

john1701a's Personal Log Book

I purchased a Classic Prius (hybrid-electric, fuel-efficient, super-ultra-low-emission vehicle) back on 9/9/2000 and drove it in Minnesota until I replaced it on 10/23/2003 with an Iconic Prius (which was even cleaner and more efficient). Then on 5/26/2009, I upgraded to a 2010 Prius (for amazing efficiency). Following that on 2/29/2012, I got my first plug-in model (pushing MPG significantly higher). The big upgrade happened 4/01/2017, when I replaced the PHV with a Prime, trading 11 miles of EV driving for 25. This book documents those personal thoughts & experiences.

From: **3-08-2012** to **5-17-2020**

- 3-08-2012** **Newbie Posts.** It's fascinating to see that newbies are appearing online just for the sake of a PHV purchase. Their forum participation is exclusive to plugging in. These are the consumers who were stirred by Prius, but not interested enough to commit. But now with the ability to boost MPG with a plug, things are different. They're interested now, some even engrossed. In fact, many of the first posts are to point out they are either awaiting delivery or just drive home with one. That most definitely qualifies as committing. Tapping into an entirely new audience is market penetration those supporting Prius for years have dreamed of. It's not just owners upgrading. This is true expansion. Each step forward leaves traditional vehicles further back. With the no-plug version so well proven, it's only a matter of time that real-world data from these new owners begins to solidify a future where having a battery-pack of some sort is the norm. One post after another, you can see it happening. I wonder how many parking spaces will show up as an enticement. After all, with a full recharge for Prius PHV only taking an hour and a half, that's perfect for a restaurant or coffeeshop visit. That works out as a draw for movie theaters and shopping malls too. This is getting very exciting!
- 3-09-2012** **Agendas.** It's very easy and quite realistic to expect someone who routinely contradicts to have an agenda. After all, not having any purpose would be rather odd. So with discussions of Volt growing on the big Prius forum, this question was expected: *"I get the impression that much of the negativity directed at the Volt is from an ideological agenda rather than anything that has to do with the actual vehicle."* I was among those who provided a response to that: That comes from such heavy focus on engineering and disregard for actual need. Had the technology been developed with choice available rather than the one-size-fits-all system we got, outcome would have been different. Sure, anyone can justify an individual purchase, but support for the masses is another matter entirely. Then there's the attitude. On the forums supporting Volt, it's not a matter of good old fashion competition & rivalry. Instead there's "vastly superior" declarations and endless excuses, avoiding consideration of consequences from weak sales. They don't acknowledge the history of Two-Mode or BAS either. To makes matters worse, there's the issue of disenchantment. You shouldn't just abandon those who's expectations were not met. Yet, that's exactly what happened. Look at the diversity we get from Toyota and the concepts they continue to reveal. It's a very situation quite unlike that from GM. Basically, there's no good way of addressing the problem without sounding negative. Setting new expectations would be wise next step.
- 3-09-2012** **Location Status.** We got word of where the driver was. He'll be spending the night near the Texas/Oklahoma border. That's roughly halfway, with the difficult part of the journey (crossing the Rocky Mountains) already complete. It probably means not arriving here until two days from now. The actual act of delivery may not take place until the following morning. That's no big deal. I have much to do at home still, including clean the garage to temporarily accommodate two Prius. Thankfully, the first true day of Spring weather is expected tomorrow... which just happens to be a Saturday. It does make passing the time a bit odd though, since there's one less hour this weekend. Daylight Savings is great timing! I'll have one more hour to play with the PHV after work. Getting dark right away is a pain. Anywho, I'm running out of stuff to think about. The wait is definitely a test of patience. Hopefully, I'll get an email update with location status tomorrow.

- 3-10-2012** **Decisions, part 1.** There are a lot of PHV newbies all wondering the same thing... why? So, the topic of Volt continues to pop up. Fortunately, there are a few dedicated discussion threads now rather than having to endlessly deal with distracting interjections. That's nice. I certainly want to move on. But there are some thought-provoking posts resulting from this. This particular one was especially impressive: *"I don't understand the engineering decisions of the Volt. GM claims it is an EREV and it is, but IMO it was a brute force design not an elegant design. Tack on a big battery to compact car is what it appears to me to be. They presented the idea of a series hybrid, but actually built a parallel/series hybrid with a larger battery."* That opening obviously caught my attention. The closing statement was just compelling: *"Why GM chose to build the Volt the way it did boggles me. They had the opportunity to build a car from the ground up and instead of choosing to build a truly interesting car, they designed a car with unnecessary compromises in utility and efficiency."* It's an interesting thing to consider. How do you get perspective from the past without looking back? Only blogs written then, as it was happening, can provide observations as they happen. Forum posts don't have continuity, though a few threads offer a brief chronology. It's up to those who lived it firsthand to share the stories...
- 3-10-2012** **Decisions, part 2.** This what I contributed to the discussion: Having followed the history of Volt from Two-Mode origins, it's easy to understand. Business desire was where the compromise came from. Engineers were impaired by what marketing had already started to promote. In other words, they backed themselves into a corner very early on. It was a commitment doomed by unrealistic expectations. Promises of outperforming the competition blinded decisions. Cost was allowed to increase without concern. The first evidence of that I can recall was the decision to abandon the custom-designed engine and just use one from a traditional vehicle instead. The claim was to keep price low, but the efficiency penalty made you wonder. It contributed to the enthusiast focus on acceleration & power. GM thrived on the resulting hype. Focus was lost. Things fell apart from there. Bringing up the topic of cold-temperature influence confirmed constructive discussion was no longer possible. Hope had taken control, long before the design had even been finalized. Later, when it was leaked that Volt wasn't actually a serial hybrid as promoted, it started to get ugly. Information about depleted efficiency was withheld, despite countless enthusiast requests. Then came the price announcement. That was the beginning of the end. Before rollout, there was disenchantment among supporters. So as owners began to report real-world data, it was already too late. The damage had been done and each attempt to repair only ended up making the situation worse. Now, we have the first PHV arrivals. What does that mean for Volt marketing? What about design? What about sales? This certainly is an interesting time in automotive history.

- 3-11-2012** **That Downplay.** The moment price was revealed for Volt, things began to change. That wasn't the kind of change enthusiasts were hoping for. With such an expensive MSRP, there wasn't much hope for high-volume sales. In fact, some of the enthusiasts themselves became disenchanted. There is an aspect of that with PHV too, but with a \$9,000 difference between that then in July 2010 and now there's little to argue. It was going to take longer than hoped for Volt but not for Prius. So, they began the downplay. To make matter worse, the reveal of EPA estimates in October 2010 confirmed that Volt's depleted efficiency wouldn't be any better than a traditional vehicle. That's not the case for PHV, it continues to deliver MPG just like a regular Prius after depletion. There's nothing to downplay. To make matters even worse yet, popularity of Prius from the new v and c models and continued growth of the regular model will benefit PHV. Sales of those no-plug Prius are positive reinforcement of the future. Sales of Cruze do just the opposite, they harm Volt by drawing appeal back to traditional vehicles. The new ECO model of Malibu will negatively impact Volt too. GM is providing it's own downplay, being it's own worst enemy. Come to the dealer to see Volt and end up buying something else. Come to the dealer to see a Prius and end up buying the plug-in model instead. This next year is indeed going to be very interesting.
- 3-11-2012** **Just 4 Hours.** It is rather surreal knowing in that amount of time, there will be a truck unloading my PHV. After years of waiting, it's on the verge of becoming a reality. I quite ready too. All those heated debates online prepared me well for this. They routinely asked on the big GM forum why I was there. This is it. I have always a clean, highly efficient vehicle for the masses. Toyota's approach is fantastic. They are starting with the smallest realistic battery-pack, just enough to significantly boost MPG without having a significant impact on price. It's easy to understand too. The engine simply runs less often than the regular model, and in some cases not at all. You don't need anything beyond an ordinary 120-volt outlet available either. Plug in when convenient. Still get great efficiency even when depleted. Not much longer to wait now.
- 3-11-2012** **In My Garage.** Quite literally 2 seconds after posting about my final 2010 Prius video, there was a knock on my door. It was a neighbor. He was excited to see my 2012 Prius PHV finally arrive... and like me, was amazed to see a massive 8-vehicle carrier rig backed down into the street. That was quite an impressive sight, even without two plug-in deliveries on top. It was getting dark fast. The sun had already went down on that cloudy evening and rain was just beginning to fall. That meant no photos and a flashlight for the inspection. Minutes later, I could hardly see anything. Talking about just in the nick of time! I barely got a glimpse of the Clearwater Blue color. The driver was paid, I signed the paper, and he was on his way. Another neighbor came out to see what I had just taken delivery of. It was all very exciting... despite seeing only 3-bars on the display. That meant no EV driving until morning. Oh well. That completes the purchase & delivery, next comes vehicle registration.

