't necessary, but certainly is nice.

Prius v could also offer Prime version too.

It's the lack of wanting to consider Toyota's entire product-line that makes the arguments here & now a problem. It follows the very same problem GM supporters had with Volt years ago. The pattern should be obvious. That same "*mistake*" was repeated too. The first time around, it was called "Two-Mode".

Do you really think Toyota didn't consider those lessons learned before making the choices they did with Prius Prime?

8-14-2016 **6 Years Ago.** It's hard to believe so much time has went by since then... when I got to drive a prototype of Prius PHV. There is was in my driveway, without any supervision. They delivered the car and had me sign some paperwork. I could explore the technology on my own... and I did. Thankfully, the wait for my own to keep wasn't too terribly long. Battery technology still needed to mature. Cost was still beyond the reach of mainstream consumers. Energy density was a bit lacking as well. It simply didn't make sense for mass rollout back then... or the 2 years later when I made my purchase. Much could be learned though. That's why the prototype was getting driven my pioneer buyers like me and why the limited markets got inventory to sell. The teaching was quite extensive too. The mere existence stirred quite a bit of industry attention. Why in the world would Toyota try to squeeze out so much from so little? Why not just take the easy route of using a larger capacity battery-pack instead? After all, prices would be lower years later... right? Turns out, they weren't. The chemistry & production had many complexities to deal with. Consumers themselves did too. Prius PHV certainly delivered on the goals it set. Unfortunately, the market itself changed. Low gas prices were quite unexpected. Even more so though was the indifference to MPG improvement. Prius buyers were drawn to that. Those seeking the plug-in experience were indifferent about blending. That 100 MPG target aftermarket sellers had capitalized on didn't draw new interest. The market had been saturated. For Toyota, no big deal. Prius PHV was only a mid-cycle release. The next-gen would be on the way soon anyway. For GM, that was a big problem. Volt had to endure the wait of a full cycle and it wouldn't offer as much of a generational improvement. Upgrades would be incremental. It didn't have a hybrid counterpart either. That's why I'm so excited about Prius Prime. The introduction of a clutch to allow the second motor to contribute power, along with the vapor-injected heat-pump, is something to really look forward to. It's a new draw, taking advantage of market change... without neglecting that all-too-important priority of keeping cost competitive. Supposedly, that will result in a very attractive price. We'll find out in about a month or so. The first 6 years went by quick. This final wait is becoming a long one.

8-14-2016 Prius Plug-In History. I posted these thoughts for consideration:

Shortly after the 2nd generation rolled out, we were already discussing what potential the ability to travel up to 100 km/h using only electricity had to offer. Unfortunately, back then all that was available was NiMH batteries, which were robust & affordable but lacked enough energy density.

Lithium chemistries emerged a few years later, showing realistic battery-pack opportunity. Toyota began testing. When the 3rd generation was later rolled out, we could see the power-split-device had been improved. Higher RPM from the motors was available. That would be conducive to more efficient EV driving.

6 years ago, I got to drive one of the prototypes. It was equipped with a 5.2 kWh lithium battery along with a heat-pump for cabin-warming in the Winter. Both features ended up being scaled back. The larger pack meant a raise floor. The heat-pump meant very short EV distances. Neither were supportive of being a PLUG-IN HYBRID anyway.

Blending was key. The system would take advantage of the gas engine whenever it presented an efficiency benefit. Maximizing EV travel simply wasn't a goal of Prius PHV.

Soon, we'll be seeing Prius Prime. That brings back the 2 design attributes previously dropped. It also introduces "to the floor" acceleration in EV. All of which put emphasis on electricity use, not taking advantage of the gas engine at times. The larger battery has become key instead.

True, the hybrid system will still be remarkable efficient, but the optimum balance of features will not. That alteration of priorities changes the consumers targeted. Toyota says that's ok though, since some of their long-time customers have changed anyway. They grew up with Prius. Now, they seek something different. There are also customers of Toyota who owned a Camry or Corolla, found Prius interesting... but not compelling enough. Prius Prime is intentionally different.

Remember, the ultimate goal is to expand the market. That growth cannot be achieved by continuing to appeal to the same audience. That catch is, appealing to a different audience means not pleasing the other.

8-16-2016 **For All We Know.** The speculation is interesting, especially when looking back years later. What seemed so important at the time can later become so trivial, it is sometimes almost totally forgotten. That's why I like documenting quotes like this: *"Toyota's already working on a 5 seat Prime even before the 4 seat Prime even hit the market."* Saved for the sake of learning from history is valuable. If it was mistake, much can be learned. If it was pointless, how was that recognized? In this case, I wait with anticipation to confirm my thoughts: You have already fallen into the same trap Volt enthusiasts did when GM said something. You heard what you wanted. The engineer stated he looked forward to doing that work. He designs things and finds the process very rewarding. No where was there any promise of actually delivering it on a Prius Prime, nor was a timeline even given. For all we know, it could end up on a different plug-in hybrid. Think about how Prius v could use that. You get one Prius oriented to offer nicer features and other that delivers an extremely practical configuration. After all, your logic of being responsible makes more sense with that approach.

8-16-2016 **Who?** That question is finally being asked by others. It isn't about Volt anymore either. That past was about preparing for this future, the present, in which this question emerged: *"Here we are talking about selectable EV, heat pumps and the ability to charge on the fly while it is reported that most buyers do not even 'get' the need for a plug in hybrid. Toyota serves those people, too. That is why I don't quite understand your saying that the Prime is for a different market. Aren't we the market for the PHEV?"* I replied with:

No, we are not. History has taught that lesson all too well. Back in 2009, a entire year before Volt was rolled out, I began pointing out how the "40 mile" promise would fall way short. The enthusiasts attacked, claiming I was attempting to undermine GM's vehicle. They just plain wouldn't listen. No matter how much I pointed out the realities of winter, they didn't want to hear it. The fighting was pretty intense... until they got confirmation on their own, discovering I was right all along. The resistance heater consumed even more EV miles than I had predicted. Warming the cabin in Winter resulted in a significant plenty.

I tried to set realistic expectations. This time around, we are constructively discussing the situation even before rollout. That's profoundly different. We aren't the market. We are the educators. Our knowledge & experience will help inform "most buyers" of the importance. It's meaningless in this format. They'll have no clue what the difference is between a resistance heater, a regular heat-pump, and a vapor-injected heat-pump. But they will figure out that the one is somehow better than the other, that not as many EV miles will be sacrificed for warming.

Prius Prime will attempt to overcome the market we represent, punching through to reach the untapped masses... those who know little to nothing about plugging in. That's a major challenge. How do you entice someone with no engineering background whatsoever?

Try explaining "charge on the fly" to some random stranger. How will you get them to not only care, but to also want to know more? You'll be able to hold their attention for a maximum of 20 seconds. By early next year, you'll know how. Reports like this... getting 28 miles from a battery rated for 22 miles... is how it starts. That's the attention getter.

8-17-2016 **Likelihood.** Shopping difficulty is a challenge to understand. Neither the buyer, nor the seller really know what's wanted. Need can be determined, but that's not enough. It's the emotion which sways the person to finalize the deal. It's based upon what is often unanticipated. It's can be unlikely. That's why this caught my attention: "*What is the likelihood that they happen to have the exact car, with the exact features, with the exact colors that a person wants?*" The not really knowing is why I put so much emphasis on the showroom floor experience. That can be an exploration of desire. You sit behind the wheel to make firsthand discoveries. After all, who is aware of what new features are available until doing some poking around? Some salespeople really do try to help with the process. Others are clueless, but you find certain things appealing anyway. Think about how much a person researches before such a major purchase. Surprisingly, most do very little. Toyota knows this. That's why targeting Prius Prime at those who are simply curious could end up to be a well thought out approach. Not everyone will bite. In fact, most may not. Enough probably will though. We'll find out next year. In the meantime, think about this perspective: It's very, very likely. Ordinary consumers simply shop current inventories, with the help of salespeople who direct them to choices immediately available. That's why Prius Prime is configured to be compelling, sharing some traits with Prius but still standout'ish. Think about how easy it will be to capture a potential buyer's interest just by taking a test-drive. That to-the-floor EV, yet still a hybrid, will be a draw.

8-19-2016 **Food For Thought.** I liked reading & responding to this: "Just food for thought. Ultimately, automakers know their situation far better than armchair pundits ever will." It came from the moderator of the daily blog. Hopefully, others will sound of with something constructive. I tried to help that process along:

The local plug-in owners group in MN met last night. Discussions there are far more in depth than any type of exchange online. Representation is wide too. Like you, some of the members have traveled else to see vehicles & infrastructure now available here. We focus on the true competition, traditional vehicles.

What I added to the discussion was how the impression of the big automakers doesn't match what they are actually doing. Toyota was the example. It seems as though they aren't interested in EV, yet there are subtle signs to the contrary. The biggest is lithium battery usage. Not seeing any plug-in vehicles available makes it seem there is no effort to advance taking place. But in reality, all but the base model of Prius has switched over. That's a lot of lithium. There's also the industry-leading advance with heat-pumps coming for Prime. This will be the first vapor-injected offering to market. Also coming with Prime, though exclusive to Japan, is the option for CHAdeMO charging. It appears odd to have such high-speed recharging ability for such a small battery. But when you think of future applications, the limited real-world rollout early will prove to be a wise move.

Look at how well the Mitsubishi Outlander plug-in hybrid is selling. Just think if they did that with Toyota RAV4 hybrid, leveraging upon what they established using other rollouts prior to that. A plug-in model could do remarkably well, here... in the land of SUVs.

We also had a discussion in length about charging infrastructure. There's a very real problem looming of how to deliver more than just a handful of charging-stations in each parking lot. There's also the look into how to provide much higher power recharging than what the current super-chargers deliver. How? Who? When?

We also talked about how to get dealers more involved, along with stirring support from utility providers. It goes well beyond just the vehicles themselves. The technology is only the first step. That's why I was so hard on the Volt enthusiasts to look beyond what's in their driveway. Stimulating interest from both consumer & salesperson presents major challenges still.

With the case of Toyota, the hope is to capture those showroom floor opportunities. Rather than seek out someone looking to purchase a plug-in vehicle anyway, the hope is to draw their own customers over. Getting them to take a close look at a Prime before considering a Camry or a Corolla is a major challenge. Heck, even getting someone interested in Prius to take a closer look at what a plug has to offer won't be easy... and we certainly know the pundits aren't taking the situation serious.

It's those quick impressions that are very difficult to overcome. What is the approach for gen-2 Volt? What will it be for Bolt? Think about what the upcoming gen-2 Leaf announcement will stir. And of course, the momentum for Tesla continues to grow.

The situation is complicated, even without having the problem of cheap gas and expiring tax-credits to worry about.

8-20-2016 **Consumer Objections, finally.** Those terrible days of "*vastly superior*" are over. I'm still amazed just how bad it got. The claims of targeting the mainstream were a massive waste. The niche was so obvious. There simply wasn't any effective way of dealing with such a fundamental mistake though. Poor assumptions were made that couldn't be backpedaled from... though they certainly tried each time something else went back. Anywho, that's finally history. It's over. Now, we move on to what I've been pushing for a very, very long time... the market for ordinary consumers. The following entries are my thoughts on that now, starting with: It's nice to see that most of the gen-1 rhetoric has subsided, now that gen-2 rollouts have begun. Finally being able to address the actual competition is great. Traditional vehicles have been absolutely crushing sales of PLUG-IN vehicles. Constructive discussion on the challenges we still face is long overdue. This topic contributes well to that effort to overcome them.

8-20-2016 **Consumer Objections: not enough electric range.** That was the first issue addressed. People just instinctively use numbers as their basis of measure, using the "*more is better*" as the method of judgment. I know from having been involved in the personal computer market from the very beginning that mindset never applied to mainstream consumers. The typical buyer would look for a balance. Even though greater capacity was available, that isn't what they'd purchase. The same has been true in the automotive market. Speed, Size, Power... things like that were always the focus of advertising. Yet, that isn't what people would actually buy. Why do plug-in enthusiasts think that won't be true for EV capacity, especially if you have an engine available? Needless to say, I have much to say about this particular point. However, it's best to keep most posts on it brief: This isn't really much of an issue anymore. Conversations with random strangers about the 22-mile range for Prius Prime come with an automatic understanding of there being a gas-engine to take over when the battery-pack is depleted. No big deal. They recognize what PLUG-IN HYBRIDS offer and the minimum seems to cover most routine driving well. With the upcoming rollouts of 200-mile EV choices, that isn't much of an issue either. No concern. They get it.

- 8-20-2016 Consumer Objections: dual powertrain too complex.** This was the next listed. It's what we heard long ago, when people first discovered hybrids. They were clueless as to how their own vehicle was actually designed. That made it very difficult to rebut. The simplicity of the power-split-device in Prius replacing the surprisingly complex design of modern automatic transmissions was beyond their grasp. They just assumed what they are currently driving wasn't a reliability concern... despite evidence to the contrary. New engineering approaches... as we have seen with Prius... were attempts to overcome those problems of the past. Convincing ordinary people of that was an incredible challenge though. Their belief stems from the assumption that sacrifices are being made to achieve higher efficiency. That isn't the case. Hopefully, these new rollouts combined with knowledge of the past will help resolve those misunderstandings. I replied to that with: One of the biggest favor factors for Prius Prime is the fact that Prius has already proven the "dual" argue doesn't have any merit. With 3 generations of Prius confirming reliability, the addition of a plug for charging a larger battery-pack is no big deal. FUD (Fear, Uncertainty, Doubt) is extremely difficult to spread at this point. Other PLUG-IN HYBRIDS don't have this direct advantage, but realistically that shouldn't matter. The category is established & understood.
- 8-20-2016 Consumer Objections: engine is redundant.** This is an interesting one. Many haven't noticed the change yet. Industry realignment is a slow, painfully slow. People get hung up on argument points, missing those signs as a result. My effort now is pointing out how things are different. Looking around doesn't work either. They just see more of the same. It's the result of treating the "market" as those who are only interested in purchasing a plug-in vehicle. That makes the overall goal of eliminating traditional vehicles harder. Taking smaller steps seems like a big waste... to those with the knowledge & money to purchase more sooner. Mainstream consumers certainly aren't in that category. That's why they praise themselves for buying a smaller, more efficient SUV with only an engine, rather than actually considering a hybrid model. Thank goodness RAV4 hybrid is doing so well. That's a good sign when considering the addition of a plug later. As for right now, it's dealing with the situation this way: Do we really believe that EV purists will shoot themselves in the foot by continuing to fight against PLUG-IN HYBRIDS at this point? I'm not seeing it with my encounters. Sure, it was easy in the past to find examples of the smug, but ordinary consumers couldn't care less. That was always isolated to enthusiast groups. Simplicity and cost-savings is obvious. That's still a challenging argument though with EV price at a premium. The mainstream isn't concerned yet.
- 8-20-2016 Consumer Objections: won't pay back.** Ugh. How do we deal with this? Most supporters fall into the trap of trying to explain the numbers. That hasn't been effective in the past. Why do they think repeating the same failed approach will work now? I don't bother. My attempts are to refocus effort, to provide a new perspective on the situation. For example: Number crunching results for overall expenses aren't of much interest to the typical showroom floor shopper. With them as an audience, there's a paradigm shift. The old arguments simply don't work. These buyers look at the bottom line, how much their monthly payments will be. That's why tax-credit benefit doesn't mean as much; they'll expire mid-cycle anyway. So, it's depending upon other draws instead... like a test-drive in EV mode. Remember, the audience is someone looking to purchase another traditional vehicle, not people already determined to get something with a plug.

8-20-2016 **Consumer Objections: new unproven technology.** This one requires time. Reaching the masses is a long process anyway. We attract whomever we can when they are ready. No amount of convincing points will sway some. That's just the way it is. They will figure it out on their own, in their own way, on their own schedule. So, all we can do is provide information and how for the best... as I attempted: That's a tough one, for now. Basically, if they feel uncomfortable, it's really an excuse to not consider the purchase for awhile. In other words, nothing you can say will convince them. However, you can eventually win people over simply by driving the vehicle. After enough are seen on the road, their concern will fade. Some don't like anything new. That's a reality of the diverse market we have to deal with.

8-21-2016 **Taking The Time.** Wow! This rant certainly caught my attention: *"I've driven the Gen 4 and wasn't impressed. It's bigger, bulkier and has the same problem - it runs the engine all the time even when driving slow just to warm it up and warm the water up to heat the cabin! I've written Toyota many times on this. The same phenomena causes one to get in the low 20's for mileage when driving 1-2 miles on short trips daily when it's moderate to cool outside. There's plenty of battery power and I turn OFF the cabin heat, yet it still runs the engine constantly - shame on you Toyota."* Rather than simply providing some insight, I took the rare approach of making it personal with hopes for the best:

Shame on you for complaining without researching. Sorry, but sometimes it's best to confront directly. In fact, that's how a few of our best advocates have emerged... from a misunderstanding based on incomplete information. So, it's worth taking the time.

In this case, you make no reference whatsoever to the reason for the warm-up process. It's to reduce emissions by getting the engine up to optimal operating temperature as quickly as possible. The supposed waste of gas you witness is actually the cleanest way of achieving that. Traditional vehicles attempt the same thing, but they cannot deliver as well lacking an electric motor which provides a buffer.

You also made no reference whatsoever to battery recharging or longevity. Do you really expect great overall efficiency and a pack that never needs replacing with the suggested operation of not warming up? A cold engine not only operates in an inefficient and dirty manner, it also has to endure greater wear. Toyota has went to extremes to optimize that process.

You have made no reference to the rest of the market either. Toyota offers the best hybrid system available. It's most efficient, most clean, and most affordable. That's just among no-plug offerings too. The upcoming Prius Prime not only resolves all of your complains, it should also score the highest efficiency rating (estimated at 120 MPGe).

You can consider yourself schooled, no worries about having been unaware of some information either. Making it personal sometimes really is effective. Just take the time now to study what's being posted for your benefit. Notice how others are also taking the time to make sure you have a thorough understanding of design & intent too. We all end up better off by exchanges like this.

What do you think now?

- 8-21-2016** **New Plug-In.** This was interesting to read: *"My commitment to sustainability is now tested by Toyota's lack of commitment to having any EV or PHEV available at all. How disappointing."* It was from someone who's been arguing against Toyota's approach for years, showing favor for Volt instead. So, seeing a post that he ended up purchasing a Volt didn't surprise me. It seemed inevitable. It wasn't pleased with his stance though, making generalizations all this time, then abruptly spinning it to really be about his specific purchase. I didn't buy that for a second. I gave me good reason to post this too: For some perspective... Prius Prime is just 3 months away and it will be rolled out worldwide all at once. Toyota is also planning a production of 60,000 the first year. How is that lacking? To add to that, all but the base model of Prius now uses lithium batteries. That most definitely is a commitment to advancing plug-in opportunities. It's a major effort to reduce cost and improve production. Want more? Look at the CHAdeMO option being offered in Japan. It bumps the current recharge rate from 2.2 to 6.6 kWh. Knowing that, there's simply no way to say they are working toward that sustainability. How about this too? We'll be getting a vapor-injected heat-pump for winter cabin-warming. It will offer a top-industry efficiency for EV travel. There clearly is commitment. The advancements being delivered are undeniable. Sorry, but your disappointment doesn't add up. You wanted a Volt. We've known that for a long time. We can thank you for contributing toward the effort to improve personal travel, but we cannot accept the claim of lack of commitment though. Enjoy your new plug-in.
- 8-22-2016** **More To Mention.** Others joined in to point out other benefits, like solar roof, blind-spot monitoring, rear cross-traffic warning, and lane-keep-assist. Naturally, I had more to contribute: Along with a much nicer heater, auto-detect venting, dynamic cruise, pedestrian safety, LED head & tail lights, drive-mode recharging, and higher MPGe. In Japan, there's also the option of CHAdeMO charging and a 1500-watt inverter. The dual-wave window in back is nice cosmetic stand-out with aero-dynamic vendor as well.
- 8-22-2016** **The End?** That was his prediction: *"Unless there's a big increase in the price of fuel, when the tax-credit disappears, Volt sales will tumble."* Not being able to get anything constructive from enthusiasts is what brought about his provoke. I poked about the end, just not in such a terse manner: The simple rebuttal to that is for someone to suggest a plan, how GM should respond when the subsidy money really does fade away? We see Toyota ramping up lithium production, by selling all the but base model (trim package two, not the eco variant) Prius with that type of battery already. It will help them reach economy-of-scale lower costs from the high volume. We also see them positioning RAV4 hybrid to take advantage of the small SUV craze, being able to offer a plug-in model when the market is ready. GM could very well do something similar. The catch is, they cannot wait. If Bolt truly is to be a Tesla competitor, it must become widely available quickly. That means bringing about the end of tax-credits for Volt sooner. In other words, we're going to see all the gen-2 offerings from every automaker face a very real cost issue mid-cycle. The significance of this should not be understated.

8-22-2016 **Next Steps.** Taking the situation seriously is a challenge... but less so now. At least I get to ask questions without fierce pushback anymore. That's progress, as this tries to convey: With hope for plug-in choices to thrive, it requires a serious look at the competition. It's not other hybrids. It's not other automakers. It's vehicles sharing the same showroom floor. What is GM's plan? Seriously. As was pointed out, gen-2 Volt is struggling even with help. Malibu hybrid is just barely squeaking by. How should expectations for growth be set for either of them? Will Bolt hit the ground running or should we give it some time to settle? What's realistic for 2017? The plan for Toyota is clear. 1.4 Million hybrids is the sales projection for this year. Gen-4 Prius will take hold. RAV4 should remain strong. Prius Prime could stir mainstream interest. C-HR debuts next year. The potential for growth is realistic. Seriously, how will the challenges be addressed? Traditional vehicles cannot be allowed to continue stealing away sales opportunities. What are the next steps?

8-24-2016 **Naming Problem.** An entirely new topic emerged today. I wonder if this would get attention prior to rollout. I've encountered the problem of "*Bolt*" sounding like "*Volt*" a number of times now. Turns out, others have too. That antagonist with a blatant hate for Prius got all riled up about it. Why? It seemed rather odd to attack Toyota. Yet, there it was. Even though the variety of Prius hybrids all operate the same way, he got all bent out of shape about package numbers and not being able to tell the difference between the *c* and *v* models. Who care? They all have an engine, two motors, power-split device, and no plug. Heck, even the battery sizes are roughly the same. What is there to mix up? The category is clear. That most definitely is not the case with Bolt & Volt. Yet, there was an attack attempt anyway. I blasted back with: Since they all the Prius models operate the same way, there is no need for clarification. Heck, even adding the words "*plug-in*" worked just fine. No understanding issue. For example, the words "*plug-in Prius*" have been used without any trouble at all over the past 5 years. With Bolt & Volt, even in the plug-in owners group we are already having problems. GM really set themselves up for trouble with this one. Ugh. Toyota added "*Prime*" in their labeling, knowing that "*Prius Prime*" would get referred to with the short name of just "*Prime*". That has already become a common reference too. That marketing forethought will allow them to associate it elsewhere later. For example, "*RAV4 Prime*" will clearly identify it as the "*plug-in hybrid*" model. No confusion with either the hybrid or the traditional model will happen as a result. GM seriously needs to reconsider the naming. Bolt is too different to allow it to get mixed up with Volt on a regular basis.

- 8-24-2016** **Holding On.** That one particular person who absolutely refused to move forward is still causing trouble. He's desperately holding on to the past. I wonder why. Hmm? Obviously, things are going well for gen-2 Volt. But why not embrace the plug-in support-group we're assembling? He aimed and fired back with: *"Apparently you don't like 'constructive' criticism of Toyota, but it's the only way forward to the future. They can't operate with blinders on."* I was ready for it, as this states: You're doing everything you possibly can to put up blinders. Everyone sees the effort being expended to avoid answering the simple "next" questions. Stop with the gen-1 rhetoric already. Geez! You are literally the only one still hanging on to that past. Gen-2 presents new issues, due to the new goal of needing to grow sales and survive without tax-credits. The rest of us are addressing how to deal with that. We see the plug-in choices as the assortment to overcome the barriers traditional vehicles face. Why in the world are you still trying to prove GM is better than Toyota? It doesn't even make any sense. Losing sales to Malibu & Cruze is the problem for Volt. Do you really want that to be the case for Bolt too? It's hard to believe in the later half of 2016 we still have to deal with such denial. The showroom floor is where battles are being lost. Stop creating new ones here, fighting the very people trying to expand the plug-in market.
- 8-25-2016** **Why?** The level of emotion rose dramatically. Why did he begin to show such desperation on such a benign topic? Who cares if the name changes? The attachment should be to the goal, not any particular labeling. But then again, we hear semantic arguments all the time. They accomplish nothing. Yet, they happen. Most are a dead giveaway of a fundamental problem having been uncovered. That would seem to be the case with this too. I poked to find out: Hollywood changes names. A few of our favorite movies were called something else all through production. You watch the behind-the-scenes footage and will discover during the shooting it was called something else. The same thing happens with other industries, like with software. Why are you blowing this so far out of proportion? Geez! It's as bad as those who threw a fit when the gen-1 Volt was revealed and it looked nothing like the original concept. People got over that, which was a collection of actual changes. This is nothing but a name. As for the attempt to compare to Toyota, that falls apart quickly. You know all too well the plug-in Prius will be referred to as just Prime, which is a different name entirely.
- 8-26-2016** **Go Away!** I got that classic *"head in the sand"* response. Pretending there isn't a problem doesn't make it go away. Some people take a long time to learn that lesson. Some never do. I wanted to know more, to find out what I am truly dealing with at this point. So, I posted: Do a search on this topic. Notice the other websites that come up? Whether or not I'm the one providing the information you don't want to hear doesn't matter. Others are already doing it. This almost sounds like you've got something against Bolt... which tends to make sense, knowing how much resentment there has been toward EV offerings in the past. Bolt has a nicer back seat than Volt too. The tall interior is a major appeal factor and the 200-mile capacity easily overcomes range anxiety. Whatever the case, it boils down to the same problem again. Other vehicles sharing the showroom floor are stealing away sales from Volt. That has nothing whatsoever to do with Toyota. That is entirely GM's own production-line being competitive for its own customers. Remember, the goal is to promote plug-in offerings for those mainstream buyers. It doesn't matter what GM vehicle accomplishes that. The point is to phase out traditional vehicle sales. It may very well be Bolt that achieves the low-cost, high-volume market for GM customers.

8-27-2016 **Get Over It.** I finally let him have it. With only 1 person left fighting efforts to unite, the time had come. Make it personal. Make it obvious. So, I did:

I've read through previous posts on this and other threads. A pattern has emerged. Examples of using me as a distraction & scapegoat are abundant. Seeing that got me curious as to why. What has been the motivation for that behavior?

The claim of me being against of all things GM is easy to disprove. My only thing against Volt is its portrayal as a mainstream contender. It's not, period. The seating in the back is impractical. That lack of headroom, 1.6 inches more in Prius, makes it clear what stirs your resentment. The high cost for 53-miles of EV capacity with liquid cooling presents major affordability challenges for Volt. Seeing Toyota rollout a system offering 22 miles EV capacity with to-the-floor acceleration makes anger understandable. But since I have praised Volt for its reliability and very nice performance (power, speed, handling), there isn't good reason for the "*anti*" label. I'm being used as a source for venting.

Next, we look to Bolt for confirmation. The only negative I have said about it is questioning the low production expectations. Why only 30,000? Of course, I have repeatedly pointed out that emphasis on Bolt popularity would hurt Volt. Only a fixed amount of tax-credits are available. Since gen-2 Volt has not stirred much market interest and 200-mile EV choices have, it makes sense allowing Volt to remain a niche. You obviously don't like that.

Eureka! You lash out at me whenever Volt loses attention in favor of Bolt. That explains the irrational posts about things like changing the name. It all makes sense now. You've been anti-EV for so long, seeing Bolt draw strong interest goes entirely against what you've been promoting for years. And even worse, it actually endorses what I've been promoting. A double whammy! That explains it. Excitement for Bolt takes away from what you've been working so hard to achieve with Volt.

Sorry, but you're going to have to find a way to get over it. I'm part of the group struggling to grow the market for plugging in and ending the dominance of traditional vehicles. That means having to cooperate, crossing automaker lines and being forthright about audience. So what if Volt remains a niche? Bolt will stir EV buyer excitement and the plug-in version of Malibu hybrid will demonstrate PHEV potential. That's all for GM shoppers, capturing their interest on the showroom floor.

Toyota, Nissan, Ford, Honda, Chrysler, etc. all have their own shoppers. Either those supporters can tough it out on their own or reach out to other automaker supporters for help. Uniting makes far more sense. Stop with the attack nonsense. Get realistic. It's time to address the real problems.

- 8-27-2016** **475,000 Buyback?** What more can be asked now? The disaster for VW referred to the world as "dieselgate" has moved beyond any sign of hope. No engineering solution proposed has been good enough. There are far too many problems. It's costly and will negatively impact performance. To make matters worse, the gen-4 Prius is starting to attract TDI owners. I read of my first report, where the words "*fun to drive*" were used. Toyota was wise to put emphasis on handling dynamics for this generational upgrade. Of course, when efficiency exceeds 55 MPG, why wouldn't you? That's better than what any diesel can deliver in real-world driving. Heck, even best-case scenario struggles to deliver that. The hybrid technology is so well proven, there's no competing anymore. Of course, those who were responsible for the cheat already knew that... hence the deception. Now, it's the owners coming to that same conclusion. As a result, it looks more and more like VW could end up buying back all of their diesels in violation of emission standards. That's 475,000 vehicles here in the United States.
- 8-28-2016** **Just the Facts.** I've been watching things for GM fall apart. The name fiasco was confirmation of problems to come. The reasoning for that is simple: no concise message. When someone just thrashes out desperately for no good reason and everyone else just allows it, that sign of trouble should be obvious. We've seen it so many times in the past, that pattern is easy to recognize. That "*Go Away!*" was rather blatant. It was followed by "*You're not helping.*" without anything else. Nothing constructive other than an attempt to draw focus away from an emotional outlash marks a turning point. I attempted to reply with something constructive, but I expect little at this point. The problem is quite clear. Uncertainty is beginning to overwhelm. This is what I posted: Notice how no one else mention other GM names just prior to rollout? Notice what all of the following have in common: "*Dual-Mode*" and "*Two-Mode*" as well as "*BAS*" and "*E-Assist*" along with "*Volt*" and "*Bolt*". There's "*Ampera*" and "*Ampera-E*" now too. All are names used to de-emphasize technologies of the past. Like it or not, there's a common complaint among Volt supports... minimal dealer support... minimal advertising... minimal automaker interest. We had hoped PHEV growth would come, but the stated reason for production in China and shipping to the US is lack of demand. Volt has found a niche, which it will serve well. Mainstream aspirations have shifted elsewhere though. In this case, we're seeing GM refocusing attention over to the EV. Whether you think I'm helping or not, those are the facts.
- 8-29-2016** **4.5 Years Later, video.** I particularly enjoyed capturing this drive on video... With over 80,000 miles driven and having plugged in to recharge over 2,400 times, the real-world results speak for themselves. This particular drive was my morning commute, taking advantage of the suburb route to enjoy maximum EV distance. I did too. 13.9 miles of consecutive drive before the engine started. That overwhelmingly proves the claims of getting far less are nothing but rhetoric, especially now with the car 4.5 years old. The drive is the first with my new route. I moved 1.5 years ago, to a location 1 mile further from work. There are a lot more hills. The up & down is no big deal though; Prius PHV handles them just fine. Surprisingly, overall MPG didn't drop much. It's quite scenic and I still have the choice of several suburb & highway routes. The camera for the dashboard information is new. The image stabilization is much better. No more vibration. It's been eliminated entirely. There isn't any refresh flickering from the screen either. That's gone too. This setup works really well for capturing drives, even with difficult lighting from sun glare in the morning. 19.5 miles was the total distance. It consumed the entire EV capacity, resulting in an overall average of 283 MPG. [Prius PHV - 4.5 Years Later](#)

- 8-30-2016** **Leap Frog.** Again with the never-ending rhetoric. It's amazing how some of the greenwash lives on, many years after those who pushed it are long gone. The "*leap frog*" topic emerged, yet again, with: "*Are some people assuming Prius Prime is going to come along and leapfrog the competition? That may not happen and Prime is also pretty late to the party.*" I was quite annoyed. Anyone who still thinks other plug-in vehicles are the competition is just mindlessly passing on evidence of desperation and blindness from pride. With gas prices so low and sales of small traditional SUVs booming, how could anyone believe plug-in vehicles are an isolated market? True, many ignore them entirely, convinced that oil-dependency and climate-change are just political banter. But to acknowledge plug-in potential only as far as the green audience is a disservice. What good does that do? My reply to the post was short & sweet: Traditional vehicles are the competition. Prime is right on time.
- 8-30-2016** **Expectations.** Seeing people ask expectation questions is a good sign. In the past, it was simply an exclamation of fear. That's turning into inquisitive posts. How do we set expectations? What subject matter is of greatest importance? Who is even the proper authority? There are no standards yet. For that matter, there is very little history to leverage from to make decisions. Discovery is on-going. All we can really do at this point is share observations and ask questions. This was my contribution to that today: How much MPG loss or HORSEPOWER loss is acceptable for traditional vehicles? The system simply doesn't work as well when it ages. That has been the norm since the automotive industry began. It's quite unrealistic to expect it to work like new as the years roll by. With batteries, what should the aging expectation be?
- 8-31-2016** **More Time.** It was interesting to read this: "*My fear is that GM will decide to milk the tax credits for as long as they can, and thus not go for breakthrough sales numbers with this car. The more time they have before their last credit is used up, the better position they'll be in to actually sell these cars profitably once it does.*" It sure is nice seeing posts like that now. Rhetoric of the past made them scarce. Heck, I was even able to respond without much stir: You're not alone with the concern for that missed opportunity. Ironically, your second sentence is what had been used countless times for arguing against Toyota. That "*more time*" approach has proven a wise one too. The gen-1 plug-in Prius provided great real-world data for them to study, while the production process was being refined, the design improved, and the battery technology advanced. The gen-2 model is now in an excellent position to take on the true competition: traditional vehicles. As for the pace of Bolt rollout, pushing into the mainstream (to achieve sustainable profit prior to the tax-credit vanishing) means leaving Volt a niche. Once the quantity threshold is reached, the phase-out timer starts. That "*more time*" is great, to a point, then the high-volume must be delivered. In isolation, no big deal, especially with gas so cheap. But we know the price will go up and that others will also exhaust their tax-credits. Pressure from Nissan will be intense. If they gamble exclusively on delivering a profitable EV, their resources are better served than with GM's split between Bolt & Volt. The struggle with Volt has been primarily blamed upon GM not promoting it (little advertising, small inventory). What should we expect for Bolt?

- 8-31-2016 Battery Questions.** Getting asked about how the plug-in Prius operates is always a pleasure to respond to. Today, that came about from this: *"Will this battery range even extend, if your average speed will be lets say -5mph less and accelerate more gently from stop? Can you tell me also please, if I will go to motorway with depleted battery, and I will drive 100 miles, how much will battery recharge? Thanks a lot."* I posted: Speed, stopping, accelerating, temperature, and terrain all play a major role in what you get out of the battery. What you saw in the video would have been a great high-efficiency commute, had there been fewer & smaller hills. Nonetheless, I'm still pleased with the results, especially after 4.5 years. As for recharging while you drive, Prius PHV was configured to deliver maximum efficiency following depletion. That meant not replenishing battery-capacity beyond the HV threshold. Prius Prime will be different, allowing the EV to be replenished as well. Remember, 2012 was a very different time and the market was asking for that. It changed. Now, they want more EV... which is realistic with the more efficient gas engine and larger battery. You'll be able to exit the motorway and do that driving in EV. Think about how much Toyota was able to accomplish with just 4.4 kWh. That small battery and gen-3 system really delivered a lot.
- 8-31-2016 EV-BOOST.** Interest is growing for not only Prius Prime, but also Prius PHV. There are some who are looking to jump on the opportunity to purchase a used one. So naturally, we are getting questions about how it works. This is what caught interest on that topic today: *"I am still all right based on this info, what PIP is doing at high speeds over 100kmh?"* With all the intentional misleading we had to deal with on that topic over the years, it's no surprise this is getting asked. Sadly, this is proof some of the greenwashing efforts worked. That's why owners like me to try to share lots of real-world data. Overwhelming discussions with actual ownership experience is a very effective way of scaring away those wanting to undermine. Anywho, this was my reply: Driving in HV mode (whether or not you have EV capacity available) will deliver efficiency slightly better than the regular model Prius. The reason for that advantage is the battery difference. Lithium can squeeze out more opportunity than NiMH. Driving in EV mode at speeds higher than 100 km/h isn't available from Prius PHV (gen-1). Driving in EV-BOOST mode is though. That's when the system takes advantage of plug-supplied electricity when going faster than the 100 km/h limitation. It's often referred to as *"blending"*, since it is EV power with the engine joining in to help. You'll notice that the draw from the battery-pack is stretched out. Toyota did a remarkable job of achieving balance. The resulting is efficiency above the 100 MPG mark.

9-01-2016 **Falling Apart.** Any posting at this point would just degenerate to anger. The group of Volt enthusiasts has become unwilling to listen. It's just the mindless cheerleading we're getting now. How many technologies in the past experienced the same? This certainly sounds familiar: *"GM underpromises but always overdelivers. We shall see soon this happen!"* I was blown away upon reading that. I couldn't believe such nonsense was being posted. Heck, even Toyota a loss from time to time. That's normal. Not every attempt is a winner. That's how the advancement process works. You learn from previous attempts. Anywho, that absolute is a dead giveaway, a sure sign of trouble... in other words, denial. Believing in that absolute of perfection is not constructive. Most isn't quite that obvious though. It's more like this: *"The new Volt is better in every measurable category than the Gen I and the Gen I was/is stellar."* That comes from the engineering blindness, choosing to only see what they want. Those categories are cherry picked. The only select to measure what they feel is important, rather than addressing every category. The on-going disregard for rear-seating is most telling. Rear headroom went from 36.0 to 35.8 inches. How is that not measurable? It's something that was complained about on a regular basis too, especially when the interest in 5th-person seating faded. I remember how shocked supporters were to discover the headroom was actually reduced a little. To make matters worse, you can point out the 37.4 inches in Prius. That's a huge difference. What I especially don't like is the fact that Prius seating in the back is nicely covered by padding & metal. In Volt, it's nothing but glass. That makes it uncomfortable in the cold & hot as well as less safe. Ugh. This is why things are falling apart. The Volt enthusiasts simply don't want to address shortcomings. They just keep cheering. Watch what happens. You'll hear more and more about Bolt in response, yet still much praise for Volt. The aspiration for it to become mainstream is gone. Perhaps that's for the best. After all, Bolt's resemblance to the popular Honda Fit and Nissan Versa is a big positive for it.

9-02-2016 **Net Yet, But Soon.** What will happen and when is what keeps some intrigued and others on edge. This transition from gen-3 to gen-4 Prius is a topic of history in the making. People are watching & wondering. I'm trying to provide a sense of anticipation, having experienced this back in 2000 (Original to Classic), then again in 2003 (Classic to Iconic), then again in 2009 (Iconic to gen-3), then again in 2012 (gen-3 to PHV), and now watching the gen-4 model rollout. That is the only upgrade I won't be experiencing firsthand. Mine will later this year, with the replacement of my PHV with a Prime. That's sort of a double-generation. I'll get the new hybrid system along with the new plug-in system all at the same time. Collecting that real-world data early on will be fascinating. It's exciting to read about the gen-4 owner experiences. My expression of what's taking place right this very moment is... not yet, but soon: The transition to a next generation is interesting. Old articles like this hold attention until done threshold, then the outgoing falls off rather abruptly. You'll see posts for gen-4 dramatically increase at some point. My guess is close to the end of the year. They're simply aren't enough on the road yet to dominate discussions.

9-03-2016 **Cargo Capacity.** The discussions about Prius Prime are growing. They are shifting away from the lack of a 5th seat too. Taking a serious look at what Volt actually offered has extinguished most of that. The rest has come from giving deeper consideration to it, rather than just having gut-reaction posts. That means moving on to the more realistic concerns, like what cargo will actually be carried. I was annoyed to no end about how shallow those arguments had been. Obvious antagonists were stirred up rhetoric by posting only volume measurements. They stayed away from discussion about actual items to transport. The push for detail will often derail attempts to undermine. Anywho, now that the constructive posts are emerging, I contributed with: Figuring out the cargo capacity isn't rocket science. I simply found a 3-inch tall box and put it in the back to see if that made much of a difference with what I routinely transport. It didn't. My bags and backpack aren't that big. The bike isn't either. The cooler never fit with the cover unrolled anyway. So, height is a non-issue. True, I will find a squeeze on rare occasions, like the patio table we purchased this spring. But then again, I could have easily just rented the pickup there at the hardware store if I truly needed it. Delivery for one-time purchases like that is always an option too. The requirement is usually length. Will I still be able to transport long cargo, like new shelves. The answer is yes. Assumingly, the massive amount of yard-waste I cut from our pond's edge that needed transport to the compost last month will still fit just fine. It was an absurd sight driving a plug-in Prius into that place. One of the guy's driving a dump truck filled with old branches went out of his way to stop and yell out: "*Wow! That's dedication.*" upon seeing it. I'll be glad when I get my Prime... hopefully soon, so some of this speculation can be put to rest. It reminds me of what people speculated about way back with gen-2 Prius, when the hatchback model was introduced.

9-03-2016 **Generations & Supporters.** I was intrigued by this snippet posted today: "*...most ardent supporters have departed...*" It was buried within a train-of-thought on a discussion thread about gen-4 Prius. Most people have no clue what happened when the Classic model Prius was replaced by the Iconic model. Since that was a very long time ago, the belief is that it really didn't make any difference anyway. I disagree. Having witnessed the large group of supporters grow out of nowhere, with no previous legacy, to fade away from overwhelming support of the new generation is a really big deal. You'd think their existence would stand out. It didn't. Instead, it was drown out. Only a handful of us predicted that too. So when that entire generation of Iconic owners faced posts from the replacing upgrade, they were at a loss about what to expect. You'd think the history would give them an idea. It didn't. That makes my anticipation of the same overwhelm to occur again a topic of fascination. Can't they see it happening this time? Prius is so well known, so well accepted, and so well proven, it is now a mainstream vehicle. That state of becoming ubiquitous apparently is beyond the grasp of some. Understanding the big picture is often elusive. That's why extremely long-term project aren't managed by just front-line leaders. It really is hard to see... sometimes. In this case, I'm not sure how many will catch on. Accepting traditional vehicles as the true competition is still a popular denial issue. Hopefully, that will change over the next year. The second generation plug-in vehicles should help make it obvious that the gen-4 Prius is the new norm. Put as shortly as possible, I summed up the situation now playing out as: That is the very definition of generation: the next taking over. Only a small number of elders will remain, to help along with the transition. We will have a new audience supported by new supporters.

- 9-03-2016** **Future Hybrids.** Discussions of what will happen in the market beyond Prius liftback (regular & plug-in) are interesting. Concern is growing for the wagon model's future. There's the popularity of small SUVs to consider too. What do ordinary consumers want? How will profit pressures influence business decisions? When should we expect widespread market acceptance of clean & efficient technology over traditional choices? I posted these thoughts to that effect: I see RAV4 hybrid pushing Prius v really hard. It's easy to see how incredibly practical they are as taxis. So, that aspect of them could provide business-sustaining justification. That may mean less frequent upgrades though. As service vehicles, that's just fine. RAV4 hybrid as a mainstream contender is an entirely different story. We all knew the return of cheap gas meant high demand for small SUV offerings. Toyota has taken advantage of that by providing a hybrid model for a very competitive price. That move is paying off too. Last month's sales bump it up to just under the mainstream minimum (5,000 per month). In other words, seeing RAV4 hybrid grow to the point of becoming so popular it puts heavy pressure on other automakers to compete directly is quite realistic... which is the unfulfilled dream Ford had a decade ago with Escape hybrid. So, expecting them to re-enter the competition is almost a given. Toyota is proving market potential.
- 9-04-2016** **Too Little, Too Slowly (revisited).** I found this declaration posted yesterday ironic: *"After 5 1/2 years people are finally discovering Volt, the greatest car in history..."* Prior to the rollout of Volt, the concern was raised about GM falling into the trap of delivering a vehicle not able to reach the mainstream. That originated from the group overseeing the bankruptcy recovery, expressing the problem caused by a rollout of something unable to generate profitable high-volume sales. Well, all these years later they have been proven correct and all those who ratified the concern vindicated. Volt was a disaster... because it did indeed pursue that goal, but failed to achieve it. There will be a lot of spin & excuses, looking back. None will fix the current problem though, looking forward. The second generation has climbed to the potential of possibly reaching half of mainstream minimum. Sales that low for a vehicle facing heavy challenge from within is a problem. Asking repeatedly what GM intends with Bolt has been met with disregard initially, then turned to resentment. No one likes to answer the difficult questions. Pressure from having a limited quantity of tax-credits cannot be ignored. Toyota halted Prius PHV rollout in the United States as soon as it became apparent the market had shifted. GM did not. As a consequence, Toyota has many more tax-credits (around 155,000) still available and 35 states without any legacy sales to deal with. Volt enthusiasts mocked Toyota for that move and attacked supporters. Now, they have the reality of roughly only 95,000 tax-credits available when the rollout of Bolt begins and new marketing & education to provide for all 50 states. That division of resources and information conflicting with the past is a direct result of not having capitalized on Volt back when it had a monopoly on the plug-in hybrid market. Gas was very expensive back then too. More & Faster could have made quite a difference. What happens now that so much is stacked against Volt? See why I documented so much history as it was playing out? This situation was foreseen. Concerned was expressed. Recommendations were not taken seriously. Finally? Greatest?

9-05-2016 **EV Criticism.** The attitudes of a select few who upgraded from Prius to a plug-in vehicle is that of antagonists. If they don't see dramatic change, they exhibit a deep negativity. They don't try to be constructive. They don't care about taking small steps. They only want an announcement to play along, even if the act doesn't amount to anything. I'm growing tired of it. How does that help? They are turning into greenwashing, portraying an image of abandonment. I'm unwilling to just watch that happen, especially having witnessed this history play out already. So, today I posted this on a new thread created to discuss Toyota's take on the EV market:

The same criteria still persists. Toyota's want to deliver a product for the masses. If it cannot reach the mainstream, becoming profitable & high-volume within a product-cycle, they'll keep the technology in a research phase.

With Prius PHV, we saw that in the form of only rolling out limited quantity in select states. They held off until that affordability threshold could be achieved. Prius Prime will be that product realistic for ordinary consumers. With Mirai, we will continue to see extremely limited availability for many years to come. It simply makes no sense offering the technology to a wider audience when that business move cannot self-sustain.

There's a lot of resentment toward Toyota by a small group of individuals for not making EV announcements like the other automakers, even if those other automakers actions are nothing but token gestures. That's annoying and unproductive. You don't advance the masses by not actually changing. To make a difference, we need choices that are actually competitive with what showroom floor shoppers would otherwise purchase.

As of late 2016, there are not any EV offerings capable of competing with traditional vehicles. That's ok, if they are able to drop cost enough prior to tax-credits expiring to retain interest. Otherwise, the very same problem with hybrids will also happen with EVs. Notice how the typical consumer couldn't care less about reducing emissions and is unwilling to pay a premium to use less fuel?

Leadership means striving to deliver a product for the masses. Look no further than Volt for an example of claiming leadership, but not actually fulfilling that criteria. Cost of what was delivered was far too high to produce & sell it in large quantity. Simply delivering more miles of EV alone is not enough. That's why aspects, like spacious seating, have proven favor for Tesla and what GM hopes to capture with Bolt. That's also why Prius Prime will deliver outstanding MPG once the plug-supplied electricity is used up.

Notice how other EV offerings, like Ford Focus EV, VW e-Golf, and Hyundai Soul EV all sell in tiny numbers, yet the automaker gets praise for embracing electric vehicles? It's a reality some choose to disregard, embracing the "*me too*" approach rather than pushing for showroom floor competition. That's sad & unfortunate.

9-05-2016 **Lithium Support.** Unwilling to give the antagonists any opportunity to respond, I immediately followed up my previous post with:

I fit well into our local plug-in owners club, despite owning a plug-in with such a small battery-capacity. The reason why is simple, my endorsement and heavy support for lithium batteries. With all the promoting I do for Prius PHV online through forum & blog posts, driving videos, and my own website, it's ok for me to self-promote a little... since the reason why is helpful to others. They can see my support extends beyond just Toyota. It's the advancement of the batteries that I'm really pushing favor for.

At the meeting last month, the topic of Toyota's high-volume production of lithium batteries due to Gen4 Prius was brought up. The automaker is considered a giant no one is paying much attention to. They are quietly building up capacity, the ability to deliver affordable choices with high reliability and consumer confidence.

Think about how many of the 1.4 Million hybrids Toyota sells this year that will have shifted from NiMH to Lithium batteries. Do consumers have any idea that the battery-pack is different from that in the past? Would they even care if they did know? The point is that they are being used by new owners, the market is expanding. Toyota is penetrating the market outside enthusiasts, something all other automakers continue struggling to achieve.

We'll see more of that progress with Prius Prime. That's a plug-in vehicle configured to entice showroom floor shoppers. How many other plug-in choices specifically target those consumers? They are the who profit on-going profit for the business. Enthusiasts certainly don't fulfill that role. Automakers are unwilling to take on huge risk. Toyota found a way to reach further into the mainstream without having to do that... and get criticized as a result. Why? Think about how many lithium battery cells they will produce in the next year.

9-05-2016 Sales Struggle. Painting a rosy picture for Volt is less of a problem now. In fact, there's a degree of constructive discussion now. This caught my interest on a daily thread discussing August results: *"As someone else posted before, the 2017 Chevy Bolt EV will cut into Volt sales, since it is a full battery-electric vehicle (no range extender needed), with sufficient EV range for almost everyone, and a much larger and comfortable interior for five adults."* It was a discrete admission of change, without recognition of who had pointed out this was coming quite a number of years ago. Oh well, better late than never. I chimed in with:

Bolt is a nice step up from Volt. Many have said that, including me. No doubt it will sell better as a result. We certainly have not seen the Volt sales growth that was expected from gen-2. Focus has already been shifting to Bolt.

The big worry is not having any specific target audience identified. Remember what was among the biggest criticisms of Volt? It was the lack of promotion from GM. Clarity needs to come prior to rollout who intended buyers are. Pushing the *"200 mile"* capacity for Bolt means sacrificing the *"range anxiety"* strength of Volt. Some won't like that, but they will be in favor of the positioning that puts Bolt it for competing with Tesla Model 3.

There's the reality of tax-credits hitting phaseout quickly as a result of sales success. GM will have around 95,000 available. Retaining the trend of a little over 2,000 sales per month for Volt and achieving the 2,500 monthly rate (half mainstream minimum) for Bolt means year-end for 2017 would have consumed all but 30,000 of the full tax-credits available.

Phaseout would get triggered in the second half of 2018, if Bolt sale remains a niche. Achieving the popularity supporters are hoping for would mean sooner. That's mid-cycle, far too early for a major cost-reduction upgrade. It's also when pressure from the other automakers will become intense. Nissan & Tesla aren't going to just abandon efforts when their tax-credits expire. They have the added benefit of not rolling out as soon as Bolt too. Delay can be advantageous.

We want advancement of plug-in choices, but they must be sustainable. Challenges await. We all see them coming. This isn't a *"wait for the next generation"* situation anymore. What should happen to prevent future sales struggle?

- 9-05-2016** **Solutions, part 1.** There has been an on-going discussion about target-market for Prius Prime. Some current Prius owners are baffled by their assumption of it being for them getting disputed. Since Prius PHV was a natural progression from hybrid to plug-in hybrid, finding out that isn't the case for this second generation has stirred many posts. I find it odd how so many threads have included acknowledgement of Toyota's effort to reach out to new consumers is met with such confusion. My theory is they believe that only applies to other Toyota vehicles, that Prius itself would never attempt new focus... despite the plug. The true supporters have paid close enough attention to notice the market shift and recognize Toyota's adjustment. After all, design flexibility accounted for such a need. A good friend of mine stated the situation this way: *"I thought the Gen 4 was meant to keep Prius owners (and some upgraded from their Gen 2). I don't think the Prime is destined to mainly attract Prius owners. Current owners who want to move forward would've bought a Leaf, Volt, or if they have the means, a Model S. They want that EV experience. The Prime will probably have to be marketed to non-Prius owners who are thinking of electrification. They have to market the fact that the Prius Prime will have the Prius name to back it up. It looks less weird/out there than the Gen 4 (or past Prii) and they have to push the currently unknown factor of MSRP."*
- 9-05-2016** **Solutions, part 2.** That post was great. I was thrilled such a well thought out reply had been provided. It was nice being able to rectify his thoughts too, confirming his careful study was what others have also concluded. This was my response to that: Bingo! It never ceases to amaze me how some don't notice that bigger picture at play. The audience is completely overlooked. Toyota has stated many times how they want to expand the market by offering new choices to appeal to new audiences. Prius Prime is most definitely one of those new choices. RAV4 hybrid is another. That's why I get annoyed by arguments about Prius shoppers being turned off by the cabin & cargo arrangement for Prius Prime. It's a red herring. The purpose of appealing to those thinking of electrification should be obvious. It's not a hybrid relying solely on gas for power. Different alternatives to traditional vehicles will have different tradeoffs. Direct comparisons simply don't make sense. The industry mindset has been conquest & cannibalize. That actually works for initial rollouts, especially when large subsidies are available. When you want to phase out older products, that is a terrible approach. You have to find a way to entice those who have yet to show any interest, not to get those who already have to upgrade. It's what economics is all about. You have to look beyond engineering & accounting. Marketing to non-Prius owners presents new challenges... which means old solutions won't work.

- 9-06-2016** **Wasteful.** The state of California is considering a new set of incentives for the purchase of a plug-in vehicle. They want to encourage continued growth of the clean & efficient choices, but simply don't have any more HOV stickers available. That option is totally exhausted. Not everyone has to deal with the heavy commute traffic anyway. Unfortunately, we still get replies like this from Volt enthusiasts: "*The rebate should be based on the battery size.*" That obsession with bigger always being better is a challenge to deal with. I want to expand discussions beyond the usual rhetoric. That means countering the posts, but presenting new perspective. After all, I know they'll try to fallback on EPA rating. The AER (All Electric Range) focus got them nowhere. Understanding MPGe is still an issue. Fortunately, that opens opportunity to look at other aspects of being clean & efficient. The biggest is winter heating for the cabin, something they outright dismissed for years. It is now finally getting some attention. Perhaps this will help that along: Why not base upon efficiency results instead? There are measurements available to gauge use of electricity. For example, a plug-in vehicle with a resistance-heater will be nowhere near as efficient in cold-weather driving than one with a gas-injected heat-pump. In other words, the less efficient will require a larger battery to deliver the same outcome. Using more electricity in that manner should not be encouraged. We don't want to provide larger subsidies for wasteful plug-in designs.
- 9-07-2016** **Electronics 101.** Sadly, the rhetoric immediate ensued. I was annoyed. I knew MPGe would be brought up, even though I had intentionally excluded it. Unfortunately, the reason why was totally elusive. The enthusiasts just plain don't take the time to figure things out. That's why they are enthusiasts, rather than supporters. A true supporter will take the time to ask questions and consider outcomes. An enthusiasts just parrots talking points. Anywho, I decided to keep my response simply, by conveying some basic education on the topic: KWH >> BTU. Some heaters require more electricity to deliver the same amount of heat. That's why Volt was upgraded from a resistance type heater to a heat-pump. That's also why Prius Prime will use an even more efficient heater, a heat-pump with gas-injection. Electricity can be wasted. Not all designs are the same. The level of efficiency is not measured by just distance traveled.
- 9-08-2016** **No Heat Pump.** Turns out, the second-generation Volt didn't actually get the upgrade. Older designs had the shortcoming of losing effectiveness in the extreme cold. That meant if you were driving in temperatures well below freezing, you'd get warm air in the cabin rather than hot. The traditional resistance-heaters overcome that, but the tradeoff is much higher electricity use. They give Toyota a very hard time for side-investing in fuel-cell advancement... never paying attention to the reality that those vehicles employ new technology that the hybrids will be able to take advantage of... like the advanced heat-pump Prius Prime will be getting. Not only is it capable of delivering heat in much colder conditions, it also includes vapor-injection. That's a feature used in commercial heating for increasing efficiency. Prius Prime will be the first ever mainstream vehicle to use that too. When technology reaches personal use, you know good things are to come. Well, you do anyway. Those enthusiasts are still clueless. They're the same one obsessed with battery-size. It clouds their judgment, preventing them from seeing what advancements are needed for acceptance by the masses... like the move beyond resistance heating. Ugh.

- 9-09-2016** **Constructive Discussion.** It's finally happening. I responded to this: "*Electric range is the primary reason why anyone would buy a plug-in hybrid in the first place.*" The post immediately disappeared. I wonder if something technically had went amiss. So, I posted it again, from a different computer. Same thing happened again. Since I couldn't get any feedback, I waited. Sure enough, the moderator had taken the advice. It was his topic detail I was making comments about. Those references had been revised. That was great. He was making a sincere effort to keep things constructive. I was thrilled to see discussions being aimed away from the rhetoric we've had to deal with in the past. Here's what I posted twice, both of which were hidden shortly afterward: The plug-in owners group here is working hard to make sure data is up-to-date and complete, so statements like that can be as constructive as possible... Ford's EV range is listed at 19 miles. That's old. It is now 22 miles. BMW's i3 tank capacity is listed as 1.9 gallons. That's old. It is now 2.4 gallons. BMW's i3 range for EV is missing entirely. The newest model offers 112 miles. Remember, the ultimate goal is to replace traditional vehicles with plug-in choices. That means being thorough, especially when encouraging competition from within the plug-in market. It shows consumers how far along the market for vehicles carrying battery-packs has progressed.
- 9-10-2016** **Coffee At Sunset, video.** Here's another documenting experiences with my Prius PHV: Same coffee shop, different starting location. I moved and now live closer. My drive there is within the EV capacity available from the battery-pack. Capturing that on video could not be resisted. I waited until a nice summer evening arrived, then headed out just as the sun was reaching the horizon. It was an 8.9 mile drive. The bulk of that is along a 55 mph road with rolling hills. Upon completion of the round trip, an estimated 2.7 miles of EV remained. That comes in handy if you need to slip out to relax, for some coffee & blogging. Since grocery, retail, hardware, restaurant, and movies are all within that same distance, taking advantage of plug-supplied electricity has been very easy with my Prius PHV. [Prius PHV - Coffee At Sunset](#)

9-11-2016 **Not Constructive.** I waited until the following day to respond to this: "*Now letting PHEVs with puny electric range (especially the original PiP...what a joke that was allowed the green stickers) receive HOV decals is something that should change. Make some minimum AER requirement (30 or 50 miles). The PiP couldn't even go the speed limit in EV mode for crying out loud! What a joke!*" It came from a well known antagonist. Rather than focus on strengths of Volt, he demean Prius PHV instead. Having to deal with the brainless banter is annoying, but nothing new... especially at this point. I carefully considered my response, choosing to make it personal rather than just post detail: The goal is reduced emissions & consumption. A larger battery-pack doesn't necessarily accomplish that. HOV lanes exist to relieve congestion in areas that commute traffic causes. Notice the locations? They are where major interchanges meet and when crosses over bridges. HOV advantage is only effective when traffic is traveling much slower than the speed limit. In other words, claiming a requirement of faster than 62 MPH is an easy to disprove red herring. As for the electric range, that heavy commute traffic where the HOV advantage exists is covered. More doesn't accomplish anything, since it's just open highway otherwise... which PiP delivers unmatched hybrid efficiency. What's most telling though is the look backward at a bill not yet passed. That makes no sense. PiP isn't available for purchase anymore. So, the entire argument is clearly not constructive. We want to promote plug-in vehicle purchases. That means being forthcoming about the market. Notice how the rear seating for Volt was described in the video? That was direct & honest. Here's what you get. Some people will like it, some won't. The point is knowing detail upfront to make proper decisions. In that light, Prius Prime will be available later this year. It will offer double the battery-capacity and to-the-floor EV drive. So, no one is laughing at your joke. We're all in this together. Don't misrepresent the situations or choices. You'll continue to get called out when that happens.