- 3-11-2012** **To The Mall, Display.** That final video with the 2010 Prius was again that same route. Only this time, the second camera was used to capture speedometer & eco-meter information from the vehicle itself rather than an aftermarket gauge. It provides a much better depiction of what most owners will observe... which is great, since there are likely few who really want to know about engine RPM and coolant temperature. Anywho, this was the description of that experience I provided: It was a challenging final capture with the 2010 Prius. The scenery camera kept failing. Turns out, it was an automatic overheat protection feature that kept shutting the camera off halfway through the drive. But since it was such a fantastic day out, the first true Spring weather we've had here, that was no big deal. The 64°F felt wonderful. Once I finally figured out the problem, a few minutes with the case off in front of a fan and cool battery did the trick. Too bad it doesn't have active cooling like the PHV does. Anywho, that meant the drive was quite representative of a normal Sunday. You get home from something, then immediately head back out for something else. In this case, it was a drive to the mall then a pleasant back route home. The 10.4 miles displayed resulted in an average of 60.5 MPG. The Prius really thrives on drives through the suburbs like that. Watch the indicator bars on the Eco-Meter and the instant MPG. There's a lot more at play while you drive than most people realize. Prius automatically seeks out efficiency opportunities. The readouts allow you to do the same. I just drive it, but still find it fascinating to watch the system operate. See: [Prius - To The Mall 3](#)
- 3-12-2012** **First Depletion.** I plugged it in last night, then headed out to the DMV first thing this morning. There's lots of new goodies to explore, not to mention the drive experience itself. I blew it though, accidentally firing up the engine by messing with the climate-control settings. Oh well. You quickly discover PHV isn't about EV purity anyway. It seeks out efficiency opportunities, taking advantage of the engine at times. Watching the HUD, it was interesting to see the difference between a full charge and the HV only I had last night. The electric power is indeed there. I enjoyed climbing the steep neighborhood hill from a dead stop at the bottom to sustaining 40 mph the way up, all with only electricity. When I finally finished running around town and headed out to work, the Prius was going 61 mph up the ramp in EV before the engine started up. So, then was a good time to switch over to HV mode. The morning's 13.3-mile charge had already depleted to 6.2 miles. To my surprise though, the value almost immediately started to climb from powering split. I drove 9 miles at 70 mph and another 3 to the river at crossing 55 mph, watching the EV value creep higher as I went. It was at 7.2 miles when I swapped back over to EV mode. Upon reaching my parking spot, there was 3.6 miles of EV still left with 22.7 total miles of travel and an average showing 78 MPG. That's pretty satisfying with a car not broken in yet on a cold & rainy day.

- 3-12-2012** **Changing Definitions.** The most common technique for dealing with a lost battle is to spin the circumstances of that outcome. For those last few Volt supporters who were fiercely fighting PHV, the approach was to change how "*hypermiling*" was defined. Their arguing degraded to the point where if you weren't passing everyone on the road, you were trying to improve MPG. What kind of nonsense is that? Driving along with the flow of traffic obeying the speed-limit is unacceptable, a blatant attempt to distort reality... according to them. Needless to say, no one had taken them seriously since then. The threads on the big GM forum and those Volt daily blogs have slowed to a trickle. Could it just be a coincidence that PHV just happens to be on the road now? Could it be that gas prices have been soaring lately. Or could the reason be all the media attention "*economy*" cars have been getting lately. Of course, even that definition is changing. Who knows all the factors involved. What I find humorously ironic is how easy it has become to improve MPG now. The PHV slips into EV mode surprisingly easy, shutting off the engine quicker than my 2010 did. The HUD in the Advanced model (Heads Up Display, which projects Eco-Meter information directly onto the windshield) provides an unheard of level of awareness & convenience. It's great! In other words and to put it shortly, things change. Some like it. Some don't.
- 3-13-2012** **Morning Commute.** I decided to take the "along the river" route to work today, which has a maximum speed of 55 mph. It was a cool spring morning (37°F) and the battery stated 13.0 miles of EV was available for the 17.3 mile trip. The defroster would be needed to clear the windshields, so I knew the engine would run from time to time. What I didn't know was that each time it fire up, it would add 1/2 mile to the EV. So, I actually ended up at my parking spot with 1.6 miles of EV left still from the engine running briefly 3 times. It was quite the journey. I didn't know what to expect. Discovering the "EV" emblem was actually an engine-off indicator was pretty sweet. Now everyone will know when 0 RPM is without needing an aftermarket gauge. The system does it all automatically too. The "just drive it" motto is very much something to continue promoting. Anywho, the average for my commute to work ended up being 156 MPG. I can't wait for it to get warmer. Efficiency will easily go higher without the need for cabin heat.
- 3-13-2012** **Afternoon Commute.** At lunch, a good friend and I drove a few blocks down the road to a park. There, I used up the remaining EV while showing off the PHV. When we returned, I plugged in for the first time at work. Leaving there fully recharged was an exciting prospect. Of course, circling down 7 flights of the ramp to exit would mean regenerating electricity from the brakes. Should I put the car in "B" mode to help prevent that? I didn't that time and did indeed gain a tenth of a mile, leaving with 13.1 miles of EV available. On the drive home, I took advantage of HV mode on the short 55 & 50 mph sections of the drive. Being able to toggle out of EV to preserve that electricity later sure was nice. It provided the opportunity for me to take a scenic detour through the suburbs. After all, the 64°F temperature was near the record high for Minnesota this time of year. Needless to say, that was a very enjoyable ride. Overall distance was 36.8 miles, with 0.4 miles of EV remaining upon reaching my driveway. 144 MPG was the resulting efficiency average.

- 3-13-2012** **Newbie Again.** Still having EV available at the end of my commute certainly reinforced the study of real-world data Toyota had collected with the early model. The system is remarkably adept, seeking out efficiency opportunities pundits never addressed, wrecking any prior analysis reports they had come up with. It's difficult to describe how dynamic the power-split system is, despite all the years of arguing with antagonists about the potential. But now finally seeing it in action, taking advantage of externally provided electricity, speaks for itself. The test-drive experience certainly will compel the curious to purchase. There's a whole new excitement to the commute now. I feel like a newbie again!
- 3-14-2012** **Everyday Driving.** Having to run an errand before or after work is quite normal. Today, it was before. So, when I drove up the highway entrance ramp, I switched to HV mode. That immediately stopped the battery depletion, saving EV capacity for me to use later. To my delight, the PHV was still remarkably efficient. So when the 70 mph segment ended 9 miles later, I was ready to switch back, but didn't. What the heck, I kept in HV on that last of 55 mph stretch before getting off. It was mostly EV then. The engine fired up twice for a hard acceleration. That resulted an EV capacity bump... something those arguing against PHV never considered. It's not the penalty they always made it out to be. The engine shuts back off remarkably fast afterward too. The result was arriving at work with 2.7 miles still available. The 22.4 miles of travel averaged 86 MPG. I took the extreme scenic route on the way home, driving through the park along the river rather than using the frontage road on the other side. That may be the final EV especially enjoyable. When I got home, the total distance came to 41.3 miles with an overall efficiency of 75 MPG.
- 3-14-2012** **Terrible Comparison.** An online article was published today. The title was: "*Is the Nissan Leaf or a Toyota Prius a better commuter car?*" Naturally, I assumed it was a comparison between plug-ins. However, no mention of electricity was made. For that matter, it was all quite vague. The only clue to which model of Prius was being compared was: "*Prius cost \$5.02 because it required 1.2 gallons of gas.*" The distance referred to was 64.5 miles. Why? That's horribly arbitrary. Since when is that a typical commute anyway? And why was \$4.19 per gallon selected for the price of a gallon of gas? It was supposedly a lifetime cost analysis, because all the five paragraphs provided was a bunch of numbers. No mention of the vehicle itself was made beyond this though: "*Leaf costs more to buy.*" The article was such a appalling example of journalism it did nothing but frustrate. Some people actually believe what they read without question, assuming the source thoroughly researched the topic and wrote about it without any specific intent. It was presented as an honest inquiry, awarding Prius as the better. To me, it looked like just a filler article written in haste without concern for content quality. That's terrible.

- 3-14-2012** **Charger Security.** How do you prevent someone from taking your 120-volt portable charger when plugged in at a public location (not a charging-station, since they already have locks)? It was the big question that recently emerged, which I had been patiently waiting to provide an answer for. I already had a solution, but no PHV yet. Today, I finally did, plus it was nice outside and I had the time available to take & edit photos. One suggestion had already been made, drilling a larger hole in the trigger-button of the handle. But the lock you could fit in there was tiny and all it did was prevent it from being squeezed. I wanted something that could allow you to secure the charger to the car in a robust way, something not easily overcome. The solution was a new type of lock. It's a cable without the traditional loop at the end. That allows you to quickly & easily pass it through the Prius's tire. Then to lock it to the charger, use a padlock. By running that cable and the charger's cord through the padlock, both would be locked together. It's eloquently simple and quite secure. That should alleviate any worry PHV may have. Here's photos of what I came up with... [photo album 173](#)
- 3-15-2012** **Today's Drive.** Like the day before, I switched over to HV for the highway portion... but only half of it this time. I had no idea just how efficient the system really was. The result of the 16.7 miles of morning commute was 111 MPG with 3.3 miles of EV still remaining. Darn! It could have been even more efficient had I switched back sooner. Oh well, so I did not plug in at work. The commute home was the long way, to the lake to walk the dog with Mom first. This was the day the water was revealed. Only a small bit of ice remaining... the perfect time to begin ownership of a new PHV. Anywho, When I finally did get back, the total miles driven was 58.0 miles. The overall MPG for the day was 71.
- 3-15-2012** **The Rhetoric.** Reading this from a Volt owner shows a glimmer of hope: *"I'm so tired of the "40 mpg highway" hype out there!"* With all the misplaced priorities and the desperation emerging, some sense of cooperation & understanding would eventually emerge. Unfortunately, that comes at a cost. The thought of compromise is quite a challenge for those previously having exclaimed *"vastly superior"* as their status. Thankfully, with enough time, change comes. Anywho, I responded with: Welcome to the club. Some of us have been saying GM is its own worst enemy ever since Cruze rollout out here. It's too bad many here only heard "Prius" regardless of what was said actually about "competition" concerns. Of course, what I focus on now is Prius. The result of my 36.8-mile commute yesterday, which included a recharge at work, was 144 MPG. Tell me when Volt can do the same thing for a MSRP of \$32,000. Whether or not Rolls Royce offers a plug-in [the topic of discussion] has nothing to do with the business-model GM depends upon for sustaining profit.

- 3-15-2012 *The Competition.*** From that same 40 MPG concern came this: *"Put the Volt and Cruze on different ends of the Dealership. Cruze is Volts biggest sales rival; trust me I bought a Cruze over a Volt."* Some are beginning to see that Prius isn't the only competitor to fear. Competition from within GM is nothing new; dismissing it as a problem is though. Hearing awareness about that is a good sign. My reply was: It's good to hear others also showing concern about Cruze. But sales strategy is complex. With Volt having so much higher of a MSRP, waiting an entire year to collect tax-credits is a tough sell. The tax-credit dependency won't work with growing popularity either, since there's only a limited quantity actually available. Cost must be seriously reduced quickly. Just think what the ECO models (aka eAssist) will do to Volt sales. Then of course, you've got people like me promoting affordable plug-ins. That's suppose to be seen as a push to get Volt cost reduced quickly, but most often all that's heard is "Prius". So, there's that distracting from the Cruze rivalry. Big problems rarely only have a single influence.
- 3-16-2012 *EV Default.*** There was an article recently published about PHV from a website which focuses on green cars. They tried their best to deal with the misconceptions caused by the EPA window-sticker information, then contributed their own by interjecting this: *"One final note: The Prius Plug-In Hybrid requires the driver to select EV mode to use battery power when the car starts up. If a driver doesn't do so, the car operates like a regular Prius right off the bat."* Needless to say, that incorrect information presented at the ending like that really stirred some feelings. EV does not have to be selected. I have no idea why they thought it wasn't. So, I posted this: That's not what happens. The default is EV mode. Everyday when I pull my new Prius PHV out of the garage, it's automatically in EV mode until I accelerate onto the 70 mph highway nearby. And when I have switched to HV mode to retain EV capacity for later, the range value actually climbs up a little as I drive... something most people never considered would happen, since they tend to forget how persistent the hybrid system is even while still delivering 50 MPG. Yesterday's commute and running around afterward came to 58 miles. With only a single charge the evening before, the result was 71 MPG. On the day when I only drove the commute and recharged at work too, the result of those 36.8 miles driven was 144 MPG.
- 3-16-2012 *Just Drive It, thoughts.*** The day was starting out great, Friday, of course. The temperature was 50°F degrees out. I was all ready to got too. I connected my ScanGauge to the PHV for the very first time, placed a video camera in front of it, then covered both with a box. That way, my driving wouldn't be influenced by what the gauge was actually telling me. Then I placed another video camera in the window, without any of my usual lighting extras or even cleaning the windshield. This was my *"Just Drive It"* footage. No mode changes. Nothing. I just jumped in the car pressed the power button and drove... while capturing it all on camera. The engine fired up around 50 mph, while acceleration up the ramp to merge onto the 70 mph highway. It stayed on until slowing down to 62 mph, when entering the 55 mph segment 9 miles later. The engine didn't start up again until I got stuck as the lone vehicle at a light with a large bunch of vehicles that caught up with me the moment it turned green. That was the perfect opportunity to show the rapid on & off of the system. To my surprise when I finally got to my parking spot, after driving a total of 16.7 miles, there was still 0.8 miles of EV remaining. That was quite impressive considering the speed of travel and the resulting average of 156 MPG. Needless to say, I'm excited about sharing video of this particular drive.

- 3-16-2012** **Driving Home.** The drive home was really with the video cameras was fun too. I made no effort to keep the engine from starting. Heck, I was just as curious as others about what would happen. So, when I got out onto the thruway, I accelerated hard. It started and ran for a bit. No big deal. Efficiency was still outstanding. Then when I got to the highway, in EV, the engine only fired up briefly. The climb up out of the river valley was at just a little over 55 mph... all in EV. The cruise to the 70 mph section was too. Then when the speed limit changed, I punched it... just as I was passing a 2012 Prius just merging on. At that same moment, I got a bluetooth call for the very first time in the PHV. That new interface & ringer sure got my attention, especially now zipping along the highway. So, I told my friend he the conversation was being picked up by the cameras audio recording and told him about other Prius. The driver was now racing to catch up to me, well aware of what I was driving. He pulled up along side, giving me a big thumbs up. That was quite amusing. The drive itself began with Entune sending me an email informing me the recharge was complete. Shortly after that, there was a text from ChargePoint telling me the charge had stopped. They were playing my song. Time to head out. 103 MPG was the efficiency for the commute home. 121 MPG was the overall efficiency for the entire trip, which was 34.0 miles total with 2 full charges.
- 3-16-2012** **Can't Win Them All.** I just reviewed today's video. The drive home gauge video is nothing but a menu screen. Oops! With so much to setup and so much excitement, I was bound to miss something. So, that footage isn't any good. The drive to work is great... and quite revealing about how well thought out the system is. Seeing sustained high MPG and low RPM at high speed says a lot. And of course, all that driving at 9999 MPG with 0 RPM does too. The flexibility of the system to deal with so much real-world variety give a lot of hope for significantly reducing emissions & consumption. Stay tuned. This is just the first of many. There will be lots more opportunities over time. I just wanted to get something out there right away for those anxiously waiting delivery and craving real-world data... just like 11.5 years! It sure is fun being able to pioneer a new frontier again. So, whatever I can share is a win regardless of when a setup or equipment problem occurs.

3-17-2012 **Did You Know?** I particularly enjoyed posting a comment to this particular forum message: *"I would go for the standard Prius at this point, it's a proven technology with a long history of reliability. When you've beaten it into the ground, the PHEV and EV's will be in their second or third generations and be far more practical!"* Most people don't know of the history. Did you? The 2012 PHV is third generation. Toyota started testing plug-in abilities back with the Iconic model, just a simple doubling of the pack to exploit the 100 km/h EV already built into the design. It was neither practical nor affordable, but it did indeed work. Then with the Gen-III model, Toyota switched from NiMH to Li-Ion. They now had both a larger electric motor and larger gas engine to take advantage of. And they did. It was clearly practical, but still pushed it for affordability. Now, there's the 2012. Cost is within grasp of the mainstream and the system is more refined. Having driven that PHV for almost a week now, I can easily see the revisions Toyota made over that previous model I drove in 2010. Besides the obvious physical size reduction, there's the way it is being used. The previous depleted the pack faster when traveling above the 100 km/h threshold. Overall, that was wasteful when you consider it would only take a few minutes to consume the entire capacity available. So, they refined the system. A quick look at Volt is all it takes to realize use of its engine usage approach is crude in comparison. I easily get 50 MPG after depletion from the PHV. Toyota did much more with much less. Yesterday's commute confirmed that, traveling 16.7 miles and still having 0.7 mile of EV remaining while delivering a 156 MPG average. The other day, I watched the EV range climb whenever the engine started up to provide heat. In short, there is a history already. Toyota's distribution of earlier plug-in models returned a great deal of valuable feedback most people are never aware of. They did the same thing back in 1999 with the Original model Prius here, making revisions before rolling out the Classic to this market. Most people had no idea there was already a previous generation test-driven in the United States by ordinary consumers.

3-17-2012 **EV replenish from HV.** The first time I saw EV range climb while driving, it was 37°F outside and heat/defrost was needed. Since the engine was now running, why not use some of that energy to generate electricity? That made sense. It's taking advantage of the power-split ability, allowing the engine to run in an optimal fashion. Power flow is divided & directed in the efficient portions to the needed components. Today as the EV range approached only 1 mile remaining, I switched over the HV mode. Naturally, the stoplight I was racing to changed sooner than expected. I was stuck there, but witnessing the warm-up cycle for the very first time with an aftermarket gauge. That was intriguing. Warm-up for PHV is different from the regular model. It wants to keep the engine off as long as possible. So, rather than shutting off as soon as the coolant temperature hits 103°F, it continues. PHV attempts to build up a heat reserve to allow it to shut off the engine as quickly as possible when still in HV mode. The result of that engine running, while I was still stationary for that horribly long stoplight, was EV replenish. The range went up. It started at 1.3 and increased to 1.7 miles. I then had to climb up a large hill and glide down the other side. By the time I got to my turn, engine & regen contribution had bumped EV range up to 2.2 miles. That was sweet!

3-18-2012 **Just Drive It, video.** This was my very first drive with the ScanGauge connected to the 2012 Prius PHV. I attached it to my filming rig with a camera, then covered them all with a box to block out all the external light. That meant I couldn't see any data until watching the video capture afterward. So, I was able to "*just drive it*" without any influence. The first thing I noticed afterward was the age and generic nature of that aftermarket gauge was inaccurate reporting of travel speed. Darn! It looks like the gauge is under-reporting by 3 MPH. Oh well, maybe there will be a new version available later for owners like me. That data isn't needed for my driving anyway, especially since I have a HUD (Heads Up Display). The next observation was engine RPM. It's accurate, but slow to refresh and reports when the engine motion has come to a halt... not when fuel is actually cut. Fortunately, the PHV model has an EV indicator, informing you exactly when that fuel consumption has ended rather than waiting for the fuel-less engine to stop spinning. MPG an unknown. Since I couldn't see the gauge while I was driving, I'll have to wait for future drives on the 70 mph highway for comparison. FWT (coolant temperature) is priceless in an fashion. You could clearly observe how I entered the highway with the system still cold, how long it took to warm up, and how long that warmth was retained once returning to EV driving. For me, I especially like seeing the low RPM and high MPG while traveling at high speeds. The values themselves are revisions to the system since the early model PHV. That one drained the battery-pack faster, not taking advantage of the engine as much as this one does. This results in an overall higher efficiency and provides more opportunity for EV later. Remember, while in HV mode, the EV range will rise due to the engine running and regen opportunities. Follow this link to watch the video: [Prius PHV - Just Drive It](#)

3-18-2012 **New Again.** There's a renewed vision of the past now. I'm looking forward to filming the drive I did several times throughout last year, those routes to the coffeeshop and back. Today was my first opportunity to try with a full battery-pack. I took the suburb route. Total distance is 15.6 miles. Since firing up the engine was inevitable with a capacity of 13.1 available, I did it intentionally. First time was by pushing the Power button for the first time ever. It was along a route with a speed limit of just 40 mph. That meant very little need for the engine. My interest was how much EV range would be added from the HV driving and at what temperature the engine would shut off at. Range was about 0.4 miles. It was hard to tell though, since some was consumed by a hill and accelerating from a stop. Plus, there was some gain from regen too. It was a similar situation on the way back. Coolant threshold (while EV is still available) appeared to be 132°F, though that was hard to tell with the value rising so quickly. On the return trip, it looked like the same temperature for the engine shutting off. 213 MPG was the final average from the entire drive.