9-12-2016 **Summer Commute Work, video.** I was able to deliver another video. This was actually the first of those with the new camera from the new location. Editing in order wasn't necessary. I'm trying to capture as much as I can, now that I have the personal time available. That means lots of testing to verify all is working as expected. Lucky for me, the equipment performed well. The Prius itself did too. Here's what I posted, along with the link to see it: This is my commute to work. Since it's summer, driving in EV through the suburbs to the highway (9 miles) is pretty easy, even with rolling hills. Just prior to getting onto the 70 MPH highway, I switch over to HV mode. That saves some of the plug-supplied electricity for later. I switch back to EV mode as the decent into the river valley approaches. The rest of the drive is pretty much all with just electricity from there. The entire drive is 18.5 miles. A total of 14 miles were registered as EV for this particular trip. It varies based on traffic, temperature, stoplights, etc. Depleting the battery-pack to the recharge point resulted in a 244 MPG average. I plug in at work, where chargers powered by solar are available. So, the commute home is equally rewarding. [Prius PHV - Summer Commute Work](#)

9-12-2016 **Turning Point.** How do you know when the enthusiasts have changed their stance? Quotes like this make it obvious: "*Also, many don't qualify for the tax credit.*" Volt had been aggressively promoted as \$7,500 less for everyone. Any mention of not having enough liability from your taxes paid to get the full amount were replied to with hostility. All we got for the entire first generation was greenwash promotion that Volt's price was that of Prius. It was maddening. I have so many blog references to that nonsense, describing the situation as a source of extreme frustration can't do it justice. I eventually turned that emotion to a feeling of annoyance. It became fairly easy to confirm those postings that had no concern for anything beyond an immediate purchase, especially when they were loaded with Prius insults. The goal of mainstream penetration to achieve sustainable high-volume sales that could deliver a profit was beyond their grasp. Pride prevented it. Turns out, if you wait long enough, that sense of pride will dwindle. They eventually feel they've said their piece, then back down. That's way provocation isn't counter-productive. Not only does it reveal clues at times, it also wears them down. In the meantime, I was able to continuously push the fact that traditional vehicles were the true competition, not other plug-in vehicles. Well, all that, combined with flat sales, low gas prices, and the reality of tax-credit expiration pushed them to change. Naturally, it's in the form of downplay. Nonetheless, that is recognition. One less greenwashing effort to deal with, a very big one too. We've hit that turning point. Yeah!

9-13-2016 **Size Matters.** This is what I saw coming, years ago. GM revealed the EPA rating for Bolt today. It's 238 miles. That's more than the 215 miles expected from Tesla's Model 3. Bragging rights are what enthusiasts have thrived on. They push all else aside for them... which means Volt is now in a very awkward position. The concern of tax-credit usage has revealed cause for true worry. Everyone is focusing on Bolt now. That affordable Chevy EV has caught the attention of plug-in followers. It will be intriguing to see how the industry responds, especially with Bolt being so much less sport like than Model 3... definitely no "cool" factor. Will practical really be a winner with this crowd? What about the masses? How will they view this newest offering? Prius Prime was designed with those considerations already. Toyota has strived to find that "just right" size for the battery, as well as include some cool features. Remember how well that worked for the regular Prius? The fact that you couldn't squeeze out long electric-only drives didn't matter. The available capacity got you through the span of heavy traffic. That's what mattered. You got some creature comforts too. Now, this one with a plug will extend upon that approach. It won't strive to deliver an all-electric experience 99% of the time, a goal Volt enthusiasts have proclaimed vital... which now doesn't make sense with Bolt available. To make matters worse, they routinely quoted you'd have to drive over 150 miles for any advantage of the gas engine in Prius to matter... which definitely puts Volt in a difficult position. They set that precedent, not me. 238 miles is much further than that. Ironically, the situation has been described as a "*game changer*". Turns out, size matters. The catch is, bigger is not necessarily better. Finding the balance to achieve mass acceptance is a major challenge, not one to be taken lightly... as history has confirmed.

9-13-2016 **Now What?** This is what the thread asked: "*What Range is Enough to Allow EV Mass Acceptance?*" This is what I had to say: Today's announcement marked the end of "*range anxiety*". It's gone. Concern of getting stranded by a dead battery have become a challenge of the past, just a memory now. It has been overcome and leaves us without any doubt of how the market will advance. Portraying the EV as a choice for everyday use has become much easier. Leadership isn't measured by progress forward alone though. With the acceptable range threshold achieved, much more emphasis will be placed on cost reduction. That pressure will grow much more intense. It will force change. That leaves Volt in an awkward position. With range substantially smaller, what will become its selling point? Keeping a performance & handling focus on Bolt to stage it as a Model 3 competitor leaves Volt with what? How will it attract buyers? It has a noticeably smaller seating area in the rear compared to Bolt. It has a look to make it fit in with other mainstream cars too. Seriously, what does this mean for Volt, especially with gen-2 still being so new? I'd sincerely like to know, so my promotion of plug-in vehicles matches expectations of supporters. How will it fit in with other offerings from other automakers? Will it be redefined as direct competition to Prius Prime? If so, that means having to attract mainstream consumers rather than the niche Volt has enjoyed. Keep in mind that the radical look of the regular Prius is catching on. Remember how the previous generation really stood out at first, then became the gold-standard for hybrids. What's not to say the same doesn't happen again? Prime offers some edge too, with it's own distinct look. It will also deliver outstanding MPG after battery depletion and is rumored to be aggressively priced. That's why I'd like to know from those who had been quite dedicated to Volt what they believe GM's next steps should be for it. Remember, some of us see the competition as traditional vehicles, not other plug-in vehicles. Your thoughts?

9-14-2016 **One Day Later.** I don't expect the enthusiasts to like this observation: Looking around at online comments from various websites, it's as if Volt no longer exists. Clearly, people have moved on. Longer distances EV has dominates interest. Seeing GM leave Volt as a niche should be just fine. After all, there is definitely a place for that in their product-line. Not everyone wants to drive a Malibu. As for those Malibu buyers, I suspect the next step for GM will be offering the Malibu hybrid with a plug.

9-15-2016 **Caught Greenwashing.** Since the very beginning, I've been looking for allies. It doesn't always work out. Today's example was among the top... Absolutely desperate at this point, the only antagonist still struggle to save some pride lashed out. It was pretty sad. That's a good sign. Finally ending this chapter is long overdue. His final act was to declare GM the leader, selling more plug-in vehicles than anyone else. Ugh. I was really surprised to see that. Not only was it that not true, it was also a very easy claim to disprove. So, I did a few searches, then posted my results: The bar was set by Toyota for hybrid efficiency and Tesla for EV range. For GM to set a bar for sales, those sales must actually happen. Claiming #1 in sales would require ignoring overseas activity, like Nissan in Japan and outside brands like Renault in Europe. Bolt certainly has the potential. Kudos to GM for that. Counts of them on the road will determine status. The way actual sales are avoided and limiting scope to just the United States is quite telling. Renault-Nissan alliance EV sales (Leaf & Zoe combined) worldwide surpassed 350,000 total. In March 2016, worldwide sales of the Mitsubishi Outlander PHEV hit the 100,000 mark. In other words, GM is a strong player. Stop pushing the #1 claims. That simply isn't true and all that does is put down those who want to work as a team to overcome the popularity of traditional vehicles.

9-15-2016 **What Goals?** Totally clueless and not even bothering to actually read what I post, this was added to the flurry of desperate messages: *"To continue to improve in all aspects, reduce costs, expand the market/technology, and educate the customer base."* That's what I got when asking for a goal. Ugh. This is all I could manage for a reply, shocked anyone could be so clueless: That is a mission statement, not a goal. A goal is a measurable objective, something with a clear quantitative value or milestone to achieve. That couldn't be any more vague. Remember the price, power, range, and count values of the past? Abandoning them is a dead giveaway of trouble. No wonder the *"troll"* alarm was sounded. Geez! Looking at the threads, the reason for moving the goalposts becomes obvious. Volt is supposed to be superior, in your mind. Prius Prime has the potential to deliver all 4 of those specific goals... \$30,000 price, to-the-floor acceleration, enough EV to cover most commutes, and sales of at least 5,000 per month. It's too bad you weren't looking for an ally.

- 9-15-2016** **Final Act.** When there's nothing left and shooting the messenger doesn't do any good, you lash out at the perceived enemy: *"What has Toyota been doing for all this time? That's why everyone has been saying too little too late."* At that point, it was obvious nothing constructive could be conveyed anymore. When pride gets in the way, there's no reasoning. All is lost. So, I summed it up the best I could, then pounded that final nail into the coffin. Chapter closed, as concluded with: Who? Even the GM enthusiasts were expecting more from Volt at this point. That's why so much attention has shifted over to Bolt instead. As for Toyota, they've switched their premiere hybrid over to using lithium batteries this year. Their 10,000,000th hybrid will be sold later this year. Also this year, they introduced a compact SUV hybrid, a Crossover hybrid, and will be rolling out a new plug-in hybrid... which will use the industry's first vapor-injected heat-pump. In addition, they will be introducing a dual-wave windshield to improve aerodynamics and carbon-fiber to reduce weight. Most importantly, they've been aggressively working to reduce cost to a level capable of drawing interest from their own loyal traditional vehicle buyers. As this thread points out, the threshold of acceptance has been reached. Priorities are now focused on delivering an affordable product well balanced for mass-appeal. The measure of success is based upon sales... not the most miles... not the most seats... not even the most posts. The new chapter is only just beginning.
- 9-15-2016** **Too Late, part 1.** I read a post from the only other troublemaker remaining. By the time I had posted a reply, he had already retracted the following statement: *"Toyota is milking HSD. They've found themselves in a very curious position where - like the silicon chip in personal electronics, there will be a point where returns on investment of time and research become smaller and smaller. We already see the limitations of HSD compared to the Volt, which is still making very large gains in electric range and MPG on the gas range extender. No Prius has a range extender. Every Prius uses the gas engine as primary propulsion - plug or no plug."* Too late. I had already included it in my submission. So, I'm keeping a copy of it here as well as the one within my post online. I found it ironic how he was pointing out diminishing returns now, as if it was entirely new. I've been posting about them in response to him for years. Anyhow, his spin was to make it seem like Toyota isn't about to deliver a capable technology. It's the same old downplay, avoiding actual quantities... just like our favorite antagonist. I got a kick out of that. No one is willing to consider detail. They know Prius Prime is quite capable of delivering impressive EV performance. They'll see impressive numbers soon enough, ones so good they won't be able to escape from them. Those with short commutes or long ones who have the opportunity to recharge at work (like I do) will be quite happy to share their real-world data. It's too late in many respects.

- 9-15-2016** **Too Late, part 2.** This is what I ended up posting in response: Toyota is now producing a massive number of lithium battery cells. All models of Prius but the base have transitioned to them. The propulsion system offers to-the-floor EV acceleration, complete with electric heating & cooling. So what if the capacity of the battery is currently too small for your liking. It's still uses all the components needed for electric-only travel. Pretending that isn't the case by not calling it a "*range extender*" doesn't change anything. Think about the production costs dropping due to that high-volume. So what if it is spread out among the masses? It's still genuine change. What are the claimed limitations of the technology? This is turning into truly desperate spin. Claims of failure don't have merit. Consider this; have a fully charged Prius Prime and Volt drive 22 miles. What differences would there be other than one having a depleted battery-pack and the other with 31 miles remaining? The answer is simple, none. Both delivering a full EV experience means what? The entire drive would be powered by plug-supplied electricity. That certainly doesn't validate the "*milking it*" claim.
- 9-16-2016** **Too Late, part 3.** This is what I saw upon waking up the next day: "*Hybrids are part of the 'too little too late'.* Like I said, they need to get serious about plug-ins." The discussion had degenerated down to just mindless rhetoric. It provided a nice opportunity to remind him what the goals are: That doesn't actually tell us anything. In fact, that's as vague as a person could possibly get. Evading discussion of detail provides confirmation that there's no substance to the claim... \$30,000 price, to-the-floor EV acceleration, enough EV to cover most commutes, and sales of at least 5,000 per month.
- 9-16-2016** **Too Late, part 4.** Denial. Rage. Dishonest. Ridicule. Demanding. Contradiction. Insulting. Hate. Exaggeration. Dismissal. Spin. It was all there. I was amazed to see such an extreme post. Since he obviously didn't care at that point (the same wounded & frighten animal behavior witnessed in the past), it didn't matter what I said. Fortunately, pretty much everyone else has moved on. Realistically, he probably has too and this only served as a sense of closure. To that end, I posted: That quite possibly could be the best rant posted since C-Max Energi was rolled out. Back then, it was also a Volt enthusiast who went off the deep end. That pattern is easily recognized. Same result too. Things fell apart and the outcome was far from what had been hoped for. The door of that chapter was slammed hard. Everyone quietly dispersed afterward. The next chapter begins.

9-17-2016 **Too Late, part 5.** My conclusion will hopefully bring about an end to the rhetoric. What a waste having to deal with such nonsense. It should be a matter of addressing issues, then moving on. Some have a much harder time dealing with change though... as this exchange has clearly points out:

That claim of "too late" does serve as confirmation of closing a chapter.

The problem is your disturbing take on what should happen next: "*Quantity will be determined by market demand, as it should be.*" That formula doesn't work. Volt overwhelming proved the masses won't change simply if you deliver a well performing vehicle. No matter how much praise enthusiasts gave Volt about performance traits, the reality of compact seating and disinterest for saving gas kept sales down.

9.9 million GM vehicles sold last year should have been the wake-up call. The other was virtually non-existent posts on the big GM forum. Volt had already been ratified as a specialty vehicle, much like GM's others. The choices for gen-2 configuration resulted in them moving on. Bolt would become the plug-in vehicle to hold the spotlight. Online posts about the announcement this week solidified that. The rant confirmed it.

Turning outrage on Toyota doesn't accomplish anything. California, Oregon, Washington, Arizona, Maine, Massachusetts, Vermont, New Hampshire, Rhode Island, Connecticut, New York, New Jersey, Maryland, Virginia, and Hawaii were the only states Prius PHV was offered in. That meant the generous incentives from Georgia, Oregon, and Colorado were never taken advantage of. Yet, despite limited availability, there were still 42,341 sales. They served to prove the technology and highlight what improvements to include in the next generation.

The topic of demand obviously stings. Downplay from your quote and the proceeding rant attest to that. It's over. Chapter closed. Focusing attention on Toyota is an obvious attempt to distract. That red herring is dead. Bolt's ability to deliver 238 miles of EV ended Volt's quest for mainstream acceptance. Market demand wasn't there. As many have pointed out, a plug-in hybrid model of Equinox holds great potential. 4,919 sales of RAV4 hybrid last month validates interest. Imagine what adding a plug could achieve. My guess is you already have, hence the lashing out at Toyota.

That claim of "*too late*" doesn't become a non-issue upon delivery of the first vehicle either... as gen-2 Volt has shown. Sales must grow. Since Toyota already had Prius Prime developed, so they figurative plug for Prius PHV was pulled... saving the growth for later. Way bother rolling it out to the remaining 35 states knowing a much improvement version as on the way, especially with consumer education required. GM has throttled back on Volt for similar reasons. Bolt is much improved. Not only will it eliminate "*range anxiety*" concerns, it also provides a more roomy interior.

Both automakers are starting fresh the end of this year. Too bad if you don't like them sharing the same business mission of significantly reducing emissions & consumption but taking entirely different approaches. Intermediate goals will differ greatly, but both face the inevitable reality of tax-credit expiration. Sharing the need to deal with traditional vehicle demands makes the plug-in market a common interest.

In other words, I couldn't care less if you don't want to cooperate. Rant all you want. There are enough of us trying to make a spirit of uniting together for the same cause convey throughout the minds of mainstream consumers. Volt wasn't the vehicle to do that. Whatever. Let it go. Move on to Bolt with the other GM supporters. Geez!

Do you really think it's all about Toyota anyway? What about the push soon coming from Hyundai? What about the long-awaited debut of Mitsubishi? What about the intent Ford has stated? Think about what Nissan is planning. And of course, there's Tesla.

9-17-2016 Video for New Shopper. Someone who joined the big Prius forum just 3 months ago with interest in Prius Prime posted a new thread, asking for reasons why it may be a better choice than Volt. I was intrigued to see where this new discussion opportunity would take us. So, I jumped in with: It depends upon what your priorities are. If you don't need more EV range, why bother with a car offering a larger battery-pack, especially if the tradeoff is less headroom for rear seating? Prius Prime will deliver much better MPG after depletion too. There's also the electricity consumption to take into consideration. Your location in the Midwest would mean a greater benefit from the vapor-injected heat-pump Prius Prime will include, rather than the less efficient resistance type heater. Having 82,000 miles on my Prius PHV, which has been averaging 72 MPG over the past 4.5 years, the decision to upgrade to a Prius Prime right away is a no-brainer. I can recharge at work using solar electricity, which will bump my 19-mile commute average from around 110 MPG to possibly 999 MPG. Since I take long trips routinely, the improved efficiency of the gas-engine will be a nice benefit too. I'm also looking forward to the variety of goodies Prius Prime will offer that have nothing to do with being clean & efficient. The LED lighting will be sweet, the color head-up-display and new screens will be fantastic, and the dual-wave rear window will be the boom. Carrying my kayaks on top will be interesting, where high-tech and the outdoors collide. For some perspective, here's a video of a commute to work I filmed last month: [Prius PHV - Summer Commute Home](#)

9-17-2016 The new "Who?" Question. I asked it this way: For some perspective on market diversity, note the recent reveal of the next-gen Outlander PHEV. It is said to deliver a 120 km range for EV. That's 74.5 miles and will offer a larger interior. That helps emphasize the "*too late*" situation. If something is tried and doesn't work, try something else. GM is. Toyota will be. Heck, even Nissan is planning to. Seeing the success of gen-1 Outlander in Europe should be a clue as to the success of gen-2 here. Who do you think the competition is?

- 9-18-2016 *The Push.*** Pointing out to someone that they have backed themselves into a corner rarely goes well. They tend to get hysterical, lashing out at anything they can... but trying the best to make what they say seem rational. This was the point at which things finally broke down: "*Volt Gen2 has the 5th seat.*" You know it's falling apart for that person when they begin to outright lie. He knew there was no way to win that argument, yet tried anyway. It's so easy to prove Volt doesn't. That spot in the middle has a seat-belt, but there isn't a place for legs. How is that a seat? Do anyone really expect an adult to share their leg area with another? It's only a compact in the first place. That makes it even smaller. Ugh. Providing proof or not really doesn't matter. It's simple to see that the claim was counter-productive. Accepting the "5th" would result in a mark against Bolt, which I was happy to point out: Eventually, you'll figure out why I've pushed for you to look at GM's own product-line. Currently, the obsession with being better than Toyota is blinding you from seeing it. For example, your quote above does a huge disservice to Bolt. The rear seating in Volt is compact. You have to duck down and lean forward to see out of the window. That isn't the case with Bolt. Your head touches the ceiling. That isn't case with Bolt. You have to squish your legs into the same area as the two other passengers in back to squeeze into the 5th seat. That isn't the case for Bolt. Who cares whether or not Prius Prime has that. You are harming Bolt by portraying Volt as if it is the same. Bolt supporters will not be pleased.
- 9-19-2016 *Summer Commute Home, video.*** Here's the description I posted of that newest video: This is my commute home, the return drive from the "*Summer Commute Work*" video. Same route, different traffic. The resulting MPG from that direction & time is lower, but 142 MPG certainly isn't anything to complain about. This particular summer drive was rather ordinary. The temperature was comfortable, due to all the clouds, and the number of vehicles was typical. I like the drive through the suburbs. The up & down through all the hills uses up more electricity than just flat roads would, but the hybrid system handles that just fine. You can see climbing them in EV is no big deal. There's plenty of power for that. As for the filming itself, the new camera for the dashboard information works great. There's no refresh flicker anymore and the vibration becomes a soft sway from the camera's stabilization.
- 9-19-2016 *No Worries.*** The craziness isn't over. This transition was never expected to be easy anyway. So much attention has been placed on plugging in. That's especially hard on regular hybrids when gas is so cheap. Discussions like this provide a welcoming refresh. No surprise, a new owner was unknowingly fighting the system, attempting to squeeze out the most possible EV driving. I posted: First, it's important to keep the "*JUST DRIVE IT*" motto mind whenever you are behind the wheel. Literally thousands of new Prius owners make the very same assumption, that more EV is better. It's not, hence the motto. They try to squeeze out as much as possible, not realizing the penalty that comes later from having to replenish the consumed electricity. That can actually result in lower overall MPG. That's not the outcome they hope for, but at least no damage comes from it. The system is simply compensating from you fighting the hybrid system. Instead, just drive it. If something was truly wrong, you'd find out after a tank or two of gas. For example, the engine never shuts off, even when stopped waiting for a light to turn green. Poor MPG would indicate that. Simply not seeing much EV means the electricity being generated is used for HV instead. Great MPG would indicate that. Enjoy your new Prius. No worries.

- 9-20-2016** **Making Stuff Up.** The eruption online was intense. That pointing out of harm being done to Bolt by defending Volt didn't go over well. It exposed his desperation. His loyalties were to Volt only, not GM. That's why all arguments against Toyota were always focused on Prius, even though their other hybrids were routinely mentioned. That's a sin you're dealing with a pride issue, rather than something actually constructive. He wasn't interested in the well being of the automaker or the industry. It was all about saving face. That's sad. Needless to say, he was just making stuff up at this point... which was a surprise, since the usual tactic was to misquote. He simply didn't care anymore. It became a survival struggle, for him anyway. I've been through this cycle several times now. Remaining true to the goal of delivering something affordable & dependable for the masses is what gets you through all the rhetoric. If it's not truly green, that weakness will eventually be revealed too. Patience is key. But sometimes, it is acceptable to throw a punch of your own: Now you're making stuff up too. It all goes to confirm the previous chapter has ended. The very idea of not being "*light-years ahead*", or as it had been stated in the past "*vastly superior*", is repugnant. Well, suck it up. Volt got outclassed by Bolt. GM's own offering brought about the change.
- 9-20-2016** **Happening Regardless.** There's a lot of anger & upset. It's inevitable the outcome won't be accepted by someone. How they handle it varies. I foresee an aftermath. With the chapter closed, there is nothing else to dwell on. We look back at the damage caused from all those battles. Whether or not acceptance of the war ending is acknowledged, the victory from EVs overcoming "*range anxiety*" is obvious. There's no denying that. Resentment will emerge. Letting those dealing with losses have their opportunity to vent can be quite effective. Of course, that entitles others to provide their own retrospective. I will too, though that isn't necessary. Having on-going blogs documents what happened as it happened... which avoids distortion from looking back. Feelings at the time were preserved. Anywho, I followed up with: The attempt to portray as "*anti-Volt*" simply doesn't work. Look back at the countless posts endorsing a "*lite*" version of Volt and the push to get Voltec spread to other vehicles, especially Equinox. In other words, I don't have any trouble with the technology. It's the configuration... and we know how die-hard Volt enthusiasts hated the idea of losing purity. (They also fiercely opposed EV offerings from GM.) That diversification was fought against intensely. That's sad. Fortunately, it's happening regardless of the opposition. We have Bolt, an EV. We have Malibu, a hybrid system with higher efficiency. And we'll see the CT6 plug-in, a variant of Voltec.
- 9-21-2016** **Repeating History.** Marking the end is near. Nothing else can be said... all rebut opportunities exhausted... all excuses exploited to their fullest... all hope faded away into nothingness. It's over. We see the cycle beginning again. This is a new chapter. Unfortunately, it's already looking like a repeat. The same history playing out is usually a bad sign, given the previous ended so fruitlessly. Early signs point at that same outcome. Remember the "*over promise, under deliver*" problem? Rather than rehash that, the choice was to state it as "*too little, too slowly*" instead. It made no difference. I noted the big-picture observation as: This is exactly what we saw when Two-Mode went out in favor of Volt. The antagonist would cry troll, followed by a flurry of childish spin. Being an adult would be to recognize the pattern and admit the leap-frog with Volt never happened. Sales remained flat, not achieving the hoped for minimum to reach mainstream buyers. Bolt will be taking on that role now.

- 9-21-2016** **Final.** He gave up with his own identity. Switching over to the one that is used only for attacks didn't do any good either. Though, I find it intriguing to see that happen, since everyone notices it. Tracking discussions is much easier. That's a benefit for both of us. Looking up posts later, knowing the most intense was used with the other, is easier. Realistically, that doesn't matter. It's just like when other chapters ended. We all knew it was final. The most significant was the Two-Mode fallout. Volt simply took its place. The same situation seems to be playing out with Bolt. That pattern matches well. All we need now is word from GM stating some type of status. As for the enthusiasts, we already got that.. as I noted: That's final confirmation. When the spin here is spun so much, the past is denied. In other words, the diversification now happening is claimed to be the plan all along... when the posts & blogs clearly confirm that wasn't what actually happened. Of course, admitting that means agreeing with those who had been saying that all along... which we know won't ever occur... hence the spin to attempt to obscure that. Whatever. Like I said, it's happening regardless. btw, this website was highly opposed to EVs until recently. So, labeling me as a troll is rather pointless, since so many others have switched over. Notice the dramatic change in daily topics?
- 9-22-2016** **Packages & Colors.** What a fitting way say to actually mark the end. With perfect timing, the spotlight just naturally shifted over to Prius Prime. We got package details today. There will be a "*Plus*", a "*Premium*", and an "*Advanced*" model. I'll be getting Advanced, which is the top offering. It's very exciting to finally get such information. That means delivery isn't too far off. Of course, I can't order one yet. But at least we know what production plans are. That includes colors too. The one that has me captivated is Blue Magnetism. It's a deeper blue than I have now with a shade of green and a metallic luster. It's a color exclusive to Prius Prime too. We'll find out pricing in a week and a half. Then, I bet specifics about ordering will emerge. The wait is interesting. We have a major election happening on roughly the same schedule. Though, the outcome certainty from Toyota is far more predictable. Anywho, I'm quite excited and the feeling is certainly not exclusive. There are quite a number of others sharing the same anticipation. We're getting closer.
- 9-23-2016** **Dealer Visit.** I stopped to visit and share information. Those package & color details was far more than they had. Though, I did find out what the number was for the package I want. Two orders were in the system for that region, but who they'd go to was uncertain. No big deal. I can wait to submit my own later. It would be nice to repeat the process like in the past... place an order online myself, then get confirmation from the dealer I chose. That makes it easier for everyone involved. It's exciting to reach this milestone. Patience is no big deal. I learned that ages ago. That's essential when dealing with Prius. The wait has been well worth it every time too. Actually be able to get in line officially ups the ante. Progress from the reveal to waiting for delivery is a step I've anticipated for a very long time. Oddly, I still remember the wait for my first Prius. The memory is quite vivid, despite it being over 16 years now. Making new ones is exhilarating. I can't imagine forgetting this stage. Portions are known. Other bits are not yet. It's a big puzzle with parts all suddenly fitting together. Yeah!

- 9-23-2016 Capacity & Range.** Constructive questions are getting asked now... on the big Prius forum, anyway. This particular one caught my interest today: *"What's the usable battery of the current pip? I thought it was 3.3 kWh. Anyone know if the primes usable battery is just double or is it more. Does it make sense to put a % of the battery in reserve or only a set amount? I think Chevy is one to change it up a bit from Gen 1 to 2..."* I was happy to contribute some detail to stimulate more discussion: Knowing how Toyota routinely understates, it makes sense that we'll actually get more EV miles than what's officially stated. The math seems to suggest that too. Volt gen-1 (11.2 kWh of 17.1) = 65%; Volt gen-2 (14.0 kWh of 18.4) = 76%; Prius PHV (85% SOC - 23.5%) = 61.5% EV; Prius PHV (85% SOC - 18.0%) = 67.0% EV+HV. We can see there's opportunity to use more energy from the battery, that a longevity-buffer so large probably isn't necessary. In other words, the doubling of the original 11 miles to 22 because total capacity grew from 4.4 kWh to 8.8 is likely on the low side, especially since we know the efficiency of the system itself has improved.
- 9-24-2016 Aftermath, hostility.** There was a lot of hostility. Rather than seek a partnership, they touted a *"vastly superior"* attitude.. which sadly, prevented any type of cooperation. I worried about that right from the start. Back then, it was referred to as the *"trophy mentality"*. Being awarded recognition for engineering achievement was all that mattered to those Volt enthusiasts, even if it didn't contribute to the end goal. That praise was more important than actually making a difference. I was annoyed... until Ford's rollout. They delivered a plug-in hybrid that fit the new definition for Volt. The original definition is what the EPA still uses for EREV; it is a SERIES type hybrid. C-Max Energi fit the same criteria enthusiasts had spelled out for Volt. They weren't seeking an ally. So anyone endorsing that, like myself, ended up having to deal with hostile posts. You'd get labeled as a "troll" for saying anything that didn't cast a light of supremacy. Looking back, it's hard to believe the 4 years that followed were nothing but a stream antagonistic posts. Fortunately, the supporters of Volt did all they could to keep a distance from those enthusiasts. Unfortunately, that meant no help stopping them from greenwash efforts... like the *"6 mile"* misleading... which ended up becoming the spread of outright lies. Ugh.
- 9-24-2016 Aftermath, upgrades.** My resentment for the double-standard coming from Volt enthusiasts seemed endless. Fortunately, I knew what they claimed impossible would come to be. The spin was that Prius was a dead-end, a waste of time not worth any type of investment. The portrayal was that of hopelessness. It was a dangerous precedent to set. So much so, I became quite surprised that it persisted all the way until Bolt's distance reveal... which was just 2 weeks ago. They kept holding on to the hope that Volt's larger battery-capacity alone would make it a popular seller, since Toyota was about to deliver several upgrades. The to-the-floor acceleration was the most profound loss. Prius wasn't supposed to be able to deliver that much EV power. Prius Prime is about to prove them wrong, very wrong. The ultimate Achilles heal for Volt was heater drain. In Winter driving, that use of electricity for warming rather than propulsion was painful. Range reduction was a major problem... and Prius Prime will be delivering a more efficient solution, making size of the battery less important. But what drove the final nail in the coffin was from GM itself with Bolt. The jump from 53 to 238 is massive. That's so big, the entire purpose for Volt falls apart. The problem of *"range anxiety"* now has a better solution. Oops!

- 9-24-2016** **Aftermath, promotion.** The resistance from me against Volt comes from promoting it as a mainstream vehicle. Sales are flat and limited to those well outside the norm for what anyone would call an ordinary car buyer. It's a specialty vehicle... which is fine. Why not offer something that appeals to those seeking more than just a reliable transport which is affordable & practical? After all, even Toyota is doing that by offering a divergent model of Prius. Notice how Prime pushes those limits? Think about it. I see the potential in the technology. I simply don't like the choice of a compact car with heavy emphasis on range & power. That was never a good idea. But cars like Camry and Corolla are labeled as boring. So, trying to draw attention to Malibu and Cruze as viable platforms to electrify is basically futile. Enthusiasts will fight that, as the blogs have overwhelmingly confirmed. That brings us to the problem of promotion. How do you promote something that really shouldn't have attention drawn to it? Mainstream consumers couldn't care less how the propulsion system operates. They just want results. It's a fundamental conflict.
- 9-24-2016** **Aftermath, outlook.** There's an optimistic outlook. True, we still here from those who misrepresent, but the solution is the same we've seen in the past... prove them wrong with a massive amount of real-world data. Those reports of owner experiences drown out the rhetoric. All you have to do is share stories of your daily driving. That's it. The lack of any real competition to Volt gave enthusiasts an inflated sense of victory. They felt the "*mission accomplished*" feeling. Reusing to look at the bigger picture was their downfall. Thank goodness that's over. It's a new chapter started. Claims of range being "*not enough*" will fall on deaf ears. The showroom shoppers simply won't ever hear any of that nonsense. True, there will be very real apprehension about 22 miles being enough from Prius Prime. But the expectation is that Toyota will take a stance of aggressive pricing. They won't squander the tax-credits. First year will be the build up, giving enough pieces in place to be able to push hard. The hope is this product-cycle (generation) will result in 1 million sales worldwide. That's the kind of volume all automakers need to overcome production costs, as well as dealer hesitation. Don't forget the absolutely vital aspect of participation. Supposedly, only two-thirds of GM dealers are certified to sell Volt. Among those, many don't bother to actually sell them. Inventory is limited and salespeople aren't interested. They steer shoppers to traditional vehicles. Toyota wants to address this problem head on. That's no easy task. Simplicity is the key.

9-24-2016 **Aftermath, simplicity.** The precedent was set by Volt. That's why I keep referring about it directly, rather than discussing the industry as a whole. It was complex. The very act of explaining how it operated turned off most who were curious. GM didn't have the option of simply saying, "*It's a Prius with a plug.*" Toyota does. That opportunity has been thoughtfully postponed too. Waiting until cost & capacity could be improved to the point of it never stirring much concern was key. A simple look at the window-sticker will cease any worry in that regard. That's the simplicity dealer & salesperson desire. They can focus on selling aspects of the car instead. For Prius Prime, that means pointing out the many features of the vehicle, like the LED lights and the dual-wave window. GM customers never got that far. Volt didn't stand a chance. Prius Prime has an appeal which will speak for itself. Simply let the curious showroom shopper take a closer look. They understand that plugging in allow the car to go without the engine starting. Nothing needs to be explained. Heck, even the range is so clear, there's not a thing to question. It's like MPG rating of the regular Prius. People simply don't ask any questions about it. They move on to the next level of shopping, which is checking out the vehicle itself. Toyota offers a few compelling draws... enough to entice a test-drive. Achieving that is a major challenge to overcome... which looks quite realistic.

9-24-2016 **Aftermath, why?** Did it really have to come to this? Remember all the posts about a "*lite*" version of Volt? It was to influence GM, to convince them that gen-2 should be configured to draw the interest of mainstream consumers... the same group of buyers who would otherwise purchase a Malibu or Cruze. They didn't. They decided not to offer a plug-in or hybrid model of Equinox either. We got news yesterday the new Equinox would be offered with 2 turbocharged gas engines and 1 diesel engine. Those will be the only choices. No battery-pack of any kind will be offered. What the heck are they thinking? Why must that even be asked? Who is making such terrible decisions? Don't they see how well the RAV4 hybrid is selling? Or are they quietly developing a hybrid after all? It's this big mystery now that Volt has almost completely vanished from online discussions. Heck, the media doesn't say anything about Volt anymore either. Bolt has completely pushed it out of the spotlight. Of course, that somewhat validates the naming choice. Sounding so close, it can be easy to overlook an omission... even on that big. That's the reason my commentary has an "aftermath" title. All the battles are over. The war has been lost. We know look to what can be saved. Volt as a niche is realistic. True, hopes of mainstream sales have vanished entirely. Thoughts of remaining appealing a particular group is enough to keep in production. Small isn't bad. It's just not what enthusiasts had wanted. Of course, they didn't want it to become ubiquitous either. Then it wouldn't be special anymore. It was a paradox none of them ever understood.

- 9-24-2016** **Aftermath, choices.** The importance of understanding audience cannot be stressed enough. It's absolutely vital. Diversity is a what you use to determine what works and what doesn't. There will typically be several that do. For those that don't, they need to be either discontinued or downsized. With the case of Volt, it's most likely not necessary to kill it off. Enough seeking more range and not concerned about rear seating could sustain it economically. Producing too many can be costly. Producing too few may or may not make a difference, it all depends upon what the high-volume choice is. Looking at Bolt to fulfill that role, we can move on to the other automakers. Finally! All that spotlight stealing wasn't constructive. It only served to stall the push for middle-market. Hyundai is seeking them. With 3 choices of Ioniq, that certainly will be interesting. Of course, it too is small. However, price is expected to be much lower. That affordability aspect may work for those buyers. Again, it's a matter of trying to see what works. We're all quite curious how Chrysler will do with they Pacific hybrid. Being a minivan with a plug is unique. That in itself may result in strong sales. After all, Mitsubishi's Outlander is in a similar position. Anywho, both are attempts to test the market. Kudos. I'm looking forward to a personal endorsement of Prius Prime. Having studied both the technology and the audience extensively, I see great potential.
- 9-25-2016** **Aftermath, competition.** Commentary about Prius Prime competing with Volt will be plentiful. The "*leap frog*" with sales never happened and advantage of hard-acceleration has been lost. So regardless of past greenwashing efforts, those quantifiable points cannot be avoided. It's a new game now, especially with the increased battery capacity. I've heard several reviews now downplaying the 13-hour recharge time using level-1 shouldn't be a concern, since the entire EV range will rarely be used for daily driving anyway. Not having any type of night-life is a hard sell. People drive to places other than work. People stay out late in the evening. People want to use all of what they paid for. All that, combined with the taller seating in back makes Prius Prime worthy of comparisons. I suspect the much higher MPG following depletion will be a big draw for those who drive longer distances routinely. There's also the dual-wave window, an obvious standout feature for those not wanting an ordinary look. GM intentionally toned down Volt's visual points to make it blend into the crowd of mainstream vehicles. Was that a good idea... especially now that we're seeing more and more vehicles with distinct LED lighting? There's much to speculate about. My guess is the aggressive pricing for Prius Prime along with the option of luxury goodies, like the huge screen, will result in a number of Volt conquests. Remember, there's only a limited amount of tax-credits available. Toyota has many to offer for Prius Prime. GM has fewer and wants to dedicate as many as possible to Bolt for beating Tesla with Model 3. That will very likely keep sales expectations for Volt quite low.

- 9-25-2016** **Aftermath, drive mode.** No one seems to have asked about this new button yet. All we've heard is just brief mention of its existence, no detail. Supposedly there's a charge option. It could be a killer-app feature, giving Prius Prime an edge that Volt simply doesn't have a way of competing with. The hope is that button will offer the ability to replenish EV capacity while you drive. The penalty of recharging on-the-fly by consuming gas is obvious; it reduces MPG. But we know Prius Prime will be more efficient than Volt once the battery is depleted. The impression given is that it will have a 10 MPG advantage. So, that penalty won't be much of an impact. When you complete driving, you'll have EV available. For me, I routinely take longer drives. Visits to friends & family easily exceed the EV capacity Volt offers. There would be ample opportunity to replenish EV. Heck, I modestly achieve that now by "stacking". But rather than having to push the EV/HV button to designate recharges while braking to be allocated to EV miles, it would be automatic and on-going. Saving electricity generated while you cruise, rather than using immediately for better HV efficiency, allows you to take advantage of EV opportunity later. In other words, we get more than just a hold mode. The resulting overall MPG could be quite impressive. Yeah!
- 9-26-2016** **Aftermath, light-years ahead.** My favorite snippet from the extreme exchange last week is: "*GM is light-years ahead in plug-ins*". He declared that, but absolutely refused to explain how. No detail whatsoever was provided. It was just stated as fact. That's just like the crazy candidate we have running for president. All you get is vague claims. No substance of any kind is given. Do these personalities actually believe people won't want validation of some sort? Blind acceptance is nuts. Then again, so is making such a wild exclamation of position. What purpose does it serve? Being vastly superior accomplishes what? Well, let me tell you. Toyota's hybrid system is able to compete directly with traditional vehicles. It's a huge challenge with gas prices so low; yet, the technology remains viable. That same extremist claims it took Toyota 17 years before earning a profit from Prius. That's just plain not true, even with all costs ever involved amortized in full. It simple doesn't matter. Detail reveals that Toyota is about to start year 20. Prius is profitable. Period. Without any tax-credit help. How is that not ahead? The plug-in model will leverage upon that technology. Only the door panels will be shared for body parts, but the hybrid system underneath will be nearly identical. Different battery-pack. Added charger. Added clutch. I'd say that is ahead, especially when you consider how refined the engine is. Think about how much lithium cell production is already taking place. How much ahead is yet to be determined. That comes from sales. Penetration into the mainstream is our gauge of success. It's the direction needed for progressing actual change. Ahead in another accomplishes what?

9-26-2016 **Aftermath, charging.** As the dust settles, we are learning more. Remember, the point is to find a way of building a relationship. That means looking for things in common, even if they come from troubled starts. For example, Volt started with "Mountain Mode". It provided the ability to retain 15 miles of EV range for later use, rather than using up the entire plug-supplied capacity first. Enthusiasts claimed that was all anyone would ever need. The reason was simple... Prius PHV offered a "Hold Mode". Why would GM ever want to do something that Toyota did first? Ugh. Needless to say, that was a good idea and it later was added to Volt. Enthusiasts were thrilled... and didn't care about how hypocritical their posts had been about the feature's value. Oh well, at least they overcame their pride with that one. You think that will happen with this too? I was able to get a photo from a Prius Prime prototype. It had a "CHG MODE" indicator light illuminated on a screen. We think that is invoked using that "Drive Mode" button, the one next to the "HV/EV" and "EV Auto" buttons on the console. Will this help push Prius Prime into a respectable position? The goal is to finally be taken seriously by those who didn't want an ally. Bragging about being superior & ahead accomplished what? This aftermath commentary highlights how wasteful that effort was. The competition was traditional vehicles and still very much is. We're supposed to learn from each to figure out how to overcome that competing force. They refused to cooperate. Now, they have no choice. They must, because sales haven't grown. It's that simple.

9-27-2016 **Playing To Your Base.** How many times did I ask: "*Who is the market for Volt?*" That question was posted over and over and over again. The reason should have been obvious. GM was listening to enthusiasts, not supporters. They were playing to their base, rather than reaching out to grow. Market expansion is absolutely vital. Yet, none of those persisting in that daily blog would accept that. It's the reason why so many supporters abandoned it over the years. They didn't want to be associated with a group so enthusiastic, they weren't taking the situation seriously. So, even their own base kept getting smaller and smaller. That's why I was so confident about the outcome. That's why I'm talking about the aftermath now. Seeing the big picture was easy. You won't win if you don't understand your base. They didn't know their audience. They assumed others were share their beliefs, it was only a matter of being able to convey the right information. In other words, they kept repeating rhetoric, rather than addressing facts. Dismissing what you don't like is a fundamental mistake. Ironically, it's the very same problem a presidential candidate is facing now. At last night's debate, he played to his base. That worked well for getting the nomination. But that's a terrible strategy for when the goal is to increase your appeal. He said virtually nothing to sway the undecided. It was just more of the same spin & disregard. Many sources are calling him on that to. The next-morning reports are overwhelming confirming those mistakes. Sound familiar? It's just like what we saw with GM... over and over again. They remained focused on refining what already worked, instead of improving trouble areas. For example, 40 miles of EV was enough for Volt. Rather than the increase to 53 miles, battery size should have been reduced. The cost, weight, and space gains from that would have increased appeal. Only enthusiasts were requesting more EV. Ordinary consumers saw a small, expensive vehicle without impressive MPG following depletion. Supporters noticed... and became disenchanted. Mainstream buyers... didn't buy. Sales have remained flat. Growth has not been achieved, despite the generational upgrade. See the problem? What now? For who?

9-27-2016 **Appealing To Wide Audiences.** The word "*compromise*" has been given a stigma. Rather than representing an effort to deliver balance solutions, it became a sign of weakness. When you compromise, people now see that as failing to stand up for what you believe in. That's sad. It's no surprise though. When things go wrong, those who failed to reach goals will attempt to spin results. They make it seem like the outcome for the winner wasn't actually a success. That's what I've been dealing with for years. Toyota stayed true to the mission of offering a product for the masses. That's not exciting. Cars that are affordable & reliable are often labeled as boring. Being green makes that perception even worse. Yet, that's what draws ordinary customers to purchase so many. Those are the business-sustaining vehicles, so common, they get little attention. Prius Prime is an attempt to deliver both, a compromise of exciting EV and extras without exceeding the affordable criteria. That's a tough one. Fortunately, the reliability part is already taken into account. The hybrid system is well established from Prius and the assortment of other HSD vehicles. The lithium battery is well proven from PHV. It's a winning formula, if well balanced... which I see. Hopefully, others will too. It's just a matter of getting one, they sharing stories. No complicated or massive advertising campaign is necessary. The basics will do. That's all the wider audience will understand anyway. Details of operation are only the concern of enthusiasts. Buyer of profitable high-volume vehicles don't seek out that information. They just want what they can glean from showroom shopping and a few online searches. KISS... Keep It Simple, Stupid.

9-27-2016 **Who?** Now that the daily blog for Volt has turned into a venue for discussing Bolt, there's no reason to participate there anymore. After all, the start of that was to find allies and to squash greenwashing efforts. That's over. Everyone has moved on. I followed. The popular posting there doesn't allow voting. That's a huge improvement. So, when there was a thread posted about the Prius Prime sales goal, I jumped in to respond to this: "*They'll need to upgrade at least the battery to make it more competitive in a year or two.*" It will be intriguing to find out what the reaction is to my sound off: That's only if you believe the competition is other plug-in vehicles and the target audience is Prius shoppers. Toyota does not, hence the anticipated growth. The regular Prius is for those who seek outstanding efficiency from their gas fill-ups. The improvement to the handling and system refinement make it a serious contender for those with that goal. Sadly though, gas prices are so low, sales are quite difficult. Nonetheless, Prius is still delivering mainstream numbers. Prius Prime targets a very different audience. It's those who seek a no-compromise EV experience. You get to-the-floor EV acceleration with a range enough to cover most commutes, yet not break the bank. It's affordable enough to survive on its own, without tax-credits... especially with a worldwide sales goal of 1,000,000 for this generation. Following depletion, you still get outstanding efficiency. Prius Prime also offers unique draws, like the dual-wave rear window and the distinct LED lighting. The 3.3 kW charge-rate allows the battery to be replenished quickly too. It may appeal to some considering Prius or another plug-in, but that isn't Toyota's primary goal. They want to phase-out production of traditional vehicles. That means finding ways to entice buyers of Camry & Corolla, not simply attracting those wanting to be greener.

9-28-2016 **When?** Talk of this generation has been a sensitive topic. Volt enthusiasts lash out with resentment when you mention tax-credit expiration happening during this product-cycle. They see the end approaching in less than 3 years, well before the next generation will be available. That emotion comes from seeing how Toyota has prepared for it. Prius Prime may not offer the most elegant battery fit currently, but the purpose of that is clear. It was to ensure the system would be affordable. It is also recognized that the physical size of the pack could shrink mid-cycle. This sets up Toyota nicely to be able to deliver high-volume that's profitable and sustainable, even without subsidies. That's a very, very big deal... one that enthusiasts have been blowing off as unimportant... but have trouble doing so now. They see the desire to phaseout the regular Prius. When? That would be the next generation. With the newest delivering the highest thermal efficiency engine in the industry, as well as the most efficient hybrid system, it only makes sense that low-cost plugging becomes a target. Offering something for the masses has been the ultimate goal all along. That's why I held so much resentment for GM's approach with Volt. It catered to enthusiasts, not mainstream consumers. That's pretty easy to see now too. The gen-2 model confirmed a niche had been targeted. That's why support has shifted over to Bolt instead. Meanwhile, Toyota is preparing for a historical rollout. This very much resembles what we witnessed (and I participated in) back when the Classic Prius was replaced by the Iconic model. Yeah! Next year will be a lot of fun ramping up interest. The early buyers have much to do. There will be a great deal of discovery, then sharing. It's very exciting to anticipate.

9-28-2016 Phasing Out Hybrids. Talk of Toyota's next generation Prius only offering a plug has already begun. As expected, that has stirred a wide variety of posts. I sounded off with this on a generic automotive website discussing the topic:

The immediate reaction to reading this news is for people to compare to Volt. Why? Target audience is completely different. Cost doesn't have the same priority. And sales remain low & flat. What is there in common? What goals do they even share?

What's most troubling is the blatant spreading of incorrect information, since some of it is intentional. There is a bit of encouragement though, because people will recognize the new generation provides improvements. So, they'll question if what was claimed is outdated.

To the topic at hand, name other automakers striving to reach middle-market without tax-credits in their current generation. That's a major undertaking not being discussed seriously. All we get is boasting about more EV range, which hasn't resulted in large sales growth.

Look closely at Prius Prime. The effort to deliver a choice with potential to compete directly against traditional vehicles should be apparent. The benefit is huge. Dealer interest has been a fundamental problem for GM. Toyota is working hard to overcome that.

Cheap gas and the lack of interest in oil dependency present monumental challenges. There's the outright dismissal of carbon & smog-related emission problems too. Enticing customers who aren't the slightest bit concerned to consider a vehicle with a plug is a major undertaking. It takes far more than the overly-simplistic portrayal of delivering more EV range being enough to sway them.

9-28-2016 Greenwash Attempts. How much more will we have to deal with bogus claims like this: "*The Prius switches to the gas engine when it reaches 55 mph for efficiency.*" That is blatant greenwashing. There is no switch. At 62 mph (not 55 mph), the engine will join in to provide some propulsion power. The draw from the battery-pack does not stop, as the statement implies. It is only relevant to Prius PHV too. The next generation Prius Prime bumps that threshold up to 84 mph. It's that kind of intentional misleading we've had to find ways of overcoming for years. Certain individuals just plain don't care. They think nothing of spreading lies. The new venues discussing Prius Prime now bringing back those problems all over again is annoying. That is telling though. Choosing to post dishonestly informs us they have nothing of merit to rebut with. It's confirmation of shortcomings they hope to avoid revealing by keeping the attention on perceived weaknesses of others. They call it spin upon being caught. I see right through the deception. Hopefully, unknowing readers will notice what's going on... because those greenwashing attempts show no sign of ending.

9-28-2016 **Published Early.** Oops! There was an article published 2 days ago that abruptly vanished. It was about Prius Prime. The new photo in the preview caught my attention. I was intrigued. But try as I may, the link wouldn't open. Yesterday, I discovered it was an embargo violation. A media source privileged with the opportunity to access advanced information ended up leaking it by publishing early. We all must wait until next Monday, an entire week later. Oh, the agony! Unfortunately, what happens on the internet doesn't stay on the internet. Now I cannot upload this blog entry until then... because I know how to find out what got published. Doing a search on cached history revealed a copy of the webpage which had been promptly been taken down. The information within confirmed what I've been saying for years. Toyota has placed a very high priority on keeping cost low. The design supports decisions being made in that regard. We only needed price to prove it. There it was. \$2,860 lower than Prius PHV's base, despite the larger capacity battery and much refined system. Prius Prime comes with added safety features too. That's absolutely fantastic news! Even better was the discovery of yet another improvement. This generation will include a battery-warmer. Temperatures below freezing cause electrical resistance within the battery to increase. That means more electricity is consumed to drive in Winter conditions. To improve overall efficiency, the system will now keep the battery warmed to 32°F (0°C). Unnecessary, but beneficial, upgrades like that are what we had been hoping for. It's very exciting to find out new information of that nature. Though, it would have been totally worth waiting for. Oh well. The leak wasn't a terrible thing. Only a small few noticed and we're all keeping quiet about it, especially since we only have to wait 5 more days.

9-29-2016 **That Daily Blog.** Discussion of Volt there has almost entirely vanished. Bolt's dominance is obvious. It has taken over. So, getting back to the topic of plug-in hybrids today was something I had been looking forward to. On the parent website, an article of regular Prius phase-out potential had been published. That meant the possibility of the blog getting it too was realistic. It happened. I jumped in right away with:

The keep-cost-low approach Toyota chose to take has been mocked relentlessly over the years. It's good to see the purpose of that finally getting acknowledged. Leadership is getting the masses to change.

Delivering a vehicle for them requires affordability to be the highest priority. There's simply no way to achieve high-volume profitable sales with tax-credit dependency. Finding a way to offer a plug without necessarily having the most elegant packaging or largest EV range has been key.

We see Prius Prime fulfilling those requirements. You get a full EV driving experience for the average commute. You get outstanding MPG after the plug-supplied electricity is used up. You get a design with production-cost low enough to be able to compete directly with traditional vehicles.

Within this generation, tax-credits will expire. Sales must grow to sustainable levels, despite the subsidy loss. Overcoming that and setting the stage for discontinuing the regular Prius means achieving & sustaining mainstream quantity for Prius Prime within the next few years.

Sales always have been the measure of change. Ordinary showroom floor shoppers are much more difficult to appeal to than car enthusiasts. Watch how mainstream buyers respond to Prius Prime.

9-29-2016 **Maturity.** There were some who didn't show any. We got repeats of the same old rhetoric. It's hard to believe pride gets so much in the way sometimes. Dropping bait is the most common response when there's a topic they don't find appealing. I didn't bite any of that. The antagonism simply doesn't work anymore. Responding only gets you labeled as a troll anyway. Confirmation of the situation simply comes in the form of them trying to lure you. The more attempts, the more you know they're recognizing what went wrong. I waited for something constructive to be posted instead. This was good enough to hopefully stir something constructive in return: "*They've stretched it to it's Hybrid Synergy limits. If this means Prius gets a plug and a bank of lithium ion batteries, HOORAY! It's about time, Toyota!*" The rest wasn't anything new. It was quite predictable. I kept the reply to that particular one short: That stretch is called reaching maturity. With both cost & efficiency improved to the point of being directly competitive against traditional vehicles, adding a plug & battery-capacity is the next natural step... which is exactly what will be happening this year. That's right on time, just as interest for plugging in emerges. Mainstream buyers simply haven't cared up until now.

9-29-2016 **Lead or Follow?** That question sums up the enthusiast view of the market. It's either lead or follow. Simply being part of something isn't possible. You win or you lose; nothing in between. Ugh. That's why getting through to them about the importance of sales is basically pointless. They don't hear you. The idea of being ahead is all that matters. It's that same old trophy mentality. Oh well. Whether they like it or not, sales are how you gauge change. Many means you have an effective solution. It's that easy to interpret. This isn't: *"To me it just strengthens the argument that GM is leading and not following."* That was the response to hearing that Toyota may choose to offer a plug exclusively for the 5th generation. Much can happen in the next 5 to 6 years. A cost-effective next step is needed by all automakers. What will the others do? Toyota's path is much easier to see. Sales will make that determination, not leadership claims, not winning awards, not declaring superiority or obsolescence. I put it this way: Sales are the measure of progress. Generation 1 (the first chapter in plug-in hybrid history) reached enthusiasts well, but ended with market saturation. Generation 2 is the chapter where the attempt to appeal to ordinary showroom shoppers takes place. That's a very different audience. So far, only gen-2 Volt has been rolled out. Sales have been flat, despite no other gen-2 offering being available yet. That's not the type of leadership the industry has been hoping for. Significant growth is needed for plugging in to be taken seriously. That means greatly exceeding levels of the past. Toyota, Hyundai, Chrysler, and Mitsubishi will all be joining within the next year. The goal is to show that plug-in hybrids are having an impact on traditional vehicle sales. Achieving that will come from new interest, convincing new customers to purchase. What difference will leading or following make?

9-29-2016 **Decisions.** Yet another rant came about. Each new thread that addresses an unpleasant topic does that. This is how I summed up what happened today:

The statement of "*Toyota is considering ditching the regular hybrid version*" is why posts have been about Prime and focus on goals. Remarks about visual appeal and more being better clearly aren't constructive. They're just fodder cluttering up the thread.

We know it comes down to low enough production cost to appeal to people outside of the gen-1 market. They aren't looking for the most of any particular aspect. They are just looking for a nice balance for a good buy. They couldn't care less about argument points made here. For that matter, they don't care about the past either.

I do find it telling that resentment for GM decisions is so often vented in the form of Prius disparaging. Those who do that clearly don't understand audience, they still have no idea who the market is. No matter how many times the importance of drawing over GM's customers from their own traditional vehicles to something greener is mentioned, there's still a belief that conquest sales from other automakers are what matter. Ugh.

Losses on the showroom floor really hurt. Pushing to prevent that by making a plug standard is seeking otherwise missed opportunity. Success of winning over Camry & Corolla shoppers with Prime would give good reason to consider the end to Prius without a plug. Those sales would confirm that next step is a wise one to take.

This isn't rocket science; it's business. Prius PHV was rolled out mid-cycle in limited quantity to limited areas. Decisions about what next step to take was made based on observations & feedback from those initial owners. How much power & range to increase was made based on real-world data and cost reductions possible in the available timeframe. That's how Prime came about.

9-30-2016 **Winter Warming.** The crazy online banter is almost over. We can finally look toward real-world data gathering. That collection of driving experiences shared is a powerful weapon. Squashing misconceptions and the fight against greenwashing is far easier when speculation ends and ownership begins. I am especially looking forward to the Winter experience. Living here in Minnesota, that's especially valuable... as well as fun to be part of the discovery process. The new preheat feature is something I had hoped would be available from Prius PHV. Electric heating didn't make sense way back in 2012 though. Far too much EV range was sacrificed for the ability. So, it wasn't offered. This time, the battery is big enough and the heat-pump far more efficient. I'll be able to run it directly while plugged in too. Yeah! In addition to that cabin warming feature, the battery-pack and steering-wheel will have warming features. Hooray! Each generation becomes increasingly more electric, yet price stays in check. That's sweet. Lowering tolerances like that won't be appreciated by many people other than early adopters, those who closely following gen-1 designs. The gen-2 vehicles, most notably Prius Prime, will just work without there ever being any type of electric concern. It will just work. People will use, but not appreciate the technology advancements. That's how you know it has reached maturity. Ordinary consumers have little to no engineering background. Most have no clue how their vehicle actually works. Those promoting the switch from gas to electricity must be keenly aware of that. Otherwise, what's advertised will be meaningless. Functionality of the past won't have any relevance now; so, there's nothing to mention. I'll simply be telling people it works great in the cold.

9-30-2016 **Smug.** For crying out loud: "*Seems that this day the Toyota fanboys out typed the GM fanboys. They had to release their frustrations on Toyota's losses and mistakes. So, for now, GM is still ahead.*" The nonsense of being ahead is baffling. What do they think "ahead" actually means? Posts have become increasingly vague, to the point of uselessness. Nothing is being conveyed at this point. For me, I soldier on. That means keeping locked on the goal and clearly identifying barriers:

Thank goodness the plug-in owners group I'm part of is working hard against such a pointless mindsets. They see the goal of mainstream penetration and take it quite seriously. Delivering the most range or being first simply isn't important. It's all about getting vehicles to potential customers.

In other words, there's a great deal of effort being focused on the dealer experience. The frustration of limited inventory and poorly informed salespeople is a major barrier to overcome. That's why being upfront about design detail is so vital. Misinformation really sets those efforts back. That message clearly isn't getting through to this group.

The nonsense here about not even wanting to address showroom shoppers is truly amazing. So much opportunity is being lost and you simply aren't interested. Instead, there's just a diversion about supposed losses & mistakes. Whether there were any or not has absolutely nothing to do with what's happens next. Gen-1 is not Gen-2. Why is that so hard to understand?

Prime stands a very real shot of reaching ordinary consumers, growing beyond the market for Prius without a plug. So what if Volt still hasn't been able to do that. It's not like GM can't later offer a variant that does. The posts here hint at a confidence concern, where you fear that won't happen, as if too much has already been spent on Volt and budget will just be shifted over to Bolt instead.

Keep doing what you want. Focus on being "*ahead*" for the sake of... ahh... what does that accomplish?

9-30-2016 **That's It!** I reached the end of my rope and let him have it. His efforts were responses out of desperation, anything to make Toyota look bad at this point. He actually gave up trying to attack me. Clearly, I wasn't going to back down. That's because I know what's coming. Intense research and online participation has its rewards. There wasn't any reason to hold back anymore. Calling those posts hypocritical wouldn't accomplish anything anyway. It was time to sight goals and call the play. So, I did: We still await that "*nicely under \$30,000*" plug-in from GM. Remember that promise for late 2010? In other words, I call your double-standard.

10-01-2016 **Due Diligence.** I thoroughly enjoyed reading and responding to this: "*Toyota is behind in this regard due to their lack of belief in the plug-in model. They were still gung-ho about old hybrid technology and didn't perform due-diligence on plug-ins.*" He's been a royal pain in the backside lately. The vague claims and growing double-standard was more than I wanted to deal with at this stage. It's over. Geez! In just 2 days, things will change. But there's always one who has to draw things out to the absolute very end. Oh well. Monday will be here soon enough. In the meantime:

Put it this way... The homework GM turned in was not what the teacher assigned. Yet, since the work itself was top-notch output and it was completed early, the expectation is to receive an "A" grade anyway. Sorry, but that's not how it works.

Ordinary consumers still haven't received that vehicle that was promised. The assignment was to deliver a plug-in hybrid that would greatly improve emissions & efficiency at an affordable price. There were no specifics on how much EV was required. It just needed to take advantage of plug-supplied electricity, then deliver hybrid MPG when that electricity was used up.

That's exactly what Toyota is planning to rollout within the next 2 months. The vehicle meets requirements and is right on time. Not only did they perform due-diligence to ensure the homework turned in was complete, they provided more for extra credit. What may have appeared to be lack of belief was really the effort to earn an "A+" grade by focusing things that may have seemed unrelated... like high-volume production of lithium batteries for gen-4 Prius.

Too bad if you don't like the idea of sharing the spotlight. It's going to happen regardless. GM is already part of the classroom, rather than the standout student that was hoped.

Look at it this way... they are in the class, they are participating in the exciting projects, they are doing good work. We'll just have to wait some more for the assignment to be completed.