- 3-19-2012** **Unbelievable.** 3 weeks later, I finally responded to this: "*The PHV gets 6 miles in EV mode and 11 miles in a blended mode of gas + electricity.*" The claim came from an outspoken troublemaker, the one from the big GM forum who mocks me in his signature. Ironically though, he doesn't actually understand that his intent to insult isn't interpreted that way by newbies. The text actually means the opposite. But anger clouds logic. I find it amusing, taking it all in stride instead. Anywho, that comment was his very first post on that daily blog for Volt. He wanted to capitalize on the opportunity to spread the misconception about "range" stemming from the window-sticker information. He knew PHV owners we easily exceeding 11 miles without the engine ever starting. He wanted make people believe that wasn't possible. I simply responded to his desperation with this: EPA estimates don't reflect real-world driving, nor are they intended to. They're just standardized testing results from a variety of measurement criteria provided as a means for comparison. 14 miles of continuous EV driving before the engine started up for the first time was what I experienced on my commute to work this morning in my PHV.
- 3-20-2012** **The Last Wait.** My purchase still isn't complete. To finalize, the process required more waiting. I needed proof from Toyota itself that the PHV delivered to California was immediately transported out of the state for registration in another state. That document was delivered to me this evening. One step closer. Now, I can go to my local department of motor vehicles to submit for title, pay my sales tax, transfer the vanity plate, and officially sell my 2010. It's been quite an adventure along the way. My salesperson was a dream come true. She handled everything wonderfully, from afar. I look forward to a trip out to the West Coast (something I've been dying to do for years) finally happening. The route will take me near the dealership, so I can thank her in person. That will be exciting! So much waiting... but totally worth it. Great memories. My first plug-in. To think about how many years I waited for this to happen. This last step in nothing in comparison. Soon, all will be done. Yeah!
- 3-20-2012** **Affirmations.** Even some of the loyal GM supporters are going tired of the mixed messages about Volt. Recently the CEO "*reaffirmed Volt's existence*" and that made big news. What does that even mean? Supposedly the far-right is claiming the far-left has failed miserably with their support for Volt and see it dying soon. Huh? Since when would any automaker kill a niche like that? Why not just remind people of priorities instead, keep the focus on business objectives? Oh! Not having any specific goals makes that difficult. But at least sarcasm helps us deal with the frustration. Needless to say, affirmations without any clarity are pointless... which explains the weary comments. That was to be expected though. With gas prices high and Earth Day approached, it's really difficult not routinely encountered efficiency technology in everyday discussions. I resonated this: It's nice knowing the game is changing anyway. This month the last of the 2011 will be cleared out and first of the PZEV models available. That's going result in a sales boom with nothing certain for the following month. CEO reaffirmations will have to be clarified at that point, especially with the Prius PHV adding a layer of market complexity for consumers. Simply saying Volt will continue doesn't actually tell us anything. What are the actual plans? How many? What cost? When?

- 3-20-2012** **All Of The Above.** We've seen how Volt turned into a politic pawn. That came about from hyping expectations. Not being realistic leads to trouble later. Sure enough, that's exactly what happened. Part of that was the portrayal of Volt as an EV. When the cold season arrived, engine running for initial warm-up became an everyday occurrence... regardless of how full the battery-pack was. That wrecked EV promoting. Then there's the direct-drive reality, when the engine contributes to thrust at times after the depletion. EV use of an engine for mechanical propulsion violates the definition of even being a SERIES hybrid. Then to make matters even worse, the MPG itself while depleted was well under expectations. Each successive disappointment has contributed to the backlash we're seeing now. President Obama has supported funding on all fronts, investing in "Energy Independence". That doesn't mean the absolute of never using oil anymore, despite all the spin saying that was his original intent. This is why Toyota's approach with PHV irritates some so much. It significantly reduces consumption of gas, rather than eliminating entirely. Remember all that original promotion of Volt's engine as an emergency device, something only ever used to prevent "*range anxiety*" exclusively? That was supposedly why MPG was no longer mentioned following the fallout of the horrible "*230 MPG*" advertisement campaign. Anywho, the point is to invest in solar, wind, hydro, nuclear, ethanol, biodiesel, and yes, more oil drilling. While at the same time, invest in technologies which reduce the consumption of those fuels. That's the all-of-the-above approach. That's quite difference from the one-size-fits-all we've seen with Volt so far. Think about how PHV is much more efficient than traditional vehicles even without plugging in.
- 3-21-2012** **Recharging Twice.** It's already becoming a blur about what I've done when. Thank goodness I'm scrambling to come up with a standardized way of easily documenting detail. Some days I get to recharge at work, others not. It depends upon if I want to and have time to walk over during my lunch. Session times allowed will be 4 hours, later when demand grows. So, I'm seeing how well that works when I have the luxury of doing it whenever now. Also, there's benefit of the "*cold soak*" wait. That's when you allow the battery-pack to rest before fully recharging it. That a good practice for longevity, but by no means necessary for the occasional replenish off right away. Setting the recharge timer (just pressing the clock button upon powering off the system) makes that easy, as well as letting you take advantage of off-peak electric rates. Anywho, I've been snapping photos randomly with my phone to note when certain events happened. It's quite remarkable seeing so many commutes above 100 MPG. Recharging twice in the same day makes that simple. You can literally "*just drive it*" to get that efficiency. Most owners likely won't have the opportunity to recharge a second time. But when charger prices finally drop, especially for the 240-volt type, that will change. Only taking 1.5 hours for a full recharge is really convenient. That's a visit to the coffeeshop, theater, mall, or restaurant.

- 3-22-2012** **Recharge Port Location.** That was a hot topic a few months ago. Then it died entirely. No one has said anything about it since. So, I revived the discussion with new information... that from someone with experience, rather than all of us just speculating. I'm curious what others will have to say about this: After having plugged in several times now using a public charging-station, the location of the port seems obvious. You want it as close to the corner of the vehicle as possible, as well as high as possible. First, in the back corner is more convenient. That makes it higher than what in front by the door would offer. So, you don't have to bend down as far. The corner also means the reach is less of a issue, since cord length and station position are often limited. Second, that makes it more visible. You really don't want anyone to ever bump into it. That back corner reduces that exposure, which you'll notice the first time you park really close to someone else. Third, plugging & unplugging can actually be done from behind, which could be handy for those of you who have tight garages. That wouldn't be possible from a front-side location.
- 3-22-2012** **That Was Fun!** My first drive-thru experience with the PHV was this morning. Tired & hungry, there was little interest in bringing attention to the technology. So, I didn't say anything at the window to pay. However, I had noticed how being close to the wall and under the awning channeled the oscillating dron of the pedestrian warning sound. Turns out, the guy taking my money did too... the moment I lifted my foot off the brake. All of a sudden, he's hanging out the window trying to determine what had just alerted his senses to my vehicle being different. He peered at me dumbfounded. I looked back and said, "Plug-In Prius; 100 Miles Per Gallon". His jaw dropped as I slowly pulled away. Think I made an impression?
- 3-23-2012** **Updates? When?** I posted a note on the homepage of my website 3 weeks ago, stating I had purchase a PHV. Nothing has been updated since then. Regular visitors have no idea of the struggle I've been having to finalize the purchase or even of my transport wait. It's a good thing I'm able to learn new things quickly and take photos every step of the way. So much of what I've experienced since then is documented... just not shared yet. Needless to say, I'm getting email now asking what's happening. One response of reassuring I thought I'd share. After all, it's rather fun keeping some of these thoughts & feeling to look back upon later too. These are exciting memories I'm living out right at this very moment. Anywho: There are lots of updates on the way. Totally new material takes time, and I've been quite busy tackling a variety all at once. It takes forever to use up the first tank of gas with the plug-in too. Learning about all the different situations having EV capacity available presents has been the most rewarding. These initial experiences make me feel like a newbie again. The opportunity be able to check the status of the recharging and interact with the car from your phone is empowering too. It reminds me of my first Prius, back when we first discovered how informative having a screen on the dashboard was. Long story short, there's stuff coming fairly soon. Hang in there.

3-23-2012 **Inflated Prices.** The backlash on rising gas prices sure is taking an interesting turn. The claim by pundits now is that it is intentional, that the prices are being artificially manipulated to encourage the purchase of efficiency vehicles. Of course, none of those making those claims will address oil subsidies. They just blame people who support hybrids & plug-ins responsible for the problem. Those who saw no reason to stop guzzling just a few years ago are not at fault, since their promotion of "*Drill. Baby. Drill.*" supposedly wasn't taken seriously. Could you imagine just using more gas? How would that help our children? Needless to say, some on the big GM forum aren't taking the situation seriously now. Instead, they are lashing out at the success of the new c model of Prius. I contributed to that nonsense, having been called out by several awaiting me to inevitably chime in, with this: Already having a top-selling clean & efficient choice is a good plan for when the oil subsidies are scaled back. GM's wait for the next generation approach is reason for concern. Two-Mode basically died in the meantime. The rebirth of BAS (now eAssist) isn't competitive. And now we wait for an unknown revised Voltec several years from now. Consumers are left wondering what affordable there is to buy... especially when Toyota is demonstrating that continued improvement from diversifying right away can be very effective.