- 10-01-2016 Dieselgate Progress.** It's slow, painfully slow. It's totally worth in though. Diesel for passenger cars has become a dead topic now. There is no future for it here. The nonsense around "*clean diesel*" has been revealed to be the biggest scam of all time. The smug owners who dismissed our empirical evidence are long gone. They were suckered into believing emissions were much cleaner and didn't want to address the reality of on-going improvements to hybrid efficiency. And now with plug-in hybrids delivered MPG so far beyond anything a diesel could even remotely achieve, it's a worthless endeavor. Gen-4 Prius was enough to nail that coffin shut anyway. Prius Prime will make that message so clear, there's no reason to even try... which is why VW dealers have wanted compensation for so much lost business. 652 dealers across the United States were depending upon VW sales. Not only were diesels not available, the inventory that could be sold became quite a challenge upon the loss of trust. VW got caught lying to customers. As a result, it looks like an average of \$1.8 million will be paid to each of those dealers. That comes to a total of \$1.21 billion. The scandal is proving to be extraordinarily expensive. It's too bad the problem wasn't exposed sooner. Prius owners were furious with the lack of attention. We kept asking how could so much be achieved by doing so little. Things just didn't add up.
- 10-01-2016 58 MPG.** I drove home from Northern Minnesota without using any plug-supplied electricity today. I wanted to see out what the MPG would be, again. It would be my last opportunity to witness that. With the temperature a pleasant Fall warmth. Why not? After all, efficiency would be outstanding... by gen-3 terms. When I upgrade from the Prius PHV to the Prius Prime in about 2 months, that gen-4 hybrid system will deliver even higher MPG. The drive was what I usually do on long trips like that, toggling the HV/EV button when approaching stops while decelerating from highway speeds. In this case, that generated & saved miles worth of EV capacity... which I did use along the drive. The goal was to make sure the estimated range matched what it did upon filling up with gas that morning, just down the road from where I had stayed the night before. That is indeed what happened too. The drive was 172 miles. The resulting average was a very pleasing 58 MPG. That's right on par with other trips that didn't use plug-supplied electricity, with top cruising speeds of 70 mph. It's great having a hybrid so efficient, it stands out even without plugging in. Anywho, I had to take a photo to document the experience... [photo album 186](#)

10-01-2016 **Final Remarks.** The level of rhetoric has reached a point of amazement. Some people choose to fight to the bitter end. The debate practice they unknowingly provide is quite valuable. So, I persisted. The time has come though to bring that to an end. I posted this:

No amount of downvoting, disparaging, and denying will stop what's about to happen... since that has been the source material for promoting it. The ultimate devil's advocate is someone not yet ready for change.

Toyota will soon reveal pricing for Prime which will confirm their heavy emphasis on cost-reduction. Being affordable and offering 22 miles of EV will draw in a new audience, one well beyond anything Prius was able to reach. That high-volume potential (profitable without subsidy dependence) within this generation is key.

GM's priority of pushing battery range has resulted in Bolt. It's success has already deprived Volt of attention (noticed discussions have almost entirely vanished) and promises to use up a bulk of the remaining tax-credits available. Since Volt is only compact and sales growth wasn't achieved with gen-2, offering that proven technology on some other platform is the obvious next step. A vehicle like Equinox stands a much greater chance of appealing to the masses.

In the meantime, Prime will be helping advance the plug-in market. Its vapor-injected heat-pump is an industry first. Combined with standard heated-seats and the introduction of a battery-warmer will push acceptance of plugging in even further. The unmatched MPG following depletion will solidify the place of plug-in hybrids among the new product-lines for automakers.

The idea of Toyota "*ditching*" the regular Prius evidence of change. Success of Prime will push other automakers. An affordable car that easily delivers over 100 MPG averages is what we've been waiting nearly a decade for. So what if GM's attempt wasn't able to lead those sales. It's not like they lost the war competing against traditional vehicles. Bolt is leading a new battle and the technology in Volt can be used elsewhere.

The effort continues. It's not over. We need people to help with this next chapter in the history of plug-in vehicles. Soon, there won't be any value to spin of what's about to happen, since it will.

Prime sales will begin. Bolt sales will begin. An announcement from Nissan is expected. Change is on the way.

10-01-2016 **Creating Confusion.** Someone read an article about Prius Prime from 3 months ago and wanted to publish comments about the points made on his website. So, he searched the internet for some material and did exactly that. The opening paragraph was a confusing portrayal of Prius PHV so messed up, I had to read the thing several times to figure out what he was attempting to tell. The article got worse from there. Clearly not understanding what the EPA window-sticker information states, he went on to complain about how Toyota could only offer "*6 miles*" for the first generation but was pleased that the second will deliver 22 miles. That type of misrepresentation is harmful. It's how misconceptions emerge. Assumptions are passed along and eventually true fact becomes very difficult to find. I was annoyed, to say the least. It's why I've been so hard on the Volt spin. That's intentional misleading. This was an effort to be sincere. He failed miserably. Readers of his webpage will have no idea that information was wrong. Retractions & Corrections are rare. The likelihood of them being read is even more rare. It's really unfortunate we have to deal with problems like this.

10-02-2016 Being Vague & Double Standards. That's what it ended up coming down to. No surprise. After all, an opponent rarely ever admits defeat. That type of behavior helps with the transition. It gives them a sense of having given the last word, as if they are in agreement. That was the case with: *"It has been for some time. And we are glad Toyota is finally trying to join the movement. They just need to step up their efforts... big time."* Of course, I couldn't let that go... because I don't want to see the cycle repeat again:

Step up? Big time?

Those don't tell us anything either. Posts entirely void of anything quantitative aren't constructive. No direction. No goal. Nothing to measure along the way. More & Faster is meaningless. This is why Volt suffered over the years. When milestones were missed, support became wishy-washy to defend reputation by using vague adjectives.

Toyota has always held true. So what if antagonists painted a misleading picture and those pointing that out were labeled as trolls. Ordinary consumers would never know and the goal would still be reached.

In this case, the effort has been to find a way of replacing traditional vehicles with a cleaner, more efficient choice. The same target price was set as GM too, nicely under \$30,000. We'll find out the results of that tomorrow. Capacity of the battery would be adjusted accordingly for each generation. They started with 4.4 kWh. For the next, the goal was to double that. 8.8 kWh is indeed what was delivered. The speed/power upper-limit was originally set to 100 km/h (62 mph). This time, it was raised to meet all driving circumstances, 135 km/h (84 mph).

Notice how easily measurable all those values are? They even state how many. In the past, it was a certain amount by a specific year... back when HSD was limited to just a few choices. Now, they have stated a quantity for a specific model & generation. In this case, they wish to sell 1 million Prime worldwide.

The concise nature of all that means easy evaluation of progress. Notice how sales were just blown off as not important in prior posts on this thread? It's because Volt fell well short of expectations and they were making an effort to avoid acknowledgement of that. Prime will be held to a higher standard. We know what *"step up"* and *"big time"* actually means... whether you specify it or not... because Volt will be expected to do the same.

- 10-03-2016** **Playing Offense.** That time to tell certain people the way things are with a rather terse approach has returned: The entire discussion has been about Prius Prime and its influence on the market... not your "traditional vehicles don't matter" nonsense. I've been waiting to find out what meritless spin you'd post upon learning Toyota reached the goals GM still hasn't. Your complete disregard for ordinary buyers, those who shop the showroom floor, is a recipe for disaster. They'll see the 25 miles of EV for \$27k. They'll see the step-up interior from the regular Prius. They'll recognize the outstanding hybrid efficiency & reliability. Who do you think you are fooling by trying to belittle what Toyota has delivered. Do you really believe that will somehow help GM, that ignoring their own goals will make it better? Hasn't anything been learned from offerings that failed to result in mainstream sales? Go ahead. Dig your hole even deeper. The rest of us will celebrate this progress. The step forward taken today by Prius Prime into the market of ordinary consumers is a big one.
- 10-03-2016** **Prime Pricing.** The embargo finally ended. After weeks of waiting, the time had come. Minutes later I was posting: Yeah! Price did indeed end up aggressive, as Toyota has been working really hard to deliver and we had hoped for. We've been waiting for that official 25-mile rating for awhile too. Knowing Toyota so well, doing the calculations, and approximating based on other markets made it a strong case of getting more than 22. After all, we often got more from the 11-mile estimate from PHV. Thanks for the info and the updates.
- 10-04-2016** **Spin Already.** I wondered how long it would take to get the perspective of change: "*I think the rear seating in the prime looks classy..and a big improvement.*" It's truly amazing how much people fight for the status quo. The majority like things as is, even if there's nothing to be gained from holding back. That's understandable... to a point. How long can it stay that way? How does a shift to improve gain acceptance? Since when do seats in back have to remain utilitarian? Why not making the sitting experience in back better? I sounded off to that with: We need more comments like that... since the anti-Prime spin has already begun. I have seen a few Volt owners attempting to paint a picture of "cheap" for Prime by using the low MSRP as their reasoning. Toyota may have foreseen that, hoping a few upscale features would offset such efforts. At the same time, it's a good move for greater diversification. They have to grow the market somehow. Why not offer something unusually nice for the price? What starts out as a luxury option tends to eventually become affordable for the masses anyway. Shaking up the industry by doing that unexpectedly soon seems a rather smart move. After all, that is how Prius started out. Think about how ahead of its time that original hybrid was.

10-05-2016 **September Sales.** Having monthly results posted within hours of the pricing for Prius Prime was an interesting twist. It immediately interjected some reality into the situation. I posted this addressing Volt supporters:

The showroom floor experience is a topic of importance that never seems to get any attention online. There are still far too many distractions.

For example, discussions end up focusing on worthless points instead, like 0-60 acceleration speed. Unfortunately, most people don't have proper perspective on, since they don't know what they really require. They simply haven't paid close enough attention. Rarely is there a ever an actual need to request full power in the time quoted. Highway entrance-ramp metering only takes place when traffic isn't moving a full speed, so you don't need it then. And when it's not metered, the vehicle is already in motion; so 0 mph is meaningless. It's a greenwashing trap many people fall into. Sadly, there are salespeople who take advantage of that for an easy commission.

Other worthless points, like the price of gas, end up making the sales effort a major challenge. People move on to traditional choices far too easily. Just ask how they'll plug in at home. That gets so overwhelming so fast, most don't even bother.

Looking specifically at GM's situation, what should happen? We have seen emphasis on Bolt so heavy recently, it's as if Volt doesn't exist anymore. There simply isn't any mention anymore. Limited quantity of tax-credits is a major contributor toward that. The greater the push with Bolt to get into the mainstream, the less there will be available for Volt.

Strategy has always been to push price into mainstream reach. For the 200-mile EV offerings, that's a generation away still. For the plug-in hybrids, it must happen in the very near future. Suggested many times for GM's next step is to rollout a Voltec version of Equinox. After all, GM prefers selling trucks & SUVs anyway. Cars are secondary... hence lack of support from dealers & salespeople.

There's the quiet giant in the room too. Toyota rolled out the new Prius last year with lithium batteries as their primary offering. Ramping up that production without much attention has went very well. We can see a reflection of that success with the low price of Prius Prime revealed yesterday. That's a clear effort to reach ordinary consumers, sharing the same goal GM has had with Volt. So... what does that now mean for Volt?

10-05-2016 **Why? How?** These questions must be asked: 4th generation brings about change. The formula of the past simply won't be as effective. A modified approach was required. The styling of gen-4 Prius was inevitable. People are burnt out on "normal" looking cars at this point. Evidence of that is the LED accent lighting popping up everywhere. That's an easy design modification will obvious results. People are draw to the standout, unique nature of what they provide. There isn't much functional benefit, but that doesn't matter. It's like the raised floor in the back of Prime for the larger battery-pack. There's a counter-intuitive nature of pride it addresses. People want to feel like they are contributing to a better future. The reduced storage space is an on-going reminder of their contribution. That isn't logical. Emotional appeal is what the automotive industry thrives on though. We may find that Toyota retains that approach, taking advantage of it later to offer more EV capacity rather than making the battery smaller. Also, how do you make it clear to the market that the new Prius isn't just another upgrade. That upgraded suspension will make it self known during the test-drives. So, the focus must be on getting customers to take notice enough to give it a try. Why shouldn't a green car be a little bit sporty? Shaking the stereotype of "eco-box" isn't easy. Look no further than Corolla & Camry. How does Toyota sell so many of those?

10-05-2016 **0-60, again.** There are very few who will remember details of the Classic Prius rollout, especially the rhetoric. Those who opposed hybrids looked to exposed design aspects that could be perceived as weaknesses. That's how want verses need entered into the story. The only possible reception problem they could come up with back then was electric-power was slow. It was a misconception they could push. So, they did. Well, the emergence of Prime has started a new chapter. They are looking for exploitation opportunities again. And sure enough, they homed in on the 0 to 60 acceleration speed. Ugh. The same old undermining efforts have returned. My first post (of many, I'm sure) on the topic was: People making the "*too slow*" comment never mention how long it actually takes to accelerate, they just assume not enough. Do they only envision a short ramp where you start from a dead stop, up hill, and have to get up to traffic going 60 within seconds? I certainly don't encounter that situation. I merge onto the highway in EV mode with my 2012 Prius PHV on a regular basis. Faster from Prime will be a nice perk, but clearly not necessary for ordinary run-of-the-mill driving. Of course, if you have much driving to do on the highway, you'll want to turn on the engine anyway. EV range gets gobbled up quick when traveling at 70 mph or faster. That's where the outstanding MPG from HV mode comes in really handy. Most owners will likely just use the "EV Auto" mode. That will favor EV as much as possible, only turning on the engine briefly when maximum power is truly necessary.

- 10-05-2016 0-60, so far.** I'm posting on a venue that serves a wide audience. So far, I'm just one of the crowd. The regulars there will either support or antagonize. It only a matter of time. They don't like change. The first clue is when they call you out wondering what your purpose is, but never say anything about their own. Not stating goals is a dead giveaway of trouble to come. Anywho, I going to walk that fine line initially: The assumption of believing 0-60 is the measure of all power available is what appears to be the issue. You point out passing. That has absolutely nothing to do with accelerating from a dead stop. Power returned is very different when the vehicle is already in motion. With the case of EV driving, you've got an electric motor that more responsive than a gas engine and only need it for a short burst. Put it this way, unless you have actually tried it, what basis of judgment are you using? Just one number does not tell the whole story.
- 10-05-2016 0-06, examples.** The push for detail begins. That will reveal intent. Constructive posts will provide realistic examples. Rhetoric will sight an extreme. I'll punt by taking the initiative in response to this: *"If I have a 20 mile commute to work, and half of it is highway at 70mph; does that mean half of my commute I have to use gasoline because the acceleration can't keep up with traffic?"* That gives the impression of an open mind really wanting to know. We'll see what kind of reply I get to this: Absolutely not. I'll be providing proof in the next few months with mine too, filming my commute to work with my new Prime as I do now with the PHV. The commute from garage to ramp (with charger) is 18.6 miles. There's a chunk that is on a 70 mph highway. I know I'll be able to merge right into traffic and cruise along with it effortlessly in EV. Watching the gauges now, it's pretty easy to see the extra power will cover that entirely drive in EV, no big deal. At work, there are 6 chargers available. The ramp has a massive 85 kWh solar-array too. So, being able to recharge there will allow my entire commute to be EV. The pre-warming feature and the vapor-injected heat-pump, along with the heated steering-wheel and seats, sure will make the electric experience in winter nice too.
- 10-05-2016 0-60, who?** I sensed things quickly falling apart. The participation in that type of posting only lasts for 1 day... but the thread discussion lives on for years. So, you have to be rather to the point when addressing potential problems. I certainly did today: What you think doesn't matter. You're not the one taking a test-drive or making the purchase. Marketing has convinced you that maximum power is required for everyday driving. It's clearly not. The EV power will easily cover a majority of our needs and many of our wants. You want more, buy a more powerful electric drive. This is no different than those insisting a 6-cylinder engine is required, when really a 4-cylinder engine is just fine.

- 10-06-2016 0-60, got ugly.** That didn't take long. One of the very frequent posters sounded off, attempting to dismiss by sighting an extreme. That's a familiar tactic and never a good sign. I was annoyed, but took advantage of the opportunity to point out: That example of an extreme didn't include an actual time. The omission is a red-flag. Most people don't have any clue how long it takes to accelerate onto a highway. That makes distorting expectations very easy. If you know you have an extreme to deal with. You just toggle over to HV mode or leave it in EV-Auto. The other problem is all the other examples omitted. Most everyday driving will easily be accommodated by the EV that's available. You'll be able to do all of your travel in the suburbs, runs along rural highways, and high-speed cruising on interstates. Avoiding detail by not bothering to include any data for us to make decisions on our own with tells the real story. Watch how long it really takes for an ordinary highway merge. It takes far longer than the vague claims imply.
- 10-06-2016 0-60, rushing.** Realistically, they'll never be happy. A great example of why comes from the intersection near my home. People fly around the curve and simply don't care if the light is red. They rush to it anyway. So, they want you to rush too. They don't care about waiting once they get there. They don't care that even if it turned green then, they'd still get through in time. It's that mindset of more being better, of want clouding judgment of need. I watch them do it to me. I watch them do it to others. I can see the frustration. It accomplishes nothing. Insisting that faster acceleration is required, even though they don't need it is similar. They never bother actually checking. They live with assumptions and get assertive when questioned about them. From their perspective, they think you're out of your mind. The fact that they are the aggressor driving too fast never crosses their mind. Whether the more is speed or size or power, there's a point-of-view of "*not enough*". So, no matter what you say, they just dismiss it. Marketing has exploited this weakness, selling countless millions of vehicles we don't need. They've learned how easily we succumb to want. Ugh.
- 10-06-2016 0-60, pointless.** It never ceases to amaze me how people aggressively pass. We all see the weaving through traffic, where they don't look far enough ahead to notice the lane they just got in isn't moving fast either. That's just plain stupid. Yet, it happens routinely anyway. The reason why is obvious: they are in a hurry and think every little bit adds up. It usually doesn't. You tend to keep up with them by simply remaining where you are. The other type of passing is especially frustrating. I can be cruising along on a highway in South Dakota at 80 mph. No one else on the road expect me and the person rapidly approaching from behind. They get into the left lane, pass by, then cut you off. Ack! There's no reason whatsoever to do that. Slowing down after passing, causing the person you cut off to also slow down, seems downright evil. It's annoying and puts them at risk. Why? Needless to say, that's where the dynamic-cruise comes in handy. Having the car deal with that rather than me needing to sure is nice. What's the point of such behavior? I suspect these drivers are the ones saying 0-60 needs to be faster. From their point of view, my guess is they don't think they are doing anything wrong. Ugh.

10-07-2016 **MPGe Rating.** The official estimates are now being revealed. The big one is MPGe. That's the miles-per-gallon equivalent value used for comparing EV efficiency. Prior to the gen-2 offerings, there was little reference of comparison anyone cared about. People would simply refer to the battery-pack capacity. More miles of EV was perceived as cleaner. The attacks I had to endure just by the mere mention of guzzling electricity was amazing. Enthusiasts would flip out. Even before Volt was rolled out, the idea of not using any gas was conveyed as the strongest selling point. Knowing their audience could handle the high sticker-price and would drive as many EV miles as possible, the amount of gas consumed too precedence. They'd totally ignore kWh usage. It was all about using the fewest gallons. That's over now. Reality is crashing down on that greenwashing. No more. The belief was this would come about from a pure EV. That makes sense. When your propulsion system is electric-only, you do everything you possibly can to avoid waste. That isn't as high of a priority for a vehicle with an engine available... or so they thought. Toyota proved them wrong. The rating for Prius Prime revealed today was an amazing 133 MPGe. That's well above Volt's 106 MPGe. So as you could imagine, the downplay of that value started immediately. They really get annoyed with those who study Prius and hold the priorities of Toyota in high regard are proven correct. This confirm of "*vastly superior*" engineering felt great. For far too many years, the idea that a much bigger battery was required to be cleaner was pushed. If you don't drive to capacity, a less efficient EV will waste electricity. It's that simple. We don't want to shift our guzzling problem from one energy source to another. We want to use less.

10-07-2016 **Omitting Facts.** You get a very different story when an important part is left out. In this case, I was especially annoyed from reading this: "*I suggest there was a 3rd blunder not developing a pure EV. Toyota went with hydrogen...*" People posting claims like that are antagonists. They stir the pot for something they disagreed with in the past and never let it go. So no matter how much changes following that, all they see is previous actions. Needless to say, I wasn't about to put up with another round of that nonsense. So, I let him have it:

That's telling a story through omission. They may not have revealed a mass-market body, but that doesn't mean nothing else happened. Not hearing knocking in the past didn't mean they were not preparing for it later. After all, Toyota has always been tight-lipped about mainstream changes in the not-too-distance future.

Toyota switched all but the base model of Prius liftback over to lithium. Of which, that chemistry has been improved. The high-volume production now taking place very much benefits future EV offerings.

Toyota is about to deliver the world's most efficient heat-pump for a vehicle. The real-world experience from that vapor-injected system in Prius Prime will very much benefit future EV offerings.

Toyota is about to deliver CHAdeMO (rapid DC charging) with the rollout of Prius Prime in Japan. There's not a big benefit of having such high-speed abilities with only a 8.8 kWh capacity, but a future EV offering certainly would.

Toyota is also pushing dealers to begin the acceptance of change. Prius Prime will usher in a graceful transition. Rather than having to face the intense support battles other automakers have to deal with, the modest EV capacity will ease them into it.

Toyota continues to refine motor, controller, charger, and software for electric-only operation. How is that not beneficial to future EV offerings?

Want more? Think about how much easier it will be to sell EV offerings to customers later, who owned a Prius Prime prior to that and upgraded their garage by adding 240-volt charger. Having that equipment already makes the next purchase yet another benefit.

In other words, the full story is that Toyota is doing far more for EV advancement than people are giving them credit for.

10-07-2016 **Growth Misleading.** The message from this quote is what I've found quite troubling: *"...Then the number of available plug-in models has grown faster in the past 6 years faster than hybrids did in their first 10."* It's told over and over again, with no regard for omissions... even when called out. It's really an excuse. They just don't see how damaging their effort is. Excusing slowness masks the true problem. The "*faster*" claim doesn't address the "*Who?*" question. On a very regular basis, we are assured all is well. They don't care about tax-credit expiration difficulties. They don't care about the growing level of conflicting choices. They don't care about the aspects of business. All they care about is better numbers than in the past. That's like being happy with a "C" grade, because you got a "D" in the past. Ugh. I posted this in dismay about such nonsense continuing: That's an overly simplistic summary which portrays circumstances as being similar. We can argue difference details until the cows come home, but it won't do any good. A fundamental mistake continues to be made... sadly, by the majority. Most people are overlooking scope. They assume the audience is just a growing number of homogeneous buyers. Who they are isn't being taken into account. Such a flaw in logic must be brought to the attention of all those celebrating the supposed faster progress. Reality is, current buyers are still only early adopters. That low-hanging fruit is running out too. We haven't seen any affordable offerings selling in a market without tax-credits either. If the subsidy money runs out before those vehicles become well established as a mainstream choice, potential buyers will just move on to something else. Why purchase a plug-in when their prices aren't competitive with traditional vehicles running on cheap gas? Audience is absolutely vital. Sighting statistics that only represent early adopters causes us to incorrectly perceive progress.

10-07-2016 **Rough Edges.** It amazes me how even the most devoted supporters of Prius don't know the history. Perhaps they don't have an effective means of learning it. You must immerse yourself to understand that perspective of the past. Simply reading a summary looking back doesn't portray the nuances required to really grasp what was happening back then. You can't appreciate how different things were, especially with so much uncertainty of what the technology will offer. When you don't know what's realistic or even possible, how can you anticipate market reaction. It's far too easy to distort and overcome assumptions long after you already know the outcome. We didn't back then. So, the rollout of Prius was different from how people then to think of it. People tend to forget about the attitude back then too. We were encouraged to guzzle oil and couldn't care less about emissions. It was a wasteful, uncaring situation. There was a lot of pressure to retain the status quo as well. Change was fought against. Looking forward to battery improvements was unheard of. There was no expectation of any sort. It was all about how much bigger and more powerful the next SUV would be. That's why original accounts of Prius are so skewed. Recognize how different things were. Take the time to read these blogs... the (gasp) thousands and thousands of entries accounting for that history as it played out. There's nothing more effective than reading documentation written at the time those events occurred. The one example I can point to is the exclusion of cruise-control on the 2001 model of Prius. People were baffled how such a basic feature would be excluded, especially when it was so simple & inexpensive to provide. It should be obvious why Toyota made that choice. They wanted to attract only those truly committed to the technology change Prius was introducing. A paradigm shift on such a magnitude requires devotion, even if it means a big tradeoff. Sound familiar? The switch to 4 seats resembles that. Of course, there is the benefit this time of introducing luxury seating in back. The feedback from those first buyers, not the critics, will determine the next choice. Leaving it rough around the edges is like not pouring cement for a sidewalk until walkers have worn a path of where they prefer to walk. Toyota could bring back the middle seat. Toyota could stick with 4 and introduce heated seats. Those are mutually exclusive, each offering a benefit. Understanding audience is key. There is no certainty. You have to try. Markets fluctuate too. Just look at what people demanded back when Prius PHV was being developed. That's quite different from what they ask for now with Prius Prime. Study the past. Consider how those rough edges should be smoothed.

10-07-2016 Prime MPG. Basically, Toyota pulled off the impossible. The belief that adding battery-capacity will reduce efficiency due to the increased weight of the vehicle is quite common. Ask yourself why it wouldn't. It's so counter-intuitive seeing numbers to the contrary, there's no precedent for the situation. Yet, here it is. ECO: 56 combined, 58 city, 53 high. REG: 52 combined, 54 city, 50 high. PRIME: 54 combined. 55 city. 53 high. The higher MPG numbers from the ECO model is to be expected, that's the "economy" configuration. No big deal. Your expectations are realistic. But with that difference between the regular model and the plug-in... Whoa! That solid 2 MPG difference really emphasizes the technological step forward... since it stirs questions how. Removal of non-essentials didn't take place, as with the ECO model. The PRIME somehow achieved improvement over the REG without taking anything away... to deliver a gain! How isn't really important either. After all, mainstream consumers don't understand the engineering anyway. They know MPG quite well though. That combined estimate of 54 speaks volumes. Even without plugging in, the resulting efficiency will be well above what a non-hybrid could deliver. It's a major selling point not to be overlooked. It means you'll get outstanding efficiency no matter how you use your Prius Prime. *Yeah!*

10-08-2016 Preconditioning. At least it's a new topic to discuss...

The definition of "*preconditioning*" is already all over the place. First, it was referred to as a battery warming method from using cabin air. Then it was direct for providing full operational temperature. Next, it was to just keep above freezing to allow recharging.

That raises a bunch of red-flags. Misconceptions emerge from the lack of clarity. Greenwashing emerges from no one making an effort to stop the exploitation of assumptions caused by so many vague mentions.

The first that jumps out is that the battery cannot be charged when its temperature is below freezing. That is implied and certainly could be interpreted that way. It's false, of course. The warming is to make the process more efficient. Colder means higher resistance, which means more electricity will be consumed as part of the transfer process (in both directions, charging & drawing).

The next problem would likely be the belief that EV simply isn't available if the temperature of the battery drops below freezing. That most definitely isn't true either. It's not as efficient, but drawing electricity for driving certainly is available. If you push demand, by firing up the heater or pushing speed & power, the lack of warming would require the gas engine to join in at some point. But we know for certain even the Prius PHV from 2012 can deliver EV at 50 mph without any trouble at 20°F just fine. I would do that routinely with mine, and it didn't have any warming feature.

Then there's the confusion of cabin warming. The system will use the heat-pump for that. Even the better informed will pause to consider whether the battery is used for that or if electricity is drawn directly from the plug. Then they'll question what happens with timing and the charge-rate at different capacities and with faster chargers.

Needless to say, topics like this open up a new cans of worms for us to deal with.

- 10-09-2016 Understanding MPGe.** This new measurement system to convey electric efficiency baffles people. Until recently, I even stayed away from it. Why mention something so different without much real-world data to compare to? People won't understand what that MPGe number is trying to tell them. For example: *"Amazing to see how Toyota is always chasing Chevy Volt in fuel economy numbers when so many years ago it was the other way around."* The big battery was all Volt enthusiasts understood for the longest time. They laughed hysterically when I pointed out electric guzzlers. They simply believe guzzling electricity was fine. You could use as much as you wanted, as long as little to no gas was consumed. How do you point out that some systems are more efficient than others when electricity is perceived as clean & abundant. I'm starting the process, now that we have a wealth of new data to work with. In this case, it was a comment to a MPGe article about Prius Prime on an auto-enthusiast website: Prime's lower production cost (and resulting MSRP) makes it a serious contender for the masses, especially since rear-seating height is midsize rather than compact. That MPGe rating indicates how much more efficient of a system it delivers, reflecting some of how the lower production cost is achieved (the other being the new TNGA, Toyota New Global Architecture). It needs less battery-capacity to travel the same 25 miles. For my 19-mile commute, where I can recharge at work, greater battery-capacity wouldn't provide any benefit. For my other driving (frequent long highway trips), the 54 MPG rating for hybrid operation following depletion is a big plus.
- 10-09-2016 Random Summer Commute, video.** This was actually test footage from my new camera. I didn't even bother with the complete glare-prevention setup. It was just an experiment to capture some video samples. Summer's end came far too soon though. I didn't get a chance to film this particular commute route in warm weather again. And since my Prius Prime has now been ordered, I won't ever get the chance with the 2012 Prius PHV. So, I'm sharing this. It actually turned out really well. You can see there's a decent amount of randomness. I start with EV mode, then switch over to HV mode after the first stoplight. Once the engine warms, you can see me switch back to EV. On the big hill, I switch again. On the ramp to the highway, I accelerate faster than the 100 km/h (62 mph) EV maximum. You can then see the system automatically go into EV-BOOST mode. That's a blend of high-draw from the battery-pack along with a low-power assist from the engine. Rather than getting off the highway to drive along the river, like I usually do, I stayed on and drove into the city. From there, I enter the ramp for work from above. Check out the resulting MPG from the ride. The average of that random mix of driving showed an impressive overall average... [Random Summer Commute](#)

- 10-10-2016 Recognizing The Problem.** Voices of reason are starting to increase. I was pleased upon seeing this today: *"still, a difficult thing to pull off in a 27k vehicle."* Problems of the past came about from not taking the cost & price criteria seriously. Enthusiasts just blew off that concern... for an entire generation. Of course, when the next generation rolled out and the same problem remained, things got ugly. That's the market Prius Prime will be entering. Having so much lower of price positions it ahead, despite no sales having even taken place. The potential gauges expectations. Being able to reach a much wider audience, as well as endure the expiration of tax-credit draw, makes it a strong business case. That was never the case for GM with Volt. I got attacked relentlessly for pointing that out too. Now, those antagonists agree. They doubt admit it. But simply having abandoned it in favor of Bolt is recognition enough. As for Toyota's opportunity, I pointed out: That has been the heart of the problem with Volt, ever since the reveal way back in 2007. Doing all that was promised for "nicely under \$30,000" defied logic. Yet, enthusiasts proclaimed it was realistic and attacked those who pointed out anything to the contrary.
- 10-10-2016 Being Fake.** I know remarks to this won't be taken seriously: *"Yes, I agree that Most Prius supporters are 'fake green' supporters."* After all these years, the brainless belief of less gas being cleaner is obvious. Most people fall into that trap. They don't give it a second thought. That's why VW was able to deceive so many. Reducing pollutants was assumed to be *"green"*. In reality, it was really just a "D" grade effort. To earn a higher grade, it would be costly and requires a paradigm shift. Toyota was willing to make that big expense & effort commitment... even if it meant greenwashing fallout along the way. Thankfully, they stayed true. The gen-4 Prius is truly remarkable. The opportunity it ushers in with Prime is amazing. I'm so excited to be part of the rollout. In the meantime, it's making sure everyone really understands the situation, as I put it: *"fake green"* is portraying MPG and using less gas as the only measure of progress. It's too bad so many people totally blow off the emissions. The PZEV and SULEV ratings really make a difference. Look no further than "clean diesel" for a dose of reality about the other aspects of being green.
- 10-10-2016 Great Analogy.** I really got a kick out of reading this: *"Naturally, Toyota is sensitive to comparisons with the Chevrolet Volt, which offers double the EV range in similar packaging. In defense of the Prime's modest capabilities, Toyota offered this analogy: When you go for a run, you don't carry a gallon jug of Gatorade."* That should make you think. A good friend of mine pushed that perspective for a long time. Why have more battery than you actually need? Depleting it 100% each time you commute is proof of money well spent; you're getting every penny possible out of that investment. Unused capacity is what? It's wasteful to have too much. Ironically, troublemakers of the past use to use the *"dead weight"* argument a lot. They have all vanished, since bringing that up exposes them as being hypocritical. I find it intriguing how some people just plain don't understand *"right size"* importance. You'd think that would be obvious. Clearly, it isn't. Perhaps the Gatorade analogy will help get the point across.

10-11-2016 **New Greenwashing.** How would you deal with new greenwashing? In my case, the effort comes from an enthusiast with obvious bias. He continues to push that 0-60 acceleration in 15 seconds is far too slow, to the point of endangering others. The fact that not a shred of evidence has been provided is annoying. He's spreading FUD. If maximum acceleration is needed, you switch modes. It's like shifting down. You have the option if you so desire. If not, you just switch to automatic mode and never ever have to give the matter another thought. Geez! This is how I dealt with it:

Your past experiences with some problem owners explains the stance you've taken. It's a stereotype not representative of most though. Look around, there are lots of other slow drivers with powerful vehicles. I get annoyed waiting behind them.

From my point of view, I see post spreading fear, uncertainty, and doubt in this thread by a variety of people. So, I seek out individuals with influence to help set the record straight... before it contributes to greenwashing.

There are dozens of Prius PHV videos that I've published on YouTube. Do a search for the "*priusguru*" channel. You'll find a collection showing ordinary driving, complete with real-time dashboard information. Some even included OBD-II data.

As for the discussion at hand... 129 MPG was the average for my 41.3 round-trip commute today, which included one stop along the way in the morning and two while returning home. Recharging the 4.4 kWh battery in Prius PHV at work provides a minimal approximation of what the 8.8 kWh battery in Prius Prime will deliver only charged once. Knowing the next-gen system is more efficient, expecting more is quite realistic.

In other words, I fail to see the point of stressing purity. So what if the engine fires up for a minute? Effortless results around 125 MPG are still triple that of what a high-efficiency traditional vehicle would deliver.

People driving shorter distances or recharging at work will get even better MPG.

Watch the videos. It should become clear that Prius Prime will offer the power you say is necessary.

- 10-11-2016** **Divert & Stop Gap.** The discussion immediately fell apart. He couldn't care less about anything other than electric-only range. It become a sad attempt to promote Volt, then turned into a dismissal of plug-in hybrids being anything but a short-term solution to EV takeover. Offering a comfortable ride at an affordable price simply wasn't a concern. Add him to the large list of those who just plain don't understand the automotive business. That particular group is made up of enthusiasts who focus on engineering above all else. Selling large numbers of profitable vehicles that only offer average performance is boring & meaningless to them. It's what I've been dealing with for just about 17 years now. They simply aren't interested in what accountants or economists have to say. It's all about getting consumers excited. Clever marketing is more important than actually delivering upon need. They figure appealing to want will cover the owner's priorities... even if it requires significant sacrifice. Seeking a balance is not acceptable. Ugh. Of course, I knew this was coming. That's why I've been participating online for all these years. The return on that research will really pay off... eventually. I know. Patience.
- 10-12-2016** **Parking Brake.** A recall on the gen-4 Prius was issued. Some articles used words like "*deadly*" and "*dangerous*", others simply mentioned an issue with the parking brake. The problem comes about if you get out of the Prius while the system is still in gear, using the brake to hold the vehicle in place rather than putting it in park. Who would do that? Leaving it in Drive or Reverse isn't something any owner I've ever heard of has done. Someone must have though. Possibly not. We really don't know. All we've been told is that clips will be added to the cable's dust boot as a preventative. No big deal. Sounds like an effort to ensure longevity. But then again, you can't fix bad behavior. Who would leave their car in gear like that when running but stationary? I guess that helps to show the diversity of buyers Prius attracts.

10-12-2016 The Next Chapter. This time last year is when things really got shaken up for plug-in market expectations. The new Prius was revealed. The diesel deception was exposed. And the new Volt was rolled out. Finding out "clean" wasn't actually true made the case for Toyota's fourth generation hybrid a simple argument. Favor clearly swung to it. However, the earthquake damage that happened just as production began at the start of the new year messed up inventory expectations... and have consequently provided greenwashing with numbers to mislead with. Fortunately, the RAV4 rollout then wasn't affected. The wait for gen-2 Volt ended then too. Unfortunately, it was already doomed upon arrival... too expensive, too small. That's why attention rapidly shifted to Bolt. The reveal of Prius Prime added to that new found focus. Now upon the rollout of both, we see this: *"Bolt EV is a step forward, a very nice but small one – a baby step, if you will."* That came from a person who had been a die-hard Volt enthusiast but was now all for Bolt instead. Today's discussion topic made the reason why obvious. The base price will be \$37,495 and the premium \$41,780. You want the "Driver Confidence" option, add \$495. You want the "Infotainment" option, add \$485. You want the DC charging (an expectation for high-capacity electric vehicles), add \$750. You want Blue, Red, or Orange paint, add \$395. A large screen and DRCC (dynamic radar cruise control) aren't even offered. How is this vehicle supposed to compete with Model 3 from Tesla? It's expensive and utilitarian. What the heck? Needless to say, all this nicely sets the stage for Prius Prime. It is a step forward. It is a baby step. But what it offers that others don't is affordability. That's a profound difference... which was sighted many years ago as the criteria for changing what the masses actually purchase. Nice vehicles beyond their reach don't accomplish much.

10-13-2016 Leaf Upgrade. Attention is fading from GM. The first Bolt deliveries aren't expected until the end of the year now and supposedly only 11 states will receive them. What happened this time? With all the bragging about no delays, this explains the sudden quiet. That's nice. It gives others a chance to show off their offerings. Nissan is making a splash with their upgrade to Leaf. The battery-pack will be increased from 24 kWh to a larger capacity of 30 kWh without taking up any more space. That's impressive. It adds 23 miles of range. The official EV estimate climbs to 107 miles. Up from 84, that sounds great. However, the price rise of \$3,350 is a head-scratcher. Keeping Leaf competitive with respect to range at the sacrifice of cost is an unknown the market hasn't faced yet. With that higher sticker, you also get the quick-charge feature. 80% capacity in just 30 minutes is impressive. How many owners will be able to take advantage of that though? If nothing else, it does help ensure resale value will hold up longer. Next year, the expectation for Leaf is a 200-mile range from a 60 kWh battery. That should be interesting.

10-14-2016 **Luxury Approach.** Treating Lexus as if it is just another dealer location for Toyota is a fundamentally flawed approach. Yet, it happens all the time. Some people don't see the difference. That's causing more and more trouble. It's mystifies me how so many just assume quality alone is how they are identified. But then again, we have lots of trouble when comes to discussion of economics. In fact, just conveying the idea of diversity often a challenge. That makes the measure of its importance almost impossible. This is why the diverge of Prime is so hard to understand. The purpose of the dual-wave window, rear seating, and large screen isn't getting any recognition. The overlook & dismiss. It makes constructive discussion quite a struggle. Anywho, you need to have a good understanding of this to appreciate what Lexus is attempting to do. The luxury market is being redefined. BMW was already seeing pressure in Europe. Sales of Tesla there have caused an interesting shake up. You get a remarkably quite, smooth, and powerful vehicle that's incredibly clean. Attempting to sell a V8 with 400HP competitively without facing the consequences of emission concerns is impossible. That audience is willing to spend more on their purchase too. As if that wasn't complicated enough, the fallout from VW's diesel cheat is forcing the acceleration of electrification efforts. Such a massive push into the mainstream puts even more pressure on the luxury market... which brings us back to Lexus here in the United States. Why would they jump into that mess? Why not wait until Tesla overcomes the challenges with Model 3 rollout? It buys time that can be very well spent. The production & sales of Prime will provide incredible insight about how to address luxury market needs, which won't be as forgiving as the mainstream. It makes sense. It's not like Toyota can just offer an upscale model of Prime as a Luxury and expect it to be a hit. After all, there has already been a number of attempts to draw hybrid interest at that level which didn't result in many sales. They are not the same buyers with a larger budget. They are totally different audiences with entirely different competition.

10-14-2016 **Charge Mode.** This new feature is stirring quite a bit of discussion. Toyota was really clever about presenting it too. With the previous generation Prius, we routinely got reports of it offering 3 modes... Eco, Power, and HV/EV. Seeing 3 buttons, it was an easy assumption to make. Almost none of the reporters were thoughtful enough to actually try them out to the point of noticing there was a 4th option available. You press the button, it turns on the mode. You press it again, it turns it off. That's a mode too. We call that state of nothing special as "*Normal*". No mention was a great indication of not researching well. The new "*Charge*" mode is even more subtle. To engage it, you must hold the HV/EV button. That's intentionally not obvious... because the way it works isn't. If you find it, there will likely be some type of knowledge transfer along with it... like reading this. The complication comes about much like stealth mode. When people first experience that non-EV electric-only propulsion, they get the impression using it as much as possible is better. It's not. In fact, using too much can actually result in lower overall efficiency. The same is true in this case too. Additionally, it changes the way the system behaves... hence being a mode you purposefully choose. The comment today from someone test driving a Prime was: "*WAAAAYYY underpowered. It felt like an ECO mode for the ECO ... :(*" He clearly didn't understand when to use it. We need to provide that operational facts, to empower owners to make informed decisions. This interactive process with supporters is what Prius thrives on. Toyota cannot provide it. The benefit is that coming from owners. It's a very effective way of drawing interest to grow the market. No advertising campaign can sway interest like that. I enjoy the opportunities to share like that. Here's a start: The intended user is for while highway cruising, when you have excess power available. It takes very little to maintain constant speed. So, that works out well for overall efficiency. It is nice knowing it works elsewhere too. Though, I don't see a benefit on suburb roads.

10-15-2016 Those Blinders. Fixing entirely on EV range, while ignoring other factors like price and seating, is an indication of trouble to come. Long ago, it was the ignoring of emissions. Focus was completely on MPG. Believing that's the selling point, that nothing else mattered, gave the impression of a different purpose. For Prius, emissions were paramount. Using some gas for the sake of cleaner emissions just plain didn't make any sense... so much so, supporters would argue amongst themselves... hence the trouble. Today's warning sign came in the form of: "*true, but with volt, you get 50 miles ev, which is huge.*" Enthusiasts can get away with perspective like that. But selling to a wider audience consisting primarily of mainstream buyers, no. We have new topics to address too, requiring those blinders of the past to be taken off for a fresh look now:

My driving consists of commute, short jaunts around town, and long trips. More EV isn't enough to justify the tradeoffs. CHG opportunity will be handy for me, since those trip destinations don't offer a plug. Also when I travel (like regular escapes up north), the seats are down to carry all our stuff. That reduction of height in the back really won't make any difference. It's the length & width that has always been the cargo benefit. I suspect many others will see those same advantages.

There's an interesting twist too. Isn't the advantage of having extra capacity not having to plug in? If I had 50 miles of EV available (rated estimate), winter commutes wouldn't have the benefit of pre-conditioning. Would you really pay for or consume a charging spot for only pre-conditioning? Capacity drops roughly 30% due to efficiency-losses and cabin-warming in the cold weather driving. That would make my 19-mile commute a challenge. Being plugged in at work means I stand a chance of making it totally with EV.

It's situations like that people haven't considered yet. We see a lot of dismissals on review article comments, simply suggesting to get a Volt instead without giving the situation any thought. In other words, we've learned that real-world outcome doesn't always match on-paper calculations... especially when it comes to Prius.

So when it comes to the variety of new design aspects, charge-mode, pre-conditioning, and higher-capacity, we really need to step back and think about all that's involved. After all, most people have no idea what that one plug-in uses resistance heating and the other a vapor-injected heat-pump. So, trying to point out efficiency differences will basically be futile.

Real-World data will speak for itself. Watch what those numbers tell us.

- 10-16-2016** **Starting Over.** We're seeing more than just a generational hand-over this time. With the emergence of Prime has come far more than just questions of how the hybrid system has been improved. Operational differences from the introduction of a clutch complicates matters greatly. There's simply no way to realistically anticipate behavior. Heck, even knowledge of the previous plug-in model (Prius PHV) doesn't directly apply. We're trying to figure out a paradigm-shift without having any way to research or even any data available. All we know is that Toyota studied the market intensely and strived to deliver the best balance of price & performance. That's obviously making discussions extremely difficult. We can't just tell people to be patient either. The level of excitement is quite intense. Some are seeing the perfect fit. Some see an epic failure. It's quite bizarre starting over like this. I can't wait to contribute real-world data. That certainly will help discussions take on a constructive tone. Right now, we're all over the place attempting to help those curious to learn more about what the technology has to offer.
- 10-17-2016** **Diesel's Demise.** What a mess. The expectation at this point is for close to 100% buyback. There's simply no way to deliver a fix. Anything you do to cleanse emission will impair performance. It's that simple. Nothing can be done to save diesel. Why bother anyway? It makes no sense pushing a 40 MPG technology when plug-in hybrids that easily deliver twice that are rolling out. The clatter of diesel for supposedly cleaner driving is now a memory of the past. VW is forced to all but entirely abandon efforts. With BMW pushing the plug, the rest of the industry doesn't even matter. That domestic competitor (in Germany) is really ramping up efforts and government incentives to do so are growing. Heck, even the certification process for sales here is much more complicated. Loss standards & testing of the past are long gone. Diesel for passenger cars is basically dead as a result. It's simple not worth it.
- 10-18-2016** **Tax-Credit Timing.** Questions are emerging. Many are random. Those asking don't have idea what to look for. It's an entirely new topic for most. You'll hear different responses for different supporters too... since there's some conflict of interest involved. GM's predicament is the big one. Pushing Bolt means sacrificing Volt. It's a simple reality of only having a limited number available. And once the tax-credits run out, that automaker is sunk. So, the inevitable expiration is a really big deal. That's what contributed to Toyota holding off on Prius PHV and Nissan being ok with reduced sales until gen-2 rolls out. Think about purpose. The subsidy is intended to help the automaker achieve high-volume production quickly, so cost will be reduced to a competitive & profitable level. Sooner is definitely better. Toyota is well aware of that too. They could seriously ramp up production of Prime in a year or two, taking advantage of timing once the quantity limited approaches. Nearing that means speed to market become vital. The trigger switches the money payout from a count to a timer. In other words, once the 200,000 limit is reached, the automaker will have 1 year of reduced tax-credits to take advantage of. Being well positioned to deliver a large quantity at that point rewards both business & consumer. I summarized that in this response: Toyota has around 155,000 credits left, before the phaseout is triggered. Then it's a 50% reduction for 2 quarters. Then again (down to 25%) for another 2. So, sometime within this generation, the credits will be used up. GM, Nissan, and Tesla's will all be gone around then too. In other words, within the next few years the entire market will shift somehow.

10-19-2016 **Way Back.** I got a kick out of reading this: "*Deja vu. Remember this thread? Prius PHV: Optimization strategy with lessons learned from the prototypes.*" He was looking back through his own posts many years ago, when Prius PHV was being rolled out. We were discussing operational approach. People discussed the pro & cons of wanting a charge button. The prototypes were configured for data collection. Toyota wanted a massive amount of real-world experience documented. Turns out, that was so effective, they continued doing that following the initial rollout. Since it was mid-cycle anyway, what was the rush? Why not restrict availability to a limited market for the sake of advancing market research? You learn far more from sticking with a controlled scope than to just open up to a wider new audience. Those better informed niches can reveal what's difficult to gain from the uninformed. In fact, that's why I pushed so hard with the enthusiasts. The knowledge gained from their resistance was priceless. Anywho, this is how I replied: I have no doubt that high priority of best use for the gas engine continued. Prius isn't going to sacrifice overall efficiency simply for the sake of offering more EV... unlike what others have done. The approach is to seek out a balance, despite the wide variety of uses it must fulfill. The expectation is that we'll see outstanding performance from charge-mode in some cases (like highway cruising), where we'll promote the use. In others, we'll discourage. But even when it's not as good of a return, it will still be clearly better than what a traditional vehicle offers. It is interesting reading those old posts. That serves as a great reminder of what market expectations were and how they've changed since.

10-20-2016 **Dumb Questions.** This is a definite sign of progress: "*OK, thought of a (maybe) dumb question. Is there a standard for the plug configuration on the car to enable the use of all public charging stations?*" It's absolutely fantastic getting a new member diving into discussions like that. There's a lot of information to share. It's difficult to know where to start and what level of detail should be provided. I gave it this attempt:

Level-2 is that standard (ordinary 240-volt charging) for public chargers. Leaf has a connector for it, but also offers CHAdeMO (like Prime in Japan). Tesla has an adapter available for it. CCS is the other high-speed type. Since both require higher voltage lines and deliver more amps, they are much less common. Level-2 is quite capable and the backward-compatible plug is an obvious benefit. That's why most of the automakers offer that.

Level-1 is supported by the normal household outlet in your garage. Most people will simply use that 120-volt connection for the slower charging overnight. The size of the battery-pack accommodates it well, a fact overlooked when considering the capacity. You just plug & play.

Prius PHV (Toyota's first plug-in hybrid) offered a great opportunity for real-world study. The limited rollout into select areas spread across just enough owners to figure out what really was needed. That's vital information when attempting to deliver a configuration capable of competing directly with traditional offering. That meant keeping costs low, but not sacrificing ability.

Watch for reports from new owners about how well Toyota targeted Prime. And of course, keep asking questions. There's nothing dumb when it comes to entering an entirely new market. People have to start the discovery process somehow.

10-20-2016 **Blog Changes.** Notice how my blogs continue to evolve? They've become longer and delve into new topics with lots of detail, despite not having real-world data available yet. That comes from the posts online. The comments in reviews and on forums are advancing into the world of electrification well. Topics of discussion nearly impossible with gen-1 offerings are now surprisingly easy with the gen-2 arrivals. Speculation has given way to specifications. That's huge. The improvement is quite significant. Rather than having to deal with rhetoric, we are seeing some thought given to operational detail. True, there's still the mindless "*more is better*" mentality. But that will be easy to squash when Prius Prime owners begin posting their experiences. The MPG results will finally shift the conversations over to KWH and GALLONS instead. That's long overdue. The senseless greenwashing of the past from Volt enthusiasts was so harmful. They'll held back progress just for the sake of pride. Thank goodness the kick in the butt from other automakers brought that to an end. Tesla, Toyota, and BMW sure brought about a big dose of reality. Now we have VW scrambling to overcome their diesel disaster by turning to battery technology. It's about dang time... and I'm quite pleased to be able to document this history as it changes.

10-20-2016 **Extreme Examples.** It annoys me to now end when someone posts an exaggeration as if it was the norm. When it's an attempt to greenwash, calling them on it is pretty easy and without consequence. When it comes from an attempt to be serious, but really being clueless, that's an different situation entirely. You really don't know how they'll respond, but what to clarify the misleading information they just posted. This was such an example: "*However if you mean it is -30°C outside with 10cm of snow and ice on the windshield, it won't clear it.*" Reading actively engaged posts in an discussion about electric heating is exciting. Entirely new topics like that are quite refreshing; however, incorrect portrayal can lead to misconceptions. So, I jumped in:

Ugh. Living in Minnesota since for the past 39 years, I'm well aware of winter driving extremes. The odds of it being both -22°F outside and getting 4" of snow at the same time is pretty much never. Snow flakes don't form when it's that cold. You get a light coating of thin ice crystals, at best.

A far more realistic example... which I will experience firsthand in 3 months... is the Prius sitting outside all day with the high temperature of -1°F. That happens every year. Warm-up takes about 10 minutes with the engine starting up right away. Defrost usually isn't needed, since I vent prior to stopping. It's just get in, make sure the seat-heater is on high, then drive away.

With the Prime, windows will certainly be clear already. In addition to the heated seat, the steering wheel will provide warmth too. Driving away will be comfortable. Heck, even the battery-pack will feel the improvement. Those extreme cold days will take a bizarre twist. What a great feature to draw interest.

As for dealing with 4 inches, no one would ever run there vehicle long enough to attempt to melt off such a thick amount. Even my idiot neighbor who would idle her diesel for 45 minutes before leaving for work would brush the windows off quick with that much snow. Of course, there are those who just sweep a tiny viewing hole and drive away with a drift on the car still. But that's only when the temperature is much warmer. Between 20°F and 32°F is when we get the really heavy dumps.

Long story short, the new vapor-injected heat-pump has much to offer.

10-20-2016 Encouraging Articles. It's nice reading articles with points like this: *"Yes, the Volt has much more electric range, but you'll pay for it. The Volt's entry point is \$33,220, while the Prime starts at \$27,100."* Glossing over detail in the past was a big problem. Of course, some still don't mention that the 5th seat is legless, only for a small child or an adult willing to straddle the middle and share space with the 2 other passengers in back. New highlights are getting attention too: *"And on MPGe, how far an electrified vehicle can go using the same amount of energy in a gallon of gasoline, the Prime bests the \$42,400 all-electric BMW i3, with a 133 MPGe rating vs. the i3's 124 MPGe."* The efficiency of EV was completely disregarded until recently. That's unheard of for gas-engine comparisons. Why was electric-motor consumption just blown off as unimportant? My guess is nothing to compare with. Offerings were so scarce, the assumption was just that a bigger battery was better. The new MPGe rating reveals that's not the case. This makes reading the comments on such encouraging articles very interesting. Those who understand are really making an effort to make sure others do too.

10-21-2016 Public Charger Concerns. The situation is quite complex.. and that's just location! Taking into account how they should be used makes it even more difficult to deal with. This is a big deal. Very little progress has been made so far too. The past few years lacked enough owners to get any type of uniform message formulated. We are very much in the early stages still. Think about how long it has taken for those Volt enthusiasts to come to the realization that the size wanted to actually match need. Heck, some continue to question the conclusion drawn. Anywho, it was this that stirred my response: *"My other concern about charging stations is how many would truly be needed if everyone was driving EVs."* It came from that website which abandoned Volt in favor of Bolt, discussing the problem VW now faces with investment into electrification infrastructure required by the diesel settlement. My reply was:

That's one of the uncertainties about plug-in vehicles holding back acceptance. How many? How much? How soon? Fundamental conflicts of intent are raising concern. What is the purpose?

If you have a 200-mile capacity, what benefit is there plugging in at a grocery store, coffee shop, restaurant, theater, or mall? Those destinations are almost certainly within range, so there's no point to recharging. A plug-in hybrid with just enough range to cover a daily commute is an entirely different matter. The gain from recharging at one of those destinations traveled to after work could be enormous.

Think about the CHAdeMO option available for Prius Prime in Japan. You arrive at a grocery store with the battery close to or already depleted. During your stop to shop, that rapid recharge would be enough to get you back home using that freshly provided electricity. The point of plugging in is obvious.

In other words, that "right size" approach has a draw those long-range EVs don't... especially when you take the lower cost into consideration. Toyota used this analogy to describe the situation: *"When you go for a run, you don't carry a gallon jug of Gatorade."*

Ordinary consumers will see it that way too. Isn't the point of have such a large battery to avoid having to plug in while you're out and about?

10-21-2016 **Wanting More.** This is as far from news as you can get: *"Americans don't like to be limited. We want/need 2-3x what is really required."* We've known about the "more" problem since the day Prius rolled out. The problem is the same. No change. Want still gets mixed up with need. Ugh. I addressed that comment with this perspective:

How many times was the "Who?" question asked? Know your audience.

You are absolutely correct about the perception of being limited. Automakers have taken advantage of that for decades, marketing based on emotional appeal rather than logical choice.

Look at how absurd SUV sales took off. The large & powerful draw hoards of buyers. That market became saturated though and fell apart. People don't buy them anymore. In fact, looking out onto the parking lot now, I don't see any. They are all small now. Purchases have shifted to more of a balance of want & need, rather than catering exclusively to want.

That is the difference between niche & mainstream. Want is limited in some manner. Need will ultimately win the quest for profitable high-volume sales. The priorities of the masses don't allow them to seek out the most desirable choice.

In other words, we'll end up seeing battery-capacity adjustments. The automaker with the best research may get ridiculed initially, but they will be the ones reaping the benefits of a business-sustaining solution rather than flaunting trophies for best engineering. It's a tradeoff. Need is more important than want.

We truly don't know what the winning configurations will be. A majority of buyers will get drawn to something. Notice how 4-cylinder engines emerged that way for middle-market? 6-cylinder engines are available still, but far fewer are produced & sold. Battery-Capacity could easily see similar demand.

The limited choices initially and lack of both commercial & home infrastructure contributes to much uncertainty. What is certain though is time. The tax-credits will be used up. When that happens to an automaker, the resulting competitive response will put a lot of pressure on the other automakers. Waiting is not an option. The clock is ticking for all.

In other words, need will win out over want.

10-22-2016 **Incorrect Information.** A big problem we've had with each new generation rollout of Prius is the poor research. Publications will get someone to write up a story on the new Prius. Many of those writers clearly don't actually test-drive the vehicle... leading to countless assumption problems. That's why Toyota has been doing so much with promotional events, providing firsthand opportunities to drive one. That's also why Toyota didn't rollout beyond the initial markets with Prius PHV. The deterrent to Prius Prime wasn't obvious then, but the wisdom of that choice is becoming easy to see now. The act of researching online isn't always well done. Some don't even realize there was a previous generation. They just find information, they write about it. A good example of that today was a slew of correct detail for Prime followed by a quote of "*11 miles*" for the electric-only range. Ugh. It's really unfortunate from an otherwise really nice article. Sadly, people researching a purchase of one will stumble across that information... thinking it is correct. Far too often, we see the trouble caused by those same people taking what they read at face value, never bothering to confirm it with another source. It's how greenwashing is unintentionally spread. They don't know what they pass along is wrong. Antagonists wanting to undermine take advantage of that. In those articles, they'll post misleading comments to support the greenwash. In forums, their posts will refer to the incorrect information. Grrr.

10-22-2016 **Pushing Lithium, part 1.** That antagonist is at it again, attempting to stir trouble by attacking with new material. This time, it was in response to comments about pushing lithium battery production. He immediately lashed out by listing models from VW (which includes Audi & Porsche). It was a pretty lame attempt to insult Toyota. I took the bait and replied with: "*Pushing means high-volume production. VW clearly is not yet.*" He took my bait by posting numbers. I figured he was that desperate. Posting numbers from VW in contrast to Toyota was a clear act of hopelessness. That detail reveals the true story. It also allows me to dive deeper into the topic. Remember problems of the past? I'd patiently wait for an invitation, then strike back with big picture information. His obvious cherry-picking meant it was only a matter of time before his effort to retaliate would be exposed. I've learned over the years, that's the only way to overcome the barrier they build to prevent constructive discussion. Holding onto lost pride feels redeeming to them, but ultimately falls apart. The rollout of Bolt & Prime combined with the reality of VW having to buyback 100% of the violating diesels along with providing compensation for environmental & financial damages is ushering a new market... one that gen-2 Volt doesn't address. No big deal, I see GM simply adapting. They prefer to sell SUVs anyway. Equinox is the clear solution. They shift focus over to it with their plug-in hybrid tech instead. That's a humbling move against what this antagonist has defended for years... hence his lashing out at me. I find it all quite intriguing to witness. Some people have an extremely difficult time dealing with change. This topic nicely points that out.

10-22-2016 Pushing Lithium, part 2. This was his provoke: "*And how many plug-ins did Toyota sell this year? .. yeah .. OK. Toyota = 52. VW group = 7,673.*" I thoroughly enjoyed responding to it with:

The discussion was about PRODUCTION of lithium batteries. That obvious attempt to mislead by changing the topic was rather desperate. But since you did change it over to SALES of vehicles, let's look at that...

VW sold 7,673 in the first 3 quarters of the year here. That is in no way high-volume. It is very much a niche, meaning it is not in a business-sustaining profitable tech. The goal is to replace traditional vehicles. That won't happen without much higher commitment.

Substantially increasing lithium battery production is a way of reducing cost. Doing that will enable lower prices, allowing the tech to become competitive.

That's exactly what Toyota is doing. They'll sell roughly 300,000 regular Prius this year which use lithium batteries. That effort will contribute to the attractive pricing for Prime. That plug-in model of Prius will benefit directly from the non-plug model. It's a smart move. It's good business. It's happening whether you choose to address it or not.

A similar approach is what made Prius profitable way back in 2002. Toyota took the Prius they had been selling for 4 years and reused it as a traditional vehicle. The body was simplified, the engine detuned, and the hybrid system replaced with an inexpensive transmission. It became the vehicle we knew as Echo. That sharing of components reduced production cost for Prius, making it profitable.

GM could redefine Volt as a competitive plug-in hybrid from the benefit of high-volume lithium battery production for Bolt. Dropping the price significantly prior to the tax-credit expiring is essential. The 16,326 sold in the first 3 quarters of the year here represents no growth. Sales were 16,348 in 2012 and 16,760 in 2013. Flat will not achieve that goal. Sales did drop to 14,540 in 2012, if you're looking to cherry-pick for better results. 2015 was obviously lower, due to the prior clearance of inventory of gen-1 to make way for the limited rollout of gen-2.

Toyota struggled this year from the earthquake interrupting Prius gen-4 rollout. Inventory was a problem for the first 5 months. That was unfortunate, but it didn't prevent the diversification effort of spreading the tech. In this case, they were able to introduce RAV4 and sell 32,989 of them in 9 months. That's another opportunity for lower production cost of lithium batteries even more. A plug-in model is a wise move. Mitsubishi's Outlander has been selling remarkably well over in Europe, the purchase total is over 100,000 so far.

GM's choice to offer Equinox as a diesel rather than a hybrid is a step in the wrong direction, the very market VW is now abandoning in favor of electrification. The settlement requiring a major investment into the infrastructure will contribute to that success too.

So... what the heck was your point?

10-23-2016 How Much? Few bother to ask that question. Even fewer actually take the time to measure. Requirements for acceleration are simply assumed, based upon comparisons of other offerings. In other words, an average is taken without consideration of the driving conditions. It's just on-paper calculations. That type of specification comparing is how vehicles have been sold for decades. More is better, period. Effective marketing convinces us of that. Though effective, it's quite a waste. Driving a Prius, you notice the waste. The screen providing detail while you drive makes that easy. That's why the guzzlers don't offer such a feature. Heck, that's why Volt didn't at first too. Now, it does. Consumption of kWh wasn't regarded as important initially. Now, it is. Yeah. Sadly, that's type of mindset improvement doesn't work with acceleration. You don't get stats on how long it really took to merge onto the highway. You just mindlessly follow the vehicle in front & behind you, keeping a safe distance. There is never any time summary provided. Imagine if there was. People would notice the 0-60 time is almost never required. The need to drop the pedal to the floor and leave it there the entire duration is incredibly rare. Oh well. All you can do is share experiences to point that out, like: I merge onto the highway now with my Prius PHV expecting the engine to start. No big deal, the EV-BOOST performance is nice and the remaining electricity lasts longer. Sometimes, it doesn't start though. Discovering I've used up most of my battery from cruising along at 55 mph in EV can be annoying... but it does confirm not as much power is needed as some try to lead is to believe. And of course, with the bigger pack, there's more EV range available anyway.

10-23-2016 Greenwash Traps. There is much speculation taking place now. Not having Prime in the hands of any owners yet is contributing heavily to assumptions. I'll sure be glad when that changes. In the meantime, this list was rewarding to compile & share:

It has been interesting to watch so many take the greenwashing bait. Having participated in the acceleration arguments for the Classic model Prius 15 years ago, I'm quite familiar with the traps you can fall into.

First is to trick you into believing a specific value is required, an essential you cannot survive without. In this case, the 10-second 0 to 60 speed is portrayed as necessary.

Second is to avoid any detail which could reveal that value stated is a misrepresentation of what actually happens in real-world driving. In this case, maximum acceleration is so rare, you'll be well aware of when you actually need it.

Third is to prevent the situation as if there are no other alternatives available, that it is an absolute which cannot be fulfilled by any other means. In this case, the "EV Auto" mode isn't an option.

Fourth is to misrepresent the alternative when it is eventually presented. In this case, make sure people don't discover that the "EV Auto" mode provides blending, like the EV-BOOST mode did with Prius PHV.

Long story short, the antagonists don't want you to discover the remarkable MPG resulting from the use of the "EV Auto" mode. They want you to ignore that button, hoping everyone believes the only way to achieve such incredible efficiency must be through the use of only EV driving.

10-24-2016 Nissan Hybrid. The refinement from 4 generations of improving design isn't obvious... until competition emerges. Toyota's smooth & seamless operation has been taken for granted. In fact, it is so uneventful, some spin that as boring & gutless. There's not a whole lot to counter such an argument point either... until now. The test-drive of Nissan's upcoming hybrid revealed roughness people had never appreciated not having. Basically, the system is a regular vehicle with an electric motor squeezed in. The shifting between without a power-split device becomes obvious. It wouldn't be so bad with just a mode switch, but that sacrifices efficiency. Taking advantage of both power sources presents challenges... ones that Toyota dealt with ages ago. Without a plug having been available, they had no choice but to dedicate engineering effort to refine. That's rather obvious with Prius PHV, which really only needed a bigger battery. The platform already had that type of operation in mind. A harmony of engine & motor was well established. Prime being able to take advantage of more electricity is a bonus. Even without a plug, the efficiency is truly remarkable. Notice how high the MPG is from some new Prius owners? You don't get that with an add-on to a traditional system. Oh well. Gas is still cheap and focus is on plugging in anyway. Nissan will figure out how to offer a choice for buyers. In this case, they are attempting to deliver a small SUV. Think about what will happen when Mitsubishi does next Summer. That will be a plug-in hybrid. Attention will turn to Toyota to do the same with RAV4, especially if Prime sales are drawing lots of attention.

10-25-2016 Renewables vs. Coal. You ever thing about how long it would be until the overall energy output from renewable sources exceeds that from coal? I hadn't. So, the announcement today on the radio about that point having already been reached was a delight to hear. I wasn't expecting that yet. Achieving that makes sense. Solar & Wind continue to produce electricity. Coal can only release energy as electricity once. That's a major fundamental difference. The growth of cells & turbines has been strong lately too. It's a market with lots of potential. The challenges of starting up have been overcome. We now see the benefits of that emerging. Heck, I tend to forget the ramp where I plug in has a massive solar array. Some of the electricity I use to recharge comes directly from that. On sunny days, there's likely quite a bit to spare with an 80 kWh potential and currently only 2 of us routinely using the 6 chargers available. Someday there will be more of us. In the meantime, use of coal will shrink. Yes, I know, some of that is being supplemented with natural gas. Fortunately, renewable is being considered more as a realistic alternative. Time will make it much easier to invest in too. The chargers at the new grocery store near me have both the cylinder type generators and solar to help draw attention to the electricity use. It take very little wind to make those things spin too. It would be difficult not to notice them. Anywho, we are on the right path. This is undeniable progress. Yeah!

- 10-25-2016 Speaking of Coal.** The publishing of these 2 particular photos is a remarkable coincidence. I had picked them out yesterday to be among the series of stuff to finally publish. So, the news this morning hit me really funny. I just happened to have proof to show that I've seen the non-renewable part of the equation firsthand. We were in Wyoming visiting family. Out for the evening to get some dinner, we took a quick sight-seeing drive along the way. Being in the heart of coal country, it was easy to encounter mind-boggling scenes of earth moving. I find it amazing to be cruising along at 80 mph in the Prius through large areas of prairie, then suddenly see massive deep excavation pits appear on both sides of the highway. The well-being of that area depends upon coal... an industry now feeling the pain of environmental pressure. Ironically, those wide open prairies are idea for wind-turbines... a technology only now they are beginning to consider. Anywho, you have to stop to look. So, we did. The monumental scale of those operations is quite impressive. I sure hope they are able to turn their resources toward renewable efforts. It would be great to see an area like that transformed to being a large supplier of clean electricity and equipment manufacturing for renewable energy technologies. Take a look for yourself at what we saw... [photo album 187](#)
- 10-25-2016 Red Road Photos.** We took a trip to Wyoming over the New Year's holiday. I finally got a chance to look through the photos and publish some. Sharing my experiences visually like that has always been rewarding. Looking back at a vacation like that is especially fun. In this case, we found a long dirt road, made up of red rocks. You pretty much never see a red road like that here in Minnesota. The minerals in are ground are different, making the color different. So, I was really excited about having the opportunity to take photos of it with the Prius. The light dusting of snow made added to the prairie background too. It was a very interest... and quite isolated... location to capture. Check out what I saw with the camera... [photo album 188](#)
- 10-25-2016 \$15 Billion.** The diesel disaster is coming to an end. Approval of the settlement was given. Virtually all the diesel cars in violation of grossly exceeding emission limits will be taken off the road, bought back from owners by VW. There was simply no way to fix them without serious compromise. The expense is a high price to pay. Most will go to consumers. There will be some dealer compensation as well, which wasn't actually part of the judgment against VW. The buyback was. Also included in the court requirement was payment to cover environmental damage and funding to help progress the charging infrastructure for plugging in. Focus is switching from diesel to electricity. It's quite an abrupt & unexpected change for the better. Who knew all that smug would ultimately end in such a victory? The outcome is great. The means to which this came was awful. Imagine if VW had just come to terms with the emission challenges a decade ago? Prius owners were well aware of the tradeoffs required to achieve exceptional levels of cleansing. Of course, that was well in excess of the minimum VW supposedly delivered. "50 state" approval is the dirtiest allowed. The PVEV emission-rating Prius delivered was the opposite end of the scale, the cleanest by a very wide margin. Oh well. It's over now.

- 10-26-2016** **An Incredible View.** When you drive somewhere in the dark, it's difficult to know what to expect the new morning. In this case, it was a destination at the end of a long dirt road out in Wyoming. Late at night, I couldn't see much. When the sun rose, we were treated to an incredible view. I had no idea. It provided a great opportunity too. My Prius was parked next to another. Shadows were still long from the early sun too. The color of the hybrids on the bleached brown prairie with a cloudless light blue sky begged me to run out into the cold with the camera to capture that memory in the making. I did too. See... [photo album 189](#)
- 10-26-2016** **Photos on Dirt.** Before encountering all that red rock, there was another road. That was the type of dirt I'm used to seeing; however, the landscape certainly wasn't. It was elevated, high above parts of the prairie. There was a deep valley too. Overlooking that made for quite the photo opportunity... with the Prius, of course. If you look closely at the detail in the background of some, you'll discover oil pumps. Way off in the distance, you can see them going up & down. That most definitely isn't anything you'd ever see in Minnesota. But there in Wyoming, it's a common sight. I took advantage of the location. That type of time of year made it especially exciting to capture. Light deposits of snow really stand out. I couldn't have picked out a better day for that either. Lucky me. Running around with the camera can be quite fulfilling. I even got to be a bit silly, intentionally leaving a set of footprints to add to the dimension of a photo. I had a good time taking these... [photo album 189](#)
- 10-26-2016** **Order Uncertainty.** It was interesting to hear from Toyota marketing today on the big Prius forum. They were surprised we hadn't received any recent notifications about Prius Prime. Finding out 11 weeks had passed since hearing anything raised a concern. We all wondered if something had went wrong with the mass-email process. I could easily see a software issue going unnoticed. Whatever the case, we have their attention now. I was responded to directly. A few others were too. Our reach out to dealers for information about how to place an order right away are being addressed. My salesperson name and the fact that she has accepted a deposit should mean help is provided with allocation of the vehicle through the region's distribution. They usually don't have to deal with buyers like me seeking out a purchase opportunity before the first shipment even arrives in the country. The variety of packages, colors, and options adds to the effort. It will all work out too. But rumor is the estimated sales for 2016 would like to be around 20,000 worldwide. Getting everything into place to achieve those sales within just 2 months is a monumental task. Is it logistically possible? How do you match supply to demand in such a short amount of time? We'll find out rather soon...

10-27-2016 Confusing Reports. We starting to see quite a few articles & comments posted about Prime that are actually about Prius. To make matters even more confusing, many of the things being reported are about the gen-3 model. Casual readers won't have a clue. Not getting information about the newest generation available is an understandable problem. People are sloppy, failing to point out their comments don't apply to the what's available now. Sometimes, it's a simple oversight. Sometimes, they aren't aware their information is outdated. Sometime, their posts are intended to mislead. Whatever the case, that's all to be expected. It happens with every generational shift. The new problem is referring to plug-in model but sharing data from the regular model. There's quite a bit of interchanging going on. That really confuses mattes. So when it comes to corrections, you're doomed. Worse is the reality that some of the facts are incorrect for either. I have no idea where the numbers originate. Today, it was an article with "Prime" being compared to Volt, but really it was the no-plug version of Prius. Why would you do that? It makes no sense. The photo and all the information was indeed about the regular model. Then a comment was posted about the "20 mile" rating. Where the heck did that come from? What a mess. Clearly, this chapter in plug-in history is the first to reach ordinary consumers. The niche audience of the past certainly didn't have issues like this.

10-27-2016 Not Yet. This blog will likely be lost somewhere in the pre-rollout memories, but it won't be forgotten. The topic was thoughts about gen-5. What could the approach be for it? Would the plug become standard? Would the hybrid-only not be offered anymore? Many questions are being asked. This is what I injected into the discussion: I thought the upcoming flip was easy to see. Apparently, it's not... yet. Think about what happened with the computer industry. Where are all the desktop computers now? That format which once dominated the market has become quite rare. Those high-priced portable devices have very successfully replaced them. They have even been supplemented with smaller version now depend upon for routine communication. Intel announced quite a number of years ago that they would stop producing desktop processors, that 100% of what they'd offer would be a portable design. Have you looked inside a new desktop computer? It's actually a notebook with a large case, lacking a battery and a screen. Mission accomplish. The desktop we all grew up with is now long gone. Hybrids will follow a similar evolutionary path. Offering a plug and some degree of EV operation will be the norm, hopefully by the next generation. Plugging in will become so convenient, there won't be any need to further push HV abilities. Prime offers a rock-solid 50 MPG following depletion. Prime also addresses every need related to EV operation. Lowering cost a little more, while also improving energy-density a little more, is all it should take to make the plug part readily available for everyone realistic.

- 10-27-2016 Mini Countryman.** The topic of battery-capacity is an interesting one. Volt enthusiasts outright dismiss everything else. If it doesn't deliver 53 miles of EV like Volt does, it's not worth bothering. Thankfully, the rest of the industry isn't so close-minded. We're seeing shorter ranges from a wide variety of automakers. All focus on that smaller offering for the same reason... cost & size. Wanting to provide more requires tradeoffs too great for competing; business need falls apart as a result. The latest example of trying to deliver that delicate balance comes from Mini (a division of BMW). The new, much larger SUV, will be available with a plug. It will be a "thru the road" type hybrid. The front wheels will be driven by a traditional propulsion system. The rear wheels will have an electric motor, accompanied by a 7.6 kWh lithium battery. It's a simplistic approach with implementation complexities. What I find most interesting is the "24 mile" estimate. You wouldn't expect that much EV range from a heavier vehicle than Prime. It makes us ask the question of estimates. If BMW's is accurate, it would tend to indicate Toyota is yet again downplaying. I suspect that's the case. Seeing a few more miles than the estimate from my Prime would be great. We'll find out eventually. Who knows when though. Winter lasts a very long time here in Minnesota. Fortunately, the plug-in hybrid Mini won't be available until later in 2017 anyway.
- 10-28-2016 Availability History, background.** Few are asking why we're seeing Prime being rolled out they way it is. They just draw conclusions based upon observation of the present. Oddly, neither the future nor the past are being taken into consideration. Pointing out what's coming is basically futile. It's far too easy to spin that information. So, I usually don't bother. I can provide lots of history though. And in the case of availability, I certainly have a lot of that for Prius to share. This series of posts is how I did that: People without a business background (having taken accounting, economics, and marketing classes, then studied the automotive industry for the past few years), will have a very difficult time understanding Toyota's approach. Look forward to a lot of assumptions and greenwashing efforts as a result.
- 10-28-2016 Availability History, first generation.** Let's start with a look back at Prius history. Rollout began in Japan. Sales began in December 1997 and continued exclusively there until August 2000 with the first major upgrade, which went to the United States exclusively. Despite providing a much improved battery-pack and more engine power, it was labeled as a first generation vehicle. Some of that came from clueless writers. Some of that came from intentional undermining. Toyota was unbothered. Rollout would only be to online orders and the vehicle wouldn't offer cruise-control. Instead, it came with a touch-screen and digital-speedometer. The reason why for such odd choices was far from obvious... until many years later.
- 10-28-2016 Availability History, second generation.** When gen-2 was rolled out (late 2003), greenwashing spin was alive & well. Fortunately, Toyota's decision to limit Prius in such a way revealed itself to be a wise decision. They had target an audience who would become strong supporters of the technology. Rather than just rolling out to an open market, they successfully limited availability and changed expectations. The feedback from those owners really paid off too. The next generation would be configured to appeal to a much wider audience. It would also be profitable right from the very first sale. All that was a major undertaking that many had either misunderstood or went out of their way to cast doubt upon.

- 10-28-2016 Availability History, third generation.** The rollout of gen-3 brought about quite a stir. The outgoing generation had been very successful. Could a more efficient & powerful system not only retain mainstream interest, but also attract new buyers? News of plug-in offerings sometime in the future was common, but the viability of the technology was still unproven. Longevity & Cost issues were very real concerns. The economy had fallen apart. Gas prices were bringing uncertainty. It was a challenging time, especially with the lack of reasonable competition. Prius was often paired up against Jetta TDI in bias and questionable comparisons. And of course, we now know that "clean diesel" was a massive deception.
- 10-28-2016 Availability History, plug-in model.** Prius PHV rollout was to be a mid-cycle update to gen-3. The platform itself was already designed to accommodate the larger battery-pack and faster EV speed. Cost was still very expensive and the market acceptance of plugging in faced with fierce resistance. The struggle with Volt sales made it all too clear that a limited rollout would be a wise move. So as the time approached to expand availability beyond the initial 15 states arrived, Toyota decided not to. Instead, they'd continue study in the established markets to provide valuable information about how to attract buyers with the next generation instead.
- 10-28-2016 Availability History, production end.** In June 2015, the decision was made to end production of Prius PHV. Almost immediately, the greenwashers pounced on the opportunity to deceive about Toyota's intent. They'd raise doubt and draw conclusions based solely on specific observations, absolutely refusing to acknowledge the fallout of having to deal with the very problem Volt now faces with having become known as a niche and being configured accordingly. They did everything in their power to deny the possibility that a much improved plug-in hybrid system was in development and that promoting the old one any further would have negative consequences.
- 10-28-2016 Availability History, very wrong.** Early this year, we discovered just how very wrong those greenwashers were... and how they'd quickly change their claims, focusing attention on perceived shortcomings instead. The exclusion of a middle seat is the obvious new highlight. Toyota's effort to explore & expand is outright dismissed. That 5th could be offered later. But then again, maybe it won't. Product diversification would suggest offering in on second vehicle choice instead. Whatever the case, it has been a distraction from the technology... a clear effort to undermine.
- 10-28-2016 Availability History, approach change.** The raised floor is another obvious issue of dissension. Toyota's choice of function over form is not new. They saw the benefit from that change of approach and went for it. The cargo benefit of a hatchback comes primarily from the ability to carry long & wide objects. The height of objects wasn't even mentioned until 9 years later when the wagon model was introduced. Notice how that touch-screen and digital-speedometer are still standard, despite having been a profound change for a vehicle's dashboard? Who will really take issue with it not being as tall? Look at how well small SUVs sell, even though they offer a lot of height but very little depth behind the seats.

- 10-28-2016 Availability History, drawing conclusions.** What allows you to draw conclusions about approach and believe it cannot change during the generation's availability. So what if Prime may only be initially available to those who are willing to hunt one down, rather than stumble across it on the dealer's showroom floor? That exactly how sales began for the no-plug model all those years ago. Heck, even the battery-pack was upgraded mid-cycle back then. Who's to say that same strategy won't work again?
- 10-28-2016 Availability History, priceless.** Think about all the unanswered questions we have. Even as well-informed online participants seeking out information, we simply don't know yet. Would you really want newbies learning about the system based on anecdotal observation, rather than basing results on a good understanding of the basics? That's a recipe for disaster. Driving conditions vary far too much for generalizations. Letting us identify a solid working knowledge first, then come up with a simple way to share that, is priceless.
- 10-28-2016 Availability History, patience.** I ended the long post describing the history with: "*In other words, patience.*" Upgrades are difficult to understand at times. But each wait and resulting improvement was well worth it. Rarely do you hear about steps backward. Not everyone will be happy though, since change will inevitably disappoint some. That need for being patient makes it harder to deal with. Uncertainty presents challenges. That's why I do my best to point out what may not be obvious. Knowledge of history is especially difficult to acquire. How would you study the past for Prius? There are few sources that are comprehensive and almost none that are easy to follow. There's so much material too. With so many years of history and the distortion associated with looking back, rather than reading about the events in the "as it happened" context, how would you do it? Fortunately, a need with patience is having something to do in the meantime. Why not read a massive collection of blogs that were written as the history played out, from the perspective of day to day observations? Hmm. :)

10-28-2016 **Greenwash, uniqueness.** This comment about our history discussion caught my attention: "*They said people liked the uniqueness of the Prius because it held them out as greener-than-thou.*" How could I not react to that? I couldn't. See:

That's a good example of effective greenwashing. Way back, Prius was the only midsize hatchback available here. So, it was unique anyway. The practical nature of the shape simply made the decision to try the hybrid easier. Attempts to conceal that advantage over competing sedans were spun by giving the greener choice a stigma. In other words, they didn't like the message, so they went after the messengers.

Notice how none of the advanced tech for the driver ever gets mentioned? People didn't buy Prius just for "green" alone. So, no amount of smug claims can conceal the detail of what really happened back then. So, there's no reason to think it will now either.

Prime is a balance of design. The choice to deliver 25 miles of EV was well thought out. Accepting size, cost, and weight tradeoffs wasn't realistic. You don't configure a vehicle for the masses that appeals to enthusiasts. Those are mutually exclusive audiences. Their preferences differ too much. So, don't get purchase advice for ordinary consumers from them.

Ask yourself, do mainstream buyers even care about being green? The market right now shows a strong desire for "good enough" efficiency. That means any appeal to eliminate gas use basically falls on deaf ears. That doesn't mean they won't be willing to spend a little bit on EV driving though. An affordable plug-in hybrid (that's profitable for the automaker without tax-credit subsidies) appears to be the ideal solution.

Toyota is giving it a try with Prime. The initial rollout won't be as fast as traditional vehicles or as widely spread, but the ramp up could following that introduction purchases could be quite impressive.

10-28-2016 **Greenwash, definition.** I got called out: "*I'm not sure your use of greenwash is accurate. Greenwashing is giving the appearance of being environmentally minded, while downplaying the damage done to the environment.*" That made be reflect upon the situation:

Interesting. Back then, there wasn't even such a term. I guess I used it with incorrect context. We called the effort to hold back and mislead about the technology "*undermining*".

All those years ago, the concept of "*green*" itself was different. People focused almost entirely on MPG. It was all about using less gas... regardless of how much you'd try to emphasize the reduction of smog-related emissions. You'd get downplay at best. The topic of carbon-related emissions was outright dismissed.

Now, the idea of "*green*" is just the collective effort to "*be like Prius*". The overwhelming success of the Toyota technology it uses leaves the spotlight on Prius. The other hybrid offerings simply don't get the same recognition. So, we just lump together the advantages of reduced consumption & emissions into a single acknowledgement.

Even more interesting is how "*EV efficiency*" is now coming into play for Prime... with will also be a trait of Prius. Being able to squeeze out so much from that size battery will get the "*greenwash*" treatment too. Look at how a few have already made the claim that 25 miles won't be easy to achieve and try to downplay the advantage of having a vapor-injected heat-pump.

How do we more accurately portray all those benefits? Ordinary consumers simply don't have the background to even know what to look for. It's very easy to deceive an audience like that. Calling "*greenwash*" is the environmental equivalent of raising a red flag.

- 10-29-2016 **Big Change.**** We're witnessing the death of diesel for passenger cars here. It's extending beyond VW vehicles. Mercedes abandoned a new rollout. The market was always small and is rapidly shrinking. Hyundai is targeting buyback owners too. They need to get beyond their MPG depiction. (The lawsuit for their inflated numbers was settled for \$41.2 million.) Attracting new customers could be an effective means of doing that. For plug-in hybrids, Prime is getting ignored. The Volt owners are at it again, doing everything they can to focus on the regular models instead. It blows my mind that they are going out of their way to make sure the no-plug Prius is used as a basis of comparison. I suspect some of that intentional misleading comes from the recent Consumer Reports rating. Prius was recommended. Volt was downgraded. That stings. There's nothing a Prius owner can say to make it better either. The enthusiasts get angry and lash out... at their usual scapegoat. Ugh. Oh well. At least there is progress in the environmental concerns overall. China is seriously considering a shift of incentives over to clean hybrids, away from plug-in vehicles. The reason is simple... a large quantity of PZEV-rated hybrids will emit less pollution than a smaller number of electric-only and plug-in hybrid vehicles. It's far easier to sell more than don't require a plug, no new infrastructure needed. Having the bulk of electricity coming from coal doesn't help either. The big picture puts the choice heavily in favor of Toyota. It's very difficult to deny how impressive gen-4 Prius results are.
- 10-30-2016 **Charge-Mode Thoughts.**** There are many. This new feature has some scratching their heads. I was surprised by that, as I stated: I'm surprised no one has mentioned that we already have a "charge mode", one that replenishes battery-capacity more aggressively than HV mode. It's been a basic part of how Prius PHV operates. It's quiet. It's smooth. And apparently, it's easy to overlook. Toyota has simply allowed it to be used more for Prime. Coupled with a more efficient gas-engine and refined software, why not? To observe the charge-mode currently available, just drop the pedal down hard with a cold engine. Notice what happens over the course of the next few minutes? It's especially interesting if you try this scenario, a situation I attentively observed knowing the circumstances would be quite informative... Turn onto a highway entrance ramp with the gas-engine completely cold (not used for many hours). Drop the pedal to the floor and hold it there. With the EV depleted entirely, I watched the entire HV capacity be consumed in those next few seconds to provide as much electric power as possible to accelerate the Prius to 70 mph. SOC dropped to the 18% minimum, then shortly afterward, began to climb. Within only a few minutes, the entire HV capacity (the 23.5% maximum) had already been restored. That's a recharge-rate clearly faster than while driving in HV mode. It's obviously not as efficient. But if all you're doing is cruising along a highway for a long distance anyway, why not keep charging beyond the HV threshold? Having that EV capacity available later could be a very efficient use of that electricity. Of course, some owners won't understand when to best use that electricity from gas rather than from plugging it. But how is that any different from an owner of a regular Prius attempting to maximize EV use? Used well, there's an efficiency gain. Used poorly, there's an efficiency penalty.

- 10-30-2016 Road Trip Photos.** To start out this year on a fun note, we jumped in the Prius and headed out to Wyoming. With the temperature below freezing and the route a straight highway drive through South Dakota from Minnesota, I was intrigued. The speed limit is 80 mph. The expectation was to do that a majority of the way. But with it being Winter, there would be spots of snow & ice to deal with. Fortunately, it wasn't bad at all. In fact, we even had a chance to go on a side trip. We drove from the plains (where the coal is excavated from pit-mines) to the edge of the Rocky Mountains. You can see some of the snow-caps in the photos I took at a scenic rest. Those are where locals go camping & hiking. It's quite beautiful. I definitely prefer the lush green & blue of home though. Anywho, I captured the moment with a few snapshots at a stop along the way... [photo album 190](#)
- 10-31-2016 Horrifying Discovery.** Propaganda spreading has begun. Intention is difficult to determine, since some people become unknowing participants by passing along greenwash material. Source is not. The second article about Prius Prime, from what started as a seemingly clueless news source, was published today. Sure enough, it was what had been feared. The first was last week, stating it was about "*Prius Prime*" in the title, but was actually about the regular model without a plug. That made no sense whatsoever, since it was a comparison to Volt. How could anyone not read that and end up walking away misinformed? It was greenwashing. I know that intention quite well now, since this one had lots of incorrect information. It had the following: "*Toyota has not release any testing results yet but is aiming to get a combined rating of 120 MPGe in EV mode, or hybrid fuel economy mode. A maximum electric range of up to 22 miles, and 84mph top speed.*" That's quite outdated. You'd think it was a mistake, that the writer simply did research well. However, the "yet" implies they recently checked. Clearly, that wasn't the case. The update came weeks ago. To make matters worse, you get the impression the writer actually test drove the vehicle. How would you interpret: "*You need to have a very steady foot to reach 22 miles on batteries.*" That sure looks like a claim from experience to me. It contradicts what testers has been saying too. Reviewers state after driving that you can drop the pedal all the way to the floor and most drives have delivered more than 25 miles. What really got me though was: "*Least that a driver wants is to be stuck in the middle of nowhere without a charge.*" I had to reread the paragraph containing that several times to determine the "*before lettings this EV's out on the streets*" the "*still too limited*" conclusion that the writer was absolutely clueless. I found a reference to Volt buried in the middle of the article. It was highlighted as giving "*better reliability*" due to it offering "*53 miles on batteries*". I find that horrifying. He actually had no idea how a plug-in hybrid works. He thought it was just a short-range EV. Wow! It makes you wonder how much of that greenwashing will be spread. Searching online, I found a secondary publish of that same article on a totally different website.

- 10-31-2016 VW eGolf.** Did you know this troubled diesel automaker actually offers a small, low-volume electric-only vehicle? There is indeed an EV from VW. It's the Golf with a plug. Sales are barely enough to even qualify as a niche. But hey, that's better than nothing. They need to gain experience somehow. Anywho, I actually saw one today. That was quite a surprise. Traditional vehicles with a motor & battery instead of an engine & tank don't exactly stand out. I may have seen it some other time around town. There's no way to know though. This time was easy. It was plugged in. That's a dead giveaway. It would have been nice to see the owner and say "*Hi!*" That didn't work out. Oh well. At least I got to see it. What will VW's first serious offering be? For that matter, how long will it take? Even when an automaker is supposedly committed, that's no guarantee of mainstream success. With cost high and production limited, good intentions only go so far.
- 10-31-2016 Retraction Requested.** I ended up sharing my frustration on the big Prius forum. That much misleading isn't good. Someone actually sent them an email requesting the article be retracted for containing so much incorrect & confusing content. It's too late, of course. That turns into propaganda material very quickly. We ended up discovering that the writer was part of a firm from outside of the country who writes & sells for publications. So naturally, they divert responsibility to those who purchase & print it. No accountability. Ugh. That means all we can do is raise awareness. Definitely don't trust without verifying. There's a lot of garbage out there. Here's my frustration express in print... This is the second article from this source to write something misleading about Prius Prime: "*Toyota Prius Prime: How EV Both Impresses And Disappoints At The Same Time*". Last week, it was a comparison to Volt. Only thing is, the title mentioned Prius Prime. The article itself was about the regular model. Mix-ups can happen for a variety of reasons. But with today's article, there's no excuse. It started with outdated claims of 122 MPGe and 22 miles. That seemed innocent enough, until I encountered about claim with: "*stuck in the middle of nowhere without a charge*". The writer was clueless and had spread FUD (fear, uncertainty, doubt) in response. To make matters worse, another publication has already picked up the article. I was left scratching my head, wondering what the heck the writer was thinking. Even with mention of having an engine, the concept of a plug-in hybrid is not understood... as the result is the spread of misleading information. Read what's written carefully and share your impressions. Notice no mention of the MPG rating? The conclusion of "*Best scenario is to only drive it around small cities and not think of driving it around back roads or on expressways.*" will leave you feeling troubled.

- 11-01-2016** **No Lithium Support.** Getting disgusted by so much greenwashing is easy. After reading a large collection of comments from the past 2 days on a discussion topic about Toyota finally endorsing lithium batteries, I sounded off. On that blog website, which attracts a wide variety of participants, it was time well spent. I doubt those with such a false impression of what has actually taken place will be swayed. You never know until you try. So, I did: It never ceases to amaze me how blinded some people have been to Toyota's advancements. Because an EV hasn't been offered, they assume nothing was being done. In reality, Toyota rolled out their first plug-in hybrid (Prius PHV) and their first hybrid (Prius 7+) using lithium batteries. They then switched over the regular Prius (all gen-4 models, except the base) to use lithium. That's obvious commitment to advancing the battery tech. Those improvements to the chemistry, the reduction of cost, and the increase in production volume all contribute to progress forward... none of which Toyota gets any credit for. Instead, people just distract by concentrating entirely on hydrogen. It's really sad that some don't understand how FCV (fuel cell vehicles) share quite a bit of EV (electric-only vehicle) components. Think about the low cost Prius Prime is rolling out with. That motor & controller knowledge gained from other Toyota research & development will benefit it directly. Think about the industry-leading electric heater Prius Prime will use. That vapor-injected heat-pump is a clear effort to improve efficiency of EV travel. Prius Prime will also offer a CHAdeMO charging option in Japan, a feature clearly beneficial to future EV offerings. In other words, saying Toyota hasn't been doing anything until now is a big disservice to the plug-in community. They've been there all along, working hard at things that go unnoticed... cost-reduction, high-volume production, and electric-efficiency.
- 11-02-2016** **Half Million.** The official total through September for sales of plug-in vehicles here in the United States was 512,137. That count from the Department of Energy is a nice milestone now getting a lot of attention. It's quite a bit less than the One Million hoped for. But then again, no one imagined gas dropping to such low prices. Of course, you-know-who getting into office would destroy hope of progress. Having so much power wanting to turn back the clock and fund dirty/wasteful energy is unbelievable. It is understandable though. People have anger for other reasons and they've found means of venting. Feeling overwhelmed and let down is very difficult to overcome. Just look at the mess we've seen as a result of "*over promise, under deliver*". Finding out you've endorsed something unable to live up to expectations really hurts. Just think of how the EV supporters felt when plug-in prospects 15 years ago turned into giant gas-guzzlers. Finally seeing recovery from that, despite being slower than desired, is an advancement forward nonetheless. Then you've got people like me endorsing smaller batteries for mass penetration. Making a vehicle lower enough cost to actually compete directly with traditional offerings means not getting a configuration that stands out. It's hard to stir excitement for anything intended to become ubiquitous. Each automaker will get 200,000 tax-credits before phaseout begins. Roughly a total of 300,000 per would work out to somewhere around 3 million vehicles. Knowing that over 14 million are purchased every year, it's easy to see how much more is needed. Oh well. At least we can celebrate this achievement. There's no denying this progress.

11-02-2016 In-Person Training. What an unexpected outcome! We saw someone pull into the plug-in spot. They parked with a strange sense of uncertainty. We had immediately assumed it was a driver who simply didn't care that they were blocking the plug from being used for recharging. Nonetheless, I decided to park across from them and potential confront the driver. Always being polite, that sometimes works fine. Turns out, they were actually confused about what to do. They also had a plug-in vehicle. In this case, it was a Fusion Energi. I introduced myself and provided a quite demo of the plugging process. You could see the desire to find out more. I got out my card and handed it to them and suggested taking a photo of the back with her phone. The information on the charger stated a credit-card would be needed. They didn't understand why, since the charger was supposedly free. I pointed out the charger-card would allow them to unlock the handle without the need for a credit-card. I used my card again to unlock the handle for them. It was a great opportunity to educate and share a brief moment of common good. That simple minute of in-person training likely had a big impact. You could see the intimidation melt away, replaced by excitement. That sure was fun. My wife got to witness it all too. I appreciate her support, but never have had the opportunity to include in an encounter like that though. What a great visit to the grocery store!

11-03-2016 Prius Gathering. We're in the early stages of establishing a group which meets monthly. There's plenty of us around looking for an opportunity to share stories and help promote. The catch is finding a location that works well. It's hard enough just scheduling. The unpredictable nature of weather & seating makes it even harder. We'll work something out. The ones I organized in the past had good participation. Owning a Prius Prime, possibly before the next meeting will obviously, stir interest. This evening's had modest participation. It basically comes down to having a clear purpose. The problems GM supporters are now struggling with due to not understanding the market and having set contradictory precedent seems to have been avoiding with us. Toyota has remained true to the mission of keeping cost low and striving for balance. That leaves you with a vehicle enthusiasts like to modify and ordinary consumers find rewarding. No matter what Prius you purchase, it's always clean & efficient. Rarely do you hear of disappointment. That often comes from knowing what you buy. Small groups around the country are what take the knowledge learned online and carry it forward into their own neighborhoods, in person. Reaching further is our goal. How can we convey the value to those without any mechanical background, those simply looking for affordable transportation that's very reliable. Selling the idea of less gas and few emissions is nearly impossible. The gain from electricity isn't though, even without a plug. We'd benefit from some type of material to share. It's nice having ideas from the past to leverage upon. As always though, the catch is audience. This absurd upcoming presidential election has everyone quite distracted. Oh well. That provides us with some time to plan.

- 11-04-2016** **60,000 Sold.** BMW's i3 hit that milestone recently. It took twice as long as the mainstream expectation. But this is a luxury offering, so that many isn't a level to strive for anyway. Achieving it sure is nice though. The goal was to prove the technology using an entirely new approach & platform. The tiny range-extending engine, along with quite a bit of carbon-fiber structure, obviously worked. We suspect the next generation will come in the form of an i5 sedan. It's an approach being proven by real-world driving. Gotta like that. It's refreshing to know what possibilities are available. You never really know what will catch on, especially in the luxury market. Though, mainstream buyers present challenges too. However, that volume & variety is more flexible. Fewer customers means a lot of experimenting is required. Fortunately, the nature of that market does allow for model changes sooner. In other words, it's a mix of trail & error. Better research yields better results. In this case, it seems to have worked out well for a gen-1 offering. The next should be quite interesting.
- 11-05-2016** **Plug Squatting.** To find a plug-in spot occupied by a plug-in vehicle not plugged in is frustrating. To see that situation with a plug-in owner driving by with disappointment on their face seeing that has no words... yet. That term hasn't really been coined. Today, I called it squatting. Fortunately, I was able to direct the disappointed owner down to the other end of the parking lot where another charger was available. Hopefully, that won't happen much. Sadly, it has been discussed at the plug-in owners meeting. I'm not alone with such encounters. Others have also seen chargers go unused by chargeable vehicles. Wasting a plug like that is wrong. Adding to the trouble was the fact that there were empty spots nearby. The owner was clearly lazy & uncaring. That's when you know a technology is gaining popularity. There are no HOV privileges here. There are no monetary state incentives. The only way to benefit from the plug is plugging in. That person didn't. We were both disappointed to see that. Oh well. Not much can actually be done about such behavior.
- 11-05-2016** **Green Herring.** Read this without wanting to post a reply immediately: *"I don't like that PHEVs are put in the same group as BEVs. Technically, PHEVs are closer to HEVs than to BEVs, because they both have ICEs. PHEV needs Gasoline, how much is irrelevant, because still has to be refueled unlike BEV."* I could not, as this expressed: Get used to it. Hybrids suffered from the same problem. Heck, this very article did that. The difference between ASSIST and FULL hybrids was profound, just they are still getting dumped into the same category. As for what is closer to what, that is a green-herring. The point doesn't tell us anything and only serves to distract. It's like arguing EV range. Results vary so dramatically based upon driving distance & conditions, the type of system is only a minor factor. Other aspects of the design become far more important instead, like the size & price of the vehicle. In other words, we aren't discussing what has actually influenced sales numbers. But if you do want to look at the graph, make note of what the lack of detail distorts. It doesn't tell you that Prius sales didn't begin until the last third of that first year. It also doesn't tell you that sales of Prius were only available via internet orders until May 2002. They weren't available on dealer lots anywhere prior to that. It doesn't tell you how long the deliver wait was due to inventory limitations either.

11-05-2016 **What's The Point?** It sure is good to not have to deal with this routinely anymore: "*I and others had stated 'back in the day' that the PiP could have outdid the Volt in sales if Toyota had committed to going nationwide with it. They choose to play it safe instead, and now their national plug in debut is against the gen2 Volt and new Bolt.*" Fortunately, that take on history is quickly fading. I asked: There were indeed a number of supporters who believed that. The catch is, they also believed audience was the same. Toyota wasn't targeting enthusiasts as GM though. That fundamental difference is why another approach was taken. Toyota already knew back then what the next-generation would offer. Saving tax-credits for that instead makes a lot of sense. It was a wise business choice, especially since it saves any need for a re-education effort. The first plug-in hybrid most consumers will encounter will be a much improved design. It's really unfortunate some people didn't recognize history playing out for a second time. That approach is similar to what happened with the Classic model Prius. Most people had no idea what improvements the hybrid system delivered in that next-generation. Their first exposure ended up being the Iconic model... which proved to be a wise business choice. Back in the day, some attempted to point out the situation. It often resulted in spin or dismissal. That's easy to understand. I'm not sure how "safe" applies. Though, being patient could be considered risk avoidance. But then again, goals would have to be the same. Clearly, gen-2 Volt is not targeting the same buyers as Prius Prime anyway. So... what's the point?

11-06-2016 **In The Now.** The best response is "*ugh*". I suspect we'll see an increase in greenwashing throughout next year. Interest in plugging will stir a few to mislead by posting outdated & extreme information as if that's what everyone should expect. I find that quite frustrating. Sadly, it doesn't just come from those against electrification either. Reading my blogs, you'll be well aware there's a superiority complex to deal with. Some fight affordable offerings, doing all they can to keep their niche vehicles special by undermining the progress of those with mainstream potential. Again, ugh. Today's example was attacking the plug-in vehicles that didn't offer liquid-cooling for their battery-packs. I was annoyed, especially with the short-sighted approach, so the response was shorter than an all-out rebuttal: Later chemistry advancements have basically proven a wide variety of configurations will work just fine. That isn't a problem anyway. It's the lack of clear goals and the uncertainty of audience. That makes marketing extremely difficult and dealers reluctant.

11-07-2016 Spin. A major reason for having stuck with what had once been a daily blog for Volt was to observe the spin. Volt has almost entirely vanished. There's only a brief mention here & there now. It's amazing to watch something like that disappear into the background. But then again, it's not much different from Two-Mode. Remember, that's what Volt replaced. It was another technology doomed to fail... not due to the engineering, it was due to the cost choices. GM felt performance was more important than being affordable. Enthusiasts were too blind to see the pattern repeating. They made excuses every time an expectation fell short... taking their disappointment out in the form of hate for Toyota. The biggest lashing out was FCV (fuel-cell vehicle) focus. They'd call attention to hydrogen as a distraction. The reason why became much more difficult to deny too. Toyota finally made an announcement about support for EV offerings. The true supporters always knew that would happen. What's the point though of promoting something years in advance, if it is detrimental in the meantime? That's why Toyota got as much hydrogen work done as possible prior to this. Since it is a mutually exclusive technology (different audience) with shared components, why not? Now that Mirai is in a good position, focus on Prius Prime can take place without harm. Both have the same goal of becoming affordable choices. Both have years to go before advancements will drop cost enough for large-scale acceptance. But in the meantime, both can establish the all to vital need of reliability reputation. That doesn't happen overnight. Unfortunately, that time does provide plenty of opportunity for spin... which happened today: *"Looks like now that Toyota has admitted they were wrong about li-ion batteries and their fuel cell efforts are not going so well, and they have already made their watered down version of a Volt knockoff, they are now going to attempt a knockoff of the Bolt EV."* That's so annoying. Toyota has been ramping up production of lithium. It started back in 2012 with Prius PHV. It grew dramatically with gen-4 Prius. Now, it will get even bigger with Prius Prime. I won't bother pointing that out though. It's not worth it. Those particular Volt enthusiasts on that blog just plain don't care.

11-07-2016 Hypocrites. Another thing those particular Volt enthusiasts on that blog just plain don't care about is being honest. At times, they just outright lie. It can be quite frustrating. Today's example was actually quite vindicating to read though: *"When developing the gen 1 Volt, GM said they relied heavily on what they learned from the EV1 and many of the team that worked on that program were also working on the Volt."* Over and over and over again, the person claiming that absolutely insisted Volt was entirely new. Since all the technology in Volt had been created from scratch, with no experience from EV1, Two-Mode, or BAS/eAssist, that was good reason for being patient. We had to wait. The *"no prior history"* message kept getting repeated, despite pointing out how GM was building upon what had been gained from those previous endeavors. Now, there's claims of the opposite. They just rewrite history anyway that fits. It's so hypocritical, responding would just be a waste of time. They don't care. They'll say whatever they want to support their beliefs. Remember how dead-set they were against EV offerings? Volt was the ultimate solution to *"range anxiety"*. There was no purpose for an electric-only vehicle. Now, they contradict themselves, abandoning that message for Bolt instead. If you want to call someone deplorable, here's a worthy situation. Ugh.

11-08-2016 **Let It Go!** Some just plain cannot: *"People are still pissed about the old lexus ads. The new ones just smack of desperation."* Reading that was annoying, but it did provide a chance to say my piece: It's hard to believe how blown out of proportion and complete disregard for the business a select few people will take a situation. First, what Lexus does has nothing to do with Toyota. They are separate divisions. Second, each automaker is a primary purpose of making profit, not being a green savior. Third, you have to be rather clueless to believe an ordinary consumer could care less. Fourth, anything can be taken out of context, especially with a quickly changing industry. Need I say more? Pretty much everything happening now will go almost entirely unnoticed. The mainstream isn't ready, so they aren't paying attention. Think about how absurd other claims were by automakers now supporting EV sales. We don't actually see any volume, yet they are praised for delivering very little. Put it this way, Toyota is the hidden giant. They have been producing lithium batteries in high volume for gen-4 Prius. No one has really noticed that ramp up though. But it's exactly what's needed to ensure a strong rollout of Prius Prime. We get an affordable electric-only platform. Who cares if some of the tech came from hydrogen research. For that matter, who cares how small battery-packs start out at. All if it contributes to a competitive EV offering in a few years.

11-08-2016 **Road Trip Photos.** 4 years ago, just 1 month into PHV ownership, I went on my first road trip. It was up north, to the usual destination. But being Minnesota in the Spring, weather is quite unpredictable. We ended up getting quite a bit of snow. I hadn't packed an ice-scraper either... since the first day was absolutely beautiful. In fact, I had brought the bikes along. The hope had been to take a trip on the trails. That time of year is beautiful. There's a mix of open water and ice still on the lakes then. The breeze has a bit of warmth. Sunshine is refreshing. It's a nice opportunity to shrug off Winter, despite driving north rather than south. Take a look at what I captured with the camera. That brand new Prius PHV looked great next to the budding trees at the boat-landing. It's the same location I took photos at many, many years ago with my Classic Prius. Check it out... [photo album 190](#)

11-09-2016 **That's Reality.** This quote from a recent article about Toyota's intent for 2020 sure stirred discussion: *"Toyota aims to develop an EV that can run more than 300km on a single charge. The platform for models such as the Prius hybrid or Corolla sedan is being considered for use in building an electric sport utility vehicle."* Naturally, there was the usual hydrogen rhetoric. But if you can get past that, there is some constructive discussion taking place. Unfortunately, that can easily get derailed with nonsense like this: *"This reads as half-assed effort, even they probably don't know what will come out of it."* Lack of substance to the claim makes you wonder if it is even worth responding. But then again, not saying anything is to enable. So, I didn't keep quiet and asked: Knowing your audience translates to half-assed effort? No, it's called market awareness. Notice what happened with the election yesterday? You can suggest a dedicated EV platform all you want, knowing it is the better choice, but that doesn't mean people will buy it. We are a market obsessed with consumption and making bad choices. Look at how poorly Volt has sold and how popular the plug-in Outlander is. That struggle for sales GM has had is far from what Mitsubishi is experiencing. They are both plug-in hybrids. The dedicated platform Volt offers simply doesn't appeal to the masses like a compact SUV with a plug does. Like it or not, that's reality. We have to find a way of playing the game. Notice how popular the hybrid RAV4 is. Why not offer a model with plug augmentation?

11-09-2016 **Measure, How?** Here's food for thought: *"The manual states not to leave the battery full for long periods of time. Unfortunately, they don't get any more specific, so it's up to each owner to decide what is best. I leave mine between empty and half full, depending on the situation, but sometimes i get caught with my pants down and no charge. Even trying to do this, i have seen about 15% degradation since new."* I'm getting really annoyed by his lack of effort to share detail. From the snippets of information he has shared, his EV range dropped that much... but is still more than I have ever experienced. If I remember correctly, he was averaging 17 miles. So, you can see why I have difficulty accepting the edge he lost over the years as a problem. Nonetheless, I still try to remain constructive:

Long periods of time would be weeks, like when you go on vacation. Shorter, it's just fine. Simply leaving it partially depleted is an easy way to avoid that. You still have a 15% buffer regardless, since "full" is really just 85%. Exceeding it would only come from routinely drive downhill for many miles at a time, those who live in areas with mountains or deep valleys.

More likely is not allowing the battery to rest before recharging. That's called a "cold soak". The timer feature helps make that easier. Chemicals inside benefit from the opportunity to settle and cool down. If you plug in right away after driving EV or expose the car to extreme heat, it will shorten battery-life.

As for your 15% degradation, that doesn't tell us much. Some owners never see levels other owners do anyway. With mine, I haven't noticed any real loss after 4.5 years. It's still delivering 13 miles of consecutive EV on good days. That's more than the 11-mile rating. How should measurements be made years later? We don't have a method available.

11-10-2016 Clickbait. That term gets heavily used now. It came about from all those enticing links publishers put at the bottom of articles, headlines & photos intriguing enough to compel you to click them. Many people do too. Most of it's a waste of time. But that's what gets you to stay. So, that's what they do to keep you. Today, it was discussion of how "hydrogen" gets those interested in plug-in vehicles to take a closer look. Virtually all of it is propaganda. Pointing that out is quite a challenge though. Far too many fall for the bait. And of course, if you read the same spin often enough, you begin to believe it. I kept my response to that short: Spin of electric-only killing off fuel-cell is indeed clickbait. They are not mutually exclusive. As much as some people will try to convince you co-existing isn't possible, the expectation of a one-size-fits-all solution simply isn't realistic. Think about how much of the electrical system they actually share.

11-10-2016 Knowing. Ugh. How do you respond when a well known troll posts this: "*Same as the Volt?*" He thrives on contradictions, so dropping that bait would be fruitful. Productive information exchanges can result. It's not always a bad thing. Perhaps this will steer the discussion in a constructive direction:

Know your audience.

GM had a major upset with Two-Mode. They targeted those yearning for a better giant SUV. Unfortunately, the result wasn't that efficient, didn't offer comparable power, and was very expensive. So, GM moved on, targeting those yearning for a better compact car for that next attempt. It didn't lack in power, but wasn't as efficient as hoped and was very expensive.

All along, I kept asking the same question over and over and over again... Who is the market for Volt? The reason was simple. I wanted clarification about what audience GM would seek for gen-2 Volt. Unfortunately, the lower price and improved efficiency didn't do any good. Turns out, they targeted those same buyers, resulting in flat sales. No growth.

Toyota isn't making that same mistake. Seeking out a niche group doesn't make any sense with a goal of wanting to sell the vehicle in high volume. They targeted the masses instead. It starts with drawing in enthusiasts, but offering compelling mainstream features instead. Power & Range is traded for a much lower price and much higher efficiency.

To grow the market, you must do more than retain the strongest traits of Prius though. This is how the seat variation in back and the large screen come into play. We will quickly see the initial interest from enthusiasts be replaced by ordinary traditional buyers. How that's accomplished is the magic part. This seemingly strange rollout availability is simply a build up for demand. Salespeople get used to the paradigm shift. Once that happens and enough early owners share their experiences, supply is ramped up. Showroom floor discoveries begin. Growth is achieved.

- 11-11-2016** **Excellent Summary.** The bigger discussion took an interesting turn: *"All I have to say about seating is if you need more seats you need a bigger vehicle. A bigger vehicle won't be as efficient which is what this prius is designed to be. Prius V or rav4 hybrids are more family oriented."* More people are growing tired of the pushback without substance. I added some perspective to the sentiment: I see the situation with Prius Prime very similar to Prius of the past. A lot of people complained that it wasn't as big enough to fit a large driver. We continually had to point out that if you wanted a full-size vehicle, you had to buy a full-size vehicle. Prius was a midsize, for midsize people. Now, we have to point out that Prius is a midsize, for midsize families. You can still fit 2 car-seats in back. You can fit 2 teenagers in back too. So, saying that *"Toyota didn't want people with families to buy the Prime"* is quite misleading. If you have a full-size family, you should buy a full-size vehicle.
- 11-11-2016** **Boost Interest.** Here's the hope: *"...will no doubt be more likely to be exposed to a Prime if they visit a Toyota dealer."* I added to that with: That snippet identifies a fundamental struggle GM has experienced with Volt. They were able to attract enthusiasts, but the scope of buyers never reached the showroom floor. With a base price of just \$27,100 and the next model up offering a 11.6 inch display, SofTex seats, wireless phone charging, and charging cable lock for \$1,700 more, it's enough to entice the casual shopper. Catching interest of someone just exploring what the dealer has to offer is a major benefit GM has not been able to achieve with Volt. Toyota certainly is giving that a shot with Prius Prime. People have always argued the standout design of Prius is what drew purchases. We're seeing market shift over to LED lighting to stir appeal. It's working too. The fact that Prime takes advantage of that should put it among the top picks for new interest. It's hard to imagine people wanting the old-school look for too much longer. There's that dual-wave glass in back as well. That adds a bit of style no other vehicle can compete with, yet. It's far too early still. But the potential advantage over offerings of the past is clear. Market growth is absolutely essential. The challenges of selling of plug-in vehicles with gas so cheap now (just \$1.99 per gallon here) and the recent election outcome threatening to harm environmental progress are really big. The approach Toyota is taking could really help boost interest.

- 11-12-2016 Shame.** A few have become disenchanted: "*If Prius sales are cannibalized, that would mean Toyota would have to do an even better job in the future. Wouldn't that be a shame.*" Much of that comes from not understanding all that's at play and considering what comes next. This is my attempt to convey that: I recognize your stance, but don't care for the mixed message it sends. The point of Prius Prime is to lead a way to the future. You can't just abruptly end production of the predecessor when it still hasn't been accepted as that yet. In other words, Toyota is taking the very risk our antagonistic posters have claimed they would not. Had Camry & Corolla seen falling popularity in favor of hybrid replacements, transition to a plug would have been the obvious next step. Instead, we have Prius struggling in conditions with gas at \$1.95 per gallon and leaders of the world having to address emission problems without constituency support. That means risking cannibalization for the sake of reaching a wider group of buyers. Imagine if Toyota had made Prime exactly like the regular Prius... no raised floor and a 5th seat in back. It would have been a logistics nightmare. Know your audience. Unfortunately, most people don't understand the complexities of all the elements at play. So, a seemingly simple message like yours could easily be misconstrued. Think about what the market will be like 3 years from now, when we are at mid-cycle with Prime and the regular Prius is on it's 4th year.
- 11-12-2016 Low Hanging Fruit.** We're back on that again: "*For plug-ins, many potential buyers are willing to part with their preferred brand.*" Hopefully, this makes the problem with that view clear: That perspective only works for the low-hanging fruit... those early buyers with little selection available. We're not in gen-1 anymore though. The audience isn't plug-in shoppers either. How many Prius owners have you talked to over the years, random ones you've unintentionally encountered? Notice how many of them weren't even in the market for a hybrid? You'd be shocked to discover the large number of them simply discovered it at the dealership while just casually browsing. The simple act of a salesperson offering a test-drive does a great deal toward appealing to that audience's desire. Those buyers are very, very different from you and I. Our purchase priorities have little in common. Saying they are "*not the same*" is quite an understatement. This is why that "*Who?*" question was asked so many times about gen-2 expectations. Market growth requires an entirely different approach.

11-12-2016 **Brand Loyalty.** I was enthralled to address this: *"From my point of view there just aren't enough reasonably priced plug-ins to allow any sort of brand loyalty. It's too limiting."* And I did:

Until this week, there was no market. None were reasonably priced. Remember the *"nicely under \$30,000"* target for MSRP? The reason GM set that goal was to be able to sell the vehicle to the masses. Dependency on tax-credits to achieve that affordability meant being trapped as a niche.

Prius Prime is the very first offering to deliver on that goal. \$27,100 for a base price is amazing. Toyota chose to focus on cost-reduction, keeping that the highest priority of their design. The tradeoffs that required meant a very real struggle in the market of the time. So, the gen-1 wasn't offered beyond initial markets. That taught them a great deal about how to configure gen-2.

Volt choices made by GM were to instead refine the system, beefing up aspects of operation rather than favoring a cost-reduction goal. Power, efficiency, and range all improved as a result of that decision not to make MSRP the highest priority. The consequence is limited audience and continued dependency on tax-credits.

How will market growth be achieved? Just 2 years ago, we were looking at \$275 per kWh for lithium battery cost. Now, it looks like \$145 per kWh is actually achievable in the not-too-distant future. With the price then around \$600 per kWh, a gen-2 battery-pack cost expectation (for the cells) would have come to about \$11,000. Subsidizing that with \$7,500 totally made sense. Obviously, that isn't how much it ended up costing. We're somewhere below the \$400 level now, putting cost at roughly \$7,500... perfect for tax-credit offsetting. Upon reaching that future cost, a drop of \$4,700 would indeed reach the goal. Base MSRP could end up around \$28,500.

That sounds like a reasonable plan... unless you look at the *"too little, too late"* claims. Toyota will already be entrenched into the market and the lower lithium battery cost would have become higher profit for both dealer & automaker... an absolute necessary for sales growth. At that point, the EV choices would have become competitive. Who will be the market for Volt then?

In other words, the bar for *"reasonably priced plug-ins"* will have changed. Just 3 short years from now, the expectation will be for those plug-ins to be able to compete directly with traditional choices, not having any tax-credits available. Toyota is striving to achieve that. This topic of selling well doesn't focus on that upcoming change... which these offerings must address.

11-13-2016 Comparisons. I wasn't happy to read this: "*The good thing is, non prius owners will never know what they lost. They'll be comparing to other plug ins with even smaller hatches.*" That's a careless disregard for the situation and a focus on the wrong thing, as I attempted to point out: Most won't have any clue what they gained either. People want one specific model of Prius to be everything for everyone. The idea of balance is lost on our market, one so confused the concept of want is thought of as need. That's how we get into our SUV mess. So many people were told by so many people that they were necessary for safety, that belief took hold. The want became thought of as a need. The same thing happened with the ability to tow. We were told over and over and over that what people had wasn't enough, that more is necessary. In other words, the longer those mindsets persist, the easier it is to lose track of want. You look at anything less as a compromise to great to make. There's no effort to identify need anymore. There's an unwillingness to change. That's why the mindless stating of EV range ends so many constructive discussion attempts. Someone will blast out numbers without thought, then not bother to consider anything else. This is why overcoming status quo is such a major challenge. Toyota gave the gen-4 Prius a radical look to make it stand out, to get people to notice it is different now. Being able to convey the message that handling has been greatly improved certainly won't be obvious to those making comparisons. Never noticing improvements without obvious numeric differences is far too easy. They won't know what was gained. They focus on what was lost, then dwell on it.

11-13-2016 Sales Spin. I'm really getting tired of this nonsense: "*Volts are indeed selling well up 63% compared to last year (ytd).*" I expressed my feeling too: That 63% is a very, very misleading statistic, to the point of greenwashing. You can't just cherry pick or omit detail like that. Sales were down last year due to the inventory of gen-1 being drawn down and gen-2 only being rolled out to limited areas. There's the "wait for the new one" effect too. Step back to consider the big picture. The goal even before gen-1 rollout began was to achieve mainstream volume by the end of year 2, a minimum of 60,000 sales annually in this market. That's an average of 5,000 per month. Sales of gen-2 haven't been even remotely close to that. The average has only been 2,000 per month recently. That's just a minor improvement upon the 1,700 per month gen-1 was averaging. To say Volt is selling well is to disregard what's happening with the rest of the market. Stating a percentage doesn't actually tell us much either. 2,191 may seem like a lot, but pales in comparison to: 16,151 sales of Malibu; 17,126 sales of Cruze; 19,664 sales of Equinox. That's why market growth is so essential. Hiding behind a limited amount of tax-credits and spinning the resulting sales to appear impressive isn't helping anyone. Toyota gets a lot of heck for pushing Prime in a seeming unpopular direction, but it clearly confirms they are willing to take a risk to achieve growth... quite unlike GM's choice for Volt.

11-13-2016 **Taking Risk.** The unexpected outcome of such a political mess is finding allies among those who you had formally butted heads with. It's surprisingly easy too, simply because they are so well informed. Falling for the rhetoric is far too easy. Sadly, many do. For us here, whether we like to admit it or not, we have become all too aware of the goals and barriers preventing them. In my case, I pushed Volt enthusiasts hard to get acknowledgement of how much of a challenge achieving cost-reduction really would be. That kind of "*compromise*" simply wasn't acceptable... until now. Hope of lithium battery improvements was enough to overcome the problem cheap gas posed. But when you have someone taking office who doesn't show any interest in reducing emissions or oil consumption, it's time to give up on pride. That can be restored later anyway. Toyota has taken a risk GM was unwilling to accept. Prius Prime will deliver a much smaller EV range than what people supposedly want for a tradeoff of a MSRP low enough to sustain profitable high-volume sales even without tax-credit help. That's a very big deal, something that will hit gen-2 Volt really hard in the few years... because it is quite unrealistic to expect renewal of federal aid at that point. What does that mean for the plug-in market as a whole? We want both plug-in hybrids and electric-only choices to thrive. Affordable for consumers and financially rewarding for salesperson & dealer is absolutely essential. We can't allow those still pushing extremes to impede mainstream acceptance anymore. There's a happy balance we need to find, quickly.