3-23-2012 **Quiet Recall.** It's been a few days now. GM is replacing all 120-volt chargers delivered with Volt. We've known about the overheating issue since last Spring, reading a variety of reports from owners since then. But replacement was always upon request. We just figured there were some bad ones, not a big deal. Though, that is something a test-program like Toyota offered would have revealed... saving GM money and potential reputation harm. Instead, they just act as if nothing is wrong. The quote given from a spokesperson today was, the new ones: "*offer some more consistency in charging*". What the heck? That almost makes it sound like a free upgrade. See how each step along the way distorts the big picture? Few will recall details like this later. For someone not in the market for a new vehicle yet, that may not matter. But for those die-hard supporters who had hoped for game-changer sales are now facing the reality of early adopter, almost as if it was self-fulfilling prophecy. Of course, even that wouldn't seem to be an issue... until you come across a Prius PHV owner not facing any of that. Remember, PHV is already in its third generation. Toyota has had them on the road in the hand of ordinary people for years. So when the first consumer sales began, they already addressed stuff like what GM is doing now. This is why it was so easy to express the "*too little, too slowly*" concern. Those having studied the need understood the complexities, knowing delivery of something both robust & refined upon initial rollout was virtually impossible. Yet, the hype was allowed to persist anyway. In fact, the hype was actually encouraged. So, now with this recall, you wonder if remaining quiet is even possible.

- 3-24-2012** **Inventory & Sales.** I find the spin the die-hard Volt enthusiasts come up with fascinating. Today, it was this about PHV sales: *"You'd think for a car that supposedly has such a high demand there'd not be one available to buy. And yet..."* The topic was actually how Prius c is dramatically outselling Volt. But the inevitable plug-in comparisons came up, and naturally I was more than happy to contribute to the discussion: It has been a common practice for Toyota send a demo/rental model and require the dealer to hold onto it from 90 days. Following that, they are allowed to sell it. That has worked well for those not already in the pre-order queue still wanting to purchase right away. It's a win-win-win situation for all involved. So, seeing 48 PHV currently listed online as available makes sense. What also makes sense is seeing 4,531 Volt available still. That totally explains why GM paused production. The inventory supply is clearly piling up. 21,951 Prius c were sold in Japan last month, along with 35,875 of the regular model. What are your sales predictions for there and here this month?
- 3-24-2012** **Timer Setting.** It's surprisingly easy, but not clear in the owner's manual. I'll have to add information in the User-Guide for it. The timer is used for setting a recharge time, allowing the battery-pack to rest and for you to take advantage of off-peak electricity rates without any interaction later. You program in a START time and and END time once, then they retained for future use. So when you power off the vehicle, it's just a matter of choosing which you want. (I didn't realize the flexibility was available.) The choice is simply made by pressing the button once for START or twice for END. That's it. When you plug in, the system will automatically start based on what time preference you specified. And of course, if the safety system is enabled, you'll get an email informed you of when charging started & ended. There's also a notification email if recharging is interrupted. It's really handy. I take advantage of the timer setting every evening I plug in at home.
- 3-24-2012** **EV Capacity.** I don't use "range" anymore to describe the EV available. If the engine comes on at all, that really confuses matters. Far too many people assume when the engine starts, no more battery depletion is possible. Part of that stems from certain Volt supporters intentionally feeding that misconception. Desperation has made them to mislead... not a good sign, that's for sure. Anywho, I noticed today that the estimate displayed on the screen and what actually happened on the road was almost dead on. I'm not sure how Toyota accomplished such accuracy. But then again, who will notice? My daily driving takes me all over the place, distracting me from observing that kind of a pattern among the randomness of real-world needs. Today was running errands first thing in the morning... short-trips, but without any engine penalty whatsoever. The estimate said 12.8 miles was available. Just after passing the 12.7-mile mark, sure enough, that was indeed the distance. (Depletion was a an impressive transition too, so smooth I wouldn't have even noticed if it wasn't for the EV indicator shutting off.) Will others notice a pattern or even care? Saying around 13 is plenty good for me, especially since the capacity varies anyway. At the ramp the other day, I started with 13.1 miles but it had increased to 13.2 miles upon driving out of the lower gate. Yesterday, 12.9 was displayed. With a commute of 16.7 miles each way, what difference does it make? I bet stating status in terms of capacity... like half or full... will be what owners say. The EV number doesn't relate directly to the resulting MPG anyway.

- 3-24-2012** **Mall Recharging.** From my perspective, the Mall Of America is local. It's only a few minutes away from home. So, I think nothing of just stopping by... forgetting about all the tourists who also come to shop. Today was my first opportunity to pick up a DVD that I ordered there. It hadn't occurred to me that the rest of the world had all decided to stop by too. Holy crap! That was quite a surprise. But for a Saturday afternoon on a nice travel weekend, I should have known better. Oh well. Even though everyone else was scrambling to find a parking spot. I didn't have to. In fact, those "closed" signs indicating status of each level in the ramp meant nothing to me. It was my golden opportunity to exploit the plug. So, I did... driving right through to the EV charging spots, which were there to welcome me. I flashed my ChargePoint card, grabbed the plug, and promptly connected it to the PHV. It was pretty sweet!
- 3-24-2012** **First Tank.** I traveled 685 miles during 2 week of driving. In those 14 days, I recharged 21 times. The refill took 8.504 gallons, which was just 3 miles after the blinking began. That calculated to 80.6 MPG. The values on the Drive-Ratio screen stated 237 miles EV and 439 miles HV. The total for electricity usage was 60 kWh. It will get really interesting later, as the weather warms. Then, I'll be driving on longer weekend trips to go biking. HV is remarkably efficient. You wouldn't have thought there would be a modest improvement over the no-plug model. But that's what I've observed so far. It will bring my average down. I don't care though. Running around on short-trips is so much more efficient now. So, it all works out. That HV/EV toggle button is really nice too. Getting to choose when to deplete is quite empowering. The system is extremely well thought out. Needless to say, I really enjoying the discovery process.
- 3-25-2012** **This Chapter.** It's coming to an end. Only a handful of antagonists on the big GM forum remain (and all have grown silent on the Volt website). So, I decided to end this chapter in hybrid history (the days beyond initial PHV deliveries) with this summarization: It sure is nice having all those blogs documenting what was actually said and believed. Volt enthusiasts refused to state goals prior to rollout. They were always vague or ambiguous with expectations. But even then, rollout disenchantment was obvious. Discussion of the 50 MPG after depletion and "*nicely under \$30,000*" hope was fiercely avoided. Heck, even the "*40 mile*" range quickly changed upon learning about what happens under real-world conditions. Then came disappointing sales, along with a long string of excuses. Whatever. It didn't matter at that point because the answer to the "*Who is the market for Volt?*" question had already been answered. This generation was an early-adopter niche. The next would be for the mainstream, is what they claim now. The goals for PHV still stand... about 20 km (12.4 miles) of EV capacity, 50 MPG after depletion, and \$3-\$5k for the package option. We always knew the engine would run above 100 km/h (62.1 mph). We always knew using the power-split for hard-acceleration and cabin-heat was more efficient than drawing from the battery-pack only. We always knew a much larger capacity would significantly increase cost. To now claim that's not the case is just a waste of time. No sense arguing what is already confirmed by the blogs. You desperately want something to directly compete with and are quite disappointed Prius targets a different market. Oh well. It's not like you didn't know those consumers in the middle were the one responsible for high-volume business-sustaining purchases. We'll discuss more in a week when monthly sales results are released. Later.

- 3-26-2012** **Wow!** It never ceases to amaze me. The level of rhetoric coming from what was supposed to be a game-changer but ended up being a poor-seller vehicle. Since I left that discussion, the spin is that PHV simply cannot compete because Volt is generations ahead. That complete disregard for the "*too little, too slowly*" concern is remarkable. They just focus on battery-capacity and pretend price isn't an issue. To have that much of a disconnect with actual need isn't much of a surprise. Years ago, the trophy-mentality was already a problem. So now after rollout and a struggle to keep attention, they focus on those who were clear & concise all along... which is the part I find extraordinary. Even though I stated very specific goals and pointed out how well the early model Prius plug-in matched them, they just say I said something else. That detail is noted heavily in the blogs, forum posts, all those photos, and a few videos. How can they think attempting to say otherwise will work? Realistically, it doesn't matter. I've started working on the publishing new photos & video, confirming what I said all along. It's not even frustrating anymore. It's more a sense of dismay. They really don't see the big picture. I sure am glad those currently awaiting their PHV delivery do. This very much resembles generation advancements of Prius we've seen in the past. That's a very good sign.
- 3-27-2012** **Ever Wonder?** When competitors can no longer compete, what happens? Well, that's what we just witnessed. It's not pretty. The signs of an end drawing near are when they aren't the slightest bit constructive, when posts don't even make an attempt to stay on topic. You get lots of politics and a complete loss purpose. They'll never admit defeat either, they just disregard the present and focus entirely on a distant future. In other words, they accept 32 MPG highway advertisements as sensible and hope that Volt will magically overcome the shortcomings from its first generation. I'm truly amazed it got so bad. But it does make sense for those who did not study the market to misunderstand its reaction. After all, we saw nearly the very same thing happen with Two-Mode. In other words, the change they were hoping for ended up quite different from what actually occurred.