11-14-2016 **EV Efficiency.** This topic is finally getting some traction. Pushback on it was intense in the past. That's because the use of electricity has been promoted as great under all circumstances. The idea of it being wasted was clearly a topic of turmoil to come. Today appeared to be the start of that. Volt enthusiasts could only antagonize for so long. Eventually, enough real-world data would emerge to reveal what they've been trying to conceal. This is why I've always expressed a bit of upset. Dismissal of facts you don't like is unacceptable. But until recently, they had found ways of suppression. EPA numbers provided a means of overcoming the barrier they built. I posted this, which takes me back to my "*not the same*" roots...

Being more efficient is very important. Here's a few electric-efficiency rating examples (fewer kWh is better):

31 kWh/100 mi = 106 MPGe = 2017 Chevy Volt
30 kWh/100 mi = 114 MPGe = 2016 Nissan Leaf
30 kWh/100 mi = 116 MPGe = 2016 VW e-Golf
29 kWh/100 mi = 111 MPGe = 2017 BMW i3 PHEV
28 kWh/100 mi = 119 MPGe = 2017 Chevy Bolt
27 kWh/100 mi = 124 MPGe = 2017 BMW i3 EV
26 kWh/100 mi = 133 MPGe = 2017 Toyota Prius Prime

Notice that Prime is the most efficient of the bunch. Its official rating is specifically 25.9 kWh/100 mi. Looking at those numbers, it's pretty clear to see that efficiency of electric propulsion varies.

- 11-15-2016 *Pacifica Hybrid.*** The big auto show in LA has begun. So, of course, we're learning more about upcoming new plug-in vehicles. The first is more detail revealed from Chrysler. But at \$43,090 for a base price, how is that going to attract a lot of buyers? Even with a \$7,500 tax-credit, that's still a high price. Though, it may be a good deal. The point of selling in high-volume for a profit is definitely questionable. Are people really looking for that practical of a plug-in vehicle. As a minivan, there is potential. It's really how to predict though. Minivans are the rage. Making one really expensive puts in in a challenging position. Remember the "hybrid premium" problem for Prius? How will this offering overcome that? Volt certainly didn't, despite a lot more EV range than this with 30 miles. We can hope for the best. 6 passengers and 260 horsepower sounds nice. But there's simply nothing to really give us a sense of demand. It's a complete mystery.
- 11-16-2016 *CT6 Plug-In.*** Quite unlike Chrysler's new plug-in offering, this one looks DOA. With a \$76,090 base price, how could it look anything other than dead on arrival? That's absurd. Wasn't anything learned from the first Cadillac with a plug? The price for ELR was simply too much. Even with cuts, the price wasn't competitive. Supporters were horrified when it started at \$74,995. The price drop to \$9,000 lower made little difference. With the CT6 also being an import from China, rather than coming from Detroit, the odds of more than just a few being sold in the United States are low. We get the feeling so few purchases will take place, it won't even do much for benefitting compliance requirements. How can a 30-mile EV range compare to Tesla? People expect more form luxury. What was GM hoping to achieve?

11-17-2016 Who's Laughing? I asked that after reading this comment posted about being cost-competitive: "*How about a Chrysler Pacifica Hybrid, LOL*" The thought that \$43,090 for a base price will draw in lots of interest isn't taking the situation seriously. That's requires heavy dependence upon the \$7,500 tax-credit. In other words, this problem emerging for Chrysler is the very same thing we saw for GM. Ugh. I proceeded with this, hoping for the best

When I came here looking for allies, that certainly wasn't what I got. For years, it was "vastly superior" cries. That eventually became "too little, too late". Since then, it has faded to nothing. Volt has been pretty much abandoned in favor of Bolt. That spells opportunity for a fresh start. So, I'll wonder again... friend or foe? How you respond to this equation is key: RAV4 hybrid + one-way clutch + 8.8 kWh

If you see that as inspiration for GM to pursue a compact plug-in hybrid SUV, we share something in common. If you see that in any way as not in favor of promoting electrification with a target of mainstream buyers, you're going to be pretty lonely. I'm not wasting time on rhetoric anymore.

Breaking out beyond the niche is what Toyota is positioning for. That potential should be obvious. You should be pushing GM hard at this point, raising attention that effort as well as what we see here with Chrysler Pacifica and with the upcoming next-gen Mitsubishi Outlander. Larger, more powerful vehicles with a plug are realistic. Finding a way to make them affordable QUICKLY is the challenge.

With gas just \$1.89 per gallon now and a new administration about to take office which doesn't believe that emissions are a problem or there's any reason to cut back on fossil-fuel use, it's time to reassess priorities. In other words, I'm reaching out now. We can all be in this together. It's not a laughing matter.

11-18-2016 Winter Photos, lakeside. I had only been driving my Prius PHV a little more than a month. The trip up north was well timing, though nothing like it was planned. I had carried bikes on back with the expectation of enjoying the trails. Early Spring weather makes that quite appealing. And with the temperatures having been so nice, I was really looking forward to the opportunity. Instead, we got a bunch of snow. Though quite unexpected (I hadn't even packed an ice-scraper), I took full advantage of the chance to capture the moment with my camera. Lots of photos were taken too. Unfortunately, they remained untouched on my computer for all this time. Now, over 4.5 years later, I'm finally sharing what I experienced back then... [photo album 191](#)

11-18-2016 Reality Crash. The flurry of excuses from just last year with the gen-2 Volt rollout was amazing. So even if you don't remember gen-1 Volt or Two-Mode rollout problems, that's a good recent example. Only thing is, with Bolt it's even easier to recognize. We have more than just fitting the pattern this time. I decided to point that out by responding to this: *"Not in CA or OR? No Bolt for you till Spring 2017."* That set me up for pointing out what should be obvious... and I did, expecting it to be taken as a reality crash:

The huge advantage GM had over Tesla is melting away. Taking an additional 6 months for delivery isn't what was expected or promoted. Meanwhile, 2 quotes in the recent Forbes article from president of GM's North American operations and head of global Chevrolet should raise an eyebrow: *"It's not about how many we sell."* and *"We need to sell them for the ZEV credits so we can sell the rest of our portfolio"*.

Each little detail like this reveals the reason why no talk of a plug-in SUV happens anymore. Those prototypes we saw years ago have just become trivia notes in automotive history. The potential popularity of an Equinox using Voltec would absolutely devastate the GM business model.

The writing is on the wall. Shooting the messenger doesn't do any good either. We've been through this before. It should be easier to recognize at this point. Brilliant engineering can be a victim of poor management choices. GM continues to repeat that mistake. Two-Mode, Volt, and now Bolt all follow that same pattern of being far too costly to sell in high-volume.

In other words, profit-margin of plug-in hybrids and electric-only vehicles is razor thin. That's why the quantity of tax-credits that remain is becoming a hindrance rather than helpful. Think about how much Bolt and Volt that would be purchased without the \$7,500 being available. There simply isn't any incentive for a business to undermine its own inventory... except for Toyota.

Prius Prime delivers higher depleted MPG than the regular Prius, mainly from having a better battery. Prius Prime handles better than the regular Prius, due to the heavier weight it carries. Prius Prime is priced competitively with the regular Prius, as a result of the "smallish" battery delivering such a huge return. Put another way, when the tax-credits run out mid-cycle, there's the potential for Prius Prime to become the "regular" Prius and the no-plug model transforming into a desirable niche.

Cost is what makes that opportunity possible. GM's unwillingness to shift away from the high-profit guzzling Pickups & SUVs is holding them back. Remember the hope that Bolt would take the market by storm? Look at this topic and other recent articles. With so many plug-in choices, what will make Bolt stand out? Remember, the supposed stand out traits for Volt didn't result in lots of sales. Also, keep in mind how the game has changed too. No one expected \$1.89 for gas or rescinding of emission & consumption goals.

11-19-2016 Winter Photos, back roads. My photo seeking took me through some picturesque back roads. I kept snapping the camera. Lots of nice scenery was available, with all that fresh fluffy snow and the wet pavement & dirt. The Prius PHV was still covered with a pile of white too. It all looked quite nice. I had no idea it would take so darn long to finally share them. But in the years that followed, I learned how to take really good quality videos to share too. Looking back to that simple beginning after all this time, I now have some nice memories of those first few days of ownership. In this case, it was a melty mess with all that fresh snow. I got really lucky having those back roads available to take advantage of with the camera, which I did, see... [photo album 192](#)

11-19-2016 Explosive Reaction. We've been through this nonsense before. The pattern matches. Only this time, it was more intense. The response to me was this: "*YOU WERE TALKING ABOUT THE TIMING ADVANTAGE !!!*" Then there was a post from that member-id created exclusively to attack me, followed by a mass voting onslaught. Seeing so much happen, so quickly, to such an extreme, was quite telling. The reason for that desperation was easy to see too. New plug-in reveals at the LA auto show showed us an industry with growth in the SUV market. The absence of GM from that stirred some raw emotion. So naturally, I was used as a scapegoat... again. They should know better than to draw attention to me... because I'll use that opportunity. And I did, with this:

Clearly, you didn't read beyond the first 2 sentences. And since that is now hidden, I'll have to post it again: The huge advantage GM had over Tesla is melting away. Taking an additional 6 months for delivery isn't what was expected or promoted. Meanwhile, 2 quotes in the recent Forbes article from president of GM's North American operations and head of global Chevrolet should raise an eyebrow: "*It's not about how many we sell.*" and "*We need to sell them for the ZEV credits so we can sell the rest of our portfolio.*"

The rest of my post provided observations and concluded by pointing out the problem: GM's unwillingness to shift away from the high-profit guzzling Pickups & SUVs is holding them back.

Explosive response to that was blatant confirmation of having nailed it. Enthusiasts had so hoped a compelling car (Volt) would shift away interest. It didn't work. So, GM moved on. Unfortunately, we already see the pattern repeating for Bolt. It obviously doesn't compete with Tesla based on visual appeal nor does it compete with GM's own offerings in terms of rugged appeal. It doesn't offer appeal to GM customers, which those quotes address.

Were you expecting a plug-in Equinox reveal from GM at the LA auto show and are now upset about that not having happened?

11-19-2016 **Once Upon A Time, photos.** It was a bizarre experience. We needed to stop while on our trip up north. It was along the way, a longer route I had taken many years ago. Unknowingly, it just happened to be across the rural highway from where I had stopped 2 other times over the years... to take photos with the Prius. I was an absolutely beautiful location next to a spectacular lake. Being right off the road like that, I had the golden opportunity to capture that scenic view by parking along side it. The fact that there was a business nearby hidden within the trees was a surprise to me... and the owner. He was shocked to learn I had taken photos there in 2001 and again in 2010. He had me connect to his Wi-Fi to show what the area looked like prior to him being there. It was a surreal experience, rewarding too... since I now have a third set of photos from that area with a third Prius. It was a remarkable happenstance. Needless to say, I'm very happy to share the photos of what I was able to capture on that beautiful and quite unexpected opportunity... [photo album 193](#)

11-19-2016 **Waiting.** This lesson not learned continues to be a problem: "*In the meantime, we will all have to be patient and wait.*" My hunch about how the unqualified trust comes about is from lack of information. The person making the comment simply doesn't have enough background to recognize what's happening. As always, I keep trying to post reasons why such a stance is a bad one:

Being reactive, rather than proactive, is how we got into this mess.

The push for GM to finally deliver something their own loyal shoppers will actually buy is necessary, now. I was amazed how complacent supporters were of gen-2 intentions for Volt. Things didn't add up. But rather than pushing, they said it was best to just wait. Ugh. We see how poorly that worked out. Bolt doesn't look promising either. There is good technology trapped in a vehicle most GM buyers simply won't be interested in.

Look at what the LA auto show revealed. The draw for plug-in crossovers is a market other automakers hope to capitalize on. It is absolutely nuts that a vehicle selling at a rate of 20K per month isn't being considered for electrification. What's happening to the hope people were expressing for Equinox being offered with a plug?

As for waiting until battery costs to drop, how does that help? The current subsidy of \$7,500 is to offset the current higher cost. It provides a means of lowering prices immediately. That allows automakers to establish reputation in the meantime. Affordable without any reliability history will hold back purchases.

What benefit comes from waiting? We are already at a cost far lower than what had been anticipated at this point. It's time to push for something actually able to compete on the showroom floor. There's simply no way Bolt is going to appeal to someone interested in purchasing an Equinox, especially with gas so cheap.

- 11-20-2016** **Charger Use.** On one of the plug-in blogs, I ran across this: "*These PP's will be clogging up chargers everywhere, just to get a little juice.*" It was a comment posted about Prius Prime earning the "Best Buy" award from Kelly Blue Book. In the past, there had been worry about EV owners getting stuck without a plug available due to plug-in hybrids using them up. In practice though, we aren't actually seeing that problem. Local travel doesn't absolutely necessitate that. The plugs being used are more of a "*thank you for your patronage*" type offering. You get the opportunity to drive a few miles more with electricity. They aren't intended for full recharges. People are starting to see that too. I'm quite curious if anyone will end up reply to my response to that. It's been an entire day now. No one has. Oh well, at least those thoughts of the moment are documented here: My local grocery store has chargers. The usual shopping stop there will provide roughly 6 to 8 miles of electricity. A rate of 3.3kW for 20 to 25 minutes is plenty. We have a retail store here with chargers too. How much juice do you need? At a coffeeshop or restaurant, being plugged in for a typical visit of 90 minutes would provide a substantial electricity replenish. The same would be the case for visits to a large shopping mall as well. What situation would cause a clog? In other words, what situation is there that could be a problem? The gut reaction is to say more is better. But in actual practice, we'll likely find that isn't really the case.
- 11-20-2016** **Distractions.** There have been enough of them lately to keep me preoccupied. Good thing too; the anticipation of Prius Prime delivery is growing intense. It reminds me a lot of my first Prius, back in 2001. Living in Minnesota, deliveries on the coast started before those here. That's what happens when you have to wait from those boat arrivals need to be loaded onto a train for transport to the center of the country. Posts sharing new owner experiences, especially when accompanied by photos, is helpful to steady the excitement. We have something to focus on while enduring out wait. I'll be contributing to it soon. 15 years ago, that worked out great too. That December just happened to be both the second snowiest and second coldest on record. Being able to share photos and my experiences with the Prius in that situation was priceless. I expect the same to happen again with Prime. That vapor-injected heat-pump will get lots of exposure to extreme low temperatures right away. We'll have lots of new material to discuss. I'll be able to share video this time too. There's so much to look forward to. Only a little more patience is needed. Soon.

11-20-2016 **Who Is The Market?** The routine "go away" response happened again. It's really odd to be treated as an outsider but not fit into the category of troll. Being constructive, while presenting yourself in a polite manner, goes a long way. There's no reason to ban someone who stimulates discussion that results in agreement. Several regulars there share my sentiment. This guy certainly doesn't though. Even though he owns a Volt and posts daily on that daily blog (now for Bolt), his unwillingness to accept the progress other automakers have achieved puts him in the position of being an obstacle. Interesting, eh? This is how I responded to the go away demand:

Here with our local plug-in owners group, there's a pro-battery outlook. Each owner shares information about pros & cons of their particular plug-in vehicle. We are working hard to get more chargers installed and to support salespeople truly interested in selling plug-in vehicles. Spreading of those details has clearly had a positive effect. We aren't afraid to address issues head on as a result.

Interesting thing is, I see how that approach has influenced you... despite claimed resistance. That transformation from anti-Prius to anti-Toyota did not go unnoticed. You recognize the huge potential available for RAV4 hybrid. Adding a one-way clutch and swapping in a larger battery with a plug would make it a viable competitor against its traditional counterpart. That's easy to see now, especially with sales of the hybrid model so strong.

I'm not going away, especially with the delivery of my Prius Prime coming so soon. It will deliver a full EV driving experience, even when the pedal is dropped to the floor and with the heater running. That's something you claimed would never be possible, that it was a dead-end technology rather than a contributor to plug-in acceptance.

Notice how the all the effort to market "EREV" has been abandoned in favor of "PHEV" promotion instead. That's a great indicator of progress. There's clear confirmation of who the competition really is. It's not other plug-in vehicles, as what had been so widely claimed & accepted. Its traditional vehicles. With gas now down to just \$1.89 per gallon, seeing that should be easy.

The goal has been and continues to be the selling of electrified technology to the masses. Continuing to lose sales opportunities on the showroom floor is unacceptable. Know your audience. Who is the market?

- 11-20-2016** **Setting Expectations.** It can be difficult to set expectations that are realistic, especially for a car, since everyone's driving is so different. Fortunately, I have quite an extensive collection of real-world data available to base those upon. This is how I expressed that today: I've been routinely recharging 2 times per day, since work offers chargers (powered by solar). That has been a great source of real-world data for consideration of how the next plug-in Prius could perform. My results of a simulated 8.8 kWh battery-pack (from having charged the 4.4 kWh twice) have come to 72.2 MPG. That's true lifetime for 84,549 miles, measured at the gas pump. It includes quite a number of trips up north with bikes on back and no opportunity to plug in. I also took 2 trips from Minnesota to Wyoming and back during the winter. That high-speed travel (much of it at 80 mph) really knocked the MPG average down. I suspect Prius Prime will do quite a bit better for me than Prius PHV, simply because the distance to work is within EV range. It's 19 miles. I'll be taking advantage of pre-conditioning with electric-heat directly from the grid. That will be absolutely wonderful in just a few weeks. Daily low temperatures are below freezing now. It won't be too long before the highs really drop. I have always seen the depleted efficiency as a major strength for a plug-in Prius. You get outstanding MPG even after the plug-supplied electricity is used up, as your 100 miles per day results clearly confirm. What other affordable plug-in hybrid could deliver such results?
- 11-20-2016** **Adequate, Typical.** I'm not sure how my response to this will be interpreted: "...you'll find this more than adequate acceleration for typical daily driving." It was from a troublemaker Volt owner who ended up abandoning GM after his lease expired, turning to Ford for his next plug-in hybrid. Those experiences with his Energi system resulted in a better understanding of Toyota's intent. He's one of those allies I've always sought out, but had to wait a very long time for the recognize of shared goals. Oh well... better late, than never... if this is taken as hoped: That's all people really need to know. It works fine. Adequate isn't exciting, but then again, you'd have to pay more for higher performance. Prius strives for balance. The 0-60 value is a marketing tool anyway. In actual driving, it is incredibly rare to drop the pedal to the floor from a dead stop and hold it there until reaching 60 mph. Most of the time, you're already moving when the acceleration onto a highway begins and you don't require maximum power. The only circumstance I can think of is turning onto a rural highway from a stop sign. But those are only 55 mph and you'd have total control of when your acceleration would begin, what mode you'd be accelerating in, and how much space you'd allow. So, it most definitely is a predication situation. Put it this way, I accelerate onto the highway in my PHV with no concern of whether or not the engine starts. To my delight, most of the time it doesn't. That means the Prime will easily fulfill the EV acceleration for the typical owner.

- 11-21-2016 Winter Purchases.** It was interesting to read the comments of a Bolt supporter trying to justify the rollout delay with: "*But IMHO, the REAL reason is to avoid chilly winter deliveries that create lower range numbers.*" I didn't accept that for a moment and fired off this in return: Real-World results is what convinces ordinary people the technology is worth consideration. That means showing the vehicle in snowy conditions, dealing with the extremes of winter. No award can compete with the endorsement an owner can provide from sharing stories of their experiences. Avoiding winter rollout delays that benefit. It also leaves people wondering how well the heater works and how effective preconditioning can be. We don't want to give a false impression of expectations either. Also, let's not forget how much grief Toyota has been given for not taking risks. Yet, they are rolling out Prime nationwide right away. Deliveries in New York and Colorado have begun. Neither of those states are warm. Allocation information for the Midwest will available next week. The expectation is extreme cold locations (like Minnesota, which isn't a CARB state) will be getting some. In other words, there's good reason to push GM and not just accept what happens. Getting a few deliveries to those other locations for the owner endorsement benefit is a gain for everyone. Think about how each plug-in offering contributes to squashing misconceptions and preventing greenwash attempts from spreading. I see no reason not to push. That real-world data is needed to help promote. Spring is 5 months from now. Gas will continue to be cheap. The political environment won't be favorable to plugging in. What will you do in the meantime?
- 11-22-2016 Order Status.** It's still unknown. The dealer will be looking into the upcoming inventory for the region, hoping that allocation will allow them to find me a Prime with my choice of colors & package. That should happen in about a week. Knowing only a handle have been delivered in the center of the country, I'm not too impatient. I understand that it takes awhile to satisfy the initial demand on both coasts and for transport to the interior to take place. If my configuration isn't the most popular, I could wait even longer. Obviously, I'd like to take ownership prior to the year ending. Otherwise, claiming the tax-credit won't be possible until 2018. That's not a big deal, unless you suddenly find your household is in need of a second plug-in vehicle that same year. The bigger deal is not missing out on cold-weather data and photo opportunities. Here in Minnesota, the extreme lows are only a few weeks away. Combine that with snow & ice, you've got great educational material available. I'm really looking forward to gathering & sharing that... but need to take delivery first. Hopefully, that won't take too long. Wish me luck.
- 11-23-2016 Short & Sweet.** I particularly liked this question: "*Begs the question though, is this a serious contender for sure?*" In the spirit of being to the point and not being negative, I replied with this for an answer: That depends upon what contender means. With respect to industry choices, it looks more and more to be the "*too little*" compared to Prime as compared to Volt being "*too much*". Toyota strived for a balance, going for a "*just right*".

- 11-23-2016** **Volt Smug.** I wonder how much this will continue: "*I now get 1,000+ mpg on my Volt, and that's driving close to 9,000 miles since August.*" The superiority attitude is very difficult to deal with. Fortunately, that isn't a stereotype. Most Volt owners are decent. It's only a few who spoil things for the rest. Unfortunately, those are the ones who make their presence well known in online discussions. They drown out posts of others... who end up becoming enablers by not speaking out against such behavior. I approached the discussion by asking a question: How many KWH and GALLONS is that? 26 kWh/100 mi, 133 MPGe, 54 MPG = Prime; 31 kWh/100 mi, 106 MPGe, 42 MPG = Volt. Prime beats Volt in each of the standard efficiency measures. Real-World results obviously differ. In my case, the 19-mile commute will easily be covered by the 25-mile capacity. So, looking at KWH and GALLONS actually consumed is required for better comparison.
- 11-24-2016** **Vague Claims.** As anticipated, we're seeing quite a bit of misleading grow. It's all in the form of relative-compare and statistical-compare. That first is when you compare a choice to another choice without the consideration of actual need. The well informed consumer is aware that marketing to want will convince you to purchase more than what you really require. That's quite wasteful, but extremely effective for emotional appeal. A sucker is born every minute... That's an unfortunate note from history. Centuries later, the gullible nature of people is still getting exploited. So naturally, when you confront someone on it, remind yourself the encounter may become a futile endeavor. Relative compares will always be that way. It's how they've been so successful. The other type is statistical. Rather than quote the actual quantitative measure for specific comparing, the value is stated in a percentage difference. That obscures the numbers by giving the impression of greater change or lesser impact. It's an effective deception method which exploits the principal of diminishing returns. In other words, you can portray something as better by sighting a higher percentage due to it's improvement or gain, rather than stating the a value measured. This type of intentional misleading is quite frustrating to have to continuously deal with; however, providing detail easily debunks their vague attempts.

11-25-2016 To Actually Compete. There's quite a bit of disconnect at play now. Many posting about plug-in offerings aren't taking the big picture into consideration. They only look at what's being compared. For the past few days, it has been comments about an article comparing Volt to Prime. That isolated perspective contributes heavily to posting battles... which is exactly what those publications seek. They want topics that stir participation. Today, I responded to such a comment in a long series of posts with:

Calling Prius PHV anything like "*pathetic*" shows a disconnect for what the market was actually like back then. It's like comparing a cell-phone of the time to what's available now. Consumer wants were very different and the technology has advanced quite a bit.

Large numbers of people were insisting upon an augmented Prius being delivered. That meant increasing the battery-pack size and adding a plug... which is exactly what Toyota provided in 2010 with their prototype rollouts.

I had the opportunity to drive one for a few days back then. It worked as hoped, the system substantially boosted MPG. Plug-Provided electricity enhanced abilities. The goal of achieving much increased efficiency without requiring a massive cost sacrifice was fulfilled.

There was no requirement to deliver an all EV driving experience. That expectation came years afterward, when it was clear that Volt sales growth beyond niche buyers was in serious jeopardy.

Think about what plugging in was like back then. Think about how few consumers there are that are even interested in purchasing a plug-in vehicle now. With gas at just \$2 per gallon and the popularity of small SUVs, the priority of Toyota to keep cost down is a really big deal.

Watch what happens to the plug-in market when tax-credits begin to expire. The pressure to have a MSRP low enough to entice traditional vehicle buyers will be a very, very big deal. Being affordable is key, not having a large battery-pack. You'll get EV driving that's able to actually compete.

- 11-25-2016 Crossover Point, part 1.** A favorite argument detail when comparing Volt to Prius PHV has always been the crossover point. That's the point at which gas-consumption is equal for the 2 vehicles to travel the same distance. Naturally, the greenwashing technique used was to completely disregard electricity use. Sadly, there are many who simply don't care about switching from one fuel to another without making an effort to consume less. They see electricity as clean & abundant and don't give it a second thought. That's a difficult attitude to overcome. They come off as incredibly smug too, dismissing your efforts to reduce consumption as anti-EV. It's a very real problem. Gas is bad, period. So, the effort to overcome their resistance to be constructive is an on-going challenge. This caught my attention: *"That 149 miles only works if you disregard total efficiency and focus only on gas consumption... which is an absolutely terrible way to promote green choices."* They never provide any detail. It's always nothing but a distance. That makes the effort even more difficult. Nonetheless, I tried: Those extra 28 miles of EV from Volt must be accounted for. That's extra consumption of 8.7 kWh of electricity more than Prime would use. That difference cannot just be ignored. We don't want to promote carefree consumption of electricity... especially if the source is dirty and/or not renewable.
- 11-25-2016 Crossover Point, part 2.** Needless to say, he got annoyed by my response: *"28 miles means 8.7 kWh? I don't know where you get this math from. Either you are completely making it up or you have NO idea how much the battery Volt uses to get 53 miles from."* That made me wonder more than ever where he got that 149-mile distance from. Not sharing any detail whatsoever, no other numbers of any sort, provides nothing to work with. So, I attempted to provide them all with my reply: Prime delivers 25 miles of EV. Volt delivers 53 miles of EV. The difference is 28 miles. You can't just omit that electricity consumed for those 28 miles from the efficiency equation. That must be accounted for. 31 kWh/100 mi is the rating for Volt. It means 0.31 kWh is consumed per mile of EV travel. Multiplying that by 28 gives you a consumption value of 8.7 kWh. In other words, the gas quantity for the 149 miles is the same but the electricity clearly is not. Volt will consume an extra 8.7 kWh of it to reach that same destination. It simply isn't as efficient of a plug-in vehicle, as the EPA ratings tell us. Put yet another way, it will cost you roughly \$1 more to travel the 149 miles in a Volt than in a Prime. That's at a rate of 12 cents per kWh of electricity.

11-25-2016 **No Truths.** This certainly got my attention: "*While the Toyota Prius Prime comes out ahead with a price tag that is cheaper, it offers the same output as the Chevrolet Volt and is more efficient in regards to MPGe and mileage, it seems that the Volt is the more popular vehicle. So let's take a look at the specs and find out why the Volt comes out ahead despite the figures suggesting otherwise.*" That was the opening paragraph to an article with this title: "*Figures Tell No Truths*". I was quite intrigued to see what it had to say... so much so, I wrote this lead up prior reading. That way, you get a clear representation of my initial impression. Now, I will read it.

Sadly, the article literally said nothing. It only posted numbers without anything to put them in context. That's seems like a good approach, giving you the information you need without any bias. Unfortunately, that's exactly how greenwashing works. A value provided without an explanation of what it represents is misleading. In other words, it contributes to assumptions. Making people assume is how the deception works.

Anywho, I looked to the closely statement to figure out what the writer's intent was: "*Despite the numbers being in the favour of the Toyota Prius Prime 56% of people chose to go with the Chevrolet Volt.*" That made it obvious. No source for that percentage was provided. Where did that number come from? Was it a survey? How many participated? When was it conducted?

All I can know for certain is that 56% most definitely wasn't based upon sales... the only quantity that truly matters. Prime isn't available on dealer's lots yet. Heck, even those of us attempting to place early orders are still waiting for delivery. There is simply no constructive way to draw such a conclusion. A consumers can say anything they want when no money is involved. Stating your opinion with your wallet is an entirely different matter. That opportunity is still not available

11-25-2016 **Bolt Rollout.** Being limited to just California & Oregon until sometime in the Spring is bringing back bad memories from last year. Not only is Bolt late, it isn't nationwide. Sound familiar? Whatever the impression, it grows worse when getting news of Prime rollout. Claims of it only being a compliance vehicle are quickly falling apart, simply by stating what states new owners are reporting purchases from. So far, I have read about experiences shared (many with photos) from owners in California, New York, Colorado, New Jersey, Arizona, Iowa, Missouri, Maryland, Washington (state), and Illinois. I know that irritates Volt enthusiasts to no end. With gen-1 having struggled, then gen-2 suffering in a similar fashion, and now Bolt, what is there to say? I know if I post anything, it will be perceived as an attack. So, pointing out articles which highlight the economy nature of Bolt's interior, rather than focusing entirely on range & power, will infuriate. Needless to say, I should just keep quiet. That long-await shared purpose of promoting green affordable choices will happen, eventually. I only need be patient. Sales challenges with this rollout will help us find that common cause.

- 11-25-2016** **Missing The Point.** It happens far too frequently. People get hung up on things that make little or no difference. It's a common problem online. Keeping the attention of some is nearly impossible sometimes, especially if you want to share detail. Some simply don't care. They say their piece have no interest in anything else. That's the nature of encounters in comment sections of articles for many. That makes any type of effort to be constructive a major challenge. It's still worth trying though. For every troublemaker, there are likely countless scores of lurkers. In today's case, I kept the reply concise and without measure, to make sure the bigger objective would stand out. Hopefully, it did: Toyota has delivered a more efficient system with a lower production cost. That's what will fulfill the goal of high-volume profitable sales without dependency on tax-credits. Those who disregard that, insisting that greater performance or range is needed, are missing the point.
- 11-25-2016** **Objective Thinking.** Phew! It's nice to get some of this now: "*Toyota has done that at the cost of a lower electric range. For people who drive less than the US average daily distance the PHEV Prius will be a good choice.*" Hopefully, my additions to that will be readily accepted: For people who drive more it will be a good choice too. 72 MPG is my lifetime average after 85,000 miles driving in a 2012 Prius PHV, charged twice on most days. Double the 4.4 kWh battery-pack is the 8.8 kWh now offered. So, even without a recharge opportunity as I have at work, they'll get that efficiency with a Prime. My driving is in Minnesota, so that real-world data includes some pretty harsh conditions. I've taken a number of road-trips too, without the opportunity to recharge. In other words, Prime will be able to reach into the mainstream with a price that's actually able to compete directly with the true competition... traditional vehicles. Think about how much of a challenge it is to entice shoppers on the showroom floor.
- 11-26-2016** **Red Herrings.** They distract from true purpose. Some are intentional Some are oversights. All pose barriers. I added this to the on-going debate: Toyota recognizes the "*almost never*" crowd and has taken a risk... the very thing antagonists claim they don't do. So, they are offering more comfortable seating in back rather than squeezing in a narrow middle spot for brief use. Think about how many times you've had 5 people squeezed into a midsize car with "*seating for 5*" in it. Toyota is being practical by altering the paradigm. You want more seating in the future, you'll end up buying a larger vehicle. It's like chasing the acceleration red-herring. Why waste resources on something that would rarely ever be used and isn't actually necessary?

- 11-26-2016** **Like Volt.** What can you say when parallels are drawn that are just plain wrong? The perception that Prime is supposedly competing directly with Volt is to be expected. It's as weak as when Prius was compared to Insight though. 15 years ago, that's all there was. So, that's all people knew. Now, people really only know Volt. That means the same type of misunderstood assumptions of purpose will occur. I suspect many parallels to that situation long ago will surface over the next few months. Remember all that "*not the same*" nonsense? We'll see. In the meantime, this is how I put the situation of who, why, and expected reach: They are not the target market for Prime. Target is striving to grow the market, to reach beyond niche buyers. Achieving sales from mainstream customers is far more difficult than appealing to early adopters. Also, there's the reality that a large quantity of small battery-packs will have more of an environmental benefit than a small number of large battery-packs. It's no different than the way renewable combustion fuel is consumed. E10 usage in every regular gas vehicle has had a profound impact compared to the tiny amount of flex vehicles actually using E85.
- 11-26-2016** **Enough Horsepower?** It's great getting doubt in the form of wanting to find out more, rather than drawing a conclusion with little to no data. Those absolutes of the past were extremely difficult to address. They wanted no part of a discussion. It was a complete disregard for objectivity. Today, one of those nice posts was: "*I appreciate Toyota's desire to keep the car in EV mode as much as possible, but I just don't think the car has enough HP to do that well.*" I was happy to reply to that: Prius PHV already delivers enough for ordinary highway merging. I've surprised myself a number of times noticing that the engine never fired up. The increase in EV power for Prime will make that even less of a need. In other words, I think people will be pleasantly surprised that in EV AUTO it will stay electric-only on most drives.

11-27-2016 Toyota's Approach. There was a new article posted on a green-vehicle website which attracts a wide variety of posters. Almost immediately, an antagonist post appeared. It was the first comment too. By the time I posted a reply though, it had already been removed. I wasn't sure why either. It wasn't that bad. Anywho, my reply was lost upon refreshing later. So, it only appeared briefly. Fortunately, I saved it here. The comment was about how Toyota is finally coming around to EV offerings, despite having supposedly be so opposed to it in the past. I posted:

The perception of "*trash talk*" was never understood. People believe and repeat what they want. So, looking back at history distorts the current reality. I remember a presentation back in 2007, where Toyota clearly sighted the reason for not offering a plug-in was cost. The reaction online was spin about lithium batteries being unsafe... despite that never having been stated.

The other 2 deterrents of plug-in offerings were a big deal too. The one was obvious: size & weight. To offer something even remotely competitive with traditional vehicles in terms of distance, you had no choice but to keep the vehicle small. Heck, even Tesla confirmed that with their first offering. The second was often overlooked: recharge speed. Look no further than Volt for perspective. Full recharge time using level-1 takes around 13 hours. Getting people to add a 240-volt connection in their garage presents a very large challenge for high-volume sales.

Think about how Prius Prime paves the way. It's a full electric platform, complete with a vapor-injected heat-pump and CHAdeMO recharging. Everything is in place for accommodating larger battery-packs. In fact, a capacity increase mid-cycle appears quite realistic. It's an affordable platform with a great deal of potential. Heck, even a plug-in hybrid version of RAV4 looks realistic.

In other words, there is no back-pedaling. The approach was well thought out, but really frustrated some who felt a different path should have been taken to get to the same point.

11-27-2016 New Hate. You gotta love posts that end with: "*You are just an ignorant ignorant Toyota fan boy.*" The ironic nature of nature of that comment compels me to reply again. Since the intent of the design variation of Prime with Prius is a clear effort to attract different Toyota buyers, of course anything said in favor of it would be considered a "*fan boy*" comment. What else could it be? The goal is to achieve market growth. How would that be possible without offering another choice? Talking about ignorant of how the economics of business works. To draw interest from those shopping the showroom, that diversity is essential. As for the decision to go with comfortable seating for 2 in back, rather than squeezing in 3 and trading off extra storage, look no further than GM. After about the first 2 years of Volt availability, arguments in favor of offering that middle position faded away. And when gen-2 finally rolled out, it still didn't. There is nothing but a legless hump with a seatbelt. Quite a number of luxury vehicles don't bother with the seat in the middle either. If you have a larger family, you're not going to be driving a midsize car anyway. That's what the full-size vehicles are for. Too bad if you don't like a shift away from the status quo. Toyota's effort to try something else should be congratulated. Just think if buckets in back catch on. Someday, they could offer them as heated seats. After all, heated seats in front are now standard.

11-27-2016 Acceleration Considerations. It's nice having constructive discussion. I added this to a comment about a test-drive post with Prime: 16 years ago, when I got my first Prius, there were many antagonists hoping to undermine hybrids success by emphasizing the slower acceleration. They had an extremely difficult time proving the 12.5 seconds for 0-60 was dangerous, as they had relentlessly claimed. The maximum-power from a dead-stop scenario was too rare and the acceleration was adequate. Being "adequate" is obviously a hard sell though. But when the next generation came out and was discovered to be faster, all those troublemakers vanished. If you carefully observe ordinary highway merging, you'll notice it takes quite a bit more than 10 seconds anyway. The flow of traffic simply isn't moving that fast. Dropping the pedal to the floor isn't necessary. EV AUTO mode provides that "*if I need it*" confidence. The default EV mode provides what some have been begging for years for, an option that keeps the engine off under all circumstances. The choice is yours. I'll be sharing my firsthand experiences with Prime soon enough. Hopefully, I'll find out on Wednesday where my order is in early December inventory.

11-27-2016 Looking Forward. Getting beyond the basics is difficult. Many have been blinded by something in the past. This is an effort to open the minds of those who hadn't given much thought to the bigger picture:

The belief of hydrogen not being able to co-exist with EVs and hybrids not being a path to full electric-only drive is successful greenwashing. People have been taking advantage of those assumptions and exploiting the opportunity to mislead about Toyota.

As for the claim of easily adding level-2 charging, you are sadly misinformed. We have many neighborhoods without the infrastructure readily available, requiring new wiring at significant expense. We have apartments & condominiums that simply won't provide support at all.

This is why starting at level-1 will have far greater of a reach. 5.5 hours with an ordinary 120-volt circuit they already have available is realistic for a much, much larger audience. You can take advantage of level-2, but not being required for a full-recharge during off-peak hours isn't necessary. The outlet & time is likely there already for a wide variety of potential customers.

We'll see expansion to larger capacities increase as support ramps up. Currently, there is a great deal of discussion taking place with electricity providers. They are struggling with approach still. My local plug-in owners group has detailed discussions on a regular of their progress. Once those providers throw their support into the mainstream to stir customer interest, battery technology advancements (like that of this article) would have been proven out.

Think about what Prius Prime will do with respect to provoking owners to upgrade from level-1 to level-2. That's a far easier endeavor than convincing someone considering the transition directly from traditional vehicle to electric-only.

Also, don't forget about the desire for more amps. How much will that level-2 charger be setup for? Will the base draw of 16-amps really be enough? What about 30 or 40? What will owners be willing to invest in? Have many will their current supply be able to provide?

11-27-2016 That Attitude. It's back! I wonder how much and how often we'll see this: "*Volt is superior to Prius.*" It's return was a bit of a surprise. With so many of the antagonists having shifted support from Volt to Bolt, that really wasn't expected. But then again, the rollout of Bolt as revealed the interior is a bit more "economy vehicle" than had been anticipated. Having it turn out to be less of a Tesla competitor as hoped means attempting to revive Volt. What a mess. Oh well. At least I am well prepared to deal with it. This time around, they have far less greenwashing material to work with. This is how I decided to reply: I remember that complacent attitude from back in 2012. Reality came crashing down afterward, when the struggle to grow monthly sales beyond 1,700 became undeniable. The next-generation of Volt was to overcome obstacles, allowing it to achieve the mainstream minimum (for sustaining profitable business) of 5,000 sales per month. That hasn't worked out either. Prime exhibits potential to reach a much larger market, so the superiority cry is no surprise. Rather than work toward something for the masses, there's an effort is to brag about speed & power. Ugh.

- 11-27-2016 Leadership.** For many people means breaking new ground. They take the definition literally and never give it any other thought. So, stumbling across this was expected: "*[Toyota is] a leader in the hybrid market and a follower in the electric vehicle market.*" It makes sense from their perspective. Prius clearly delivers the highest MPG and there is no EV offered. The idea that about technology being more than just the concept of "*bigger is better*" isn't ever considered... to the point of bewilderment. Being ahead in the race is only a matter of being further away. That concept of affordability isn't part of their mindset. It comes from having been raised in an obsessive & competitive environment. Things like being practical is for the weak. Ugh, again. Anywho, I'm curious if this new audience on a new green website will be any more receptive to there being more than one way of being a leader. Curious, I posted: Leadership is getting ordinary people to change. We still very much see EV owners as niche buyers. They don't represent people from the mainstream. Those ordinary people have yet to be enticed by plug-in options. Reaching the masses is far more difficult than appealing to early adopters. Taking a look at the market, you'll see that much of the low-hanging fruit has been picked. Leaders will be determined by whomever is able to attract new interest and grow sales.
- 11-28-2016 Hybrid Trucks.** I knew responding to this would stir trouble: "*Toyota would save more fuel by hybridizing large vehicles instead of building more Nissan leaf type cars. Pickup trucks, minivans, etc.*" There's a blindness in certain groups. There's a mix of poorly informed with those who choose to see only certain things. That makes big-picture type discussions nearly impossible. So, when you point out something counter to their belief or stance, they often lash out with anger... which is clear confirmation of the message having been received... which is why I post stuff like this: Toyota has continued to advance their large vehicle efforts, rather than abandon them as GM and Ford. Highlander hybrid offers 5,000-pound towing capacity with 4WD, delivering a 28 MPG combined rating. That's a large vehicle. It's available today. Their smaller hybrid, RAV4, been selling remarkably well since it's debut early this year. Think about how easy it would be to add a plug option, following the design approach used for Prius Prime. Note that the AC plug option from Toyota has been available in Japan for a few years. It can deliver 1,500 watts.

- 11-28-2016 Shareholders.** What do you think upon reading this: *"It took this long for Toyota to see the light, I wonder what the shareholders in the future will think of the CEO's performance during these last few years."* Since sales of Toyota vehicles have been quite strong, it seemed absurd to express such a stance. That success has allowed for investment in hybrids, plug-in hybrids, fuel-cells, and now electric-only vehicles. Where's the problem? What's the concern? I knew what he was getting at, since the context of the discussion was about leadership. That belief is the most EV range how you identify the leader. Such a gross-oversimplification is a very real problem. Volt enthusiasts still suffer from such short-sightedness. Oh well. All you can do is point out the other factors of importance, as I attempted: Shareholders invested in the company's long-term well-being don't fall for the "*leader*" trophy distraction. They want strong business returns, which don't focus on racing to be first. Toyota understands the wisdom of targeting the masses by offering a well-balanced choice, rather than stretching for a maximum. The future is about competing with traditional vehicles directly. So, none of the petty plug-in bickering will matter anyway. Shareholders are well aware of what sells profitably in high-volume without tax-credits. They understand the true competition.
- 11-28-2016 Rant on Owners.** Whoa! One of the long-time residents, those intense daily posters who think they own that particular forum, jumped on me screaming stereotype today. I wondered how long that would take on the new website. He was pretty angry too. Ironically, he was a cookie-cutter absolutist. All electricity is good. All gasoline is bad. That type of purist attitude is quite familiar. In this case, it was an example provided by the exclusion of EV miles. As far as he was concerned, they don't matter. All that matter is how much gas you use... which is what we've heard for years from Volt enthusiasts. They just omit KWH usage, only stating GALLONS. I wasn't willing to watch that nonsense continue: Because it's electricity, it doesn't matter how much is consumed. Wow! That is an absolutely terrible attitude. Wasting a renewable resource is still waste, especially when it is far from abundant. We need to strive for the most efficient use of electricity. Some EV systems are less efficient than others. Intentionally excluding that data is just plain wrong.
- 11-28-2016 Wild Spin.** I have no idea how to deal with someone who thinks I'm in fighting against efficiency technologies. It's quite bizarre to encounter someone so close-minded or paranoid of change. Shakeup to the status quo is becoming apparent, but I certainly didn't expect anything like this: *"No, intentionally spinning the story to favor a mostly gasoline burner is just tactic that often a fossil fuel supporter would do."* That is so twisted, wild spin isn't enough to describe it. My thought is to begin with a question, followed by pointing out how to view the situation: What is a "mostly gas burner"? Vague labels with arbitrary levels don't help anyone. That's why there are rating systems and quantitative measures. You get a grade, not a pass/fail.

- 11-28-2016** **Blatant Attempts.** The response to my wild spin reply was an outright lie, a blatant attempt to greenwash: "*Prius Prime is mostly gasoline burner when more than half of its miles are powered by gasoline rather than electricity.*" I couldn't believe it. He had posted statistics from other plug-in vehicles, claiming they applied to Prime. We're back to that "not the same" problem. That happens when you attempt to fit everything into a single category. It's how his obvious stereotyping came about. He's been fighting for so long, he's lost perspective. Dealing with the change Prime brings is something he clearly isn't prepared for. I wonder how well I am. This is how I responded: Such blatant attempts to mislead. Without any real-world data at all, you just declare "half" and label THE results. Stop wasting our time. Readers of this aren't that gullible. They'll see how shorter drives will easily be 100% electric and that longer ones will still be over 50% which is both arbitrary and vague. The keen observer will also notice the effort to avoid actual quantities, choosing to use relative measure knowing it can distort impressions and contribute to assumptions.
- 11-29-2016** **Rain.** This was refreshing to see: "*Are there any issues with plugging in when it is raining?*" I was happy to reply to that too: Yes... you get very wet. :) Unlocking the public charger really does prevent a quick & dry experience. It's no big deal though. I've done it countless times over the years. What's more of an issue is unplugging after getting a few inches of snow. The act of brushing off the snow prior to removal gets a bit messy. I've found myself a number of times blowing, to avoid too much staying behind the door. What's interesting is how well design the actual socket it. The specs were very clearly thought out. Plugging in rain & snow works just fine.
- 11-30-2016** **No Plug.** Eeek! No electricity available. Oh, the horrors. It's not really that bad. The topic does come up on a regular basis though. Being able to contribute with very recent real-world data is great. This evening, I had an opportunity to share such an experience: I'm quite curious how Prime will do here without plugging in. Hopefully, I won't have to wait too much longer to find out. This evening, it was a run out to go Christmas tree shopping... shortly after getting home and not having any electricity available. 42 miles of driving, mostly highway, with the temperature only 36°F out resulted in a pleasing 49 MPG average. Back when it was warmer (2 months ago), my 172-mile drive home from up north came to 58 MPG. That was especially impressive for no plug results. So, there's definitely much to look forward to. Here where the heater is absolutely essential, efficiency from the engine even when you have plugged it will be nice. It will be very exciting to witness my Prius PHV performance records being easily shattered by Prime. We take a number of very long drives over the holidays to visit family.

- 11-30-2016** **\$9,000 Loss.** An opinion article was published today, claiming that GM will see a \$9,000 loss from each Bolt sold. Whether that is true or not, it does raise the concern of profitability. If there is enough evidence to support such a large amount belief, odds are quite good the best-case scenario is only a razor-thin profit... which means a very serious challenge when the tax-credits expire. This is how I jumped into the discussion on the big Prius forum about the article: The point is that GM continues to follow the same approach... deliver something unprofitable with the hope of cost dropping fast enough to catapult the technology from niche to mainstream in only a few years. With Volt, that failed on a colossal scale. So, we should ask what makes Bolt different. How will it avoid the same pitfalls? The approach Toyota has taken is pretty much the opposite extreme... offer a vehicle with specs that won't compromise profitability. That naturally leaves enthusiasts wanting more and provides antagonists lots material to undermine with, but it doesn't sacrifice the opportunity for high-volume sales. In other words, how will GM proceed with so few tax-credits available for Volt & Bolt, knowing how important it is to reach mainstream consumers?
- 12-01-2016** **Suddenly.** As expected, that opinion article claiming a massive loss for each Bolt sold stirred quite the uproar. That nonsensical daily blog had it's spin on the situation: "*Why is Toyota suddenly jumping in with both feet? So they can lose \$9k on every sale? Doubtful.*" That was such a lame attempt to take the spotlight off GM, I had to really think about how to respond... since you typically only get a single chance, then the spin overwhelms your original message. My choice was: Toyota is waiting until the next product cycle. That's not suddenly. Ford, Nissan, Honda, and Hyundai are all waiting too. Heck, even Tesla is 2 years out still. Cost is very much an issue still. That's why GM is proceeding cautiously with Bolt volume and holding back on Volt. Once the tax-credits expire, it becomes an even bigger issue. This is also why Prime will offer full EV abilities but keeps capacity to realistic minimum. More can be provided later, like with a mid-cycle update. The key is focusing on everything else in the meantime. In other words, offering a plug-in hybrid while waiting for the EV with a large capacity to become cost-competitive... which is why an article like this came about for Bolt. Compared to the profitable vehicles, losing even a small amount of money from each EV sale means a lot being available simply isn't going to happen... yet.
- 12-01-2016** **Silence.** It was wonderful to see something constructive emerge: "*GM's silence speaks volumes.*" Of course, there was little chance of it leading to much useful discussion. Online comments tend to fall apart quickly. We'll see if this results in anything: 21,600 Equinox were sold last month. Not hearing anything whatsoever from GM about offering a more efficient choice makes you wonder, especially with GM's history of favoring tech for the larger vehicles. Remember Two-Mode? Not only was that developed for making their SUVs more efficient, it resulted in prototypes of plug-in models. How come we haven't heard a peep since? What happened? Why was that effort halted?

- 12-01-2016** **Deflection.** You try to have a constructive discussion. As soon as something is stated that resembles the success formula Toyota has had, they switch the subject over to either Prius or fuel-cells. They attempt to deflect a valid point by changing the subject. It's so juvenile; yet, it happens all the time. Heck, we even saw that with the presidential debates. When has good even come from attempt to avoid dealing with a problem? I don't even bother anymore. I just state a relevant fact to end the claim and restate the original post. In this case, it was that Toyota is doing nothing to improve efficiency of their larger vehicles... which was an obvious deflection of the "*silence*" response. I posted: Deflection doesn't work anymore. Toyota offers a 4WD hybrid with a 5,000-pound towing-capacity (Highlander), an AWD compact SUV hybrid (RAV4), and a plug-in hybrid with full EV driving (Prime). RAV4 hybrid has been selling well and the potential for it to offer a plug using the same approach as Prime is very real. Again, why is GM not saying anything about any type of efficiency offering for Equinox?
- 12-01-2016** **More Deflection.** Wow! Talking about desperate: "*I don't think Camry Hybrid and Highlander Hybrid are big sellers.*" That had absolutely nothing to do with why GM was pushing Bolt, rather than focusing on offering Equinox as a high-efficiency vehicle. Of course, if they actually studied GM plans, they'd discover Equinox will be getting a diesel option... clear confirmation of lack of intent with battery tech. I didn't bother. The obvious avoidance of RAV4 made it clear they understood customers were being left without any purchase option, the very thing they accused Toyota of in the past. So, I commented this way: More deflection. What does that have to do with anything? 3,757 RAV4 hybrid were purchased last month. Substitute the current battery with a 8.8 kWh capacity pack, then add a plug and one-way clutch like Prime. Combine that with a \$4,500 tax-credit. What do you think will happen? In other words, Toyota is far closer to offering a plug-in compact SUV than GM. Yet, we are constantly having to deal with the claim that they are not doing anything and demonstrate no leadership. Equinox is a very popular GM vehicle. Why in the world are GM supporters not pushing to have it offered with a plug?

12-02-2016 **Zealots.** Seeing an attempt to label someone a troll requires consideration of source. The niche disaster with Volt made this statement today a major point of contention: *"By and large, current Volt owners are EV Zealots."* Extreme frustration has come about from seeing that sales still haven't achieved mainstream levels, despite the gen-2 upgrade. So, identification of a bulk of the owners being enthusiasts stirs deep emotion. It's confirmation of a goal not being reached. The result is lashing out, trying to belittle & insult the messenger. With GM tax-credits now divided between to fundamentally different vehicles, concerned is raised for expectations. What should they be? I climbed up onto the soapbox to express my concerns, with respect to the quote above:

There's been a fierce resistance to audience. That's why *"Who?"* continues to be asked. They just plain don't understand GM's own loyal customers. That's why when sales get brought up the discussion inevitably gets turned to Prius. It's because Toyota found a way to draw interest from their own showroom shoppers.

This topic of Bolt being a money loser serves to stir bad memories, when Volt sales came in the form of unsustainably low leases, followed by a massive price-slash. The upgrade to gen-2 did very little to change the sales struggle too. As was stated today: *"Total year to date sales of 21,048 units put it in range of narrowly topping peak sales years of 2012 (23,461 units), and 2013 (23,094 units)."* That says it all.

Growth to the mainstream minimum of 5,000 per month continues to be a problem, Bolt only makes that situation worse. The tax-credit is to help establish sustainable sales from the automakers own customers. Conquests don't achieve the necessary replacement of traditional vehicles with cleaner technology.

The purist mentality contributes heavily to the problem. Notice how the *"gallons saved"* promoting completely fell apart? It was fundamentally flawed; forcing people to look backward rather than forward. There was nothing to contribute to growth. Stirring interest wasn't possible... which sales overwhelming confirmed.

It's really unfortunate how they intentionally choose to promote niche thinking, rather than reach out to understand what those ordinary traditional vehicle buyers actually wanted. Too bad if they don't like the engine starting up from time to time. Too bad if owners don't upgrade to level-2 charging. Too bad if power doesn't throw you back in your seat. The goal of getting people to embrace the idea of plugging in for their primary travel is still achieved.

Looking back through this thread, it's quite clear that there isn't recognition of the problem and it will persist as a result. There are claims of intent, but there is no supportive action. All talk is what you get from zealots, attempts to win daily debates rather than taking on actual change.

Again, those tax-credits will only last so long and the number of full-value ones is limited. Squandering them away without setting very clear accountable goals is such a waste.

12-02-2016 Plug Placement. On a random blog site, I found a comment about Prime's plug placement interesting. He's an expected owner, impatiently awaiting delivery like me. The opinion expressed was that the position on Prime that Toyota decided upon was a mistake. That brought me back to the discussions we had about PHV prior to its rollout. My thoughts were shared. No common theme emerged. Different people have different ideas, all without actual plugging experience. Following rollout, we didn't hear a peep. The impression was the choice was a wise one. This is an opportunity to find out more, from a new audience. Only this time, there are some (like me) who have years of experience to share. So, I did: You'll discover that plug placement not a mistake, it's an advantage for at home. The location in the rear on the passenger-side allows those with tight garage parking to conveniently plug in. Park with the passenger-side up against a wall, leaving the driver-side open so the door has room. You'll quickly notice the benefit. You can easily reach the socket and there's no cord to have to walk around. It can be close to the location of the charger too, being near the corner of the car rather than near the middle. I know this quite well. I've owned a Prius PHV for 4.5 years. At the house I lived when I first got it, I backed in with the passenger-side against the wall. (btw, that is a breeze to do with EV mode. The power and slow RPM available from the electric-motor really simplifies the process.) That allowed my wife to just pull in with her car and both our driver's door to have ample room to open. (If she also would have had a plug-in Prius, she'd be able to plug in too.) At the house we moved to, the door for entering the house is directly in back of the garage, rather than off to a side. The benefit of that should be easy to recognize. The plug handle & cord would be sticking out in the walkway between the cars. That would be quite annoying to have to routinely deal with. I'm pleased Toyota decided to retain that same placement for Prius Prime.

12-02-2016 Prime vs. Volt. A comparison video is making the rounds online. It's quite constructive too, very well thought out and without bias. So, I was quite curious when it got posted on a GM supporter website. This was the first comment that resulted: "*The Chevy Volt will beat the Toyota Prius Prime in all details except cost and long distance driving MPG.*" That claims was a gross over-simplification, if not considered misleading. We know for a fact Prime is more efficient. If you drive only EV miles, there is no contest. Volt is the guzzler in comparison. But it's not worth addressing that aspect until an ample amount of real-world data is available... since the enthusiasts only care about EPA ratings when it is to their advantage. Anywho, the person who posted it is an antagonist who seeks out the opportunity to belittle and does all he can to avoid detail. That meant being creative with the reply post: Cost is far from trivial, most definitely something GM cannot just brush off as you did. Prius Prime is well configured to be able to compete with the true competition (traditional vehicles) when tax-credits expire... which is key to reaching high-volume profitable sales. Ordinary consumers want something well-balanced and affordable. Paying for more EV they may not necessarily even use isn't a priority. And if they do use it routinely, they'll need to invest in a level-2 charger and a 240-volt line for their garage, since 13 hours recharge time for Volt on level-1 isn't realistic. For plug-in choices to be adopted by the masses, it is necessary to step away from the niche perspective. Remember, most people have no issue whatsoever with using gas. So, pushing the perspective of EV purity falls on deaf ears. They simply aren't interested in gas elimination. They do express a desire to greatly reduce gas consumption though.

12-02-2016 **Trouble Coming.** There's a very real hate growing for Prius supporters among Volt enthusiasts. Reaction to sales results today makes that quite clear. Growth of gen-2 Volt simply hasn't materialized yet... *"too little, too slowly"* really hurts now. The outlook is for 2016 sales is for them to match that of 2012 and 2013. That look really, really bad. With Toyota, Hyundai, Chrysler, and Mitsubishi all rolling out plug-in hybrids within the next 9 months, that's even more pressure on the struggling Volt... which soon faces competition from within. Bolt is about to steal its thunder (pun intended). That growing conflict from within GM itself is hard to deal with. That frustration cannot be taken out on loyalist; so naturally, they lash at the most obvious target: Prius. I find that quite annoying. But what's more telling is the posts in response: *"Plug-ins have well surpassed 5k/month. We're averaging around 12k/month..."* That was astonishing to read. I couldn't believe it, hence this: That's an interesting new & desperate way to spin the profitability requirement. You know very well that GM set the 5,000 per-month level for one vehicle model (Volt), not the entire market of plug-ins. The reason is obvious. Overcoming losses requires a least that level of sales. The fact that you aren't even trying anymore is a clear indication of trouble to come.

12-02-2016 **The Trap.** This quote came from a well-known troublemaker working aggressively to misrepresent: *"Sorry.. not going down the rabbit hole this time."* It has been interesting to see the extremes he exerts to conceal the past. Ironically, he calls what I do as revisionist history. In reality, he is projecting... accusing someone else of his own doings. It's an odd situation to deal with, especially when the personality you're fighting believes in absolutes. Anywho, it's quite clear that sales trouble is on the way. The *"good enough"* attitude is a dead-giveaway. That's the trap many fall into. As he would say, they *"rest on their laurels"*... which is exactly what he's doing. Ugh. Oh well. All you can do is try to point out the mistakes being repeated: Yet, you are anyway by absolutely refusing to acknowledge the sales struggle. Remember when we pointed out the traps Two-Mode supporters fell into? The response was that the same thing wouldn't happen to Volt. It did anyway. Now, we see Bolt following that same path. It boggles the mind that the choice continues to be to not address the problem of audience with the hope of significant cost-reduction in a very short amount of time. High-Volume sales are absolutely essential. For the third time, who is GM attempting to attract as buyers?

- 12-02-2016** **Desperation.** A sign of this is an abrupt change of stance. Monthly sales of Volt were always a point of contention. Everything conceivable was done to avoid addressing the bigger picture... annual sales. He finally did, but switched to only stating those of the entire market: *"Today, we are at 535,000 plug-ins sold in the US."* The evasion of particular detail tells the true story. He hated reading this summary the moderator provided: *"Total year to date sales of 21,048 units put it in range of narrowly topping peak sales years of 2012 (23,461 units), and 2013 (23,094 units)."* It highlighted the lack-of-growth issue for Volt. In other words, it's time to move onto something else. GM's move to emphasize Bolt will make that effort easier. Inevitably, a plug-in hybrid choice that actually is competitive will be introduced. The problem right now is the trap led them to focus on offering the "best" performance, rather than a configuration able to replace traditional vehicles. It's unfortunate, but understandable. I saw the obvious side-step, refusing to acknowledge Volt by looking at overall plug-in sales instead: 14 million cars purchased in the United States each year. That comes to roughly 75 million for the past six years, subtracting out some to account for weaker economy in the past. That still means less than 1% of the market has a plug. That low-hanging fruit came with generous tax-credits too. So, why are you doing everything you can to make excuses for such small market penetration? Traditional vehicles are absolutely dominating still. Refusing to accept the economics of competing with them directly is a recipe for disaster.
- 12-03-2016** **It Fell Apart.** We've seen denial many times in the past. Rather than address observations, the choice was to suppress them. That's easy to do when you label to poster as a troll. Protecting an antagonist, rather than actually dealing with the issue of discussion, is pretty much par for the course in forum posting. That's why the effort to clean up on the big GM forum was so appreciated. They saw the reputation problem those antagonists were causing. It simply wasn't worth allowing those long-term members to direct discussions to their favor. The moderators wanted threads of integrity. That's why I don't get banned. I try my best to be polite and back my claims with solid facts. It become quite a challenge when you encounter this though: *"I suggest you buy a plug-in w/a decent EV range, and then come back & comment."* He tries to avoid red-flags of the past. But even that really stands out. It's quite as blatant as the cries of *"vastly superior"*, but the message is clear nonetheless. I posted this short reply: That level of rhetoric is the smug countless scores of people have always stereotyped owners as... and you actually just dropped down to it.