3-27-2012 **PHV Video.** First-time setup for Eco-Meter filming with the PHV was quite a challenge. I encountered a variety of new problems, like not knowing where the HUD (Heads Up Display) light-sensor was until after laying out all the new glare-mats. Getting the camera mount to stay stuck to the dashboard didn't go so well either. As a result, I forgot to dim the display itself to prevent over-exposure... which means extra edit work later to tone down the excessive glow. The new higher-quality screen with a faster refresh rate left me clueless about what to expect. Then there was the frustration of using up some of the battery-capacity while setting up... which means less available for the drive itself. There's wasn't much I could do to prevent that though. The weather wasn't exactly cooperating either. Sitting there in the car, I was getting bombed by the tree dropping new spring buds onto the windshield, leaving trails of pollen behind... which I didn't remember to wipe off afterward. When I finally started the drive, being hot & tired, I forgot that turning on the outside vent would result in a lower EV capacity value being displayed on the Eco-Meter. Ugh! It automatically assumes a loss from climate-control usage, revising the estimate shown to a lower value. So when I got to the halfway point, I turned it off (note the 0.7-mile increase). Fortunately, there was still plenty remaining to not have confused that information sharing. Despite the hills, traffic, and not starting with a "full" battery, the drive still resulted in 13.0 miles straight of EV travel. That was nice to capture on video. What was odd was the traffic incident at the intersection shortly following the engine start. Watch for the yellow sports car, then the reaction by the police car. Overall, it was an enjoyable experience. It was a casual Summer drive on a beautiful windy day through the suburb to the coffeeshop and back. With a top speed-limit of 45 mph, it's the slowest by most scenic route. Notice the bike-trail on the side; I ride that with the bicycle from time to time. Watching the Eco-Meter, you'll that most of the there's plenty of EV power available. You'll also see the capacity go up a times from hills and regenerative braking. When the engine finally starts near the end, you'll see MPG plummet. That's a strange sensation watch it drop from 999 MPG. You'd feel disappointed if it wasn't for the absolutely outstanding result for that 15.7-mile drive. 282 MPG is incredible! Here's a link for it: [Prius PHV - First Eco-Meter](#)

3-27-2012 **8 Bars.** It's really an interesting twist how the long-time owners of Prius go out of their way to assure newbies that seeing only 6 bars for battery-pack capacity is normal. Counting the 8 slots available, the newbies expect all 8 to be filled... like when you recharge your phone. Of course, they don't take into consideration that only the PHV actually has a plug available. It makes some new owners really concerned. Then naturally, they panic when all 8 are actually filled, not understanding the bleed-off behavior. Why would the system intentionally consume electricity even when the vehicle isn't moving? It doesn't cross their mind that such an approach is for battery longevity. They're so use to replacing their phone every 2 to 3 years, owning the same battery for over 10 years is a concept totally new to them. So, we just provide comfort saying it's ok. That begs the question of what uninformed PHV owners will think. Currently, all those newbies have studied plugging in well. During their long delivery wait, they research extensively. Someday, that won't happen. Someday, a consumer will be able to purchase a PHV immediately... right off the dealer's lot. Then what? 8 bars is a common sight for PHV. But so it seeing the EV capacity increase while driving. Will those plug-in owners have the same concern as those not having a plug? You'd think not. But predicting consumer responses is a very difficult matter.

- 3-27-2012 Political Pawn.** I still shake my head in dismay about how Volt enthusiasts self-inflict problems. They complain and complain about Volt having become a political pawn, yet continue to draw attention by declaring it as government success which is "*far superior technology*" to all else. They learned nothing about the smug attitude and simply don't care about sales. They just keep saying HSD is struggling to survive and totally obsolete at this point. Some even make up stuff, things that don't even make sense if you give it a little thought. The same old propaganda we saw in the past is back. Remember how the hindered sales of Two-Mode led to the same defiance? Back then, as it is now, discussions of a political nature are frowned upon in the big forums. Moderators try to close threads when the topics no longer address the technology or the vehicle itself. But when there's nothing actually left to say except things political in nature, they become hesitant... not wanting something else to get the attention instead. That's actually the sign of being obsolete... when nothing else remains. To think that it all began by focusing on bragging-rights rather than being realistic about expectations. They shot themselves in the foot way back then and are only realizing the consequences of that choice now.
- 3-27-2012 Just Drive It, revision.** Coming from an owner of two Prius already, reading this give reason for pause: "*OK- maybe I'm just naive; maybe I'm a compulsive worrier; but maybe I'm getting in over my head by buying a PiP. I keep reading posts by new PiP drivers about trying to stay in EV, or the car kicking on the gas in EV or the heater not working right and on and on. This is all starting to scare me...*" It's the web-effect, when experts get together to discuss rocket-science and newbies have no idea all you actually have to do to fly it is push the launch button. They just assume everyone else has that level of knowledge, not realizing there countless unheard guest readers observing the few of us extreme to which we analyze the system. They don't realize that's far from the norm, that you don't have to be an engineer to benefit & enjoy Prius. And now the PHV. So, I quickly jumped in with: This is quite fascinating to hear the same old worries from over a decade ago repeated again. You read online about the things of us with automotive & engineering background are observing & trying with our cars and become concerned. Remind yourself that we are the extreme, the few who research every little aspect of the system... quite unlike any ordinary person would do... hence that "*Just Drive It*" motto we came up with all those years ago. PHV is no different than the regular Prius when it comes to driving. You just remove the plug and go. That's it. You may toggle out of the default EV if you want, but that's not necessary. HV will automatically engage when needed, then automatically disengage afterward. It's great that Toyota enabled owners to take advantage of their high flexible design, but not the just slightest bit necessary. However, I think a revision to that motto is now worthwhile, something like: "*Just Plug, Then Drive*"

3-28-2012 **Hold Button.** There's one available on the PHV. Toyota labels it as "HV/EV". That ability to toggle on & off driving in EV mode is great. I've found it very handy driving my PHV. Why use up the EV capacity available right away, knowing you can better use it later and that you'll get 50 MPG cruising on the highway in the meantime? Those supporting Volt have been fiercely against it, claiming there's no benefit. They've worked really hard trying to prevent PHV supporters from drawing attention to that feature missing from Volt. Some Volt owners have even been down right rude & insulting at times, defending the exclusion... despite the fact that there's a "mountain" mode available, which totally contradicts their argument of simplicity. Anywho, it hasn't been pretty. The downplay attempts effectiveness have been mixed, mostly since PHV is still so new. Turns out, we won't have to wait as long as we thought for that to change. The European counterpart to Volt now being rolled out, call Ampera, is working against their effort to undermine... since it offers a "hold" button. Why that's not available here remains a mystery... and many would like an explanation. The last thing Volt supporters wanted was to draw attention to that difference. It's quickly becoming a topic of frustration for them.

3-28-2012 **Coolant Temperatures.** Knowing the temperature of the engine coolant is empowering information. In the Winter, it tells you when warmth is available from the heater. There's no point in turning the fan up to high if the coolant temperature isn't hot yet. The reverse is also true; there's no reason to turn down the fan if there's plenty of heat still available. The other need for heat is to cleanse emissions; too cold won't allow the chemical conversion to occur. The engine will shut off remain off as until until the temperature of the coolant drops below a particular threshold. Having an aftermarket gauge connected to the Prius offers an insight to how it operates. 145°F is the standard threshold. When coolant is at least that warm, the engine will shut off and remain that way until additional heat is needed for cabin warming or battery-pack draw exceeds the "green" level as indicated by the Eco-Meter in the Gen-III Prius. (Neither the Classic nor Iconic models of Prius provide draw information.) 114°F is the ECO threshold. This lower temperature tolerance is a feature introduced with the Gen-III Prius. It allows the heater to extract warmth from coolant much longer than the previous models, which results in the engine remaining off longer. 103°F is the ECO warm-up threshold for Gen-III when the heater is not used and the Prius is not in motion. This feature is nice if you have to wait for a stoplight after only driving a very short distance. 157°F is the EV threshold for the Gen-III Prius. EV mode (up to 24 mph) is available as long as battery capacity is at least 3 bars on the display and coolant temperature stays at least that hot. 130°F is the engine warm-up threshold for Prius PHV. While driving in EV mode (up to 62 mph), the automatic switch to HV mode will not end until coolant temperature warms up to this point. As soon as it does, if power demand is within the EV range, the engine will immediately shut off. Knowing about the 130°F threshold is quite empowering with PHV. If already close to that or above, you know that engine shutoff after using it for hard acceleration will happen surprisingly quick.

- 3-29-2012** **New Signature.** For the first time in a decade, I haven't provided any website updates for an entire month. PHV ownership has altered the parameters of what to report. Learning about the affect having a plug has on real-world driving situations takes time. So, the 3 weeks it took me to recognize some trends from my own observations shouldn't be much of a surprise. How does one simplify presentation enough to make a large volume of data to be collect easy to understand? Just following the new concept of tracking electricity consumption is a challenge. Adding to that the effect it has on MPG under a wide variety of circumstances is enough to make a person go bonkers when you realize engine warm-up and acceleration really mess up the equations. Just a quick glance at the new graph I composed makes that quite clear. That graph is quite vindicating too, easily confirming my claims about generalizations would lead to very inaccurate estimates. Anywho, I finally did come up with a new signature, one that thoroughly conveys my current driving statistics in a plain and easy to understand manner. That's important when you want to share vitals without overdoing. Here's how it debuted: "685 miles 8.504 gallons 60.0 kWh 80.6 MPG"
- 3-30-2012** **Accepting Change.** This week's online education was witnessing firsthand the fallout which comes from realization that market change has taken place. In other words, those stilling clinging onto "*most is best*" mindset struggled with the idea of balance, desperately trying to fight acceptance. Naturally, I was the scapegoat. But their reaction to the messenger meant the message had been received. March is turning out to be a significant month. Prius c is what started it, based on an initial sales report stating it had surpassed Volt's monthly trend in just 3 days. On the big GM forum, trouble was expected from that, especially when there is still such a strong effort there to portray PHV as an EV rather than just acknowledging it as a plug-in hybrid. That's because they focus solely on Volt offering the "*most*" MPG with no regard for cost. That's also why Prius c irritates them so much, which had a major priority of low cost. To make matters worse, their worry of PHV sales is becoming rather blatant. 1,915 were purchased in Japan in February, the first month of sales there. March is the first for here. Just half that makes Volt look bad. But then again, the last of the 2011 Volt were being cleared out with discounts this month and deliveries of the 2012 Volt eligible for HOV access began. So, Volt should have a temporary surge anyway. But that puts a heck of a lot of pressure on next month's expectations. Evidence of change will be difficult to deny then. Needless to say, I found their comments on the subject matter very informative... especially their arguments in favor of traditional vehicles.

3-31-2012 Smashing Prius. The lack of perspective is truly astonishing sometimes. Arguments on the big GM forum have become pointless. If it doesn't happen in the United States, it doesn't matter. With attitude like that, how does one have a constructive discussion about economics & business... especially when they insist the global market is taken into account. Such blatant contradictions amaze. I found this one posted today fantastic: *"Well, if you are looking at sales numbers, the Cruze smashes the Prius quite handily, as does Toyota's own Corolla."* It came from someone who obviously hasn't been looking at the forest, still only seeing the tree directly in front of him. Oh well. Sales results coming soon should change that. Here's what I posted in response: Looking at the big picture (economies of scale from high-volume production) the sales in Japan are reason to acknowledge a shift in priorities. Prius sales surpassed Corolla quite awhile ago, there. Here, they came within striking distance last month... hence all the attention the recent C model rollout has stirred... since March could be the first ever here to make people consider Corolla no longer being the default compact choice anymore. The potential to surpass its sales this year is very realistic. Take a good look at the specs for the regular Prius and the C model. What the others omitted was the fact that Cruze is in between the two... making for an uneven basis of comparison, which they cannot stand. That's same reason why attempts to force PHV into an EV perspective happen so frequently. They cannot claim Volt is vastly superior if it isn't even in the same category. And based on my first 3 weeks of driving a PHV, the real-world data clearly shows their guestimate of how it operates were quite incorrect. Long story short, next month brings about a fresh look from consumers... now that hype & hope are being replaced by actual sales.

3-31-2012 HeadCam Video. Filming 3 different subjects each with different illumination all at the same time presented quite a challenge. For the HUD (Heads Up Display) to be seen properly projected onto the windshield, the camera had to be located extremely close to the driver's eyes. For both the speedometer-cluster and HUD to look sharply focused, waiting for an overcast day to have soft & consistent lighting was essential. For there to be enough EV capacity available to demonstrate a hill-climbing trip, only a single test-drive to calibrate equipment would be possible. Confident I was well prepared, I strapped the GoPro HD video camera onto my head, then pressed record. On the two turns where you could see me in the mirror, I put up an Eco-Meter photo to conceal that. On the one turn where there's only a glimpse of the silly filming setup attached just above my eyes, I allowed that to be seen. It's good to have a sense humor. After all, the content itself is very exciting. Watch the video carefully. There's lots of detail to observe. Driving exclusively in EV like that is not in any way necessary to achieve outstanding MPG. In fact, when the engine does run, you'll find that switch to HV mode will actually replenish a little bit of EV capacity while at the same time deliver the usual 50 MPG you get from Prius even without a plug. I enjoyed filming this. Hope you like watching it, in addition to finding it informative: [Prius PHV - HeadCam](#)

- 4-01-2012 Presumed Purpose.** There are so many newbies now, it's hard to convey a clear intent. I'm still gather initial data and furiously taking photos to capture key moments. Of course, we're so early in the rollout process, it's rather remarkable how much interest there is already. In fact, there are some PHV owners joining the big Prius forum who have no experience with Prius prior to taking delivery. That's quite an endorsement for such a new product. But then again, Toyota planned so far ahead that virtually all but the battery-pack itself was already in place way back when the first 2010 was delivered back in the Spring of 2009. However, there are fundamental questions still being asked: "*I would presume the purpose of the PiP is to reduce the use of gasoline!*" I think it's great that the clean aspect of Prius stirs so little attention, people just take it for granted. Being green has become so easy, it's forgotten about... which is far better than the downplay from antagonists of the past. Anywho, my response to that presumption was: That's actually secondary, though still a high priority. The primary purpose has always been emission reduction. This has been what sets Prius apart from many of the other hybrids. It intentionally consumes gas for the sake of maximum cleansing. MPG while in EV mode with the automatic switch to HV for warm-up is still outstanding. There's also some EV replenish that occurs as a result of the engine running. So unless you drive nothing but short-trips with hard acceleration, the gas usage is somewhat of a wash anyway.
- 4-01-2012 First Road Trip.** The weather finally got nice enough out to take my first bike trip with the PHV. Knowing that Prius would deliver 50 MPG even without taking advantage of the plug-supplied electricity, I was really looking forward to the experience. I get relaxation time on the trail and behind the wheel. That's a great way to spend a weekend day. Of course, the car itself is still a bit stiff. It will take several thousand more miles for break-in to complete. Driving into an intense Spring wind wasn't exactly the best for efficiency either. To make matters worse, my trip home would be in the evening, after the wind had died down. Oh well. The entire trip was 115 miles. 90 of them were on the highway at 65 mph over rolling hills. Only 1 recharge opportunity was available, overnight at home before I left. The end result was 57 MPG. That's not too bad, especially coming from such a new Prius with an EV capacity of just 12 miles. I'm certainly pleased with that. It should creep up some by the peak of Summer, even with A/C use. Road trips like that are totally worth it, even when they cause my Lifetime MPG value to be lower than average.

- 4-01-2012** **Are What They Are.** It's really odd reading a goodbye. There's a mix of feeling. This one came from a long-time Prius owner who leased a Volt. He tried really hard to bridge the gap and keep discussions constructive. Volt owners constantly pushing the EV perspective upon PHV made that especially difficult. He said: "*I have enjoyed the vigorous debates here.*" But with opinions so entrenched, his respect & courteous contributions not making any difference took the joy away... hence just turning focus to the numbers themselves, saying they "*are what they are*" and leaving it at that. It's what I've said for a long time. But the smug still thrives in some places. Regardless of how hard you work to set realistic expectations, some just plain aren't receptive to being practical. All that "*vastly superior*" taunting certainly confirms that. The real-world data will finally change that attitude, we hope. But not even acknowledging the difference in consumers being targeted makes anything else basically futile. Fortunately, the debates themselves should end as the next generation of design is revealed. We all knew this first generation of Volt faced a painful rollout. Some just take longer than others to accept things like that. I personally appreciated his help. It's not often you get someone so will to expend so much time attempting to keep the peace while we waited for those numbers to become available. I wish him well.
- 4-02-2012** **New Misconceptions.** The source hasn't been newbies or published articles or even comments from those articles. It has been Volt enthusiasts. I saw that coming, hence so much focus on them. This was the good example posted on today on the big Prius forum, from Volt owner: "*Prius PHV drivers will want go slow and hyper-mile it to to get to 15 avoiding ice.*" First, notice how incredibly vague that is. What does "slow" actually mean? For that matter, what does "*hyper-mile*" imply? And since when is trying to squeeze out 15 miles of EV driving before the engine starts up even a priority? It's a plug-in Prius. You get a significant MPG boost regardless of how you drive it. It's quite frustrating how they continue to force an EV perspective, rather than just acknowledging the efficiency increase. I tried to refrain from showing any emotion and just post something constructive: Once the engine goes through the warm-up cycle, using it again becomes trivial... because it shuts off so rapidly afterward and replenish a little EV whiles it running. In other words, those of us driving PHV on a regular basis have quickly discovered some of the pre-rollout assumptions didn't reflect the actual design. You'd be surprised how well Toyota studied everyday driving behavior. That early rollout program really paid off. They certainly did their homework to yield high returns for those consumers who simply get behind the wheel and drive. And for those who do want to game the system, PHV offers lots of opportunity using the Eco-Meter and HV/EV button.

- 4-02-2012** **Real-World Data.** It's now available. Maybe it surprises you that it took so long to provide some. But then again, perhaps not. I collected & analyzed, sorting out important from trivial. And I wondered what would be practical to document on a daily, monthly, and tank basis. The first thing that hit me was filling the tank on the last day of the month would no longer be realistic. It takes much longer to use up the gas when there's a plug. Numeric truncation was another concern that popped out at me. The display only shows the whole number. So, short duration reporting could be misleading. What's also misleading is the difference between kWh of electricity the PHV consumes verses how much is actually drawn from the outlet. Some electricity is naturally lost as part of the conversion & storage process. All this needed to be taken into consideration... before even thinking about how to represent it online. The ideal is on-going graphs. With the 2.5 years of daily-driving data I collected from the 2010, that was already well established. However, I didn't have a convention yet for mapping that to the wild fluctuation of MPG yet. Basically, you drive less, the value is higher. But how does one associate that with the lower value shown for distance? And what about plugging in multiple times per day? Accounting for so many factors, not to mention seasonal influence, too awhile. There's was lots to consider. I think I did a fairly decent job of documenting the essentials. Take a look for yourself... [PHV tank data](#) & [PHV daily data](#)
- 4-03-2012** **Smashed By Prius.** Remember this quote from a few days ago: "*Well, if you are looking at sales numbers, the Cruze smashes the Prius quite handily, as does Toyota's own Corolla.*" I couldn't believe such a disconnect with the actual market was made. But then again, we hear about claims not based on reality routinely from politicians. I was so excited to post this March sales numbers, starting my post in response to that quote (again) with: "*Not true anymore.*" and ended with: "*Change happens.*" These were the official tallies... 21,607 Cruze; 28,289 Corolla; 28,711 Prius. The breakdown for Prius was: 891 Prius PHV; 4,875 Prius C; 4,937 Prius V; 18,008 Prius. Even Camry-Hybrid had a great month with 5,400. It was a crushing blow for those who boasted that hybrids were still far from being mainstream. What can they say now? Getting smashed by Prius isn't what they expected. Traditional vehicles were supposed to remain the norm until Volt becomes well established. Finding out the "*too little, too slowly*" concern was a warning that should have been taken seriously is a very problem. What happens now that it's too late?
- 4-03-2012** **10-Foot Pole.** Whoa! Sales results were posted today... and no one on the GM forum wanted to address them. That thread which had been extremely popular just prior to that abruptly went silent. Even using a 10-foot pole (something off topic) was avoided. Nothing. They wanted to stay as distant as possible. My post with totals and the model breakdown was too much to bare. Their expectations weren't met... and mine were. That's a recipe for retaliation. But since I was posting nothing but brief responses, they didn't actually have anything to retaliate with. It's really difficult to spin clear & concise statements. I knew it and they knew it. That made me curious. Each month has brought about new excuses. What would come this time? It was said over and over again to be patient, wait until the second year for that 60,000 annual level to be reached. In fact, some got quite angry when 2 years back when I question how they believed such a sales rate would be possible. They felt insulted. I simply noted their unrealistic claim for reference later... which is now. The priority of price should have been higher. They didn't take that seriously. Now, it's a big problem and the proof is overwhelming. This next month's tally will be very interesting.