- 12-03-2016** **Keyboard Warriors.** Coming across this opening-line in a review article posted very shortly after my online encounter was extraordinarily well timed: "*The keyboard warriors have brushed the Prius Prime aside as not having enough pure electric driving range. But Toyota is still the best at making efficient cars that people can afford.*" I hadn't ever heard that term. I figured something would eventually be coined to better identify antagonists. After all, the term "*troll*" came about and stuck. It was extremely effective at pointing out those who came from outside with nothing but the intent to stir trouble. Sadly though, it's use helped conceal the behavior of those working hard to defend the status quo. Those individuals who worked extensively over the years to carve out a nice place for them to routinely post with the voice of authority. Someone like me, coming in with the purpose of advancing discussion, is seen as a troublemaker... resulting in relentless attacks to shut me up. Simply asking the purpose of a thread or forum is seen as an invitation to fight... which aggravates them to no one when victory isn't harsh & swift. This is why the audience question is so effective. It forces readers & participants to consider purpose. What the heck is the point of those posts? Needless to say, I'm thrilled about having learned of this term. Defense of the status quo is quite challenging. To have another arrow in the quiver is quite nice.
- 12-03-2016** **It Got Worse!** Posting a comment in third-person, with consequence of insult to the person who originally said it, is dirty play: "*My wife is not an EV zealot, but even she understands that 25 miles of all-electric range is not worth the trouble of plugging in.*" How can possibly reply without that coming off as disrespectful of his wife's opinion. It's the type of bait you rarely see anyone use, since the outcome is rarely ever good. It tried regardless of consequence: We have seen quite a number of excuses over the past few days attempting to justify the lack of sales growth. Some were weak. Some were misleading. Some were desperate. None tried to dismiss the advantages of plugging in though. So, seeing that claim is truly astonishing. It is so extreme, I'm left without a way to respond. Even if a person has a 40-mile commute, they'll see an average returned of 100 MPG. There is simply no possible way to say that such a result isn't worth it. And for those whose daily driving is less than 25 miles, they'll see absolutely incredible MPG. The low-hanging fruit is almost all picked already (early-adopter purchases) and the help to establish the market is running out (tax-credit expiration). So, how could anyone be so determined to undermine the advancement of plug-in technology that they would make such a blanket statement against the use of electricity?

12-03-2016 **Letting Them Have It.** Knowing we're at a tipping-point, summaries are helpful... especially when the plan looking forward is so unclear. This is what I added to that very heated thread:

Enthusiasts of Volt claimed much would change when the rollout of gen-2 took place. Clearly, they were correct. Quite a bit has indeed changed.

The biggest is GM shifted interest over to Bolt and supporters followed. So much attention has been lost by Volt, it has become all but forgotten. We barely hear anything about it anymore and there is a very real concern production-volume will be kept low so sales don't use up too many of the tax-credits remaining.

The next significant change is the reality of low gas prices and the fear of a new administration heavily favoring traditional vehicles. There simply is no interest in consuming less petroleum from the masses. The ever-increasing efficiency from the status quo is good enough for them, especially now that diesel is basically dead for non-commercial use.

Then there's the problem with the supposed competition: other plug-in hybrids. With Toyota, Hyundai, Chrysler, and Mitsubishi all rolling out plug-in hybrids within the next 9 months, how will Volt stir new interest? The opportunity for conquest sales is rapidly vanishing and GM showroom shoppers have been choosing Equinox, Malibu, and Cruze in large numbers.

We have the push from antagonists attempting to build resentment for the one plug-in hybrid that is now demonstrating a great deal of potential: Prius Prime. This is the first offering to achieve the "*nicely under \$30,000*" goal for MSRP. It also delivers outstanding efficiency following battery depletion: over 50 MPG. With a solid reliability reputation already well established, we can see the struggle for gen-2 Volt to come.

In other words, because so much has indeed changed, we have to return back to that original question: "*Who is the market for Volt?*"

12-03-2016 **Lack of Clarity.** Uncertainty of what comes next is the root of the problem. There's a lot of anxiety now. Bolt is late and the selling-point of range isn't dominating attention, as had been hoped. It's the same type of mistake enthusiasts made with Volt. They assumed performance was the only selling-point that would be necessary to sustain strong sales. Recognition of that false belief led to a lot of damage-control... keeping those keyboard warriors very busy. Milestones being missed and definitions changing were the signs to look for. The same is true now. Watch for that. Casual readers won't notice what's going on and certainly won't be aware of the pattern. Fortunately, I'm happy to point out what's going on: The smug amplifies greatly whenever monthly sales are posted, and I get used as a scapegoat for numbers falling well short of the goal stated a decade ago for sales to be a minimum of 5,000 per month. Remember how much I pushed for an affordable model of Volt, one with a smaller battery-pack to compliment the standard model? Hysteria from Prius caused many to lash out in fear of that diluting what Volt was. Remember how much they proclaimed EREV was the only solution possible? Now we see Ford, Honda, BMW, Hyundai, and Toyota all taking different approaches to achieve the same goal. Those antagonists were clearly wrong. Now, you are doing what? Not speaking out about the excuses and not doing anything to stop the misleading is being an enabler. Shoot the messenger all you want to feel better, but it won't change what's happening. It's ok to celebrate a good sales month, but don't lose sight of the big picture. That goal to make Volt a popular choice among GM shoppers is absolutely essential. Substantial growth is required, soon. No amount of spin or diversion will change that.

12-03-2016 **Anything Else? part 1.** Rapid fade away of GM problems allows us to put focus back on the technology. Dealing with actual questions of owners, rather than rhetoric, is fantastic. I certainly hope the newcomers, like Ionic or Pacifica owners, are receptive to cooperative efforts of plug-in endorsement. It blows my mind how a few key Volt enthusiasts become the spokespeople for all of Volt online, giving it a terrible reputation of smug. Unfortunately, we see that happening in Prime reviews. Comments of Volt superiority are easy to find. I sure how partnerships can be built elsewhere. We've been able to collaborate with BMW i3 owners. But with so few and with a vehicle little is known about, that only takes you so far. Leaf owners are quite receptive, but the relation of EV owners with plug-in hybrid owners hasn't even been a problem. It's only with Volt. Ugh. Oh well. At least we have new Prime owners helping stir up new topics to discuss.

12-03-2016 **Anything Else? part 2.** The question asked of Prius Prime from a new owner was if there was advantage of battery-charging with the gas-engine beyond the hill-climbing and warm-up cycle. I see this as a growing source of contention. It reminds me a lot of how the hybrid-system was originally perceived. Some people readily picked up on that opportunities and others totally misunderstood. Simply reverting to a "*never use*" stance will yield the best results overall all owners. But there are some who will be able to identify advantageous situations. Why not provide that knowledge to educate? Why treat everyone as novice drivers only? Why shouldn't we strive for well-informed owners right away? Collecting enough real-world data to confirm operational results shouldn't take that long. Perhaps the current membership simply doesn't have the tools necessary for that collection. I'm not sure... and won't let that stop me: Yes. As I state each time Charge-Mode is mentioned, there is a clear advantage to using it on long trips. Far less horsepower is used to maintain a cruise on a highway than what the engine has to offer, which means the introduction of a minor load won't result in as much of a penalty as one would think. It's counter-intuitive, much like how the hybrid system works without a plug. Extra load can actually result in a gain. That's how higher MPG is achieved. So with the plug-in, once you get off the highway, having a recharged battery pretty efficiency opportunities which would otherwise be lost.

12-04-2016 **Charge-Mode.** This innocent comment today got a rather stern response from me: "*As far as force charge, it's mostly a gimmick and bad for mpg's and thusly pollution.*" Since it came from a frequent and well-informed Prius PHV owner, my pounce should be well understood. He'll know it's with best of intentions:

You're asking for quite a bit of conflict making generalizations like that. I'll be bumping heads with you on a regular basis, pointing out that USED WISELY there can be circumstances in which you will see an efficiency gain (and subsequent emission reduction) from using Charge-Mode.

This will be a education effort for newbies, very much like what we did back when Prius was new to most people. The assumption was made that more electric-only driving was better. We know that's not the case. The engine can indeed encounter situations of lower efficiency though, where a benefit can be realized by adding load.

Your use of "*mostly*" should be changed to "**except on long trips without plugging opportunity**". After 4.5 years of driving a Prius PHV, it's easy to see how those distant drives on the highway are always followed by running around with the Prius upon reaching your destination. In that particular circumstance, I know for a fact there will be an overall improvement from taking advantage of Charge-Mode.

In basically all other driving situations, I don't envision recommendation opportunities. So, I'm with you in that respect. But with a vague "*mostly*", expect routine replies provided clarification. We're at the early stages when assumptions & misunderstandings happen. So, extra care will really be a boost to our desire to help. Best of intentions...

12-04-2016 Diesel Plans. Major cities in Europe have announced the intent to ban diesel vehicles by 2025. This death was inevitable. There was no possible way an engine-only diesel passenger vehicle could possibly compete with second-generation plug-in hybrids. That alone was enough to see the writing on the tombstone. Recent embracing of EV choices has pushed that shift into the fast-lane. Much of the acceleration came about as a result of the VW disaster. Nissan & Tesla's push was a great start. BMW joining in was a great endorsement. Now with GM about to stir halo efforts, we can see momentum growing. What will catch on in the plugging world is still unknown, but the potential of Prius Prime reaching mainstream consumers faster than anyone had imagine is a big boost. So, even without the news coming from California, there's reason for a very positive outlook. \$800 Million of the \$14.7 Billion settlement with VW will go to the sunny state. They will be installing a lot of charging-stations with it, as well as introduce sharing & hailing services for zero-emission vehicles. The 10-year plan will be divided into four 30-month spending cycles. I really like that accountability with clear & quantifiable milestones. The horribly ambiguous and ever-changing plans GM stated over the years was a good example of what not to do. After all, California wants to enforce clean mandates. Investing heavily into infrastructure with this money will really help build momentum for that progress.

12-04-2016 Just Drive It. Having both a plug and a charge-mode is moving us to the next level. This stage in hybrid evolution requires a rethink. It happened right away: "*The only non-trivial or extreme corner case reason this notion of EV in the destination city after a long trip has merit that I can think of is to reduce engine warm-up routines.*" Coming from a new Prius Prime owner, I am quite intrigued what the reaction will be to my post of this in response:

That is far from trivial or extreme. In fact, that is so profoundly significant, you just very effectively talked through the process to disprove the original hypothesis. Doing that at work (I'm a software developer) is an extremely helpful tool for understanding & confirming design. We stress the importance of taking the time to do that. Great job!

Whenever I go on a trip, there is always some running around that would greatly benefit from avoiding engine warm-up. The runs for food, shopping, entertainment, and recreation are MPG killers. Often only a few miles, it should be very easy to see how driving those short distances using only electricity would be hugely advantageous.

After owning a plug-in hybrid for awhile, you'll see that those opportunities aren't actually trivial or extreme if you travel. Not having a plug available, but having the ability to substitute some wisely consumed gas for recharging, can be an effective use of the system. We're moving beyond that "*Just Drive It*" advice of the past.

12-04-2016 **Damage Control.** It's easy to get really annoyed when you are accused of revising history, yet clearly, you can see they aren't remembering events correctly. My personal log entries (blogs) are a written record of what happened, when it happened, and what the impression of it was at the time. It's super easy to look back on them. Google makes those searches a powerful tool at my disposal. I can quickly confirm the actual history. There's no need to try to remember. It was documented at the time those events were occurring. That leaves you with a sense of confidence to face the spin head-on. I have been too, to the point of being annoying back. This moment in time will soon vanish. Rather than awaiting Prius Prime deliveries and discovering what Bolt really can do, we'll know those details. The shift from speculation to confirmation is a big one. That's why I'm doing all I can to document these moments as they're happening. Someone, I will search back for them too. Here is today's dealing with that trophy-mentality problem: I will continue to point out the misleading that takes place here. For example, the recent claim of halo. It was intentionally vague. Yes, GM did indeed make the statement about Volt being a halo vehicle. That didn't come until the end of gen-1 production drew near though. There was nothing stated about gen-2 being the same way. In fact, it was quite the opposite. An expectation was set for gen-2 Volt to very much be a mainstream vehicle selling at mainstream volume. The misleading posts are damage-control efforts. Ask yourself why gen-2 would only be a halo. It doesn't make sense without any mainstream offering available.

12-04-2016 **Learn & Educate.** Those discussing Prius Prime are facing the expected generational split. It's very easy to make assumptions and not want to shake up the existing unity. Upgrades don't always play well with that though. So far, that's the case we're seeing: *"...like the thousands of people who believe trying to keep the lift back in EV is more efficient than using gas."* The discussions about Charge-Mode are building up to debates. Some just want to pretend it doesn't exist, to keep things simple. I'm not simple. I feel people can be educated, especially if it has the potential to become a draw to learn more. I sounded off about that with: It is more efficient in EV. Toyota knows that all too well. For everyone else to know why, they must ask the reason for putting an EV button on the liftback model. Understanding that is vital. It's the same reason the Charge-Mode feature is engaged by holding a shared button, rather than having one of it's own. The key to that understanding is to realize the topic is a WHEN situation, rather than an IF. In other words, you're asking the wrong question. So, the answer will never been correct. We can easily see the feature will be misused. It should also be easier to see that recommending "never" won't work. Many will inevitably stumble across it by some means. Then what? Not even trying to learn & educate about it would be to dismiss the reason why Toyota provided the mode. Put it this way. How hard would it be to get an owner to change the way they use it after discovering there can be a MPG penalty when used at inefficient times? That sounds pretty darn simple to me. After all, we do it on a regular basis with "B" mode.

12-05-2016 **Loss of Purpose.** That's what it ended up to be after the dust settled. The "*too little, too slowly*" concern became an outcome. They knew it was going to happen too. The obvious sign of acknowledgement was the subtle shift over to a good enough attitude. They'd declare monthly sales as "*doing well*", then simply move on to something else. You could predict that. What was uncertain though, which could be an indicator of the pattern breaking, was no longer attacking Prius. Remember how I got involved with the Volt enthusiasts in the first place? It was to correct the steady stream of misinformation being posted, clear attempts to greenwash. That revealed itself to be an opportunity for finding an ally... which unfortunately, fell apart quickly. The introduction of Prime and the rollout of Bolt presented a new opportunity. Knowing that enthusiasts were facing an identity crisis, having a complete loss of purpose with the "*range extender*" philosophy having fallen apart, I took the chance. Seeing change meant the possibly of a new audience. No such luck. What a mess. There is no clarity, no sense of what to promote. Rather than a unified sense of plug-in support, the original trophy-mentality problem is tearing them apart... consequently preventing anyone else from joining. Ugh.

12-05-2016 **Tree, Not Forest.** It's hard to believe just how deep the denial got: "*Actually I'd say plug-in sales growth is doing quite well.*" That sums up the situation quite well. He absolutely refused to ever state goals. No consideration of the overall market (forest), instead only seeing plug-in sales (tree). It was always a wait-and-see approach. That meant he come just make up whatever he wanted to declare victory. There was no accountability or scale. It was all about being looked upon as "best". What happened for ordinary buyers meant nothing. Only the image of GM was important. That selfish & uncaring attitude was terrible. Evidence of that is emerging too. There still isn't anything other than Volt. All that bragging how GM would deliver more & faster and Toyota with Prius was a load of crap. It's why saying anything with respect to that status appears to the Volt enthusiasts as praise for Prius. Even if no mention is every made, that inability to successfully "*leap frog*" really hurts... because they didn't want an ally, they wanted superiority. The very idea of forming a plug-in partnership repulsed them... which sickened me. Those I know here who own a Volt (in the local plug-in owners group) are very nice people, open-minded and very inviting. I thoroughly enjoy working them... quite unlike these keyboard warriors. Oh well. I had a short & bittersweet response to share: That's called settling. Remember the "*too little, too slowly*" concern? It was about exactly this, considering the progress made to be good enough, rather than actually meeting the goals set.

12-05-2016 **Too Little, Too Slowly.** Those overseeing the bankruptcy recovery for GM certainly did well. Their concern for not delivering enough and taking far too long was right on the money. 7.5 years later, the promise of the technology invested into Volt becoming a core offering failed miserably... so bad, there's no denying it. Bolt is the antithesis of Volt, the very approach to plugging in GM was fiercely against. It should have been complimentary. But taking that stance means at least partial acknowledgement about having made a fundamental mistake with Volt... not designing it to be affordable. The very real problem of limited tax-credits makes it even worse. GM squandered them, focusing on building image rather than using them to rapidly establish a market. It's such a waste. True, there was much learned from the technology itself. But was the customer sacrifice worth it? I certainly don't see the end-state we are at as constructive. Bolt won't achieve high-volume prior to Tesla Model 3 and Nissan Leaf gen-2 rollouts and Volt will be left struggling to find an audience. Ugh. Just think if focus had been on drawing in their own loyal customers instead. I put intent of the recent online sparring this way: Pointing out sales of other GM vehicles, those sharing the same showroom floor, provides context. Do you really want Volt to stay just a halo vehicle? The concern for what happens when the \$7,500 tax-credit expires is very real. Those traditional GM vehicles currently sell far better, without any subsidy help. Avoiding what happens at the dealer is not wise, something my local plug-in owners group is working very hard to overcome. Why is there so much resistance here?

12-05-2016 **Convincing Yourself.** What do you think upon reading this: *"Then there's the problem with the supposed competition: other plug-in hybrids. With Toyota, Hyundai, Chrysler, and Mitsubishi all rolling out plug-in hybrids within the next 9 months."* That's what I posted 2 days ago, with the purpose of pointing out the rapidly growing competition. After all, this particular antagonist absolutely refuses to acknowledge the market as a whole, recognizing traditional vehicles as the actual competition. Instead, he insists it is only other plug-in vehicles. That puts his reply into perspective: *"This is a GOOD thing. It's called validation."* He has worked so hard to present Volt as the ultimate purchase, it's easy for him to just outright dismiss other choices as unworthy. It's the blindness that comes from the trophy-mentality. He simply doesn't see the problem. That's why the "Who?" question never made any sense. He thinks the requirements of an enthusiast apply to everyone. He doesn't understand diversity. Wanting to pay less for less simply makes no sense. He's convinced himself one-size-fits-all. It's why I'm about to move on. The confrontations certainly have been educational for me. Learning about why he made such fundamental mistakes was very informative.

12-06-2016 Game Changer. What a wonderful way to walk away from the online battles with: "*Can you say "game changer" ?*" Reading that was remarkable. It was the same old nonsense of the past, the very thing the enthusiasts vowed not to repeat. What game? Change how? It's so incredibly vague, there's almost no point in responding. No one did either. The thread ended prematurely as a result. They knew that was a pain wound that just got reopened. It had been the battle cry for years. Volt would be a game-changer, finally dethroning Prius as the green & efficiency sales leader. GM fell well short of that, embarrassingly so. It's why constructive discussion is so difficult now. Anything negative is feared as an attack. Even with the insanely low lease offers, the enormous price drop, and the generous tax-credits, sales were major struggle. The quantity was low and GM customers simply weren't interested. Hope fell upon conquest (stealing sales from other automakers) instead. That's a terrible plan and the consequences are becoming apparent. So, we have to ask what game and what change to expect now. If Bolt is to be the Volt successor, what will be the criteria for success? Wasn't this all about replacing dirty & wasteful with green & efficient? The technology obviously works. Implementation has been a disaster though. Great engineering spoiled by horrid management decisions. I declared victory of my own, by asking a fundamental question I know to be the true game changer: Competing directly with traditional vehicles?

12-07-2016 Prime Test-Drive. I had great things to say about this: "*Saw my first prime today.*" It was on a new discussion thread titled: "*Prime in the wild*". My excitement of having something to share made that opportunity too good to resist. Absolutely delighted, I posted:

That wasn't me... though, I was driving a Prime wildly today. :)

I got a chance to meet with my salesperson and we took the dealer's fleet model out for a spin.

It was a lot of fun. I took advantage of the full battery-pack. With the heater on, I hit the nearby highway. Whoa! The increase in EV power and the quieter interior sure was nice. Prime's upgrade over the PHV model will certainly win over a lot of fence-sitters. Those not interested in Prius sure are in for a surprise from the one with a plug. The effortless electric-only driving makes the sale simple.

For those who take a deeper dive into the test-drive experience, find yourself a small roundabout. The one near my dealer was really fun. I hit it hard too, thrilled about how much of an improvement the gen-4 design brought about. The reduced body-roll, combined with a lower center-of-gravity from the battery-pack, sure made that a key experience. It will win over the naysayers. We ended up going back for a second round. Once simply wasn't enough.

What I especially liked was the wide-array of small improvements, like adding cupholders in the rear doors and the folding-seat redesign. The view out of the dual-wave rear window was astonishing... no distortion and increased visibility. What new customers will like is Toyota's approach to simplifying the interface. The intentional de-emphasis to details enthusiasts normally get hung up on are presented in terms easy to understand & follow.

I hope mine gets delivered soon. If not, I'll manage. The wait is totally worth it.

12-07-2016 Pacifica Details. The official EV rating was released. It will be more than anticipated: 33 miles. That's enough of an EV range to really mess up arguments. With so many arbitrary "*it needs at least 30*" claims to undermine Prius, this now appears as an endorsement. However, that's the only strong selling point. Delivering 32 MPG following depletion is indeed impressive for a minivan, but the \$41,995 base price kills that. It's quite a bump up from the \$28,595 base for the traditional model. Minivans are a difficult market. Ford & GM abandon it years ago. All the other automakers, except Chrysler, have only a small showing. So, this is a great opportunity. It's still a tough sell. The interior space is great. Promoting it as a hybrid is rather odd though. Rumor is that there will be an unveiling of an EV version in a few weeks though. That helps to clarify the naming choice. It boils down to knowing audience. Who will they be trying to sell Pacifica to? How many do they hope to sell? What else will they sell?

- 12-08-2016** **Climate-Change Deniers.** That's who our president-elect has been seeking for certain key roles in the new administration. Ugh. That's not good. Could you imagine the head of the EPA being someone who has a history of fighting carbon-reduction efforts? That's exactly what appears to be happening. We'll end up seeing investments in dirty industry with non-renewable resources. How is that a good idea? You don't create jobs for the future by spending lots of money on technology of the past. My travel to Europe last year revealed how much more we could be doing with solar & wind. Not being leaders in that regard is disappointing. Finding out their likely won't be any effort to improve that situation is really a let down. Thank goodness Toyota is offering a solution that won't rely on heavy infrastructure improvements... because it certainly looks like those in key power positions here won't be providing any support.
- 12-09-2016** **Diesel News.** There was quite a stir this week, when 4 major cities (outside the United States) announced a ban on diesel vehicles. They want to prohibit their use in those cities by 2025. With so many hybrid and plug-in choices entering the market, it makes no sense to depend upon diesel anyway. It's expensive, barely meets minimum clean requirements, and isn't anywhere near as efficient. Why bother is a reasonable question to ask... which leads us to GM. They will be going forward with the rollout of a diesel Cruze. Why? With a \$24,670 base price for the manual transmission and an additional \$2,000 for the automatic, what's the point? How will potential buyers be enticed? A hybrid version would offer better efficiency. A traditional version would cost quite a bit less. Meanwhile, there's growing interest in Prime coming from VW buyback people. The uncertain timing & complexity of selling back their TDI to get the a plug-in hybrid is stirring new discussion. The thought of going back to gas isn't appealing and many were quite against regular hybrids in the past. We are most definitely in a new chapter of automotive history now.
- 12-10-2016** **Bolt Surprises.** Finding out the advertised 90-mile recharge in 30 minutes only applies to 80 kW connections sure caused a stir today. The high-power DC rechargers currently top out at 50 kW. That resulting speed limitation primarily comes from pricing. To deliver faster, the customer must be willing to pay for the next higher tier for that electricity. It's expensive too, a major deterrent. To complicate matters, the home setup for fast charging requires as 32-amp capacity. Those with level-2 chargers in their garage at home already are likely using something with less power, which means longer recharge times. Originally, there were a number of 16-amp choices. Those would be much slower. Needless to say, there's much to cause confusion, misunderstandings, and assumptions. To make this even worse, there are a number of references in older articles about the recharging expectation for Chevy Bolt to be "*90 percent*" rather than "*90 miles*" in 30 minutes. It's too bad the Volt enthusiasts squandered their time away worried about superiority. They didn't bother taking the advice to educate. What a waste. Of course, the knowledge was dangerous. It would have informed people of shortcomings... as some are discovering now.

- 12-12-2016 Heater Improvements.** Some people just plain don't know what has been done and what could be done. That uncertainty of audience in a public forum makes it difficult to know how to respond to posts too. Fortunately, there are a few who ask questions, like: "*What sort of things would Toyota have done to conserve the heat?*" It's nice to encounter such open-mindedness. Far too often, people draw conclusions based on anecdotal observation or just make wild assumptions. Getting that on a regular basis makes threads a cumbersome mess too. Heck, that is a contributing factor to these blogs. At least I have a means of finding the information later. Forums aren't laid out in chronological order either. Threads overlap and there is no way to find highlights of what happened on any particular day. That contributes heavily to online problems. It's really unfortunate. The big picture is lost in that format. Oh well. That's why blogs exists. They compliment the forums. Anywho, here's what I shared about the heater: The new "*active grille shutter*" is a nice improvement for getting the most of the heat available. Some owners have been doing that blocking themselves for years for heat-retention and reducing the amount of air blowing through under the hood. Now, it's a standard feature. The "*vapor-injected heat-pump*" is an obvious improvement too. It's the best in the industry for electric heating in terms of efficiency. That's a nice advantage other plug-in vehicles can't compete with, using just regular heat-pumps or resistance-heating.
- 12-13-2016 Delivery Wait.** You wonder how long it will take for me to actually be until I take delivery of my Prius Prime? I expect there to be a wait of a few weeks still. It just doesn't seem realistic for such a new approach to be established so quickly. Think about that fleet model. Seeing that Toyota is delivering some to dealers with the "*not for sale*" notice is a clear indication of intent to educate. Much needs to be done for all involved to learn what needs to be taught. That requires hands-on experience. You have to drive the vehicle a number of times to even begin to figure out what questions need to be asked. Finding the answers then takes awhile. You want to ensure the information is correct too. There far to much opportunity for misconceptions to emerge. After all, why study something that will remain limited inventory for perhaps years, especially with the profit-margin so small. From a sales perspective, you'll make much more commission from the wide assortment of vehicles available on the lot instead. After all, demand for plugging in is a big unknown and gas is still cheap. Understanding the technology is key. Batteries have proven to be robust. How they actually work though isn't common knowledge yet. That's why I have a growing expectation of wait. Spring will be here soon enough. By then, I would have been driving the Prime and collected lots of real-world data to share. In the meantime, that education at dealers is taking place. It's still a challenge to be patient though, despite it being totally worth it.

12-14-2016 **Seeing What You Want.** The choice for you or I means little on its own. Do other share the same sentiment, priorities, interest? Sometimes, asking those questions provides a surprising answer, like: "*I bought the car I wanted to drive.*" It's not often to get a confession of that matter. Purchases based upon want, rather than need, are good to know about. It's not wrong to fulfill desire, but please don't misrepresent that as it being what everyone else does too. They don't. A large chunk of the population simply cannot afford that. This is why I asked "*Who?*" so often. Being aware of such fundamental differences in reason for buying is a very big deal. It's also quite frustrating when having to deal with someone who isn't. They see what they want. Today, I dealt with it this way: That is the very reason why you have yet to understand who the market is. Want is for enthusiasts only. Need is what everyone else makes decisions upon. This is why the common SUV keeps getting smaller and hybrid options are beginning to be offered. This is also the competition-with-traditional options... like Prime... possess the potential for real change. Say what you want. There is now 6 years of sales confirming great buys for those enthusiasts but little to draw interest of ordinary consumers. We have overwhelmingly seen disregard & dismissal from the mainstream. Face the facts. Overcoming the status quo takes far more than what you want.

12-14-2016 **The Trap.** Far too often, something is posted online to mislead or undermine. That certainly was happening today. This post speaks for itself: Determining "*compliance*" is a red-herring, an undermining distraction from the goal of traditional vehicle replacement. It's a trap far too many fall into. Achieving minimum mainstream demand levels (5,000 per month without tax-credits) is far more difficult than initial low-hanging fruit sales. In other words, don't get hung up in greenwash labels. Stay focused on the effort to reach ordinary consumers. Their purchase interest is vital... that means actually being able to compete with vehicles they share the showroom floor with.

12-14-2016 Bolt Deliveries. Remember range anxiety? We're seeing even worse now. At least that tried to sell you something you really didn't need. What does Bolt bring to the effort of replacing traditional vehicles quickly? A online friend of mine put it this way: "*Which part of bovine fecal matter applies?*" He sees the inability to deliver something able to be sold in high-volumes for a profit. It's all show. True, the technology should work fine. But what's the point if so few are built & purchased? My joining of the topic was with: I had to deal with a tremendous amount of that when pointing out how Volt was following in the path of Two-Mode. The pattern was remarkable too. This repeat chase-the-halo episode is worse though, since there's a such a heavy dependency on tax-credits. The consequence will be stifled availability followed by an abrupt loss of interest. It's a disaster in the making, even without taking into consideration the other choices that will be available. We can see the strides Nissan & BMW will be making, with some odd "me too" effort on VW's part. That will add a lot of pressure to GM's growing struggle to capture the interest of their own customers. With respect to Tesla, how can there be any comparison? The difference between Model 3 and Bolt is obvious. They clearly aren't targeted at the same audience. As for Ford, who knows. We could see interesting things from Chrysler though. That brings us to Toyota. The potential Prius Prime offers for winning hearts of showroom shoppers is profound. The effort to transform the hybrid we've grown quite attached to very real competition with traditional choices is becoming difficult to dispute. It's come down to the basics. You don't have to do anything other than plug it in to get absolutely outstanding results. The interface is elegantly simple. There's nothing to learn and nothing to set up. It's a "just drive it" design with realistically profitable configuration. That's why looking at Bolt makes you wonder. GM expended quite a bit to deliver maximum range, making sacrifices resembling sales problems of the past. Why was the formula for achieving something able to compete on the showroom floor so carelessly abandoned?

12-15-2016 Cannibal Sales. A new thread was started today, one that addresses a topic I take to heart. It was able how an automaker will cannibalize their own sales. Right away, it was clear that definition wasn't understood. This required correction right away: "*ok i get it . . . cannibal as in eating sales of similar cars. But are there any 200 mile moderately priced ev's? For now - the bolt (a kind of small & not too sexy looking car) only matches range of the much more luxurious Tesla.*" His thoughts were misguided. That's a very, very easy trap to fall into. Losing perspective is common. It happens with the best of us. Hopefully, this clarification helped: No. Taking away sales from other automakers is: CONQUEST. Taking away sales from other vehicles within that automaker's own product-line is: CANNIBAL. In other words, cannibal doesn't achieve the goal of growth from within. In this case, we can clearly see GM is putting Bolt against Volt. There are only so many tax-credits available, making the concern of spreading too thin very real. Look at it this way, how are they going to promote those choices? The point of Volt was to overcome "range anxiety" from having an EV with a small battery-capacity... a limitation Bolt doesn't have. Mixed messages to consumers will just keep those mainstream buyers away, rather than attract them. What will draw their interest? It boils down to loss of focus. Rather than sticking to the purpose of replacing traditional vehicles with clean & efficient choices, we are seeing a king-of-the-hill battle. Where's the effort to attract Malibu, Cruze, and Equinox buyers?

- 12-16-2016 Horribly Vague.** When a person actually calls himself a troll, how do you deal with comments like this: *"Until gas prices really climb, I think the Prius and Prime will have some type of discount from Toyota."* I gave it a try: What does *"really climb"* actually represent? Are you talking \$4 per gallon? What does *"some type"* actually represent? Are you talking \$1,000 off MSRP? I'm tired of having to point out horribly vague posts so often. Remember what happened in the past from not providing detail? Let's try to be constructive. That means addressing the why & how. Discounting costs less than advertising. It's an effective means of getting loyal customers to switch from their usual choice to trying something new. The price of gas doesn't even have to come into play then. For that matter, neither does the tax-credit. It's a compelling enticement to draw interest that would otherwise be a missed opportunity. Remember, the ultimate goal is growth. That means getting more than just early adopters to purchase. The low-hanging fruit (enthusiasts taking advantage of tax-credit incentives) is in no way any part of the mainstream tally. Look at how GM has struggled to reach beyond that initial group of buyers... hence the cannibal concern. Toyota is striving to avoid that same trap by offering something with a compelling sales price. It's a configuration actually capable of competing with traditional vehicles.
- 12-17-2016 Another Halo.** I enjoyed responding to this: *"Think about 3 years from now. Will GM sell more volts on their own, or a combination of volts and bolts, and hopefully other cars developed using voltec technology. It's a no brainer to GM that wants to use plug-ins to off set trucks for cafe to innovate if they can."* The blindness that comes from being overly optimistic (or just poorly informed) is really worrisome. 3 years from now is mid-cycle, not a good time for financial help to end. The incoming administration won't be green friendly either. We're in for a number of big challenges. Looking at them through rose-colored glasses is a recipe for disaster. That's why I'm pushing harder now. After all, the gen-2 Volt is stumbling along with a struggle even more difficult than what gen-1 faced. Cheap gas, increased plug-in hybrid competition, and a growing number of EV choices puts Volt in a bad position... even without taking Bolt into account. My thoughts were: Tax-Credits will be in the phaseout stage then. Think about how growth will be achieved with subsidy money gone. Sales will be a challenge just to maintain. GM desperately needs to offer a plug-in SUV. No offset nonsense. Just do it already. We see the other automakers heading in that direction. As nice as Bolt may be for the EV push, it's clearly another halo vehicle.

- 12-17-2016 Plug-In SUV.** One of the very helpful Prius PHV owners who frequently posts on the big Prius forum is facing a new audience. It's similar to what we see with any generation upgrade. Things change and more than just the status quo hadn't been considered prior to this point. Understanding all that Prius Prime has to offer is challenging enough. There's a lot to learn and it's way too easy to make assumptions, especially when the big picture hadn't really ever been discussed. Why would you? You're on a big Prius forum. All was going well. Abruptly switching to discussions of EV competition and sales beyond early-adopters is very confusing. Reading this confused me though: "*toyota needs to offer a plug in suv.*" Had he not been paying close enough attention over the past few months? We've had discussions about potential other plug-in offerings from Toyota. Heck, I seem to remember him even making a comment about a potential Camry Prime. So, his growing puzzlement about putting pressure on GM was a bit odd. Anywho, I responded with: RAV4 Prime is quite realistic. The technology is being established and the hybrid has been well received. Toyota is clearly pursuing that endeavor. From GM, there's been avoidance. Cruze wasn't offered as a hatchback (which had been extremely popular in Europe) to avoid cannibalizing Volt sales. Equinox we be offered as a diesel, rather than a hybrid for what?
- 12-17-2016 Volt Owners.** Pretty much every article published about Prius Prime ends up with a comment to this affect: "*I bought my 2012 Volt and my current lifetime MPG 99. There are no prius out there, even the plug in, that can give these numbers and drive highway speeds all EV.*" You have to read the rest of what they post to get an idea of their intent. In this case, it was a superiority post. He claimed Toyota is falling even further behind and will really be in trouble if they continue to dwell on hybrids. It was obvious he had no idea how much of a challenge getting traditional buyers to even remotely consider plugging in really is. Loss of perspective is easy after a few years of plug-in ownership. That's why I so thoroughly enjoy the monthly Prius meets here. I'm the only plug-in owner. That group keeps me in check about priorities. It's how I came up with this for my reply: Clearly, you don't know how Prius Prime actually works. I have a 2012 Prius PHV. With only half the battery-capacity of Prius Prime, a top-EV speed of 62.1 MPH (100 km/h), no electric-heating or pre-conditioning, and no battery pre-warming, my current lifetime MPG is 72. Reaching 99 MPG with the larger pack, an EV speed increase to 84 mph, an industry-top electric-heater, grid pre-conditioning, and warmed battery, that's quite realistic. I'll be able to prove it too, when my 2017 is finally delivered. Take a test-drive. You're in for a surprise. This newest model of Prius provides quite an upgrade.

12-17-2016 Cannibalization Thoughts. The topic has been a big one lately. We're finally taking a look at the big picture. Yeah! Naturally, GM has a bull's-eye on it. There's no way around the publicity that automaker thrives on. It can't be avoided. So, why not give it some attention? I saw the plug-in SUV interest as that opportunity to get feedback and posted this to get it:

What was the point of "Voltec" (second-generation Two-Mode system, with a plug added) rolled out in 2010, then upgraded again in 2015, if there was no intention of ever using it in a SUV of any size? This is exactly what I mean about kicking the can. How much longer must we wait for the need to finally be addressed?

We were shown a prototype 9 years ago, at the Detroit 2008 auto show. Anyone remember GM's Green-Line vehicles? That next step of introducing a Saturn Vue which used Two-Mode with a plug was to fulfill the dreams of many. Bankruptcy negotiations in 2009 even addressed that program, resulting in assurance of was no reason for a "*too little, too slowly*" concern.

Now, after nearly a decade, some are wondering why we are so negative. Really! Why shouldn't we be? How many "*under promise, under deliver*" rollouts should we be willing to accept, especially when it comes with federal assistance in several forms? We should be pushing GM hard to finally offer more than just a halo or niche vehicle. The masses need a choice.

Cannibalization (like how Bolt will take away Volt sales) isn't a wise move. That's why getting Equinox buyers to purchase a plug-in hybrid model makes so much sense. Yet, we hear nothing. Not even a peep, despite promises of a small SUV offering a plug, makes you wonder. Will GM squander away all their tax-credits on Bolt to compete with Tesla, rather than actually improving their own product-line?

12-17-2016 More Cannibalizing. I keep pushing: Many believed those promises. They gobbled up hype. That was the point. People bought an idea, not a vehicle. I knew from the initial reveal it wasn't going to happen... and got attack relentlessly for providing evidence to support that. In fact, to this day, there are some who still hold some resentment toward me for the vaporware claims... since those were proven true. Being able to logically reason through spin, able to analyze facts, puts in at odds with the majority... who react from their gut and believe hype. They want to be sold hope... and find ways to excuse resulting failures. I see a mismatch of action & goal. An analogy is a teacher assigning homework and the students handing in something well done, but not at all what was assigned. In other words, how does Bolt or Volt change what Malibu, Cruze, and Equinox shoppers actually purchase? With Toyota, we see a clear effort with Prius Prime to reach out beyond Prius buyers... the hope of attracting Camry & Corolla buyers without cannibalizing Prius sales. It's a move to diversify, just like the introduction of RAV4.

12-18-2016 **Newbie Perspective.** This was thought provoking: "*Hey, this EV thing isn't bad. The only downside, in my opinion, with the PiP was that it used just about any excuse to turn the ICE on. Then, there's the Volt.*" I posted this in response to that newbie perspective: Toyota clearly stated from day one that Prius PHV was designed exactly as the market had requested, for it to be a PLUG-IN HYBRID. That history was documented in great detail back then, as it was playing out by me... so many years later, I could prevent innocent comments like yours from getting distorted by the looking-back-long-after-the-fact perspective. Volt was designed to serve as an EV with a backup power-source, to prevent "*range anxiety*" concerns. That idea fell apart though. The system ended up being far more of a "*blended*" hybrid than the original vision of it being a "*series*" type. The gas engine was needed in the cold and it served as more than just a generator. Sales didn't "*leap frog*" Prius either. So, in a way, Volt really was a game changer. But rather than changing the game as intended (becoming an EV leader), it got stuck between the plug-in hybrid and electric-only vehicles. That became an identity-crisis over time, leading to uncertainty of intended market as the gen-2 rolled out. That technology worked, but wasn't configured in a way to attract ordinary buyers. That's why the lower-cost approach of Prius Prime is really beginning to stir interest. That idea of augmenting the hybrid system is no longer the focus; instead, we're seeing more of a "*Volt done right*" configuration. Why? It's because the market changed their request. The EV drive is indeed what's desired, as GM had hoped. However, there is an unwillingness to pay a great deal more for that... hence Toyota's newest effort. They are striving for more of a balance of purchase priorities.

12-18-2016 **Personal Attacks.** Sometimes, your rebuttal is so good, there's nothing for the person to reply with. That means you should plan on getting personally attacked. I did today. It was rather brief though: "*As usual John, wrong.*" Nonetheless, it still offered good reason to respond. I did too, with: I call out those who attempt to misrepresent history. For that claim to be correct, GM could not have any motor & battery experience prior to Volt rollout... since that is the way it was for Toyota with Prius. Turns out, that couldn't be further from the truth. *GM already had extensive experience from both EV1 and Two-Mode.* Also for that claim to be correct, GM could not have any subsidies or incentives for the first 5.5 years... since that is the way it was for Toyota with Prius. Turns out, that couldn't be further from the truth either. While there was nothing but a \$2,000 DEDUCTABLE for Toyota with Prius (which came to roughly \$400 on the typical tax return), *GM gets a very generous \$7,500 CREDIT* (which is the full amount of \$7,500 for most buyers). Lastly, let's not forget how many Volt got the benefit of HOV lane access, where Prius got nothing. Lastly, ELR and Malibu aren't really much for diversification, by no means the same. Camry used a larger gas-engine, electric-motor, and battery-pack. It wasn't just a rebadge with a different body and operational limits altered. It was a truly new system. Highlander (along with Estima in Japan) added another motor, to provide AWD. That provided yet another unique choice for consumers. What does GM have to compare re-using Voltec? Of course, if you want to match histories in this market, *Volt should be selling at 4 times the current rate.* Rather than the 24,000 annual rate we're seeing, it should be the 108,000 Prius was selling at.

- 12-18-2016 Oil Trouble.** We see the wave of resistance building. A formal oil industry CEO will become Secretary of State. A former presidential candidate who has expressed extreme dislike for the Energy department will now become the head of it. And sadly, we will see the Environment Protection Agency run by someone who has been strongly opposed to efforts unfriendly to the fossil-fuel market. It's an ugly situation we'll soon have to deal with. That much power in favor of promoting oil consumption is very bad sign. Watching funding get cut is the obvious early fallout effort you can expect. Another is extending time-schedules and delaying dead-lines. That's so difficult to witness. Rather than help energy production become cleaner, there are plans being made to exploit natural resources. We're turning back the clock on progress. Of course, this is coming from a president who doesn't even use email. His setting up of new administration that favors old-school ways of business is no surprise. He's in a position to strongly oppose and is clearly preparing to do so. Remember the "*too little, too slowly*" concern? None of use ever expected all those missed opportunities to become a regret on this scale. 2017 certainly is going to be one for the history books.
- 12-19-2016 Higher Priorities.** Claims of seriousness pretty much all focus exclusively on battery placement. Even cost of the battery itself is dismiss in favor of not trading any storage space. How much more it would add to the price isn't addressed. Detail is entirely absent. They don't even try. All we get is vague comments like this: "*If Toyota was serious about electrification, their TNGA would have been designed for batteries. Instead the Prius makes do by trying to find a place to stuff them.*" I was annoyed, but tried to respond constructively: Toyota placed production-cost, ride-quality, and EV driving as higher priorities. Are you saying that should have been traded off for the sake of offering more cargo room? GM has already provided quite a bit of real-world data from Volt showing the price consumers are willing to pay is absolutely vital, it must be competitive with traditional vehicles. From Prius itself, Toyota learned the value from improving rear-suspension and cabin-sound. And of course from the market as a whole, it's easy to see the emphasis being place on the EV experience. All those priorities were taken very seriously. That's exactly what has been delivered for Prime. To just toss those aside without care or consideration of how they'd be impacted by another lesser priority isn't constructive... especially when you know that mid-cycle could potentially introduce an improved battery-pack, one that's smaller. In other words, I'm not buying the "*need more space*" argument without any reasoning. It's easy to get on-paper claims that fall apart in real-world experience. That happens in a regular basis. We need solid examples. After all, that's how those other factors became higher priorities.

- 12-19-2016 Follow Up.** Someone else called me out on my response to that personal attack. There was an item of importance he objected to: *"let's also 'not' remember that genII Prius (2004) did have yellow stickers in the largest state, California, as well as access in other states' HOV lanes."* That seemed a valid point. I wanted to find out for certain. Often, the devil is in the detail. It's quite common for a timeline to be forgotten or the scale to be misrepresented. Fortunately, the big Prius forum doesn't dismiss facts like that daily blog. Finding out more about what actually happened and when will sometimes bring a debate to an end. So, I gave it a shot by hunting down some detail: September 23, 2004 is when approval for the yellow stickers was given. Distribution followed shortly afterward. They were not effective until January 1, 2005. So... the HOV access was first available for the 2005 model. Again, writing off the first 4 years isn't exactly a true representation of what actually happened. I do appreciate the fact-checking effort to keep it all on the up & up though. Point being, we're still getting a lot of excuses from GM supporters. The need still very much exists for targeting showroom shoppers. Watching the Bolt vs. Volt battle play out isn't helping those who simply want a high-efficiency SUV.
- 12-19-2016 -20°F.** All I can say is: *Whoa!* The temperature plummeted and our plans for staying inside all day didn't work out. A few errands needed to be run. That meant jumping into a very cold Prius PHV and starting the engine right away. It was not a time to be taking advantage of blending. Use of plug-supplied electricity isn't helpful when the heater is powered by the gas engine. Warmth from the coolant is how the current generation of Prius I'm driving gets heat. There's just an old-school core transferring that energy to make the cabin comfortable. True, that is a very efficient method of warming (since the energy would otherwise be wasted). But I am looking forward to electric-heat with the Prius Prime. True, that uses a heat-pump which won't work in -20°F conditions. So, I'll still be relying on a heater-core anyway. But thankfully, it's not that extreme outside here often. We routinely see temperatures in the teens throughout the Winter on average. The heat-pump will work fine then. It does indeed get much colder, but those are cold snaps... not the entire season. We get a few days in a row with below zero. Today, it was quite a bit colder. The Prius drove just fine anyway. We stayed warmed too. The only penalty was MPG. It dropped to 35 for that short trip into town with a few stops. That's actually impressive. Think about how much lower a traditional vehicle would operate in the same conditions.

- 12-20-2016 Buyback Complications.** There really aren't any now. That hope VW had to fix the remaining 60,000 of their TDI vehicles is rapidly fading away. These are the ones with the larger engine, those more expensive luxury models. It makes sense that their would be an effort to make the diesel emissions from those clean enough to meet minimum clean criteria; otherwise, it will cost VW a great deal to pay for those too. That's not realistic though. The \$15 billion in settlement claims will have to grow. Those only accounted for 20,000 in the larger-engine category of 80,000. Adding those others is pretty much inevitable now. Of course, we knew from the start the buyback would be loaded with complications. Far too many issues arise with retrofitting. The existing design is compromised too much. Owners won't be happy with fixes. Owners will be happy with compensation. Being able to purchase a new replacement vehicle with that money from VW is very appealing... especially at this point with so many much, much greener choices emerging. We never imagined an abrupt end to diesel. The reveal of a scandal exposing the violation of 475,000 vehicles is a trying remarkable point in history. On one specific day, the death can in the most harsh of possibilities imaginable: penalty enforced buyback. Whoa!
- 12-20-2016 2017 Kia Niro.** This upcoming new hybrid is stirring interest. The official rating is 51 city, 46 highway, and 49 combined. With MPG values that high, its supposed SUV appeal should draw more than just attention. The estimated \$24,000 price is raising questions though. That's quite low. How is such a vehicle possible? Something does add up. It would be great to have another automaker reinforce the raised efficiency bar. It doesn't seem realistic though. Maybe the body is really small. Perhaps it is underpowered. You'd think Ford would have been working to deliver something like this, no Kia. But then again, the parent company (Hyundai) has been striving to improve product & image after their previous issues. There is potential. There is also good reason not to just accept claims without proof of some sort. Estimates leave much to wonder about. We need detail to really know for certain.
- 12-20-2016 Growth.** The fundamental question of purpose is coming up on a regular basis now. Growth is vital. That essential nature of the business isn't being taken seriously though. I'll continue to point out its importance: Prius PHV was a mid-cycle update, rolled out allowing for change based on market response, with gen-2 already well into development. At the very same time, Toyota introduced Prius V and Prius C. Additionally, prior to gen-2 rollout, Toyota also introduced RAV4 hybrid. We most definitely didn't see anything of the sort from GM for product diversity. It was a one-size-fits-all solution. They bet the farm on Volt, which hasn't achieved mainstream sales rates. Bolt doesn't have high-volume expectations either. That's why what's happening now comes into question. What should we expect from GM? We know Toyota will be promoting Prime. The potential to draw new interest is clear. It's not a regular Prius with a larger pack and a plug. There's opportunity with this unique & affordable configuration, even in a market favoring low gas prices and little desire to reduce consumption. What is there to attract ordinary consumers to Volt or Bolt who simply aren't interested in spending much for getting a plug? It's similar to the problem hybrid have always had, but amplified due to the tax-credit dependency. In other words, how will growth be achieved?

- 12-21-2016** **So Early.** This came up from an unexpected source: "*why do so many suspect low bolt sales (especially so early) ?*" You wouldn't look to someone who talks down Toyota's approach to electrification on a regular basis to suddenly pop out a question like that. The response was an easy one: Because GM said that's what we should expect. That's why I've been questioning supporters, to find out what they expect now that the bar has been set. How will growth be achieved?
- 12-21-2016** **Fundamental Question.** Almost immediately, I had more to contribute... and ask? Clearly, that question was a popular one. It was evident that others had been thinking the same thing. So, I added this to the discussion in response to the "*why do so many suspect low bolt sales (especially so early) ?*" question: We also recognize the pattern. Things just don't add up. Then when you look to find out why, evidence showing goals being missed becomes obvious. So, we ask a fundamental question. Years ago, it was: "*Who is the market for Volt?*" That ultimately revealed the problems with gen-1. Now that there's nothing too prove technically, the question had changed. The fundamental question is: "*How will growth be achieved?*" How that is answered will tell us much about GM's electrification future.
- 12-21-2016** **Inventory Call.** I finally heard back from my salesperson. There's only so much she can do for me. Living so far away from both coasts, delivery to the center of the country simply takes longer... and in this case, isn't a priority. Next month will be different. Right now though, the end-of-year focus means taking advantage of high demand right there near the ports. That means very limited availability here in the Chicago distribution region. My phone rang. She did the best to reduce my expectations right away. I was told the package I wanted could be obtained, but not my color preference yet. They had a gray one in inventory. I knew that was coming. Waiting for the color unique to Prime meant an inevitable extra wait time. It's worth it too. And with plenty of Winter still to come, there really isn't any rush. True, it would be nice to take delivery prior to year-end; that certainly isn't necessary though. I thanked her for the check. Verifying that my interest still was very much on getting the Blue Magnetism color was nice work on her part. I appreciate that. I also feel good that a few deliveries will be taking place locally, even if it isn't mine yet.

12-21-2016 **Good Enough.** The spin & denial got out of control. Excuse after excuse in defense of GM. That pattern is quite familiar. Do whatever you can to mislead & distract. It was an amazing display of desperation. I posted this to bring the discussion to a screeching halt: "*TRADITIONAL VEHICLE SALES ARE ABSOLUTELY CRUSHING PLUG-IN VEHICLES.*" It did too. That harsh reality is painful to acknowledge. No matter how much they try to sugarcoat the situation. The actual numbers to support the optimism. And that's with the status quo perspective! Once you take into consideration the mounting opposition from the upcoming new administration in addition to the inevitable expiration of tax-credits, the situation does not look promising for GM. That's why Nissan has been so incredibly quiet lately. That's why Mitsubishi has been on their continuous delay. That's why Ford & Toyota aren't committing to long-range EV offerings until the next product-cycle. That's why we don't actually get any detail from Chrysler. It boils down to uncertainty and the unwillingness to admit change is needed. Since Toyota embraced change by halting PHV production and switching over to a new approach with Prime really stings. Toyota actually took that step. Meanwhile, we see GM taunting Tesla. Why? What the heck will that accomplish, especially at the expense of Volt? It makes no sense spreading resources so thin... knowing that was one of the problems contributing bankruptcy. If the goal of competing with traditional vehicles was taken seriously, the risk could be acceptable. But with nothing but a stream of excuses with a good enough attitude is totally unacceptable. Settling is not how you get the masses to embrace change.

12-22-2016 **Fake News.** Everyday now, I'm seeing articles posted about Prius... all saying something about how it competition is eroding away it's popularity. It's clearly a propaganda effort. The source is unknown, but the websites publishing the content adhere to the template. The style is very easy to spot. I've seen it so often, the pattern is obvious. A great deal of effort is being spent to spread this fake news. The appearance appears credible. But when you read for content, there isn't actually anything there. The articles don't actual say anything. There's just a string of vague implications with the attempt to get you to assume there's a problem with Prius. Seeing that over and over and over again is how they get you. The feed of information is so consistent, the hope is you will just keep reading that rather than do any research on your own. That's how the successful brainwashing happened with the election. So, that's what we are seeing in the form of greenwashing in the automotive market. Just keep saying bad things about your opponent. Whether they are true or not doesn't matter. Even if facts don't add up or are incomplete, it doesn't matter. None of it matters. All they do is keep repeating the same message. Sound familiar? That's how GM built up hype for Volt.

- 12-23-2016 New Education.** We're are now starting to see the real questions of new ownership emerge. Unfortunately, I still don't have my Prime yet. So, the real-world data is quite limited. I can provide examples from the past though. There's enough of that to have proven importance of certain information. In this case, it was about how the ECO mode works. We have forum participants who have never been exposed to any of the detail; their basis of knowledge is only anecdotal. That presents opportunity. I took advantage of that today by posting about the heater: With gen-3 came ECO mode, which would lower the "*engine on*" threshold from 145°F to 114 °F for the coolant temperature. That enabled the heater to run longer when the engine was off, since that trigger could be adjusted by the driver. It resulted in less gas being consumed. With PHV came a tiered approach, dropping thresholds even lower depending on heater settings and battery-pack temperature. (I've seen it down to 82°F). That resulted in an even greater return from ECO mode. You need an aftermarket gauge to see the sophistication of the system. Toyota does not provide that level of detail in the owner's manual.
- 12-23-2016 Charge-Mode Misconceptions.** It was only a matter of time before they emerged. This is what I stumbled upon: "*My understanding is that I can use charge mode to give the battery a boost with the ICE. Would it be advantageous to force this charging when descending a long hill, or would the car, in normal operation, do this charging without my intervention?*" That seems innocent enough, until you read the discussion thread for context. Posts had been related to power and lack there of. It's subtle enough to overlook, especially if you focus on the when part. There had been concern expressed about how the electric system behave when the battery is low. I jumped in with: That's an interesting new misconception. It's easy to see where that assumption came from too. Volt has a "*Mountain Mode*" which is designed to fulfill that very need. It provides a 10-mile buffer on the battery-pack for times of high-demand. That most definitely is not what "*Charge Mode*" is for. Prius Prime already has plenty of power readily available. That's what "*EV Auto*" will provide automatically. "*Charge Mode*" is for special circumstances when you don't have the opportunity to plug in, but would have the advantage of EV mode efficiency if that electricity was available. In other words, if you are on long highway trip and your driving around at your destination will be just short jaunts where preventing engine warm-up would be beneficial, go for it. I routinely take trips like that. Once there, the running around from place to place is only a few miles. Being able to do that entirely in EV from electricity generated while efficiently cruising along the highway prior to that will be great. Being able to avoid having to run the engine at all will be a nice improvement, clearly enough of a gain to offset the earlier charging.

12-24-2016 **Hope & Progress.** You ever wonder what will ultimately happen with GM's efficiency efforts? We're now hearing that MPG shortcoming fines won't be enforced as planned. There's been a massive push to delay any type of reaction to violations of the agreement already in place. In this case, we can clearly see the demand for SUVs and Trucks is preventing automakers from reaching targeted levels. With potential enormous penalties, it's easy to see how much hope was placed on the success of Volt, then shifted over to Bolt. There was a strong belief in the "*if you build it, they will buy it*" motto. Turns out, that doesn't always work. You have to carefully study want & need. With GM, they surveyed small groups and enthusiasts. It was a flawed approach... since focus was entirely on want. You have to seek out the opinions of those showing no interest, those who stick strictly to need. That's how progress is made. If you can find a means of swaying their beliefs, that supply will result in demand. It's a tricky balance though, since want & need are so easily confused. Some people genuinely mix them up, to the point of swearing a want is actually a need. That's how hope came about. It was an expectation of a goal being fulfilled that didn't actually represent a step forward. Delivery didn't result in a progress. That's a very big oops! It's the reason why GM gets so much attention. You wouldn't think repeating the same mistakes would be so easy. Yet, that's what we are seeing. Ugh. Thank goodness the other automakers don't follow the same approach.

12-24-2016 **TDI Buyback.** All I can say is: *Whoa!* There was talk online of a few VW owners very angry with the "*clean diesel*" scandal. It seems to be a cause for humiliation for them. Think about how relentlessly some harassed Prius owners. The arrogant & cocky attitudes outweighed any type of hybrid smug you'd encounter online. They posted MPG data on a regular basis, driving situations that were clearly bias. We'd call them on it too, pointing out that highway-only results are not representative of ordinary driving. Daily commutes consist of a variety of driving conditions. When it came to emission, the "*clean*" data was always exclusive to carbon. When the smog type was brought up, they'd just dismiss it as unimportant. We'd point out the "*50-state*" certification was a meeting of only the minimum to qualify for sales... the opposite end of the spectrum compared to the PZEV rating for Prius. Even on paper, the diesel technology didn't compete. In real world, we wondered how the MPG quoted could actually be achieved. With so many engineers owning Prius, our breakdown of engine operation didn't add it. How could VW have achieved such a miracle. Turns out, they didn't. They cheated instead. Now those owners have to deal with reality. Hearing about retaliation in the form of stripping down a TDI vehicle prior to buyback is one thing... seeing it is quite another. One owner actually removed all the doors and all but the drivers seat. The car had been gutted down to the bare metal in places. Photos of that were quite a sight. Needless to say, it got VW's attention. That resulting bad PR is part of the healing process... hopefully.

12-25-2016 Sales & Song. With the hope of a good feeling, this spiteful poem was re-posted yesterday: "*The Night before Priustmas*". It was a creative attack on myself along with a good friend from a Volt enthusiast very unhappy with the outcome of gen-2 rollout. Things were not going well and scapegoats were needed to express disappointment. I found it quite telling. The childish attitude toward goals of change resulted in massive disappointment. An entire year later, that feeling hasn't diminished. Some still feel hurt. One even reposted that spiteful poem... on a thread summarizing plug-in vehicles for 2016. I took the time to layout facts and point out goals. My response was to address actual need, not engage in games of chest-pounding. It's hard to believe they'll allow it to come to this:

Scores of times this question was asked: "*Who is the market for Volt?*" For years, the answer to that was calls of "*O Come, All Ye Faithful*". But to the dismay of performance advocates, they didn't come.

Instead, celebration turned to conquest sales based upon great lease offers. Victory became shallow, since many simply abandoned Volt when expiration was reached. Loyal customers of GM weren't ever swayed. Their support for Malibu, Cruze, and Equinox remained strong. Gas was cheap and the newer model was much nicer than the one it replaced.

That now changes the question to: "*How will growth be achieved?*"

Despite an upgrade of Volt to second generation, sales still are not attracting those loyal customers. They still are not interested. They still lack the a desire to plug in. To complicate matters, GM is rolling out Bolt, focusing limited tax-credits on an effort to attract those interested in Tesla Model 3. Does that mean the answer to the who question remains unchanged?

This topic features plug-in vehicles of 2016. The surprise newcomer that this group in particular, claimed would never be possible, was revealed and rollout has begun. Enthusiasts of Volt mocked, belittled, and insulted the system Toyota offered, absolutely insisting it could never be upgraded to compete. They refused to address the possibility that it could, and at a substantially lower production cost.

A plug-in hybrid capable of actually taking on the true competition... those traditional vehicle sharing the same showroom floor with loyal buyers very difficult to sway... is now being delivered. With a MSRP price so low, even when the tax-credits expire, it will be able to draw interest from consumers currently without any desire to plug in.

Rather than Volt being an ally in the fight against traditional vehicles, enthusiasts chose to represent it as "*vastly superior*" in the very limited market of plug-in choices. They refused to consider the big picture, to acknowledge how much faster sales must grow, to embrace the changes that must occur. That's really unfortunate.

Oh well. We will now hear songs from loyal customers, telling us it is Prime time. The affordable price, combined with enough EV range to cover commute & errand driving of many, along with outstanding HV efficiency, will achieve that sales growth.

12-25-2016 **Enjoying The Holidays.** With the onslaught of fake news (articles with almost no substance posted to spread rhetoric), it's difficult from some to really get an understanding of what the market has to offer. Some see the "*business as usual*" and just ignore the green choices entirely. They view them as alternatives, rather than the next step. There are others who simply look at anything with a battery in an overly simplistic manner. They simply lump all of them together, never even bothering to see if there are any differences. Then you've got some who think they are a good idea, but don't see them as something to decide upon. It's seen as an option for others. In other words, a bulk of the population couldn't care less... and that's before the next administration takes office, one who plans are quite counter to concerns of oil dependency and protecting our environment. The holidays offer an opportunity to not have to worry about those things for a little awhile. I look outside and see heavy rain. This is Minnesota. We are supposed to have a White Christmas. That means beautiful cold scenes outside while drinking delicious warm beverages inside. Instead, we watch the ice-skating rink on the pond wash away. Our climate most definitely has changed. Whether you agree upon cause or not, that's no reason not to try to reduce the impact. Prius is on the 4th generation now and there's a growing variety of hybrid options. What will it take for people to embrace them? Remember the good old days when we looked forward to a predictable holiday season? Those were the days, back when the grandparents were still hosting family gatherings. Now, it's up to us to make things nice for the children. They need happy memories too.

12-25-2016 At Home Charging. Not at all pleased by the unprovoked personal attack on a website I haven't even posted on for quite some time, it was an invitation to say whatever I wanted. After all, the article was about the plug-in market in general. There was no reason whatsoever for the lashing out. But then again, when someone is looking for a scapegoat, they tend to find one. It was actually rather vindicating to get such a response without any participation. It confirms the message had been received. So, I used the stir to direct attention to something actually helpful:

Want to have a constructive discussion?

Let's post about "*at home charging*".

The recommendation from GM for Bolt is to use a 32-amp level-2 charger. To accommodate that, one must have a 40-amp line in their home. How many people actually have that much capacity available? Many older homes only have 100-amp circuit boxes. Upgrading to support more and run a new line to the garage is an expense no one wants to provide any details on. In fact, all we've heard is that GM will provide financing for it, allowing you to roll it into the loan for the vehicle.

For Volt charging at home, there are many who bought & installed a level-2 charger. What amp rating was that? Choices years back were less powerful than now, which means slower recharge times. Will they upgrade line & charger? How much will that cost? Using a 16-amp charger would get the job done overnight, but will gen-2 buyers understand that time difference upon purchase or make the discovery later? How is GM educating people about charging needs?

Toyota kept it simple. Using the most basic 120-volt outlet at home, an ordinary 15-amp line will provide full recharge in 5.5 hours. That's easy to accommodate with overnight charging. Using just level-1 means no surprise extra expense. If you have an ordinary 20-amp in your garage, there's an option to plug in 2 chargers at the same time. Each can be setup to draw 8 amps instead of 12 to provide that option for dual plugging. Capacity of the Prime battery is small enough that the added recharge time would still fit into an overnight timeframe.

Think about how easy it is to plug in a 12-gauge extension cord into an ordinary 120-volt line rated for 15 amps to provide electricity for a level-1 charger. You may understand what all those numbers mean, but a mainstream consumer probably won't have a clue. They will have the outlet though. So, even in a cluttered garage, they'll still be able to recharge a Prime overnight... even if the line is shared with something else, like perhaps a chest freezer. No big deal. The sale is simple for both salesperson & buyer.

Make fun of the "*25 miles*" of EV all you want. Only enthusiasts care about that. Consumers shopping the showroom floor want a vehicle that's affordable and easy to plug in.

12-26-2016 **Vastly Superior, history.** Witnessing it repeat is an expectation. Those shallow & empty claims online we see on a regular basis impair progress. It's really annoying. Reading though though brings up memories that stir opportunity for change: "*In my mind, the Volt is vastly superior to the Prius Prime...*" The reintroduction of that same problem was a great invitation to try to break the cycle, using a new approach: You need to tell us why Volt is supposedly "*vastly superior*" to the Prius Prime, so people will buy it instead. That's called advertising. Not actually conveying any information won't convince many of superiority. First step is to consider audience. Who the heck is the advertising for? Targeting enthusiasts is far different from targeting ordinary consumers. Second step is to consider venue. Where will the advertising take place? Drawing attention randomly from television & internet is far different from stirring interest on the showroom floor. Third step is to consider features. What aspects of the vehicle do you wish to emphasize? Selling a performance vehicle is far different from appealing to a family transport shoppers. Fourth step is to consider timeframe. How long that specific promotion takes place can be a major factor as to how the message is received. Bing bang is far different from on-going repetition. Finally, you come up with a simple message. This is what advertising will build upon. Something is needed as a take away from the advertisement. How should those seeing it react? Needless to say, there is much more to advertising, as the history of "*vastly superior*" claims has taught us.

12-26-2016 **Vastly Superior, advertising.** He responded, but with a evasive move to avoid providing any detail. That intentional effort to not acknowledge what was posted is the same old nonsense we saw in the past. I stayed on track, pushing for a proper response instead of taking the bait. It was surprisingly easy how to accomplish that too. With a little ambiguity about which vehicle I was referring to (with the hope of it stimulating thought, rather than just another avoidance attempt), I posted this clear & concise list of detail for each step:

Audience = *ordinary consumers*

Venue = *showroom floor at the dealer*

Features = *EV drive, 21st century styling*

Timeframe = *beyond tax-credit availability*

Simple Message = *affordable and easy to plug in*

- 12-27-2016** **Vastly Superior, grade.** The troublemaker quickly sounded off, drowning out all the other posts... including what I my attempt at being constructive. He wasn't happy. He'll never be happy. His purpose is to promote superiority at all costs. It's intriguing to watch someone who you know won't ever give up, even when everyone else has moved on. I was intrigued... since that type of stubborn dismissal of facts is often where ideas emerge from. When else would anyone ever push such an extreme? Anywho, this was how I responded: There's no need to debate. Advertising an ability to educate serves a purpose, but it doesn't do anything to stir emotion. The best you could give that is a "C" grade. Homework delivered, but in no way deserving of praise, isn't what you want to spend on television commercials. Toyota has this nailed with Prius Prime. The quad-headlights, dual-wave window, and larger touch-screen are standout features, a clear effort to stir emotion. Here, we also get an optional color heads-up display. In Japan, customers also get the option of all-wheel drive, solar charging, and a 1500-watt AC inverter. Again, each can draw interest in a strong & unique way. There is a collection of safety features included standard that other vehicles lack. Prime also includes a charge-mode standard. All that is an effort to earn an "A" grade. What compelling features are there for GM to advertise about Volt?
- 12-27-2016** **Vastly Superior, sales.** When cornered and there's nothing else left, the originating source of conflict tends to emerge. In this case, it was clearly: "*No. Too little too slowly is referring to making weak technology, later than the competition, thus not being compelling to the market. (see PiP)*" I got a kick out of reading such a revision of history, so easy to disprove. In this case, it brings us back to the ultimate purpose too, sales. It's unfortunate that unsuccessful attempts to introduce a new product are viewed as utter & complete failures, rather than just an opportunity to adopt, adapt, and improve. You learn from the experience and move on... unless your you was to prove a technology was "*vastly superior*" rather than just come up with something that sells well. Ugh. Why does pride get so in the way sometimes? Oh well, this is how I dealt with it: That most definitely is not true! The blogs of the time clearly confirm that fact too. The automotive task-force overseeing the bankruptcy expressed the "*too little, too slowly*" concern to GM executives about Volt, wanting assurance that it would be sold in high-volume for a profit shortly after rollout. That's how the 60,000 annual-rate target for sales by the end of the second year came about. We have yet to sales even remotely close to that 5,000 monthly minimum... hence all the grief I'd had to put up with about yet another "*over promise, under deliver*" problem. That's why focus on advertising has become a topic of discussion. It's an effort to figure out how to deal with the situation. After all, many here have complained about Volt not be promoted enough... so it makes no sense for you to respond with that "*good enough*" attitude.

12-27-2016 **Vastly Superior, growth.** This is clearly the new question for this generation Volt: "*How will growth be achieved by not trying anything new?*" None of the efforts with the first resulted in sales growth. Even that massive price reduction didn't do any good. Sales remained flat. Hope turned to the second. No growth resulted from that either. So far, all we've seen is signs of trouble to come. Bolt will gobble up interest, as well as tax-credits. With such an extensive list of features that Prius Prime offers, it makes sense that we are seeing a final lashing out. Reality is finally setting in. Prius isn't the competition. Leaf isn't the competition. The vehicles competing with Volt are others from GM's own product line. I can see hints of the online arguments revealing that mindset shift. Of course, much of that comes from pride. There's simply no way to argue against Prime's improvement over PHV. The same thing is expected from the upcoming inevitable upgrade to Leaf. These next-gen vehicles wreck how Volt was promoted. Claims of "*vastly superior*" are of no interest to mainstream consumers. Those shoppers have very different priorities. All that leaves are those who have moved on to other choices. That leaves the question of growth in a state of utmost uncertainty... which explains the fanatical behavior lately. How?

12-28-2016 **Vastly Superior, features.** Things did end up getting interesting. The discussion turned in a constructive direction. Yes, I know it will ultimately become destructive. But what the heck, why not take advantage of this opportunity: "*But you can get a Corolla for \$10K less. Why buy a PP?*" Comparing within a product-line, rather than cross-automaker is quite shift. This came from an antagonist who absolutely refused to acknowledge anything without a plug, in the past. Things are changing. This was too good to resist. I gave it quite a bit of thought before choosing to post return in this fashion...

These are all standard features, included in the base model:

- * 25 miles of EV
- * 54 MPG without plug
- * SULEV rating with TZEV
- * Star Safety System
- * Toyota Safety Sense P
- * dual 4-inch displays
- * quad LED headlights
- * LED tail & brake lights
- * dual-wave window
- * heated front seats
- * hatchback with folding seats
- * smart-key door & button start
- * backup camera
- * remote A/C

Star Safety System = Enhanced Vehicle Stability Control (VSC), Traction Control (TRAC), Anti-lock Brake System (ABS), Electronic Brake-force Distribution (EBD), Brake Assist (BA) and Smart Stop Technology (SST)

Toyota Safety Sense P (TSS-P) = Pre-Collision System with Pedestrian Detection (PCS w/PD), Lane Departure Alert with Steering Assist (LDA w/SA), Automatic High Beams and Full-Speed Range Dynamic Radar Cruise Control (DRCC)

- 12-28-2016** **Vastly Superior, struggle.** When dealing with someone who will never accept defeat, bringing it to an end requires giving them a good fight. Then they feel like pride has been retained. What seems to work best is just head-butting the best you can, then leave them confused. He certainly was today too. References to other vehicles and options having nothing to do with plugging in were outright dismissed with the claim of being off-topic. The comments most definitely were not. But when your world is a simplistic view, omitting everything you feel has nothing to do with the purchase decision, it's easy to say something is incongruous. I was somewhat surprised that the entire list was summarily rejected. It was comprehensive, addressing a variety of features ordinary people express interest in... efficiency, safety, greenness, techy, style, comfort, and convenience. I repeated it too, stressing the diversity. It has always been a struggle for any of the hybrid & plug-in choices to reach beyond the stereotypical audience. Growing the market requires new approaches... something he clearly is unwilling to accept. He continued to recite the same old advertising criteria from way back in 2011. That stay-the-course-and-be-patient approach is what I call a "*good enough*" attitude, unworthy of spending any more time on. So, I concluded with: Dismissing the rest of what GM builds & sells has been a fundamental barrier to understanding why sales have struggled.
- 12-29-2016** **Vastly Superior, signs.** There are things to watch out for when certain personalities are encountered online, clues that indicate you are in a no-win situation. The first sign should be obvious... when they take something personally that has nothing to do with them at all. Just out of nowhere, an emotional respond abruptly appears from someone who was offended without them ever actually being addressed or anything of a personal nature having been posted. Not much can be done about that. There isn't an preventative either. In this case, there was a need for superiority in a market where finding compromise is required. It's a guaranteed losing situation when winning isn't even an option. The second sign is much more difficult to notice... when the topic switches to something popular to discuss. Those red herrings are very compelling, temptations so irresistible, someone will inevitably respond. It's not trolls dropping bait either. This situation is simply that of strong interest. But once that is responded to, getting back on topic is nearly impossible. You won't win that either. The original line of logic is lost. In discussions that are nothing but a daily thread, there is simply no hope of return. The third sign is when a desire is stated rather than a goal. They'll just state it over and over and over again, as if that was a need being fulfilled. But when you step back to look at how it accomplishes a business objective, there's nothing supportive about it. This is what we see at auto shows. You hear great praise about an aspect of appeal that isn't ever a priority when actually shopping for a vehicle. Long story short, this is how we've fallen into the trap with Volt. Some developed a mindset of superiority so self-confirming, they've lost sight of what the ultimate purpose was. Remember the intent to replace traditional vehicles?

12-30-2016 **Vastly Superior, defeat.** Remember how Two-Mode faded away? Without a spotlight anymore, the sales struggle turned to dealer disinterest. Why bother? Not only has Volt lost the spotlight to Bolt, it also faces a wide variety of plug-in hybrid competition. That makes traditional competition even more difficult, since the plug-in hybrids still have plenty of tax-credits available. The delightfully low MSRP for Prius Prime puts even more pressure on the situation. Once tax-credits run out, Toyota will still be fine. Volt is in a world of trouble. What will GM do for it, especially with so much emphasis being placed on Bolt delivering high-volume prior to Tesla's rollout of Model 3. So much time was wasted on proclaiming Volt as being "*vastly superior*" to Prius. It boggles the mind how pride could lead to so much lost opportunity. It's still happening too. The idiot posts of recent confirm it. My favorite quote coming from all the desperate spin was: "*Toyota again has settled for another weak offering.*" That shows us how little this individual actually cares about ordinary consumers. He's been so obsessed with EV performance, sacrifice for that benefit became the norm. He was willing to dismiss the priorities people shop for in favor of promoting superiority. Only electric purity matters. It was amazing to witness such blind hope. And after so many years of excuses and an obvious end approaching, he's still not going to admit defeat. Of course, I'm not looking for a surrender anyway. I just want the next step to be taken. Get over it. Analyze lessons learned. Move on.

12-31-2016 **Vastly Superior, evade & avoid.** The situation growth well beyond tolerance. I was quite willing to be patient though, waiting 2.5 days for a reply. That's an eternity on a daily blog. It was worth it though, to draw the year to a conclusion with a reply to this the morning before: "*No one is dismissing anything.*" That was his final post. He clearly just did too. But rather than follow that bait, I decided to make it very personal by addressing exactly what he had posted. This is how:

Yet, that's exactly what your list does, by specifying such a narrow focus:

- * superior drive
- * 100% torque off the line
- * 1000 mile between gas station visits

You have also had several days to provide detail, but still have not. So, it's time for me to attempt to look in depth at what you did provide.

The claim of "*superior drive*" is interesting. It very much resembles the common advertising approach we've seen for decades: "*new & improved*". That does indeed grab attention, but it doesn't actually tell us anything. Compared to what? Which components are superior? How much more will it cost?

Next is saying "*100% torque off the line*". We rarely ever see people racing away from stoplights and rush-hour merging certainly doesn't require full-throttle. When is this important? Who is that trying to impress? How does less matter?

Lastly, the "*1000 mile between gas station visits*" raises even more questions. That is obviously impressive compared to the usual 400 to 500 miles people typically get with traditional vehicles. But you have told us many, many times that other plug-in hybrids are the competition, not traditional vehicles. That being the case, it's easy to see the trouble... since Prius Prime does too.

Sorry, but that's the precedent you set. We've also been told by you how absolutely vital it was for the drive experience to be 100% electric. That came with the implication that Prius wouldn't ever be able to deliver it. Not only does Prius Prime fulfill the same criteria, it is also a little bit more efficient in the process... which earns it an "A+" grade.

The ultimate selling point though is price, a factor you continue to evade & avoid. GM set a target of "*nicely under \$30,000*" for reaching their high-volume profitable goal. MSRP for gen-2 Volt hasn't achieved that yet. Could it mid-cycle, with battery improvements and some package tweaks? Possibly. That current \$33,220 for the base model may be able to drop enough by then.

Toyota's approach for the plug-in Prius was quite different. They set a target of a "\$3,000 to \$5,000" premium over the regular hybrid model. They clearly didn't reach that goal with gen-1, which was a major factor in limiting rollout to only 15 states. But since that was only a mid-cycle update anyway, it was a great opportunity to collect real-world data to help with gen-2 refinements.

The first nationwide rollout is that gen-2 design. Price of the base model Prius (package

"two") is \$24,200. Price of the base model Prius Prime (package "plus") is \$27,100. It does indeed achieve the MSRP target. It delivers a superior drive, more torque, and more miles between gas station visits. It also includes an appealing array of standard features to draw new buyer interest. There are some attractive unique optional features available as well.

In other words, it's time to come up with a new way of advertising Volt.

Happy 2017.

- 12-31-2016** **More Fake News.** The flow of articles published, an obvious effort to undermine Prius, continues. The content of each has been reports of inferiority. There's quite the collection at this point. The series follows the same pattern still too... with the exception of title taking a hostile turn: "*2017 Hyundai Ioniq Shows The Toyota Prius How Much It Sucks*" The data provide was haphazard. That's what you want to when leading people to assumptions. Being vague & ambiguous helps as well. No real substance and lots of generalization is all we've been getting. Clearly, it's some staff writer searching the internet for something to write about which they can sell. Making money from such articles is likely what's feeding the effort. Never having actually driven any of the vehicles or even having anything beyond a stock photo is quite telling. It's unfortunate such things exist. Why do we have to deal with such nonsense, when there are several reputable websites? The war of propaganda is well underway. We have evidence of election influence by such efforts. Now, it's becoming clear the green choices are struggling with similar problems. I wonder what counter-measures will be dreamed up to deal with it. Hmm?
- 1-01-2017** **Happy New Year!** We're seeing a trend emerge. Many of the automakers seem to be targeting the 25 to 30 mile range for EV capacity of plug-in hybrids. That's clearly adding to the annoyance of Volt enthusiasts. They continue to absolutely insist that more is necessary to achieve high-volume sales. It's really unfortunate how uncooperative they've been. Rather than usher in plug-in hybrids as the next step to ending the reign of traditional vehicles, we're seeing a confusing collection of contradicting messages. Emphasis on EV driving makes sense. Disparaging electric-only vehicles to convey the value doesn't though. Belittling the smaller capacity plug-in hybrid offerings doesn't either. Remember 10 years ago, back in January 2007 on the 6th? Most people don't. I do. Looking back at my blogs, I can confirm my memory. Problems immediately emerged. There was a "*trophy mentality*" that undermined attempts to have constructive discussion. When a sensible question was raised about battery capacity & cost, it was met with unusually stout resistance. That made no sense. How could such blindness come about so easily? Prius certainly didn't have a history like that. Toyota talk was well balanced, with a sincere effort to address all concerns. GM support came in the form of cheerleading, optimism based solely upon hope. Any type to clarify ended up getting the "*vaporware*" label. There was a stubborn push to avoid & evade. Now, a decade later, we're still seeing it. Ugh. Oh well. Happy New Year!

1-01-2017 **Vastly Superior, advertising.** The thread topic was advertising. It exposed yet another vulnerability of Volt, showing how the mismatch to mainstream consumers is making a bad situation worse. It's really unfortunate. The technology itself works fine. The configuration is at issue. Think of the situation as a computer configured in a manner unhelpful to the user. If the case is smaller than needed, the hard-drive bigger than needed, and the processor faster than needed, asking someone to pay more than what they budgeted for to purchase it just plain doesn't make any sense. Yet, that is very much the way Volt is. The capacity (battery) and speed (acceleration) are overkill. The small case size (cramped rear seating) makes usage difficult. No amount of advertising can overcome the shortcoming of priorities. Need isn't fulfilled. Needless to say, I'm quite pleased this is all coming to a close now. We're starting the new year with an effort to move on. Yeah! Here's what I wrote:

I titled my commentary on the post yesterday "*evade & avoid*" without any idea just how much the reply would reinforce that.

Choosing to start the response with a textbox exaggeration followed by several denials of easy-to-confirm facts made the effort to not actually address the advertising topic quite obvious. Should I even bother to reply to such counter-productive posting? Well, perhaps I could with a summary by highlighting "*EREV*".

It was a failed attempt to promote "*vastly superior*" status. Problem was, the definition kept changing each time a new plug-in hybrid offering was rolled out... since they ended up fulfilling the criteria stated, which wrecked the superiority claim. That advertising by enthusiasts became a confusing mess; adding to it was a series of ambiguous press releases, all so vague that hampered the entire market. There was no clear message of goals or intent.

Now, we start 2017 with that continuing... more spin & rhetoric with no effort to even try to discuss advertising. The final sentence wrapped it up really nice though: "*I haven't seen a single advertisement for a PP.*"

That shows a lack of understanding how advertisements are distributed. Toyota has clearly stated they will not be promoting Prius Prime in a traditional manner. Generic television commercials are a waste of money in many cases. Unless there's a specific sales event, those only serve to build or retain reputation. That's why targeted advertising is being used now instead.

Do a search online for "*Prius Prime*". Watch what happens to the websites you visit afterward. Notice the flurry of advertisements promoting Prius Prime?

1-01-2017 **Not The Same.** Our resident troll on the big Prius forum is well informed and likes to debate. So, he routinely drops bait. Heck, he even calls himself a troll. From time to time, I bite. It can be informative. Stirring the status quo is ok, if done in a constructive way. This is what caught my attention today: "*That's like saying NiMH prices didn't fall fast enough to save the gen1 Prius.*" It was in reference to pointing out that battery-cost did not drop anywhere near as fast as GM had anticipated or Volt enthusiasts had hoped. I responded with: How is that the same? Toyota didn't set a mainstream level sales goal like GM. Whatever the case, it isn't gen-2 Volt either. That \$7,500 dependency is a very big problem still. Battery cost for 18.4 kWh capacity simply is not going to drop \$7,500 in the next few years. If the beliefs of \$200 per kWh are true, that means the entire pack for Volt is only \$3,680 in terms of lithium cost. It would currently have to cost double that just to break even. To actually grow the market, price of the vehicle must come down too. And what the heck does "save" mean? That generation ended production as planned, following the usual product-cycle schedule. The plans for Volt achieving mainstream sales was mid-cycle. The gen-2 is expected to go full cycle. That means at least 4 more years of sales. The tax-credit will run out long before that. Bolt will be gobbling them up. Look at Prius Prime. With an MSRP of just \$27,100 for the base model, there is no dependency. Even without any tax-credit, it has the potential to grow. Any mid-cycle update will contribute to that. It most definitely is not the same.

1-02-2017 **Television Advertisements.** All that recent "*vastly superior*" nonsense emerged from a daily blog commentary about an article published claiming television advertisements for plug-in vehicle are radically fewer than that for traditional vehicles. While true, it really didn't address what is actually needed. It was only a count analysis based on the assumption that more advertising that way is better. I wholeheartedly disagreed, but couldn't express that until I dealt with the onslaught of trophy-mentality. Thankfully, that ended. So, I posted the following:

Television commercials are what people like to skip. They are generic, poorly timed, and really don't tell you anything. How much can actually be conveyed in just 30 or 60 seconds anyway? The very idea that showing more of them can be better is fundamentally flawed. Who really wants sound-bites forced upon them from an automaker? All they do is draw attention. There's no detail, no real information to make an informed purchase decision.

Spending a lot of money to show commercials hundreds or thousands of times on cable & broadcast television simply isn't a good idea anymore. Automakers should be using more effective means of reaching consumers. It's not the 20th century. Why use such an outdated medium like that to advertise a plug-in vehicle? To actually learn about the vehicle, you have to do research on your own. Automakers should invest in material which provides that type of advertising instead, not television commercials.

Simply go to YouTube and search for "Prius Prime". Look at the long list of results. There are dozens of in-depth reviews from third-parties. Those are the advertisements that actually compel people to seriously consider a test-drive. All Toyota had to do was provide those third-parties with a vehicle to drive for awhile. Getting an endorsements from someone who has had an opportunity to film their own experiences, their own way, then publish a long video telling you about it is far more effective than anything the automaker can provide.

1-02-2017 **From Volt to Bolt.** On the eve of Bolt's debut month sales results and the 10th anniversary of the Volt concept reveal, an automotive journal published an interesting article today titled: "*GM's journey from Volt to Bolt. A troubled vehicle paved the way for more audacious bets.*" Upon reading the first paragraph, it's easy to see why there was so much resentment toward those like me pushing for cooperation rather than superiority. It stated this short & painful description of Volt: "*It flopped.*" The article went on to describe the failure to achieve annual sales of at least 60,000 even with a money-losing price. Fortunately, the battery technology will survive the perils of business reality. That's what was used to create Bolt. So, even though the small, expensive, niche-configured vehicle has no expectation of mainstream acceptance anymore, its successor does. It's a gamble only the die-hard Volt enthusiasts were not willing to accept... until recently. That series of "*superiority*" posts appear to be the final battle. There's so much excitement about Bolt deliveries now, it's as if Volt was just a step in the evolution of plugs which had this planned obsolescence all along. In reality, we see the abandonment. But then again, that was expected by those like me, who witnessed the very same thing with Two-Mode fell apart. Volt replaced it in similar same manner... though, the time span was more drawn out. This is rather abrupt. Of course, news travels much faster nowadays. It's really unfortunate the Volt enthusiasts absolutely refused to recognize the pattern. I repeatedly pointed out the history parallels repeating. Their denial of the possibility of those same mistakes being repeated ran very deep. They didn't want to accept the evidence provided... then, as it was happening. Now, it's being published as a retrospective by automotive journalists.

1-02-2017 **Looking Forward.** We are approaching the point which automotive battery technology for plug & drive is no longer easily dismissed by misconceptions. It's becoming recognized as feasible. To advance to it being realistic, we have to address efficiency & affordability. This is where shortcomings of Volt get looked upon as problems of the past, rather than issues of contention still. The gen-2 model was rated at 31 kWh/100 miles. That made it somewhat of an electricity guzzler. When rolled out, that was just brushed off with the "*electricity is better than gas*" excuse. Now, we can actually take an objective look at electric efficiency... since Bolt is improved with a 28 kWh/100 miles rating. That undeniable progress from GM makes discussions easier. Being constructive is still a problem though... since Prius Prius is even more efficient with a 26 kWh/100 miles rating (specifically 25.9 when the value isn't rounded). In other words, less battery is needed to travel the same distance. It's how affordability comes into play. That next step is a very important one too. Mainstream acceptance requires a price low enough to still be profitable when competing directly against traditional vehicles. The challenges between electric-only and plug-in hybrid appeal are quite significant; however, they do still share efficiency & affordability requirements. Looking forward, we will hopefully find more in common. After all, the ultimate goal is to replace traditional vehicles.

1-03-2017 **Teaching Moments.** We've all heard the phrase "*teaching to the choir*", but how many people actually go out of their way to seek an audience that isn't already receptive to your ideas? There are very few. In the online world, most who come from outside and stir the status quo are labeled as a "*troll*". The nature of people is to resist change, especially if you can find a place where you can post daily. Messages which disrupt the happy flow of cheerleading are regarded as unwelcome. But if you really want to learn what the market is like outside of your protected sphere, that's what you have to do and where you have to go. I've heard that same suggestion from many successful journalists. You have to go where the problems are. That's what I've been doing for many, many years too. It's quite stress dealing with the continuous onslaught of resistance. But that's where some of my best material comes from. Their different mindsets are what provide new ideas... for me. Every now and then though, the flow of knowledge works in reverse. That absurd "*vastly superior*" argument ended with a teaching moment. My comments about television advertisements actually sunk in. He parroted back a "*That's why GM is using targeted advertising*" response. Looking back through all the posts over those past few days, it was quite obvious he had no clue of that approach prior to me posting about it. That was clearly a me-too measure. He got caught unaware and didn't want to admit that I had a valid point. Acknowledgement of having overlooked something so important isn't something you should ever expect from an antagonist. Reading them post about something later you originally pointed is an entirely different matter. It's confirmation of change. I got the message through to a very stubborn opponent. It's really unfortunate he still believes the competition is other plug-in vehicles. That's such a detriment to the effort of replacing traditional vehicles.

1-04-2017 **2016 Sales.** Understanding the opposition to plug-in vehicles is quite a challenge... except with Volt. That "*vastly superior*" attitude revealed the intention to dominate, rather than collaborate. The enthusiasts simply didn't like the idea of a smaller battery-pack and performance on-par with mainstream vehicles. They felt better was absolutely necessary... a need, rather than a want. That fundamental clash of purpose has caused many problems over the years... because the measure of success is sales, not engineering extremes. Volt enjoyed a major spike in purchases during December. That's no surprise. Between the growing popularity of plug-in and the usual year-end rush to collect tax-credits, the spike was a realistic expectation. Stepping back from the monthly numbers to look at annual totals, you get a different story. Expecting the first full year of gen-2 to climb close to mainstream minimum was reasonable. After all, the enthusiasts boasted about doing it for years. That number count 60,000 sales. For the first full year of gen-2 Prius sales, the total came to 53,991. Enthusiasts had set an expectation of exceeding that. Why not? The new generation represented a massive amount of engineering with years of refinement. It also would have a \$7,500 tax-credit. That wasn't the case for Prius. All it had was a \$2,000 tax-deduction, which only came to between \$300 and \$400 on your return. Toyota didn't have an much experience as GM at that point either. That's why the 2016 total for Volt of just 24,739 is really a source of concern. That's well short of the target... and now there is the added pressure coming from Bolt. Growth is essential. Watch how things play out over the next few months.

- 1-06-2017** **Freaky Cold.** The usual temperatures well below zero are here no, right on schedule. First week of January here in Minnesota, you have that expectation. Being cold so much lower than just the freezing point means the engine starts up right away. Seeing that negative sign though gets me quite curious. What will I experience when I finally get my Prius Prime? Being able to warm the cabin with electricity supplied directly from the charger will be a nice perk at work. But how effective will it be then, when heat-pumps don't have much warmth from the air to draw upon? There's a point at which the engine will start up anyway. Of course, it won't need to run as long with the battery-pack also having an electric warming feature. The steering-wheel and seats will be electrically warmed too. So, comfort for all is covered. There is that reality of needing to clear windows though. Whatever the case, it will be even more efficient than the Prius PHV now. It will also warm faster. That's good, exactly what you want from a next-generation upgrade.
- 1-07-2017** **Repeating Fake News.** It's really getting frustrating. Yesterday, an article with this title was published: "*2017 Chevrolet Volt Brushes Off Prius Prime Success*". It contained lots of greenwashing. The technique most common is to omit vital detail. In this case, there was no mention of availability. Sales results were presented as if availability was the same. You are led to believe people actually had the choice, that inventory was available to decide upon. That couldn't be further from the truth. There are people going nuts in the Midwest waiting for Prime to arrive. There simply aren't any yet. What makes that frustrating is when you read the same article again, word for word, published the next day on a different website. Today, that happened. The new title of the article was: "*2017 Chevrolet Volt Doesn't Care About Success Of Toyota Prius Prime*".

1-07-2017 **More Cheerleading.** The blind optimism never ceases. The enthusiasts see what they want. Yesterday, it was a reflection of last month's sales with: "*Bolt and Prime validate Volt. Sales, regardless of incentives, are up. Way up.*" I waited a full day before responding. I was curious if anyone had anything constructive to say about that. Turns out, none did. So, I sounded off, pointing out and asking:

A spike in sales at year-end is the usual expectation. People rush to take advantage of being able to collect tax-credit money right away, rather than having to wait an additional 12 months. That influence cannot simply be dismissed. Sales going up temporarily is normal. What happens in the following months is what tells the real story.

As for Bolt validating Volt, how? The premise of Volt was to alleviate "*range anxiety*" by providing an engine for backup power when electricity runs out due to battery limitations. Bolt doesn't need that. The 200-mile EV range overcomes the same concern... which invalidates. Bolt's capacity growth through increased energy-density and cost-reduction counters the selling point of Volt.

With respect to Prime, what is the Volt validation? We always knew the mid-cycle, limited-rollout Prius PHV would be replaced by a nationwide next-gen model featuring a larger capacity battery and more power, for a price competitive with traditional vehicles. That's exactly what Toyota has delivered. What influence did Volt have? It certainly wasn't a need for liquid-cooling or much further EV range.

Put it this way. The sales goal hasn't changed. 24,739 is well below the target of 60,000 set for mainstream penetration and maintainable profitability. Bolt will be competing for the same limited quantity of tax-credits with Volt. Rapid significant growth is essential. That record high 3,691 needs to climb to 5,000 and remain there. Otherwise, what's the point? Replacing traditional vehicles with plug-in choices requires strong sales without subsidies.

1-07-2017 **April 2012.** Once upon a time, when my Prius PHV was only 1 month old, I took in on a trip up north. We unexpectedly ended up getting a bunch of new snow. That provided an amazing opportunity. The fresh, sticky white stuff coating all those trees in isolated, scenic areas was great. I went nuts with the camera too. Unfortunately, those photos remained unseen for all this time, nearly 5 years. That new plug-in hybrid had me busy with lots of other stuff. So it wasn't until now, as I'm preparing to upgrade to a Prius Prime, that I'm catching up and finally publishing some of the photos. There were many. Choosing the best is a challenge. It's rewarding to have such a collection available. Here's what I ended up selecting to share, those long lost PHV photos from many years ago... [photo album 197](#) [photo album 198](#) [photo album 199](#)

- 1-07-2017** **2010 Prius.** Believe it or not, I had even older photos that never got published. In this case, they were of my Prius prior to getting the plug-in model. Interesting thing about them is the captures were underexposed. The setting was a icy dirt road just after sunset. That made the lighting extremely difficult to work with. In other words, they were too dark. Correcting problems like that is easy nowadays though. I found a digital filter able to bring out the sections needing to be brighter without washing out the sunset. The results look great. Lots of detail was revealed in the foreground, stuff you wouldn't have been able to see otherwise. I guess waiting in this case really paid off. Sure glad I didn't just abandon these. They look nice, capturing a circumstance few rarely ever see... especially with a Prius. Check them out: [photo album 199](#)
- 1-07-2017** **Wind-Turbine.** I'm still finding treasure in my archives. More photos of the 2010 Prius were found. In this case, it's especially exciting. I found photos at the same location from 2 different times of the year. One set was from late harvest, in the Fall. There's corn fields in the foreground and a big wind-turbine in the background. Being able to park right along side that looked really nice. Catching that scene right before sunset made it even better. The second set of photos is the same place, but Winter. 3 months later meant snow instead of corn. It was also right when the sun was setting. Seeing the same place like that under different circumstances is really interesting. There's 2 that especially peaked my excitement though. I turned off the paved road to a dirt road, for photos from a different angle. That was the very location I was at in the previous photos... 2 years later, that same icy road... only a few feet from there, but facing the other direction. Check out my 2010 Prius with a large wind-turbine in the background: [photo album 200](#)
- 1-07-2017** **Even More.** Yes, more unpublished Prius photos. This collection was stored away on a memory card, not forgotten... just set aside for someday. Finally getting to look through what I had captured over 6 years early was very exciting. I still remembered taking them quite clearly. It was at the old military testing facility from World-War II. There were nothing but concrete frames remaining. Some of it was surrounded by untouched land in a secluded location. Other parts were bordered by corn fields. Much of which is accessible anymore. Some was fenced off. The rest sold to a manufacturing facility. So, having taken them is a nice way to preserve the time... with the Prius, of course. Remaining unpublished for so long isn't so bad. I wish I would have had time to share them sooner. But it sure is fun now looking back at those treasured memories from long, long ago... [photo album 201](#) [photo album 202](#)

- 1-07-2017** **Plug-In Prototype.** I had an opportunity way back in the Summer of 2010 to play with a prototype Prius for a few days... a plug-in model. This was the testing configuration put on the road for use by ordinary people to collect real-world data. 2 full years before the production model was rolled out, some of us were experiencing the dream firsthand. It was an augmentation of the hybrid system. Toyota added battery-capacity and a plug to enhance operation. The goal was to provide a MPG boost. There was no EV drive requirement back then or later when the PHV model was rolled out. That didn't come until other offerings stirred the market, carrying it in a different direction. All those years ago, focus was on making the hybrid even more of a hybrid. Nowadays, that sounds counter-intuitive. Back then, the adding of a plug was viewed upon from a very different perspective. Anywho, I took that prototype out to a beautiful country setting, an isolated road surrounded by fields of corn. The photos turned out great too, see: [photo album 202](#)
- 1-08-2017** **Fake News Deception.** These attempts to undermine Prius has turned to outright lies. Today's new article claimed "*The latest generation Prius is severely struggling to attract a lot of buyers...*" without providing any actual numbers. They hope you will assume the quantity is low and you won't do any comparisons. Reality is, there were 989,863 of the regular model Prius purchased here in the United States last year. How can that be considered a struggle, especially since sales didn't begin right away. Remember, the gen-4 sales didn't begin until February. There was also a "stop sale" for almost an entire month due to the parking-brake recall. They don't tell you that though. They don't tell you the popularity of Prius in its domestic market either. They just say "*struggle*" and hope you assume the worst. They carefully avoided mention of other vehicles also using that hybrid system... like RAV4, which was the second-best seller here last year with 45,070. Instead, they paint this picture: "*Toyota Prius: Did Losses Cause Secret To Escape?*" That title was to get you to believe Toyota is becoming so desperate, they must now sell their secret technology to other automakers to allow it to survive. That's an outright lie. Rebranding is a common business practice... so common, Toyota already did that years ago. It's not a secret, as the article claims. There was a Nissan Altima hybrid. Reading new articles published everyday that are clearly designed to undermine Prius is quite frustrating, but at the same time vindicating. To see some group going to such effort is confirmation they are worried, that the technology has become so capable of competing with traditional vehicles, they feel it is necessary to greenwash about it.
- 1-09-2017** **Reporter Mistakes.** Wow! What a mess: "*Because the Prius Three is larger and heavier, don't expect any record quarter-mile elapsed times but you'll be pleased how peppy the package actually is. However, the ability to drive 25 miles on full electric power is quite impressive.*" That was bizarre to read. The article was about the gen-4 Prius, specifically the package 3 that had been tested and was featured in the photos. Yet, there was that added comment about the 25 miles. How could that be? My guess is the reporter assumed he was driving a plug-in hybrid, but never bothered to actually check on anything related to electric driving. Somehow, he got information about Prime and must have assumed that's what all Prius offer. Needless to say, that made it an extremely misleading article. But more concerning than the obvious reader problem is the fact that such terrible reporting can take place. Doing so little research is as disturbing as people making decisions solely upon sound-bite impressions. Mistakes like that are what contribute to greenwashing. Don't assume the writer is well informed. Always confirm facts. Like in this case, some will be found to be wrong... which makes dealing with fake news even harder.

- 1-09-2017** **Voltec SUV.** Has the message finally gotten through: "*Most of us on this forum had been begging GM to release a Voltec SUV; however, even though GM had a major lead on all other players, it was Chrysler that stomach punched them with the Pacifica Hybrid.*" Asking doesn't do any good though. There's basically nothing in common. A minivan does not compete with a SUV in any way. We see the potential, but don't see action being taken. That old "*too little, too slowly*" concern has been so overwhelming validated at this point, it's hard to know what to do next. Basically, GM doesn't express any care. They don't want to disrupt their SUV market by offering plug or hybrid technology. That abandonment happened years ago with Two-Mode. I can still attempt to keep the topic alive: 242,195 Equinox were purchased last year. That's a massive amount of missed opportunity. We see the potential from the popularity of the plug-in hybrid Outlander in Europe, over 100k purchased overall so far. We also see the purchase of over 45k RAV4 hybrids last year as potential too. The opportunity to offer a Voltec model of Equinox still remains an excellent idea.
- 1-10-2017** **2018 Camry.** Things are getting interesting now. The very old hybrid is getting a big improvement late this Summer. Sales last year were respectable at 22,227. The expectation is much higher though for a best-selling vehicle, at least 30,640 like the year before. But then again, the much newer Fusion hybrid only had 33,648 purchases. We need more. Growth is needed. The potential for this next-generation doing that is looks good. The reveal yesterday showed us a stylish sedan hinting at "*Prius-like efficiency*". There will be 2 flavors of hybrid too. One with a NiMH battery-pack, we assume similar to the base Prius. One with a lithium battery-pack, featuring a design which allows it to be hidden under the rear seats, rather than consuming space in the trunk. None of that is the interesting part though. It's the sport mode. That will offer simulated "gear" changes with a paddle-shifter. Since Corolla's CVT has automatic simulated gear-shifting, providing a type of manual for Camry can be a realistic purchase enticement to try out. Why not? Since production will be TGNA, expecting a competitive price isn't too much of a stretch. This is what we've been waiting for. Yeah!
- 1-10-2017** **Classic Cars.** How strange. I ran across a glowing review of Prius Prime today. The detail was spot on and the photos were outstanding. That certainly was unusually. It stuck out as an oddity among some of the other news twists lately. This was quite nice. It got me wondering though, even before I finished reading. What was the source? How did something so different emerge? The answer became apparent when I scrolled down to the bottom of the webpage. Vehicle after vehicle was decades old... all in incredible condition too. What the heck? Why so many articles about classic cars? Oh! I was on a classic car website. That was intriguing. Somehow, Prius Prime was so impressive, the website decided to provide an endorsement for it. That quite an unexpected twist. Who knew such a positive could come out of nowhere like that? I've been growing weary of all the negative. That certainly was a welcome change.

1-10-2017 **Why No Announcement?** The autoshow in Detroit sure is stirring the pot. Bolt rollout already being underway means people are looking to find out what comes next. Nothing is being said though. Silence from GM is obviously causing some to become concerned. What will become of Volt? Knowing the success of SUV hybrid RAV4 and expecting the upcoming Nissan Rogue and the upcoming Kia Niro... both SUV hybrids as well... should put pressure on GM to finally offer one of their own, I couldn't resist asking about Equinox. I started by pointing out that last year's sales were 10 times that of Volt; yet, we nothing of intentions to offer it as a plug-in hybrid... or even a hybrid. That must frustrate supporters to no end. You can't really label me as a troll for pointing out such an obvious situation either. Wasn't the point of Volt to establish "Voltec" as technology to spread to other GM vehicles? With Equinox being so popular and the continuing strength in that market almost a guarantee, why haven't we heard anything still? No announcement of any kind is reason for concern. Opportunity is being missing, as I pointed out: Sales went to guzzlers instead... a lot of sales. What is GM waiting for? Seriously. Why no announcement of any sort, especially from an automaker which thrives on publicity like that? There should at least be something to look forward to. Way back in early 2005, there were hybrid SUVs. Where is GM's plug-in taking advantage of the already well established Voltec? With gen-2 Volt widely available, it makes sense to shift focus and set an expectation on what GM primarily sells... not compact cars... SUVs. What is the delay?

1-11-2017 **Opportunity Missed.** The same old antagonist wasn't happy, again. This time, it was from an article highlighting the redesign of Camry, specifically this snippet: *"for its redesigned Camry lineup which includes a Hybrid version with *Prius-like* efficiency."* You could tell his lashing out was specifically to me, even though I hadn't actually made any comment: *"Why didn't they put a plug in it? What a missed opportunity?"* The intent was obvious. I pointed out just yesterday that reality of *"too little, too slowly"* in the form of opportunity missed. Why haven't we heard anything at all from GM? It's a good question. Meanwhile, we can see that progress happening with other automakers. So, I was happy to answer those questions: Who's to say they won't? Switching Camry over to TGNA production is the first step. Toyota is currently busy ramping up lithium battery production. The gen-4 Prius uses it. Camry hybrid will now too. At the same time, they are also introducing the C-HR hybrid. So, much is happening with electrification besides the Prime rollout. Remember, the goal is to have the architecture in established. Adding a clutch and switching battery-packs is a small part of the equation, an easy next step. Don't forget that RAV4 is already being positioned for that. What step is GM at with SUV plug-in choices? How about Malibu hybrid with a plug?

- 1-11-2017** **Shame & Anger.** My opportunity post resulted in an explosive retaliation, a clear confirm of having got the point across and the message having identified a weakness in their stance. There was definite anger. The return message made that obvious: "*So, how many of the millions of P-cars sold were plug-ins? Shame on Toyota!*" An abrupt shift over to attacking Prius is a dead giveaway, especially when there is also an emotional appeal. So, I took that invitation to punch back and went all out: Ironically, all those millions of P-cars saved more gas than Volt. There's power in numbers. The point is, the design readily supports the transition to a plug. Adding a clutch and swapping in a larger battery is quite basic. Prius (hatchback) already does that. RAV4 (compact SUV), C-HR (crossover), and Camry (sedan) are all positioning for that too. We see the potential for GM to do the same thing. Should we push for that or shame them for not? Wasn't the point of Volt to have its tech spread to other vehicles?
- 1-12-2017** **Tax Credits.** This started off the morning: "*If change is to be made to the Plug-in credit program, hopefully it is the change that should have been made long ago.*" Then he went on to endorse Tesla, GM, BMW, and Nissan with the reasoning of them having done the most development and taken the greatest risks. Why not include Toyota? If the intent of the vehicles is electrification, how isn't attempting to convert the existing fleet to hybrids not a risk? And what about the work done to shift Prius over to lithium and to do it using only air to cool the pack? There's also the problem of Prime undermining Prius. A runaway hit with the plug-in model means the regular model will suffer. How is that not risky? Neither Volt nor Bolt have any risk of taking away existing green customers, because GM doesn't have any. Toyota does, a very large quantity too. That's why Prius took a radical turn with gen-4. It was a risk Toyota was willing to take that none of the critics are willing to acknowledge. Anywho, this is what I posted in response to that hopeful comment: Changes didn't happen because there was no agreement upon purpose. Are the credits for the automakers or for the consumers? Then there's the subjective problems of "*most*" and "*biggest*" measurement, especially when there is no agreement upon what should be delivered. Think about goals & risk... Nissan really took a gamble with their effort to deliver a system not requiring liquid-cooling. Ask yourself: why?
- 1-12-2017** **Honda Hybrids.** They've been a little odd. The hybrid technology delivered, but was expensive and demand was surprisingly low. Adding a plug didn't do anything to boost interest either. Accord simply faded away last year. By the end of this year, there's a renewed expectation. In a vague announcement yesterday, we heard about an upcoming plug-in hybrid version of Clarity (Honda's fuel-cell vehicle). Supposedly, it will offer about 40 miles of EV range. That's all Honda reveal to us. Nothing else to ponder is disappointing. But then again, getting that is a whole lot better than being left to wonder... especially since the CR-Z hybrid just faded away too. Production ended and nobody noticed. This could be a new twist to help shake up the industry to help it move forward... or it could just be yet another expensive choice that doesn't provide any benefit. We hope this isn't one of those deterrents, making the option to plug less appealing simply because it is out of reach financially. We'll see. At least one encouraging point is that it assists with the effort to demonstrate confidence in batteries. Each automaker contributes to that advancement in forward thinking.

- 1-13-2017 Road Trip.** There's nothing like planning a 1,600-mile trip for the coldest time of the year. It's what you do when you want to celebrate the holidays with family that doesn't live close. With the temperature below freezing on the way there and driving at a steady 80 mph, hopes for high efficiency aren't good. To my surprise though, results weren't too bad. The MPG displayed after 716 miles of driving that first day was 41. That's pretty good. I had only used 60% of the battery available too. The drive home is expected to be much warmer. It really makes me wonder what the same circumstances will yield with the Prius Prime. The engine is more efficient, so results will naturally be better. Having the ability to recharge while driving will be an interesting new twist too. All the travel once off the highway will be using electricity. That's an operation/efficiency tradeoff which I'll be able to take advantage of. In the meantime, I look forward to the drive home in the Prius PHV. It drives really well, even at such high speed.
- 1-14-2017 Assumptions.** Talking about making incorrect assumptions. Read this: "*Although Toyota sacrificed fuel economy for style by altering the Prius' typical backside, the Prius Prime still gets excellent mileage at an estimated 55 mpg on the highway.*" The style does quite the opposite. That dual-wave curve in back is for increased fuel economy. It provides greater aerodynamics. The measure of reduced air disruption is an easily quantifiable figure. The improvement should be obvious. How a reporter could come to the opposite conclusion is disturbing. Apparently, some don't do any research at all. We know many are written without ever taking a test-drive. But to not even consider that increased shape could lead to a more slippery profile is quite strange. Think about sports car design. None have plain, flat surfaces. Instead, you see elegant forms. Some are quite costly to achieve. In fact, that's where some of the carbon-fiber forming originated. You could get complex shapes with the added benefit of reduced weight. Anywho, I found that quote quite annoying.
- 1-14-2017 Commitment.** Between the spin and the effort to restore pride, this was no surprise: "*It's possible to see the tiny Prime EV range as a lack of commitment on the part of Toyota rather than as a deliberate strategy. 20 – 25 miles is about as small a range as they could get away with and still claim value. It does seem like Toyo is at least five years behind and that Prime is *too little, too late.**" I especially liked that vague 5 year claim. What does that even mean? Volt struggled with sales growth until just recently. There's no guarantee demand will be retained either. Bolt rollout influence may only be temporary. Heck, it may end up drawing prospective Volt buyers. Where is GM's commitment to draw interest from those shopping for Malibu or Cruze? I ended up posting: It took awhile to figure out how to respond to such a profound misunderstanding of purpose & risk... Attempting to deliver as much as possible with as little as possible is a huge gamble that takes a great deal of research & development. Anyone can simply add more battery and hope for the best. It takes a lot of guts to deliver a minimum instead. Toyota is doing that with the 25 miles from Prime. Adding to that risk is taking the chance of not including liquid cooling. It's an expense & complexity avoided, which puts them ahead of others who are not investing in better chemistry for cooling. All the excuses & deflections attempting to draw attention away from the goal of replacing traditional vehicles simply won't work. How can something be too late when others haven't delivered on that goal yet? Nicely under \$30,000 selling profitably in high-volume is the purpose. We see the risk being taken. That's substantial commitment.

- 1-15-2017** **Lease Cheat.** I wondered what the situation truly was. The sales spike of Volt in December seemed to be more than just a rush to take advantage of claiming tax-credit money right away, rather than having to wait an additional year. Even if GM had planned for that, it still struck me as odd. I had contemplated the possibility of the new administration canceling the tax-credit too. It didn't strike me as likely though, since the president-elect had recently put an emphasis on American automakers. Why hurt GM like that... especially when you want to avoid drawing attention to solutions not favorable to the oil & coal industry. Then I stumbled across this: "*The Volt had some very aggressive lease incentives in December. You may not have been aware of this.*" So oddly written really caught my eye, knowing it came from a source normally not so clumsy with the keyboard. Why? Hmm. Anywho, that's quite plausible. GM has used lease incentives to stimulate numbers in the past. That very effectively conveys a false impression of strong demand. In reality, you get just short-term sales that harm long-term business. Look at the ineffectiveness the leases for gen-1 Volt were. How will gen-2 be any different?
- 1-16-2017** **Short-Term.** The limited mindset of short-term thinking never ceases to amaze me: "*I suggest that the Prime is mainly for traditional Toyota buyers who might otherwise trade in their Prii for Volts or Bolts. Toyota has noted what gets traded in most often for the Volt...*" He then went on to reinforce that spin with claims of desperation to stop those losses. Even if that was true, what difference would it make toward the clearly stated mission of traditional vehicle replacement? Toyota's effort to appeal to the masses is undeniable. That's far more than losing a few immediate sales to a just a small group of people. Ugh. Oh well. Thinking that way is futile... which would make my reply that way as well. I wanted to say my piece anyway: Quoting outdated data is misleading, but leaving out vital information is what tells the real story. True, Prius was indeed the most traded. But that was way back when gen-1 Volt was still new. There wasn't any other choice available. GM took advantage of that by offering very enticing lease deals. Who wouldn't trade in their old Prius for a dirt-cheap Volt they could part with after 3 years? In other words, GM took the risk, but lost out in the end. Those "*most traded*" people simply moved on after lease expired to other automakers; many were drawn to Tesla. Heck, we've even seen some of the most loyal Volt supporters declare a loyalty shift over to Bolt instead due to that desire for more EV. The purpose of building up owner to grow the market from within (attract GM's own customers) didn't happen. Traditional buyers weren't interested. That brings us to a question of purpose. If Prime retains Toyota showroom shoppers, what does gen-2 Volt do for GM? Hybrid owners cannot be the only target. Conquest & Cannibal sales are short-term only.

- 1-17-2017** **Weekend Getaway.** I was excited to read this: "*Sometimes I go on trips of 1500 to 3000 miles with no ability to charge. A Prime is going to obliterate a Volt for that, and not just in efficiency but also in space and comfort.*" That excitement came from having mine own recent experience to share: I just got back from a 1,600 mile long-week escape... which was hoped to be in a new Prius Prime. But with no sign of that yet, it was with the Prius PHV... which performed wonderfully. Efficiency at 80 mph (we crossed South Dakota) was remarkable, even at the freezing temperatures. Knowing Prime is even more efficient due to the engine's improved thermal efficiency and the fact that it can recharge on-the-fly for no-plug EV later will most definitely be a big plus over Volt. The raised floor will be a complete non-issue too. The seats are down for our convenience, leaving lots of room in back to shuffle stuff while on the road. So, I'm very much looking forward to the next trip. In the meantime, there's new photos for me to share. We got stuck in Wyoming due to an ice storm in Minnesota. Finding ourselves very close to Devil's Tower on a federal holiday was a golden opportunity. We had the place almost entirely to ourselves. With a light coating of snow, a cloudless blue sky, and a windless warm day, it was a remarkable experience. I went nuts with the camera.
- 1-18-2017** **Distractions.** This was an interesting question: "*Is it just me, or does anyone else feel like autonomous driving is a distraction from alternative fuels?*" With both the Detroit auto show and CES reaching for automotive industry attention, it does make you wonder. Remember all the V2G hype a few years ago? Did you even remember that stands for vehicle-to-grid. Supposedly, the next big thing was having battery-packs for plug-in vehicles serve as a storage medium for supplying power. The charge would be used for other electric devices elsewhere, rather than propulsion of that vehicle. It seemed bizarre. Why would you want to use of cycle of the battery's life for that? There are inherit losses with conversion too. At least with autonomous driving, it has something to do with driving. Why is taking away the experience of driving so important though? The reasons for "*fun to drive*" make no sense whatsoever if you aren't in control anymore. The feel of power & handling is completely eliminated then. Who will want to buy that? It goes against everything marketing has focused on over the past few decades. You'd wouldn't experience any of that with a computer driving the vehicle instead. In fact, the more you think about it, the more bizarre the idea becomes. Why?

1-19-2017 **Enthusiast Publications.** How do you respond to commentary about an article written by a performance favoring resource? They've been publishing reviews for enthusiasts for decades. Their reputation is built upon the study of design to deliver speed & handling. Acceleration reports are their life-blood. They drive vehicles hard to report findings for you to satisfy curiosity... not for the purchase of a family hauler. Your desire for "sport" is fulfilled, not wallet protection. That's fine for enthusiasts, but in no way representative of mainstream interest. That made the recent article comparing Volt to Prime a source of quandary. I ended up posting:

A fundamental problem with this article is the source it came from. Dating all the way back to 1999, nothing published from a performance magazine about Prius ever made sense. It's a mainstream vehicle, not something for enthusiasts. Yet, they still write about it, since that draws attention to them. So, we keep getting new articles.

Right from the start, it was problematic. With a mainstream perspective, you want to compare base models... since that's what those buyers will first consider for purchase. Ordinary showroom shoppers consider what packages to step up to based upon what they find from that entry-level offering. Comparing the Premier model to Advanced clues us in to the intended audience, one clearly different from mainstream buyers.

The true reveal of intent was the terrible representation of efficiency. Why the exclusion of efficiency ratings? Omitting that, yet including detail of acceleration observations is an blatant indication of what they prefer, which is clearly different from someone interested in what the plug actually delivers. Simply specifying EV capacity doesn't really tell much. Perhaps they don't understand what those values mean.

54 MPG combined rating for Prime verses 42 MPG combined rating for Volt should be obvious. Why was such obvious efficiency information excluded?

133 MPGe for Prime verses 106 MPGe for Volt won't be understood by ordinary consumers. Shouldn't the job of journalists be to explain what that means, rather than avoid mention of those ratings?

25 kWh/100 miles rating for Prime verses 31 kWh/100 miles rating for Volt tells us the true story. Yet, that wasn't included in the article either. It reveals to us how much less efficient of an electric vehicle Volt really is. Prime shines in this regard. Why only a 6 (out of 10) for efficiency then? It simply makes no sense giving Volt a 10 once you discover that detail. Volt is a guzzler of electricity in comparison.

Needless to say, the article caters to a "performance" audience, which misleads about the purpose of Prime.

- 1-20-2017** **Welcome.** What do you do when you encounter a die-hard GM supporter who just joined the big Prius forum and posted this: "*That'd be pretty frustrating if I was a Gen 1 PiP owner looking to upgrade to a Gen 2.*" Being such a staunch Volt enthusiast and having purchase a Bolt out-of-state, I figured the best approach to his obvious provoke was to welcome him, as well as point out his position: Hello. I see that you just joined this forum. Welcome. Having been a very active participant on the Volt website and now owning a Bolt, you know very well the importance of audience. How many times did I ask "*Who is the market for Volt?*" The upgrade from gen-1 to gen-2 is a big one, providing lots of enhancements. Owners will get lots of EV driving from Prime. They aren't looking for purity though. The engine will start-up from time to time, just like with Volt. Notice how you forgot to mention the time/distance criteria for Volt? The point is, you get outstanding MPG from Prime. So what if the engine runs. Seeing MPG well above that for even the regular Prius is the point. You get lots of EV for an affordable price.
- 1-20-2017** **Excuses Again.** Witnessing history repeat is fascinating. You are astonished to see mistakes be repeated. Who would not bother to study the past? Not learning from previous attempts is just plain stupid. Yet, that's what I see. What would you call such carelessness? It grows from innocent comments, like: "*With over twice the EV range and Hold mode, a Volt doesn't need a charge-mode to drag down its highway fuel economy. But if desired, Mountain mode can be used to provide 20 miles of EV to a depleted Volt battery.*" The omission of real-world data should raise concern. That's what got GM to change their stance. Initial impressions did not match reality. Look at the claimed necessities for a 5th seat and 0-60 speeds. Both have stirred major issue, despite real-world data. That realization suddenly makes dealing with the rhetoric far more complicated. The feature is nothing but a software alteration. No cost is involved. What does it mean to give drivers a choice? Excuses to justify no offering it is a very good indication there's a shortcoming being avoided... which is exactly what we saw in the past. I put it this way: Sounds just like the same weak excuses Volt enthusiasts used years ago to justify the lack of a HOLD mode. GM ended up delivering that with a mid-cycle upgrade. The trip I took just last weekend, from Minnesota to Wyoming with stops in between, would most definitely benefited from having a CHARGE mode. My routine trips up north would benefit too. There is plenty of driving around once you reach your destination that could be EV instead. Using some gas while cruising along the highway to provide that is a good balance of resources... which is what being a hybrid is all about.

- 1-20-2017** **Rogue & Niro.** First reviews have emerged. Both are new entries into the SUV hybrid market. Rogue is Nissan's attempt. With 330,000 purchased in the United States in 2016, there is definite potential to explore. The success of the RAV4 hybrid debut, which Toyota sold 45,070 of last year, further reinforces the reason to try. Setting expect is a challenge though. What will buyers want? It looks like a decent effort to compete. Kia's upcoming Niro takes a different approach at dealing with the same problem. It appears to be just a crossover wagon, not an actual SUV. The different is no AWD option. That would make it just like Toyota's upcoming C-HR hybrid instead. Whatever the case, it is still an endorsement for traditional vehicle replacement. After all these years of proving battery & motor technology is robust enough, this next step at affordability and packaging to appeal makes sense. (Next is to begin to dominate auto shows.) We are clearly making progress... at least with the technology. We are about to regress politically. That's really unfortunate. To know the new administration is strongly opposed to change is terribly disappointing. To all those who voted for that backward thinker, I hope you can overcome pride quickly. We going to need your help to get out of this self-inflicted disaster.
- 1-20-2017** **New Venue, fanbois.** After years of just barely hanging on, that daily blog for Volt has been all but abandoned. Bolt ended up killing it. There's simply nothing of interest related to Volt to draw attention anymore. The valuable accidental-reveals from arguments against Toyota have become highly unlikely now too. It's a resource that ran its course. So, the fanbois have moved on. I'm finding the same names elsewhere. The catch is, those other venues are only new to them. They are well established... by those who took the "*too little, too slowly*" concern seriously. That makes rhetoric much more difficult to spread. I obviously like that a lot. Far less nonsense to deal with is wonderful. They squandered their time, defending a niche with excuses rather than working to establish something for the masses. I hold a great deal of resentment for their push against mainstream offerings. Now, I have more allies who feel the same way. This is going to be fun!
- 1-21-2017** **New Venue, shame.** This didn't come from a crazed antagonist attempt to justify Volt, it was just car enthusiasts without much understanding of mainstream priorities or how Prius Prime actually works: "*It's a shame the PRIME's electric motors are so small. Buyers will need to learn how to put it in hybrid mode before entering highways...*" It took careful consideration of how to actually respond. With so many different approaches available, I chose to reply with: The assumptions many make online never cease to dumbfound me. You'd think they wouldn't knee-jerk react to numbers. Yet, we see it all the time. Thankfully, the test-drive experience reveals the true situation. That's the audience Toyota is targeting, those who give it a try, not those who just read enthusiast publications. The current Prius PHV offers 38 kW (51 hp) in EV mode. I've merged onto the highway quite a number of times without the engine starting with mine. Prius Prime bumps up the EV power to 68 kW (91 hp). So, it's very clear ordinary driving is easily covered. Spreading of a misconception about a "*learn how*" owner necessity ends here & now. EV-AUTO MODE is what those reading this need to learn about. That's a feature Prime offers in between EV and HV modes, when you want to favor EV as much as possible but need extra power in rare circumstances. In other words, that shame above is without merit. Please don't make assumptions. Upgrades offer improvements. Learn about them.

- 1-21-2017** **New Venue, obstruct.** I wasn't surprised to read this: "*12.2 seconds is slow enough to obstruct traffic.*" I knew exactly what to post in return too: What traffic? You're implying maximum acceleration is needed, without any context or example whatsoever. You've been greenwashed to believe faster is necessary. Driving a Prius PHV for 88K miles, I know quite well that is definitely not the case. I don't have to drop the pedal to the floor when merging onto highways. I have already test-driven a Prius Prime (while enduring the long delivery wait for mine) too. It effortlessly merged onto the 70 mph highway into to traffic in EV mode just fine, even with the electric-heater running. The claim of obstruction is without merit. Wanting more power to be a leader, rather than just going along with the flow of traffic, is fine. There is plenty of real-world experience proving there is not a need for it though.
- 1-21-2017** **New Venue, efficiency.** I really enjoyed responding to this: "*The difference between 106 mpge and 133 mpge is also huge. I wonder why...*" It really makes me wonder how people will reply in return to my post: There are many, many factors of influence beyond weight & aerodynamics. Pointing out why Prime has a more efficient EV drive than Volt will result in much retaliation though. So, be prepared for spin. The first reason should be obvious, the electric-motor. The type of wires and how tightly they are coiled are easy to understand differences. You can think of the efficiencies gained from just comparing to CPU design. The material & size make a big difference with electricity consumption too. The next thing that should easily come to mind is battery chemistry. Tolerances of electrical operation (discharge, temperature, responsiveness, etc) will have a major influence on the output. Then there's the not-so-obvious, the controllers & software. So many hardware components and lines of coding could have an impact about how the system operates. Heck, there's even the connections & wiring to take into consideration. GM's emphasis on simply providing more battery capacity reduced the priority of squeezing out greater efficiency from everything else. Toyota didn't take KWH for granted like that... hence the resulting higher MPGE value.
- 1-21-2017** **New Venue, phaseout.** A newly relocated antagonist posted: "*But the tax-credit doesn't go from \$7,500 to 0. It's phased out.*" He has been a royal pain in the you-know-what. Having him misplaced in this new venue, no longer in a safe haven should be interesting. I hit him with: Once the quantity limit is triggered, the phaseout starts a timer. The credit value is then reduced and the limit switches to a measure based on months. Success of Bolt will bring about that \$0 problem well before the product-cycle for gen-2 Volt is complete. How will GM sell Volt profitably then? There is currently a heavy dependence on the tax-credit money and battery-cost reduction is not enough to compensate. Toyota is already positioned to deal with that. (They have far more tax-credits still available too.) The Prime base-model MSRP is just \$27,100. Mock & Belittle all you want about battery-size. Prime is designed to deal with the lack of subsidies. Volt is not. That's a harsh business reality we will watch play out in the next few years.

- 1-21-2017** **New Venue, superiority.** It was only a matter of time before ranting about domestic automakers being better and (ironically) hydrogen being a distraction got posted. That came about on a thread comparing Volt to Prime, in comments related to that recent enthusiast publication. It wasn't about to let it get any traction. I jumped on that right away, firing off: Misleading about the other choices is a terrible approach to promoting electric propulsion. That 25 mph limitation is only prior to the system warming up and only applies to the models without a plug. So, it makes no sense whatsoever even mentioning it. What do you think the competition is anyway? If you believe it is other plug-in vehicles, you've lost your mind. They represent only a teeny tiny fraction of the market. Sales of traditional vehicles are absolutely crushing the choices offering a plug. Grow up and stop with the rhetoric! There's no place for that. We need to find ways together to offer affordable plug choices for mainstream buyers that automakers & dealers will gladly supply. That doesn't come about from misleading.
- 1-21-2017** **President Who?** Remember way back when, shortly after hybrid rollout began here? The impressive PNGV (Partnership for the Next Generation of Vehicle) program was canceled. That was the very effort which inspired Prius. It was the federally funded program to support research & development of advanced automotive technology to deliver clean & efficient solutions. Only Americans automakers were allowed to participate. Those from Japan were forced to compete without the same opportunity. Little did anyone now such exclusion would result in a profoundly better vehicle far sooner. Anyone, the program was replaced with "Freedom Car". What a joke. It didn't get as much funding, the timeline was extended dramatically, and expectations were lowered. That effort was clearly greenwashing, a ruse to distract & delay. What a terrible letdown by that new administration. Most people have no idea such a major undermining action ever took place. That same naive nature is what those proclaiming "*give him a chance*" will allow similar action to happen again. Heck, the repeating of history is what my blogs are loaded with. Complaint after complaint about not recognizing patterns fell on ears of those in great denial. Yesterday introduced us to a new president. Do you really know who he is? Already having strong ties to the oil industry and having proclaimed strong support for the coal industry during his campaign, there is reason for concern. Don't just sit by, choosing to react after the fact rather than stating demands. This is America. Shouldn't our market be the leader in green acceptance? Embracing solar & wind offers so much potential for new employment opportunity. Why not push for action before any executive decisions are made. Make sure it is well understood that we want abundant renewable electricity in our future. It makes no sense investing heavily in oil & coal. I know this all too well, having some family in Wyoming. The potential demonstrated here in Minnesota makes the solution so obvious. We just need to make sure others see that too. Start with a serious consideration of Prius Prime... an affordable plug-in for the masses.

1-22-2017 **Delivery Delay.** When you study Prius Prime, it becomes easy to see the future soon to arrive. We aren't talking years from now, after there's a scramble to deal with tax-credit expirations. It's later this year, once ramp-up is achieved. Toyota worked hard to deliver a configuration actually capable of competing with traditional vehicles, not dependent upon subsidies or incentives. That's something GM has yet to address... and the fanbois know that all too well. It's why the rhetoric attempts on that new venue failed to stir interest. Not being on their blog that catering to cheerleading has confirmed a variety of shortcomings. They wouldn't listen to me, but could simply use the label of "*troll*" to get their message heard. That doesn't work elsewhere... which they are finding out the hard way. No more spotlight. No more cheering. No more control. They have to address the true problems. That's quite vindicating; however, it can be humbling too. There are true problems. There are delivery delays of Prius Prime. We aren't sure how much each factor influences the overall results. All we know is there are bottlenecks in the production/assembly process. This is how I summarized the situation for a good friend: Worldwide rollout all at once, combined with carbon-fiber and wave-glass manufacturing challenges, along with industry sensor shortages, is a recipe for delay.

1-22-2017 **Back to asking "Who?"** The attempt to move on to growth took me back to audience again. Reading this comment from that on-going Volt to Prime comparison article did it: *"The whole point of driving a PHEV like the Volt is that you are driving it as close as you can to 100% of the time in EV mode. If you are doing the same in the Prime that means you're stuck with a 91 hp car most of the time. No thanks."* Most people have absolutely no clue what the numbers actually correlate to. They only know that more is better, from having been told that. Actual firsthand experience is an entirely different matter. I know. I have extensive experience. That much real-world data emboldens what you say. Hopefully, it wasn't too abrasive: 91 horsepower may not be to your liking, but it is clearly enough. With the 51 horsepower available in the Prius PHV (which I have been driving for nearly 5 years), local errand running and cruising along at 60 mph works just fine. Heck, I even routinely accelerate onto the highway without the gas-engine firing up. Adding another 40 horsepower raises the electric-only speed threshold to 84 mph and allows you to mash the pedal to the floor. I test-drove a Prime (while trying to patiently await the delivery of mine). Even with the electric-heater running, acceleration onto the nearby 70 mph highway was no big deal. That 91 horsepower of EV is up to the chore. The desire for more horsepower is easy to acknowledge. Though, that begs the question of who will be willing to pay for it? Who does Volt & Prime appeal to? Who are the intended buyers?

- 1-22-2017** **Appearance or Technology?** A new post this morning was about the shopping experience someone had. He and his wife simply couldn't get over the looks of Prius, so they purchased a Volt instead. It's entirely possible the "*ugly white plastic*" was a deterrent, but that's why there is an choice to get black instead. Of course, he never actually test-drove a Prime. He didn't even mention seeing one. My guess is there was an assumption of bigger battery only, not an entirely different interior & exterior... despite the 23 Prime photos included in the article. So, I injected this into the discussion: Huh? Your comments were about the regular Prius, not Prime. This further confuses what you posted: "*The full electric miles with no charging anxiety gives it an advantage that Toyota's technology just can't match. Car and Driver was right on with their honest review.*" Are you unaware that Prime provides 25 miles of full electric driving, at speeds up to 84 mph? With the new electric gas-injected heat-pump, it's even more efficient than what is offered for Volt. What is the "*can't match*" claim about technology based upon? Are you unaware that Toyota builds other hybrids with more powerful electric motors? Take a look at the RAV4 hybrid. Think about how little it would take to add a plug. Being a SUV with AWD makes it an especially appealing candidate for battery augmentation.
- 1-23-2017** **The Nightmare Begins.** Reading this today was confirmation of the disaster we feared: "*...a loosening of environmental rules and taxation for a major increase in manufacturing in the US.*" The context of that isn't necessary to even bother wasting any time on. We knew this administration was determined to turn back progress. It was inevitable. Elections of the past made it easy. They'd simply promise lower gas prices. That was all people needed to hear... since no other solution was realistic for mass acceptance yet. Now, we have far more than just a handful of choices. There are a large assortment of hybrids, plug-in hybrids, and electric-only vehicles either already available or being promoted as available in the next few years. That large of an alternative presence is too much to dismiss or ignore. That's why the technology itself isn't getting attention from the new administration. In fact, it's being ignored entirely. I haven't heard any mention whatsoever. All efforts are focused on undoing mandates established by our previous 8 years of environmental & technological advancement. It goes well beyond a "*why bother*" attitude. The feeling now an attitude of "*that has been proven ineffective*". We are watching a strong effort to bring back dirty guzzlers. The nightmare begins today with this confirming of intent. The goal was reachable too. They just didn't want to. Imagine telling your children how we had the ability, but decided they weren't important enough to try.

- 1-24-2017** **Focus.** Trying to get back to the simple things hasn't been easy. There's a lot of barriers to overcome, which makes getting stuck the norm. That's where "be patient" gets abused. Legitimate delay turns into excuses if you are not careful. Objectivity is nearly impossible online though. The venue doesn't promote that; instead, it encourages participation through rhetoric. That's what compels many to sound off... hence the problems we had with the election. Focus was on hype, not constructive exchanges. Needless to say, that situation applies to the clean & efficient market too. They focus on praise for engineering achievement... not with the lack of accomplishment. Addressing the need to reach ordinary consumers is almost a taboo topic. Heavy dependency on subsidizing through tax-credits is the problem. The seemingly endless supply is shrinking. We can actually see the end approaching. That's very bad news for vehicles with uncompetitive MSRPs. A price too high to champion what mainstream buyers expect spells imminent doom... and the Volt enthusiasts know it. So, why not focus on what can be accomplished instead... namely the move of Voltec to a vehicle that will actually result in growth. My commentary on the situation today was: With the technology GM delivered proven and the pool of enthusiasts exhausted, there are questions about next steps to achieve growth... even without an administration opposed to changing the status quo. Concerns of business challenges were brushed aside in the past, claiming great engineering of Voltec was all that would be needed. We clearly see now that isn't the case. What should the focus be?
- 1-24-2017** **Unacceptable.** Someone totally new to what's left of the daily blog for Volt joined, with a very open mind. The attempt to be constructive showed signs of weakness right away though: *"Sales growth is not THE GOAL. In a period of lower than average petrol costs, a compelling design, efficiency, unit profitability, marketing value, and sales volume are ALL important. If GM has found right volume mixes for the Volt and Bolt in the current economic climate they are doing the right thing for GM."* The fallback to defending the status quo with excuses emerged far too soon. That was a big let down, especially on a discussion thread addressing the problems EPA now faces under this new administration. Deflated about the lost potential, I replied with: EPA rulings being changed will continue to keep gas costs low for many, many years to come. The right thing to do is pushing for sales growth regardless. That means offering a configuration fitting that criteria... compelling, efficient, profitable, marketable... in high-volume. Otherwise, the clean tech only makes it to a limited number of drivers. Each sale of a plug-in means one less dirty guzzler in traffic for the next decade. A small battery-pack is far better than no battery-pack at all. I had to put up with the *"wait for gen-2 rollout"* promises for years, despite knowing the push for more drilling and more pipelines would result in cheap gas challenges. Yet, excuses for delay were the mantra. Climate-Change is a problem now. Clean air is a problem now. Good enough is unacceptable.

- 1-25-2017** **What Does Competitive Mean?** I really wanted to get a sincere answer, instead: "*It means GM has a 200+ BEV targeted for mainstream buyers and Toyota does not have one.*" Getting that was annoying. The greenwash of more is better clouds judgment. How can that be the only solution to replacing traditional vehicles? They are the competition on the showroom floor. Knowing that basically anything I post is futile, it's difficult finding a way to proceed. But if you want others to break out of that mindset, you have to keep trying: How can not having any competition be the definition of competitive? The competition we've been expecting from GM is for Volt technology to be offered as a model choice for its own mainstream vehicles, not conquest sales from other automakers. Toyota is working to have its own traditional offerings compete with plug-in hybrid models of the same vehicle. Imagining a Prime version of RAV4 is very easy, especially now that we've seen how affordably that was achieved for Prius. Bolt seems like an abandonment, as if Volt was only a stop-gap until a long-range EV could be delivered. Will we ever see a Malibu hybrid with a plug offered? What about any type of Equinox hybrid? How will AWD and towing requirements be fulfilled? Do you really expect GM customers to just purchase a Bolt instead? In other words, know your audience. Who the competition is makes a huge difference. If GM customers don't have better choices, they'll just settle for traditional models.
- 1-25-2017** **Audience Differences.** It's very interesting to read the results of the same testing interpreted a very different way. Good Housekeeping published an article listing Prius Two Eco as the "*best new hybrid*". That wasn't the conclusion Car & Driver came to though. Their audiences have basically nothing in common. One caters to ordinary mainstream consumers, the other automotive enthusiasts. So, it totally makes sense to see their opinions vary so much. Testing involved driving 1,200 miles on both test tracks and open roads. Rating included value, safety, smoothness, handling, interior design, comfort, and onboard technology.
- 1-26-2017** **What Happened?** Emotion is stirring. Consequences of Volt failing to target GM's own showroom shoppers is increasingly becoming a problem. That realization of conquest not paying the bills really hurts. It's not a victory if loyal customers don't change. Yet, this gets asked anyway: "*Why can't it be conquest sales of mainstream (non-plugin) vehicles from competitors?*" That clear denial of the situation is deflection, attempting to justify an outcome that didn't achieve the goals that were set. I'm getting really tired of the fight to keep the status quo. Change is necessary. Find a way to deal with it. Stop making excuses. Look at how much Prius Prime differs from gen-3 Prius. Both were configured to appeal to the masses. Both faced major challenges to fulfill requirements of a difficult market. Volt didn't do that. Production cost is far too high. That much EV range was not needed. That much power was not needed. Improved efficiency & seating was. To make matters worse, we're seeing an acceptance of diesel... despite the VW cheating scandal having seriously damaged appeal for diesel. In dismay, I posted: Continuing to turn a blind eye to all the popular cars & SUVs that GM produces is just plain terrible. What a horrible attitude. That is totally unacceptable... especially after so many years of plug-in promises. Remember all the hope for Voltec to be spread to other vehicles? What happened? Why are Cruze & Equinox getting diesel instead?

1-26-2017 **Blind Eye.** There has been a ramping of of rhetoric lately: "*What has Toyota done? Nothing other than a hydrogen fool cell science project.*" The reason is simple, the competition is coming. Toyota is deploying Prius Prime to dealers under the must-hold program. They are forced to retain a demo-model for 6 months. After that, it can be sold. Until then, there is a guarantee customers will have something to look at and test drive. That was a very effective rollout technique we saw with the Classic model. It was a painful process though. You'd have to endure the long delivery wait after placing your order. I did that back then and I'm doing it again now. That time seems to drag on forever. But during the Winter here in Minnesota, it's easier. I can wait until Spring emerges. Photos & Video will be much easier then. Anywho, this was my punch back:

Sounds like an alternate reality. By year end, Toyota would have introduced and rolled out in that same time:

- C-HR hybrid
- RAV4 hybrid
- Corolla hybrid
- Prius v
- Prius c
- Prius PHV
- Prius Prime

There were also these next-gen upgrades to long-available hybrid offerings:

- Prius
- Camry hybrid
- Highlander hybrid

In addition to new vehicles & upgrades, the production of dual-wave glass (for better aerodynamics) and low-cost carbon-fiber (for weight reduction) has also been put in place.

The attempt to evade answering the on-topic question about diesel and instead attempting to divert attention to hydrogen is quite telling. The claim that Toyota hasn't done anything is a flat out denial, which makes your reply quite ironic: "*Who's turning a blind eye?*"

1-26-2017 **Nissan Rogue Hybrid.** Some details have been released. It will come with a 4-cylinder 2.0 liter gas-engine and a 30 kW electric-motor. Resulting 176 horsepower is lower than the 194 from the RAV4 hybrid, which has a larger engine (2.5 liter) and more powerful front electric-motor (104 kW). The Toyota also has a rear electric-motor (50 kW). Nothing was mentioned about towing for the Nissan. We know that Toyota's is 1,750 pounds. Resulting efficiency from the AWD model is 33 MPG, which is 1 MPG higher. Rogue price is expected to be similar; however, RAV4 comes with pre-collision braking, adaptive cruise, automatic high-beams, and lane-departure alert with steering assist standard. In other words, it will likely be a nice choice for Nissan customers but a challenge to compete with Toyota. Seeing Nissan make this move is reassuring. Nothing but EV offerings could make the future difficult. A mix with hybrid balances out the product-line. Not everyone has access to a plug.

- 1-26-2017** **Desperate Deflection.** It's getting really bad: "*How much longer do we have to deal with *too little too late* from Toyota?*" The news of Equinox getting a diesel upgrade rather than Voltec has infuriated the last of the enthusiasts. Everyone else has given up and moved on. That's why we see so much attention being paid to Bolt. Discussion of Volt is just a distance memory now. Sales settling at a rate well below sustainability is a very real concern. It's too expensive to survive without tax-credit subsidizing, money GM would prefer to use for Bolt instead. So, getting that desperate deflection, I asked about Equinox diesel: Why is GM endorsing such a dirty & inefficient technology? It simply makes no sense, especially so long after having rolled out Volt. The expectation has been that their popular selling compact SUV would finally get a Voltec system; instead, it gets diesel. No amount of spin will make that competitive with a plug-in hybrid. GM's weak attempt to supposedly compete is being called out. Say whatever you want about Toyota. They already offer a compact SUV with AWD that has a hybrid system, which continues to sell very well. We know the hybrid design can accommodate a larger battery & plug too. GM doesn't have either. That's why you have to deal with it. How much longer must we wait?
- 1-27-2017** **Critical Decision Time.** My ranting has begun. It's time to push for change. Hearing that we must endure more of the same isn't acceptable, especially with the rapidly growing problems coming from the new administration. There's an obvious effort to undermine progress. Controversial oil projects are getting clearance to proceed and work is being done to dismantle environmental protection acts. I came out swinging today: Seeing Volt almost vanish entirely from discussions, now that Bolt is available, has stirred curiosity. But it was avoidance of the topic of Equinox that keeps me coming back, especially with so much favor for the Chrysler's plug-in Pacifica recently. Avoidance of the topic of Two-Mode prior to Volt rollout remained a nagging theme. Why was that history an issue? Despite such obvious parallels, there was a fierce effort to evade references pointing that out. Volt was the successor after all. How come acknowledgement of that was such a problem? Then it hit me: GM's preference for SUVs over cars. The reason for gen-2 Volt remaining a compact car with rear-seating size complaints not having been addressed was the clue. There's more room in a SUV. Any hint of GM planning to offer Equinox with Voltec would have an immediate negative impact on Volt sales. No wonder even the mere mention of showroom shopping stirred such anger. It really was the true source of concern. Volt's biggest threat is GM wanting to sell SUVs instead. Equinox is already a best-seller. Adding the plug-in system to it would make a major draw... enough to raise concern from die-hard Volt enthusiasts. There's a very real fear of cutting losses. The plug-in market is volatile and compact cars are not popular. The hope of gen-2 Volt reaching a sustainable sales level, enough to overcome tax-credit expiration, is far from certain. Watch how things play out. A critical decision time is approaching.

1-28-2017 **Too Late For What?** The concern is very easy to see now. Like with both the downfall of Two-Mode and gen-1 Volt, the situation becomes clear as the 2-year mark approaches. Rather than making excuses though, there are attempts to somehow claim Toyota failed. The obvious question is: what? Stating goals was always the problem. Enthusiasts would evade accountability... and have been for many, many years. Continuing that has become extremely difficult though, hence the approach change... they repel... I strike right where they are most vulnerable. Changing the status quo is my goal. They are stuck in a rut and don't want to admit it. This was my provoke:

"Too Little, Too Slowly" was the concern expressed as part of the bankruptcy recovery. The response to that was assurance that Volt would target the mainstream and become an ordinary part of the product-line, an improvement loyal GM buyers will choose instead. Gen-1 ended up falling well short of that. We were told to be patient, the next-gen would overcome sales obstacles. Gen-2 ended up falling short too. We were told to continue to be patient.

That's changing now. The response is switching to *"Too Little, Too Late"* expressed about the supposed competition. That's clearly an attempt to draw attention elsewhere, to conceal the true on-going problem of *"Over Promise, Under Deliver"*. That was the very problem GM was dealing with prior to the bankruptcy. Evidence is building to reveal something significant must change.

More and more, it's becoming undeniable that GM delivered a "sport" car rather than something intended to result in an improvement in the product-line. Bolt is what Volt should have been. GM delivered that long-awaited roomy interior to a different vehicle. Volt didn't get the much requested upgrade.

The explains why the idea of Equinox with Voltec results in so much deflection. Evidence is growing that people will be happy to trade EV range of a compact car for a plug-in SUV instead. In fact, that is why Bolt isn't a SUV. It's not even a FWD crossover. It's a wagon, so it won't clash with GM's upcoming reset.

No matter what the spin or the number of deflect attempts, that reality of Volt unsuccessfully drawing sales of loyal GM customers cannot be avoided. GM sees how Toyota, Mitsubishi, Hyundai, and Nissan are all preparing to deliver plug-in hybrid SUVs. We even got a hint recently that Ford may be working on that too. Voltec was claimed to be a *"game changer"*. What happened to that GM leadership we told to expect?

1-29-2017 **Electric Improvements.** There was an article today posted about the Fusion Energi, the plug-in hybrid sedan offered by Ford. The writer reported it taking 6.6 hours for the 19-mile rated 7.6 kWh battery-pack to recharge. That's interesting to read. It only takes 5.5 hours for the 25-mile rated 8.8 kWh battery-pack in Prius Prime. The speed improvement from a gen-1 offering to a gen-2 years later is good news for any of those who will be plugging in at home into an ordinary 120-volt household outlet. I suspect many won't bother with a level-2 charger. Why spend the money for a 240-volt system when what you have already will work just fine for overnight recharging? Improvements like that are great. There's another good electric improvement to highlight though. The EPA continues to tweak rating information. Detail was limited back in November. But now with new vehicles being tested, like Hyundai Ioniq, the rating values are being reviewed... and revised, if necessary. Turns out when looking up the Ford information, I discovered the Prius Prime value had been updated:

35 kWh/100 mi = 97 MPGe = 2017 Ford Fusion Energi
35 kWh/100 mi = 98 MPGe = 2015 Chevy Volt
31 kWh/100 mi = 106 MPGe = 2017 Chevy Volt
30 kWh/100 mi = 114 MPGe = 2016 Nissan Leaf
30 kWh/100 mi = 116 MPGe = 2016 VW e-Golf
29 kWh/100 mi = 111 MPGe = 2017 BMW i3 PHEV
28 kWh/100 mi = 119 MPGe = 2017 Chevy Bolt
27 kWh/100 mi = 124 MPGe = 2017 BMW i3 EV
25 kWh/100 mi = 133 MPGe = 2017 Toyota Prius Prime

1-29-2017 **Whoa!** Things are getting quite out of hand. One particular Volt enthusiast very angry with Toyota is attempting to push the fake news theme way further than I have ever witnessed. Rather than post misleading or alternative facts, he's trying to portray the situation as if there is no such thing as Prius Prime. Pretending it doesn't even exist is so desperate, I don't quite know how to react. That's denial to an extreme. Here's my attempt at trying to deal with it:

Pretending Toyota isn't in the process of rolling a new plug-in is truly bizarre. It meets the EREV criteria Volt enthusiasts have held dear for years. So, origin of that denial is easy to understand. But why would you keep chanting "*too late*" without anything actually having been missed yet?

Consumers are only now learning of plug-in vehicles and very few mainstream shoppers have actually begun considering the purchase of one. Prius Prime is an affordable choice they'll stumble upon. With a MSRP of \$27,100 and a full electric driving experience for 25 miles, we can see the beginning of the market for ordinary consumers taking shape. It's the first to break out beyond being a niche.

Claiming "*too late*" and ignoring new choices can be detrimental. People will notice that behavior and question motive. Keep in mind, GM was once so opposed to EVs that they filed a marketing trademark for "*range anxiety*". Change does happen. It is ok to accept.

1-29-2017 **Not Seeing The Point.** It's really a matter of not wanting to see it: "*When is the Prius gonna die already? Sheesh, it was great in it's time, but Toyota just can't let go of ICE. Granted, they make a huge amount off the brand recognition alone, but now with a 240 mile Bolt, I don't see the point??*" That's the same type of person who simply dismisses the rest of the market, pretending the vehicles purchased today won't be on the road a decade from now still. All they actually see is what they want, reassuring themselves that if the most possible battery capacity is selling, even in extremely low quantity with the help of subsidies, their work is done. Care about reaching the masses just plain isn't there. It's that engineer-only perspective. If the technology is there, people should be buying it. Things like affordability are totally disregarded or claimed unimportant or justified by total cost of ownership. It's really unfortunate we have to deal with such attitude. That is reality though. So, we do: \$27,100 MSRP and overnight recharge with existing ordinary 120-volt household outlets is the point. Toyota wants to reach mainstream consumers right away. Bolt doesn't come even remotely close to fulfilling that criteria. It depends heavily upon the tax-credit subsidy and expects owners to upgrade their garage. Those are business & consumer expenses Prius Prime doesn't require. As for letting go of the ICE, are you implying Volt should be abandoned in favor of Bolt? If not, what is the point of Volt?

1-29-2017 **Revising.** Every time a milestone is missing, there's a revision. The resulting spin can be quite compelling to read too. Desperation stirs imagination... but not always. Sometimes, the person just twists the situation around and accuses you of what they are guilty of: "*your revisionist history is showing*". That comment today didn't stir much though. These blogs contains quotes of the past, documenting the stance they had taken back then... clearly confirming they are the ones revising. I simply responded with some facts to mull over:

I am looking forward to your revised definition of EREV.

Remember how it started, while Volt was still being developed? Back then, the expectation was for the system to be a series hybrid. That meant the gas-engine never directly powered the wheels; instead, it was only used for generating electricity. When that was revealed to not be the case, the definition of EREV was changed to fit what Volt would actually deliver.

Then when C-Max Energi came about, it sent the Volt community into a state of panic. Another plug-in hybrid had fulfilled the same requirement criteria. They got over it though, since Ford was a domestic automaker. But when Prius PHV came along later, renewed panic resulted in a new definition. To be EREV, there was now an arbitrary electric speed & power minimum to deliver... values obviously derived to exclude Toyota's offering and obscure the goal of boosting MPG.

Now, here comes Prius Prime. It fulfills that requirement of more speed & power without any doubt. 84 mph with to-the-floor EV acceleration, along with a very efficient low-temperature electric heater, prevent any debate about satisfying the EREV definition. So, I await revised criteria.

Need I point out that BMW's i3 actually does fulfill the original definition? The gas-engine is nothing but a tiny generator. There is no mechanical connection whatsoever the drive-shaft. There are only wires. And with so much larger of a battery-capacity (97 miles verses Volt's 53 miles), need for the gas-engine is significantly reduced.

In other words, we need to start looking at plug-in hybrids for what they deliver. It's those end results that count, not how they are achieved. That's how we win the fight against traditional vehicles, which is especially important knowing GM is about to push diesel for Equinox.

- 1-29-2017** **Embarrassing.** You can see an end drawing near; the spin is showing signs of desperation: *"25 miles of electric range, from the company which made the first popular full hybrid car, is downright embarrassing. It doesn't hold a candle to the new Volt's 53 miles of EPA rated electric range."* It's really sad how some don't see that the true competition is traditional vehicles, not other plug-in offerings. The catch is, they have to admit some plug-in choices won't be good ones. Facing that reality of a failure is extremely difficult... and self-inflicted. If you know change is part of the process, acceptance is much easier. That's what made Prius PHV such a problem for some. They recognized it was mid-cycle offering with a very limited scope. Having rolled out to just 15 states and only a small quantity made taking the next step to Prius Prime a simple one. The mess Volt left with gen-1 meant gen-2 would struggle to re-educate. Finding out gen-2 doesn't appeal to mainstream buyers makes the situation even worse. So, enthusiasts turn to emotional appeal, rather than remain constructive. Oh well. All I can do is confront them with facts: Embarrassing? You've totally lost perspective. The goal is to replace traditional vehicles with plug choices. \$27,100 MSRP positions the technology to be directly competitive. Prius Prime is configured well in that regard, an accomplishment to be proud of. \$33,220 MSRP for Volt is what? It's heavy dependence on tax-credit to subsidize sales and compensate for the smaller rear seating certainly isn't a bragging point. We want plug-in purchased by the masses. Don't forget how much importance they place on price.
- 1-29-2017** **Lots Of Potential.** What I posted wasn't well received... since it made sense. That was predictable. So, I just kept posting. The next step was to point out the potential and explain reasoning. The catch is you have to be to the point. Losing the bigger picture can happen when you provide detail. Antagonists get hung up on pointless facts, spinning a web of deception simply by misdirecting. So, I summarized instead: We see that same *"too little, too late"* chant regularly now. It's the result of Toyota having successfully delivered an affordable plug-in hybrid system sooner than GM. No need for the complexity & expense of liquid cooling. Like Nissan, Toyota invested in better chemistry to prevent that need. And to make a Prius into a Prime, all that's basically needed is a clutch, charger, and a larger battery. So, it's easy to see lots of potential.
- 1-30-2017** **Charge Mode Data.** A report from driving around with a Prius Prime. Yeah! The information we get from actual owners is so much better than having to deal with undermining. You have no idea how welcome this is. The a change of pace this hints at is wonderful. We have much to look forward to in the coming months. In the meantime: *"Highway driving 12 miles around 65mph for 11 minutes. In CHG mode shows 37.2 MPG while battery charged from 0 to 25% (6.5 mile ev range). 8.9 kw charging rate consistent with..."* Others have also observed that aggressive recharging ability. That's a nice new feature few have ever experimented with. Results vary quite a bit though. In this case, the efficiency hit was exactly as you'd expect. There should be a penalty of some sort when using gas to generate electricity. Reports of others witnessing less impact is what peaks my interest. What are the circumstances then? Knowing when to recommend use of the charging feature is very important. It's easy to misuse something like that. It's easy to misinterpret impact to overall efficiency too. Whatever the case, we'll eventually figure that out. For those, we're in the early stages, still sorting out the few details currently available.

- 1-31-2017** **Fuel Cells.** Wow! What a dramatic end to an absolutely desperate attempt to divert focus from Volt. For years, GM supporters have ridiculed Toyota supporters for their diversification effort. They don't spin it that way though. The misleading is to get you to believe all of Toyota's research is devoted to fuel-cell development, that plugging in is looked upon as a wasted effort. Over and over and over again, mention of Volt sales struggle would be rebutted with "*hydrogen*" anti-propaganda. Some were so dead set against the diversification, they believed that was all they ever needed to mention for Toyota arguments. It was amazing to see such close-mindedness play out. It comes from the one-size-fits-all stance. Fighting an array of choices, rather than just a single solution, is beyond their understanding. So, the approach of fighting anything that doesn't fit your expectation is considered valid. That took a dramatic & permanent turn today though. GM announced an \$85 million partnership with Honda to advance their fuel-cell technology. GM embraced hydrogen. The very thing these smug antagonists most feared became a reality. I couldn't have been more delighted. The timing was absolutely perfect. The idiot who had just posted a rant about how terrible fuel-cells were and how thankful he was that GM would never endorse such a technology now had several headlines in major publications stating the very opposite of that. My guess is that he was so angered by the revelation that I'll never hear that line of arguments ever again. And if it does happen, I'll just requote his post. I saved a link to it, just in case.
- 2-02-2017** **Bittersweet.** Monthly sales results often stir new discussion. This was today's quote of interest: "*There's some bitter sweetness to the Bolt EV. I think we will see the Bolt EV outsell the Volt.*" Seeing certain enthusiasts already mulling that perspective is encouraging. Steps forward have to begin somehow. My issue has always been packaging. Choosing such a small vehicle and squishing so much capacity into it was an imbalance too great to overcome. Ordinary consumers wouldn't be willing to accept that tradeoff of cost & comfort. And sure enough, that was indeed the outcome. That's why reaching mainstream buyers has become such a issue of contention now. I expressed that point with: The lack of growth from year-2 of gen-2 Volt does paint that picture. The massive drop from 3,691 in December to just 1,611 in January provides reason for concern. Dropping back to gen-1 levels, despite significant increased support for plug-in vehicles recently, isn't encouraging. The overall goal of replacing traditional vehicles can still be achieved, but there will need to be adjustments along the way. In the case of Voltec, the compact car packaging continues to be a barrier to growth. Choosing to offer it in a small SUV would be a wise next step.
- 2-02-2017** **Choice.** Some people either don't learn or don't want to accept certain outcomes. With one person, who is rather well respected on the big Prius forum, it was using inflation to justify the still too high price of Volt. After arguing in circles, without making any progress, we ended up getting: "*Choice is good.*" I continued to push: A choice of "*nicely under \$30,000*" was the price goal set by GM. The reason for setting that was simple. A configuration able to achieve that with low enough production cost would be both competitive & profitable with other choices available on the dealer's showroom floor. Otherwise, those shoppers will just purchase a different GM vehicle instead. We still don't see that choice of GM plug-in hybrid yet. True, taking the tax-credit subsidy from the MSRP would achieve that goal. But it limits inventory to well below competitive volume and is extremely short-term... hence the close look at Toyota's design. People want to know how Prius & Prime are able to overcome both engineering & business obstacles.

- 2-02-2017 Acknowledgement.** Being quite annoyed by the obvious effort to deflect, I finally lashed out. The constant attempts to change the subject to Toyota are signs of desperation so obvious, it's hard to believe so many enablers are putting up with it. It persists, continuing to post information about GM itself, keeping on topic rather than taking the bait. Sales results bringing out the worst in them is why I end up taking such a terse stance. Today, the response to January sales was to post them... but not cherry-pick only plug-in vehicles. This was showing numbers for the traditional vehicles too. That perspective is quite harsh, especially looking at the entire year. They speak for themselves: It's been nothing but positive news the last 2 months, no matter how you try to spin it. They say the most difficult step to overcoming a problem is acknowledgement... For 2015: Equinox = 277,589; Cruze = 226,602; Malibu = 194,854; Impala = 116,825; Camaro = 77,502; Sonic = 64,775; Trax = 63,030; Corvette = 33,329; Spark = 32,809; Volt = 15,393. For 2016: Equinox = 242,195; Malibu = 227,881; Cruze = 188,876; Impala = 97,006; Trax = 79,016; Camaro = 72,705; Sonic = 55,255; Corvette = 29,995; Spark = 35,511; Volt = 24,739. See the problem now? Growth of sales does not come from pretending all is going well or crying foul. With Bolt now stealing away both the spotlight and tax-credits, it is time to finally get serious about the situation with Volt.
- 2-02-2017 Price Points.** He responded with the same old pigheaded response: "*How am I moving the goal post? Inflation exists.*" I wasn't even the one who mentioned goal-posts this time. Someone else got annoyed by such a lame excuse, giving me a like and him a scolding. My reply was a simple counter: That's why PRICE POINTS exist. You can't just pick the economic factors you like and disregard the ones you don't. An automaker targets a vehicle for that, then makes adjustments as the years pass to retain that positioning. Yes, we've seen a gradual climb over the decades, but being that far off target has proven a barrier to mass acceptance. In fact, that is the very reason why the subsidy exists, to temporarily counter pricing while those adjustments are being made... and time is quickly running out.
- 2-02-2017 Disruption.** It's well known and nearly impossible to argue, gas consumption of the large number of Prius replacing traditional vehicles is much lower than that of the small number of Volt. Looking at the big picture makes that obvious. This is why debates focus solely in individual vehicles. In other words, bragging rights outweigh that of actually making a real difference. Again, this is why the motive of enthusiasts has so little in common with that of supporters. Goals clearly have not been the same. There is a bit of hope though: "*It will have to sell in mass in order to disrupt as much oil consumption as the Volt does. The AER is pitifully small.*" That glimmer of change... actual acknowledgement of fleet impact... is encouraging. I wonder how this will be responded to: With the Premium model \$28,800 and a large number of \$4,502 tax-credits available, selling twice as many Prime as Volt won't be that difficult. That's seriously good short & mid term pricing. The base MSRP of \$27,100 certainly sets up the offerings as a realistic long-term contender too. Even with the supposed "*pitiful*" range, owners will see very high MPG regardless. There's the advantage of Prime being more efficient than Volt in both electric & gas modes too. So, more battery isn't necessarily better. In other words, stop with the "*vastly superior*" crap already. It's time to address what needs to be done to get the masses to purchase plug-in vehicles. Just because the packaging of Volt hasn't resulted in significant growth doesn't mean the same tech in a different body won't.

2-04-2017 Challenges. Some constructive talk is emerging out of the chaos. I suspect some of it is the result of early Prime sales are showing strong rollout potential. This was the post I selected as discussion worthy: "*The Prime can probably challenge for best selling plug-in for 2017... IF Toyota actually wants to sell it en mass.*" This was my response: Rollout is worldwide, all at the same time. So, even if the sales total for the year is similar to others here, there are many more which must be accounted for. The big part of the first-year ramp-up challenge for Toyota is the effort to improve efficiency in new ways. They are delivering a low-cost carbon-fiber component: the back hatch. That's a complex shaped piece which gets banged shut routinely. Being able to deliver that in high-volume opens up great opportunity for other pieces in the next generation. The weight-reduction benefit is obvious. The other effort is delivering a dual-wave rear window. Doing that in an affordable manner provides an aerodynamic benefit. It also delivers style we have only seen elsewhere on very expensive vehicles. GM deserves compliment for making Bolt a practical shape. That can be counted as exploring new options. It clearly addresses the low rear-seating issue in Volt. The catch is, that success should finally result in a Voltec variant offering something similar. In a body like Equinox or Trax, it's easier to justify the higher price than with Volt, a compact car. Car sales only represent part of the market anyway. We can see plug-in SUVs on the way. Toyota, Nissan, Hyundai/Kia, and Mitsubishi are all heading in that direction. There's the Chrysler minivan too. It seems odd for GM not to be part of that.

2-04-2017 Validation. He completely exhausted all excuses, turning to spin: "*True, Toyota is following the Volt's design. Great validation!*" It's bizarre how desperate a few get defending a lost cause. Oh well. Losing a battle is not like losing the war. You acknowledge the error and move on. I couldn't let it go without looking back to point out the attempt to damage-control mislead: Toyota was already increasing EV top speed with Prius upgrades. It started at 42 mph. Then it went to 46 mph. Then it got bumped to 62 mph. Then it was raised to 72 mph. Then it finally settled at 84 mph. Each was direct result of the battery improvements. So, there is nothing to claim in relation to Volt. Toyota determined liquid-cooling for the battery-pack was an unnecessary complexity that added cost to the design, so they definitely did not follow Volt in that regard. The biggest did not follow though was not rolling out a design dependent upon cost-reductions coming later or tax-credits. Toyota offered battery-capacity based upon what they determined to be profitable. So, that validation claim is not true. It isn't even an alternative fact.

- 2-04-2017** **Competing.** There's quite a bit of spin near the end. We saw it with Two-Mode. We saw it with BAS. We saw it with gen-1 Volt. We saw it with eAssist. Each time GM attempts to dominate a market segment with a new high-efficiency technology, things get ugly. The process of dealing with it starts with the goals having been missed entirely or falling well short, which could be constructive... but sadly, hasn't been. The effort to get back on track is circumvented anyway. GM simply introduces a new product instead. That's what we are seeing take place with gen-2 Volt. The spotlight has been shifted over to Bolt instead. The whole idea of "*range anxiety*" has completely fallen apart. The anti-EV automaker has embraced the EV. All that marketing for Volt as the superior choice was for what? It wasn't just an idea on paper or something advertised on television. The campaign resulted in 100,000 sales... which sound impressive. Unfortunately, the heavy dependence on subsidizing profit using tax-credits has become a very real problem. What should be done now? That's a very good question. But rather than answer it in any fashion, the choice has been to seek out validation. Today, it was this spin: "*Toyota is following the Volt's design. Great validation!*" That came about by asking what the purpose of gen-2 Volt was now that "*range anxiety*" has been alleviated by Bolt. Ugh. Oh well, this was my follow up: It was nice to see gen-2 Volt take on the blending characteristic of Prius. That was validation of common goals. You know all too well that Voltec didn't go for traditional vehicle competitiveness (matching mainstream purchase priorities). For gen-1, that was fine for the sake of proving the technology was capable. But for gen-2, it's revealing itself to be an overkill approach... which is how Bolt fits into the picture. That engineering was carried over to make a worthwhile EV introduction... and clears the way to alter Voltec into a matured configuration, so it can compete directly with traditional vehicles.
- 2-05-2017** **\$1,000 Shipping.** There is one dealer in Wisconsin who somehow has had a few unspoken for Prime to sell. How could just that one have them available? It was making some of us crazy... especially after hearing the story about a Prius owner on a trip from Missouri who just happened to stop there out of curiosity and ended up driving home in a new Prime. Talking about lucky! Turns out, that dealer has been purchasing them out on the East Coast and having them shipped over on a truck. For their effort, a fee of \$1,000 is added to the sale. It's a convenience some people have been willing to pay for. I did something similar 5 years ago to get my Prius PHV. Knowing an absolutely wonderful salesperson in Los Angeles, it was just a matter of placing an order with her and contracting my own delivery truck. That would cost me less than \$1,000 to do that again. So, the dealer is clearly making a small profit, especially with the truck fully loaded with Prime. Ordering locally was important this time. Being part of the local plug-in owners group, there's a huge benefit from establishing dealer contacts. We seek out well informed and helpful salespeople, they direct plug-in business to them. It's a win-win situation. One thing we hadn't expected was a dealer being so willing to help, they'd take it upon themselves to seek out distant inventory rather than waiting for regional distribution. Education of business & customer needs to start somewhere.

2-06-2017 **72 Degrees.** Having enough battery power to drive the entire depletion of coolant heat almost never happens. Today was different. Traffic was really heavy due to the snow falling. My wife and I (we commute together) decided to take the back way to work. That route is quite scenic and likely wouldn't take much longer than the heavily congested highway anyway. That meant a lot of EV driving opportunity, after the engine got fully warmed up. I got excited when I saw the circumstances play out. I announced the temperature drop as the degrees fell. Witnessing surprises lows was nothing new. Even with the temperature outside well below freezing, it was still quite realistic to drive several miles with the engine off. That inevitably concluded with the end of EV capacity of the end of suburb driving. Today, luck was in my favor. True, I had just jumped onto the 55 mph highway to cross the river, but the battery-pack was almost depleted already... and the coolant temperature had already exceeded the lowest state I had ever seen. My chance to confirm a prediction was about to come true. 72°F is the well accepted standard comfort-level for many. Was the system in this Prius capable of drawing out heat from the warmed coolant all the way down to that point? From 130°F to 72°F is not what the regular model supports. Turns out, PHV does. I got to watch it happen firsthand too. Being able to keep the engine off to that point is really smart. Toyota clearly thought out every little aspect of how to squeeze out efficiency.

2-06-2017 **Defending Pride.** That individual who had become quite a standout antagonist has recognized what "*too little, too slowly*" really meant. The pain of learning just how much opportunity had been missed and now dealing with the consequences of such blind hope is obvious. Oops! My push to take the next step stings too. That means having to admit making a huge mistake and worse... acknowledging a Prius owner understood the market. No amount of engineering excellence can overcome stupid executive decisions. Harm to business for the sake of pride is nothing new, neither is seeing enthusiasts fiercely defend it. That's why they are called "enthusiasts" rather than "supporters". A true supporter of business wouldn't let pride get in the way of reaching sales goals. If an error in judgment is made, you look back at what could have been done better, then move on. I'm not seeing that. I do give the opportunity to let go of the past... which is take a step forward: It's easy to see which particular questions are being evaded. Attempts to divert attention away from GM are obvious too. The condescending attitude though, that's the real giveaway. That's what leads to discoveries. That's why I have endured so many "*vastly superior*" posts. Bolt's heater is the latest oddity to be revealed. It was said to "*use a resistance-heater that circulates coolant through a heater core*". Why not just a resistance-heater by itself? Does the added complexity of coolant use improve efficiency? If so, is it more efficient than using a heat-pump instead? Or what about using the even more efficient a vapor-injected type of heat-pump?

- 2-07-2017** **Fleet Demo.** I certainly wasn't thrilled to read this: *"Just for the fun of it, I called the closest dealer to us, in Florida. The guy seemed pretty up on what's going on. He said Toyota sent them one, which sold right away."* It was no surprise. Imagining how disinterested some dealers are toward selling a difficult to acquire vehicle isn't much of a stretch. They earn very little profit and have to answer lots of questions. Wanting to just stick to selling the money-makers right there on the lot with a variety of packages & colors is the preferred, by far. At least with Toyota, they already have the Prius reputation well established. That makes participation much more likely. As of this now (early in the rollout stage), only 40% of GM dealers have expressed interest in selling Bolt. We saw the same type of struggle with Volt. So, the situation with Prime isn't so bad. Not being discouraging is good. It's still annoying though. I provided this insight into the situation: Ugh. It's the same old dealer problem Toyota corporate faced back with the Classic model rollout in 2000. They'd deliver a *"fleet demo"* model to the dealer with explicit instructions not to sell it for 6 months, that it was to be used exclusively for education purposes in the meantime. Some dealers respected that, using it for customer demos and salesperson training. Others sold it without any regard for what it was intended.
- 2-08-2017** **Sales Deception.** I'm growing really tired of seeing fake news on a regular basis now. This morning's attempt at deception was: *"This makes the Prius Prime a highly attractive car on the brochures but the poor design is holding the car back from enjoying good sales."* It's bad enough excluding availability information, giving the false impression of dealers having them in stock and consumers choosing not to purchase. But to make a claim of *"poor design"* without providing any indication of what that actually meant is an entirely different matter. I couldn't find anything even remotely revealing of what that could have implied. It was simply a blatant slander attempt. Nothing whatsoever was stated as to what it referred to. Fortunately, only those looking for redemption to back their stance care anyway. Taking claims at face value isn't what someone researching a purchase will do. Those who stumble across the article, due to interest in the topic for whatever reason, will want to find out more. They'll search for clarity. There's also the approach of first-year sales being disregarded too. Mainstream buyers tend to wait until the second year of rollout before even considering a test drive. They wait. The sales deception won't matter by then. So, were good.
- 2-09-2017** **Affordable.** There are some who absolutely hate affordable cars. They look down upon them as a waste, unworthy of their time. So, even bothering to consider one is behind them. That makes any sort of acknowledgement a problem; however, you can sometimes get lucky by pointing out a new perspective. I pointed out that room is being made for the rest of the Toyota product-line to be offered as hybrids, exactly as their long-term plan has stated. Prius is going one direction. Prime is going another. Corolla hybrid will fill in between that. This came about in return: *"But the elephant in the hybrid room is the affordable plug-in."* It wasn't the direction hoped for with the discussion, but it was at least somewhat of a larger perspective being taken into account. So, this seemed a good way to reply: \$27,100 MSRP for the base model Prime, which is fairly well loaded, fulfills that criteria. That affordable price provides the potential to compete with traditional vehicles directly. Also having a \$4,502 tax-credit available will stimulate demand and speed education.

- 2-10-2017** **Better.** We're getting a lot more spin lately: *"It's not that the Prius is losing it's mojo, it because it has taken many years for the public to realize the Volt is a better car."* That's a good indicator of change. When the same old rhetoric doesn't work anymore, they try something new. I enjoyed exploring this angle: For mainstream vehicles, the term *"better"* indicates that it offers a nice balance. The expectation is that they fulfill a wide variety of criteria. That's why those which sell in large quantities are so popular. For other vehicles, you get some type of feature emphasis. Whether it is speed or power or size or agility, there was always some type of trade off... resulting in low-volume purchase. Prius was among the first of the modern vehicles to not require that, consequently selling in high-volume instead. You'd get high-efficiency and low-emissions within the realm of ordinary performance. Gen-3 made that point especially clear. Gen-4 took an odd side-step by actually stiffening the body and upgrading suspension for improved handling, but that was achieved without trade off. So when it comes to "", we need some type of clarity. For starts, are you referring to the regular Prius or the plug-in model (Prime)? In either case, both are much more efficient than Volt in HV mode and both have much lower base prices. If the reference is to range, the *"many years"* makes no sense... since Prime rollout is still in the earliest stages (low volume on the coasts and none available in the Midwest).
- 2-09-2017** **Paradigm Shift.** It's happening. The painfully slow acceptance of gen-2 Volt is getting the best of even the most stubborn. Those enthusiasts of the past are no longer enthusiastic. Failing to draw in a new audience can no longer be denied. I'm writing this on the wall now: GM milked high-profit vehicles for all they could prior to the market collapse and expensive gas. We see them doing the very same thing now. We also see battery cost dropping. At some point, there will be a competitive market for EV cars, able to compete directly with traditional vehicles. They won't offer much of a profit-margin, but they will make driving a guzzling SUV or Pickup passé. Evidence of an upcoming shift is the preparation for it. Both plug-in offerings, Volt & Bolt, are establishing the technology but not actually drawing GM's own loyal customers... who just replace their old SUV or Pickup with a new one. Notice the heavy emphasis on conquest sales? When demand rises for the low-profit choices, GM will have no option but to adapt. We saw this history play out already with the computer industry. Now, it's time for the automotive industry to bite that same bullet. This is known as a paradigm shift.

2-09-2017 **Not Moving.** Sometimes, you actually get constructive discussion: "*It must be profit margin that drives their not moving Voltec to a larger CUV or SUV.*" I was pleased to finally see and respond to that: What else could it be, you ask? There's little reason to wonder if Voltec would work scaled up. The system is clearly overpowered for a compact car and it originated from Two-Mode, which was used in Yukon & Tahoe. The cost of Voltec is still high though and giving up profit isn't the GM approach. There is the possibility of market collapse worry, a paradigm shift resulting from interest in efficiency. That taste for EV propulsion leading to the abandonment of the mighty SUV in favor of sleek aerodynamic style instead isn't too much of a stretch. After all, that is exactly what draws people to Model S and people have found compelling about Model 3. People desire change after awhile. The SUV has been done to death. The sedan has become plain looking. Signs are starting to point in the direction of the sport look again. Remember what happened in the early 80's? There isn't anything to stop that from happening again. With the advent of LED lighting, the trickle down of carbon-fiber, and the re-introduction of waved glass, why not? It all adds up nicely for Prius Prime. The pattern fits with Toyota's history of leadership too. This time though, it looks like a one-two punch. It doesn't take much to imagine RAV4 hybrid being augmented with a plug. The base system is in place already... and selling well. We see other automakers on that plug-in SUV path too. We'll never really know why GM is allowing their opportunity to slip. Of course, the antagonists here will just spin this post as an attempt to change the topic anyway. So, let's simply end with an outlook for what 2017 will bring in terms of Prius sales. My hunch is the regular model will remain relatively flat, right around the mainstream minimum for monthly sales. For Prius Prime, expect it to open up the market for affordable plug-in hybrids. In other words, Toyota will max-out their supplier quota and be scrambling to significantly bump next year's production. Fortunately, Prime's worldwide rollout (Japan, United States, and Europe) all at once does help provide a realistic gauge for estimating demand in subsequent years.

2-10-2017 **Ford Plug-Ins.** It's easy to forget this big automaker. Quite the opposite of GM, they are quiet about high-efficiency offerings. Rather than clamor for the spotlight on a regular basis, you hear virtually nothing. Yet, sales are surprisingly similar. Last year Ford delivered 23,895 Fusion Energi and C-Max Energi models. The total is a combination of plug-in sales, but looking at total in this regard is fine. We aren't talking about major numbers of any offerings yet. Mainstream really doesn't apply until sales grow to the 60,000 annual level without tax-credit help. There's no way to consider them competitive with traditional vehicles prior to that fulfilling that criteria. It puts the 24,739 total for last year from gen-2 Volt into perspective. This is why hybrids without plugs are talked about so infrequently now. Either people are interested in those or they are not. The technology is so well established, there's nothing to mention anymore. The addition of a plug is an entirely different matter though. Yet, you still don't hear much from Ford. We certainly get our fill of GM spin on the other hand. I'll sure be glad when that settles down.

2-11-2017 **Fake Trouble.** Simply publishing a random article with a disconnected title works too: "*The Toyota Prius Prime Proves That The Prius Hybrid Sucks*". There was literally nothing of any substance to support that. It was just a bizarre collection of vague comments. You'd think there was potential. But the trend we've been seeing is that catchy titles are all that's needed. Many don't bother actually reading the article all the way through. Proof of that is how short the articles have become and the complete absence of comments. No one posting anything is quite unusual. In the past, you'd see reader participation everywhere. The diverse audiences were always quite eager to post their opinions. We're not seeing that with the articles fitting this new profile though. Thankfully, the ones with actual detail remain quite active. Nonetheless, it is still quite troubling to see a regular flow of "*fake*" news now. We're hearing how these are being used to simply vindicate the stance a person has taken. They simply want confirmation of their own opinion without bothering to understand the actual situation.

2-12-2017 **Method of Measure?** Concerns of battery-life continue to pop up as the plug-in cars get older. The seemingly basic complications of chemical & component aging make expectations very complicated. Does aging alter internal resistance? How would you measure that? Don't forget the influence vehicle break-in or the increased grip from new tires. Needless to say, it's messy. Some complain about EV range loss, but the accounts are always so vague, there's no good way to respond. How do you make sure to include all influences? How are they even measured? For that matter, who even has a baseline to compare with? This is how I addressed the situation today:

On Friday, my commute was a balmy 27°F (quite comfortable here in Minnesota), so no need for the heater. That meant an opportunity to measure. I went the full 9.2 miles of hilly suburb EV driving before running out of sub-62 mph road. At that point, the remaining EV was indicated to be 0.4 miles. Being able to drive 9.6 miles of EV in those conditions (hilly & sub-freezing) for a Prius PHV just 1 month shy of 5 years sounds right on par for aging expectations.

Right now, I'm at the coffeeshop blogging. The temperature for the drive was 32°F. The route 7.6 miles of all flat suburb (45, 50, 55 mph limit roads). The entire drive was EV. The remaining capacity was stated to be 2.7 miles. The SOC was 39.6%, which confirms accuracy of the estimate. That gives me a total of 10.3 miles of EV driving, which is right on too. There was only 1 stop along the way. Both lights were green and the 3 roundabouts you only have to slow down for. Again, that seems quite reasonable for almost 5 years of use.

Note that during the work week, I recharge twice. At home with 120-volt connection and at work with 240-volt. Both include long cold-soaks (many hours). For random full charging, I always wait a minimum of 90 minutes. When stopping at the grocery store, the quick 10-minute top-off is immediate. The battery-pack rarely ever saw extreme heat. It simply never gets that warm this far north.

In other words, my aged battery-pack is working great still.

Can we get some fresh accounts from others, using a format like that above to describe their own experiences?

2-12-2017 **Calculations for EV.** Being able to move on to a Prius focus (not having to deal with rhetoric much anymore), it's time for some calculations. It sure will be nice when I have my own numbers to work with. But for now, we can use EPA reported values. I did that for this response: *"I can still do 10.3 miles at 32 degrees, but it was more like 12 at one time."* Knowing how imprecise anecdotal observations of the past can be, this is how I worked out the expectation:
Simple math would seem to indicate your pack is just fine still.

$85\% - 23.5\% =$ usable EV capacity available is **61.5 %**

61.5% of 4.4 kWh = EV capacity calculates to **2.7 kWh**

$2.7 \text{ kWh} / (29 \text{ kWh} / 100 \text{ miles}) =$ EV range is **9.3 miles**

That doesn't take into account hills or regen, of course. It's just a basic measure of potential using the EPA measure of efficiency for Prius PHV. Nonetheless, seeing 10.3 miles years later looks good.

2-12-2017 **More Calculations.** Running those same calculations on Prius Prime is interesting:

$85\% - 23.5\% =$ *assumed* usable EV capacity available is **61.5 %**

61.5% of 8.8 kWh = EV capacity calculates to **5.4 kWh**

$5.4 \text{ kWh} / (25 \text{ kWh} / 100 \text{ miles}) =$ EV range is **21.6 miles**

Anyone know the actual usable value? There was speculation that deeper discharging with the new chemistry was realistic, especially since GM decided to expand usable capacity for gen-2 Volt. I haven't heard actual numbers though... and I don't have my Prime yet. Based on the calculation result, it's easy to see where the original EPA stated range was 22 miles. I have found a mention of 6.18 kWh usable. In that case:

$6.18 \text{ kWh} / (25 \text{ kWh} / 100 \text{ miles}) =$ EV range is **24.7 miles**

Note that using the 133 MPGe rating (to be more precise), we get 25.3 kWh / 100 miles. That's 33.7 kWh per gallon of gas / 133 MPGe. Values reported for EPA are truncated, rounded, and adjusted. So, be careful of trying to get too precise. And of course, YMMV.

- 2-12-2017** **Charging Observations.** The official number from the wall is what was reported for EPA is 6.33 kWh. That takes into account charging losses, which are given a standard factor of 15%. That means the usable capacity calculates to 5.38 kWh. The value matches up nicely with observations a friend of mine reported with his Prime. It's a good confirmation. I'm not sure where that higher number came from. That's why I document what I find in these blogs. Sometimes you come across a clue to an aspect of design no one had really notice the significance of yet. Other times, you stumble across the birth of a misconception... which makes understanding its origin very important. Whatever the situation, we start with observations. In this case, it's with respect to charging. That topic is unknown to most people. So, having some accurate numbers readily available to share can be quite help. I can't wait to contribute to Prime's rollout. In the meantime, I'm using the observations collected from my Prius PHV to help document that history. After all, you never know what kind of spin will emerge. Having 5 years of detail available could certainly come in handy.
- 2-13-2017** **Concern.** You can tell how much the attitude from Volt enthusiasts is changing, from statements like this: *"...I'm surprised they haven't offered more models, but it would be foolish to not offer as many models as they can during the phase-out period."* The realization of gen-2 having failed to achieve growth is moving into the acceptance stage. It's trapped as a niche. The clock is running out... and there is no sense arguing it anymore. That crazy lashing recently out over the *"too little, too slowly"* really was the finale. It's over. Time to move on. Evidence of this change came from my simple post today. It wasn't attacked. In fact, the opposite happened. I got positive votes! Gasp, eh? Even the most staunch saw the writing on the wall. GM will need to play catch up if they don't offer the technology they developed in packaging their customers actually want. In other words: Getting caught mid-cycle without any subsidies has been a problem expressed for years. That's why there's been such a big push for a SUV with Voltec.