- 4-03-2012** **Repeating Questions.** The attempts to discredit are becoming so transparent. Geez! They ask same old question you've been asked countless times already. Then they accuse you of ignoring them when you don't respond. I think they believe the casual reader won't notice the pattern; however, drawing attention to me defeats that. Forum regulars stand out. So making me into a regular on the big GM forum by always targeting me for attack is counter-productive. Yet, they do it anyway. They even call me out when a new thread is started that they know I'll be interested in but haven't posted anything yet. I find it quite educational. After all, my purpose is to confirm market progress and find out what they fear. It's somewhat bizarre how they so unknowingly expose themselves like that. You'd think they'd realize it eventually. But years later, it's still the same thing with each new high efficiency vehicle. When their own vehicle expectations are not met, attack the competition. There's an aspect of disbelief with so many failures caused by not setting realistic goals. Learning from previous mistakes should be a given. But that still hasn't happened. Stop bragging. Just focus on what can actually be delivered rather than always wanting to over-achieve. Long story short, watch for repeating questions. That's a sign.
- 4-04-2012** **Charging Stations.** You have to wonder where some resistance truly comes from. Some origins can be traced to assumptions. Some emerge as the result of misconceptions intentionally being spread. But the resistance itself is a choice of each individual. No one forces them to have a particular attitude. That's their own purgative. The one which always irritated me (and still does) was brand loyalty. Some people actually believe there's no way cooperation among plug-in supporters is actually possible outside of a particular offering. Spanning across the automaker divide is impossible in their minds. The response is thoughtless contradiction, rather than actually considering a mutual gain. So when it comes to charging-station availability, that's just outright dismissed as being capable of contributing anything to the acceptance of plug-in vehicles. It's actually the same old close-mindedness we dealt with in the past with no-plug hybrids. On the big Prius forum, where they try really hard to be constructive, I pointed out a senseless remark (from an individual with a passionate despise for PHV) recently been posted on that daily blog for Volt: "*Public chargers will do nothing, notta, zippo, for plug-in sales.*" Then added: I simply reminded myself his "*vastly superior*" claims fall on many deaf ears now. Seeing charging-stations become available here will indeed be an influence. Focus is shifting to the market in general too, rather than hope & hype of the past. This previous month's sales of Volt included 2011 clearance models and HOV-eligible 2012 models with both federal & state credits. So, it doesn't provide any basis to measure trend. What April, May and June reveals will be telling... especially now that PHV deliveries are in progress. There really isn't an early adopter phase either, since there is already a widely accepted charging standard and PHV is actually on its third generation. There isn't much for misconceptions either. The challenge now is basically setting realistic expectations for ordinary consumers.

- 4-05-2012 First Photos.** My 2012 PHV got dropped off after sunset, so the first photos were at night. Since it included new LED lights which no one had posted any images of yet, I was happy to oblige. It was exciting to see something intended to be unique. After all, that's what the luxury cars have been doing for a little over a year now. Why not a signature look from PHV as well? There were also new lights for the back of the Prius. It was a great opportunity share something entirely new. I didn't hesitate either. Being totally dark outside, it wasn't exactly the way those DRLs would be seen though... the big ones on the bottom, that is. The fancy "Zorro" type slash on top would be seen anytime any light was turned on. Anywho, I managed the darkness by parking near a street light. And in the parking garage the following day, my curiosity compelled me to use the camera to see what those DRL lights looked like under moderate lighting when you could actually see the car. So, I took a photo that way too. It was especially memorable. You can see exactly what I saw, here on this webpage... [photo album 172](#)
- 4-05-2012 Display Photos.** The PHV model provides some new information and new screens. With the video I captured, there were photos to be taken too. It was real-world data, finally. No more wondering or speculating, complete with detail. That's what we've been waiting for... for a very long time. There's lots to share now. That feels great... especially since some of it will help keep the misconceptions from getting out of hand. There's also the reality of those few who intentionally mislead. It all makes the benefit & urgency clear. It's rewarding too. After all, my brief data-collection opportunity 1.5 years ago only represented a few days of travel with an early model. This is the first of many, in an on-going effort to collect & document as much as I can. It's a good way to study the design, starting with those displays you'll see while driving... [photo album 172](#) [photo album 173](#)
- 4-05-2012 More Photos.** My commute on a pleasant Spring day, complete with a recharge at work was documented with my camera. More photos right away is good. It's exciting to have such a stream of real-world readily available. Later on, I'll appreciate for my own reference too. Winter changes everything. This upcoming snow season will be my first with a plug. That means making discoveries firsthand, sharing them with others having those new experiences, and reminding myself how much it will transform after that snow finally melts away. With a Prius, that cold to warm routine each year is quite refreshing. I've looked forward to it for over a decade. Now, it will be even more so, based upon these very photos I just took... [photo album 173](#)
- 4-05-2012 That Other PHV.** Two were delivered to Minnesota. Mine was officially the first. That other PHV was delivered the following morning. The owner drives quite differently too. His trips are shorter, but more frequent. His recharging opportunities are more abundant too. As a result, he just filled up for the first time today. I've already burnt through 2 tanks and am working on my third. His statistics were much more exciting than mine too. 1,097 miles in EV. 516 miles in HV. Whoa! That's quite remarkable. 229 kWh of electricity and 8.75 gallons of gas to travel a total of 1,613 miles. He even had 4 miles of EV capacity remaining at the refill. Doing the math, the result is 192 MPG. That's the type of potential we've all been hoping to see someone take advantage of. With all his city driving, the benefit is quite obvious. It really makes me wonder how others will interpret his real-world data, especially when it's in such contrast to mine. Of course, even mine is impressive. But with such variance, it takes that "*your mileage will vary*" disclaimer to a whole new level.

4-06-2012 **100,000 Sold.** This was asked about the sales record GM just set: "*Where's the problem here? GM are selling more cars that are economical.*" I climbed up on the soapbox: It's the same old "do the minimum" problem we saw prior to the bankruptcy. In fact, the auto task-force raised a "too little, too slowly" concern about the bankruptcy recovery plans. And sure enough, that's the problem being faced now. All that highway-only advertising paints a disappointing picture of what to expect. They're proud of selling 100,000 cars that offer "*30 mpg or Better*". But when you look up the MPG for city, you quickly realize real-world efficiency is going to be must lower than that highway value. Look that the 2013 Malibu eAssist. No level of "percentage improvement" spin can hide the reality that it only gets 29 MPG combined. They've lowered expectations and hoped no one would notice. Remember how 40 MPG use to be the goal? Now it's only 30. Why should people settle for that, especially when you've got Toyota & Ford making that their minimum, on hybrid platforms with will support plug augmentation? Hyundai & Honda are working hard to offer that too. Here we go again with the GM trouble. Read posts about Volt from supporters. There are some who post comments that aren't the slightest bit constructive with little resistance from their colleagues. That's a bad sign. It's the same thing we saw years ago.

4-06-2012 **Done The Math.** What do you say to someone who insults with malice? There are some who are themselves smug, but see it as though they the one being civil. It's an odd situation without a good solution, despite how often we encounter it. After a few comments from others about that emotional expression, I felt the need to chime in too... especially since the originating topic was one Prius owners have grown quite familiar with over the past decade... mathematical equations trying to disprove the value of the hybrid. Of course, this time, we were insulted by not having done the math. Supposedly, that would beyond any doubt prove Prius was not worth it. Ugh! Oh well, this was my discourse: Remind yourself that many of the "break even" analysis of the past treated everyone except hybrids owners as idiots. Hybrid owners took the time to consider the world around them. Everyone else was believing what they read without question. It was mind-boggling that they'd use prices like \$1.69 as the projected price of a gallon of gas in 2010. Even those those later analysis with revisions to \$2.50 were so far off the mark, there was no reason to take them seriously. Did they honestly think the United States would have cheap gas when the rest of the world was already paying so much more? Do they still think that? Prius makes the math easy now... and it still has nothing to do with being seen. Years ago, Prius was the only midsize hatchback available... making it an extremely practical vehicle. That's difficult to deny now that the other automakers offer a midsize hatchback too. There's a balance of priorities. Be weary of any analysis that focuses exclusively on a single trait. Consider the big picture, other factors like emissions rating, vehicle size, purchase price are important too. And remember, efficiency estimates generalize, which means the "your mileage may vary" reminder shouldn't be dismissed as these analysis reports often do.

4-06-2012 **Hypermiling.** Those few remaining Volt troublemakers went on and on trying to discredit me. You know, if you don't like the message, shot the messenger. My strategy was to respond with just 2 or 3 sentences, remaining on topic. It was an implied acknowledgement of having seen their claims, but not actually taking the bait. One recent series of attempts was to cast me as a hypermiler. Of course, anyone who knows me is well aware of how I promote the "*Just Drive It*" motto. So, they cautiously avoided actually providing any definition of what hypermiling actually meant. They'd just imply I was doing something extreme while driving to squeeze out much greater efficiency than an ordinary Prius driver would get. It was shallow & desperate. But when sales fall well below expectations, that response was easy to predict and it was pointless express any emotion. So, I just posted goals again. Interestingly though, the actual definition of hypermiling doesn't make sense with a PHV model Prius. The HV/EV toggle button allows you can take advantage of the system with the greatest of ease. Little effort is needed too, since you quickly become familiar with the results of your routine driving. For example, when I leave work I drive about 1.5 miles through the city in EV. Then I switch to HV, allowing the engine to casually warm up for the next mile of driving. Doing that means no EV capacity drain, as would happen from a rapid mode switch at the moment you accelerate to merge. In fact, the opposite happens. You watch capacity creep up a little bit. That replenish is a nice benefit from FULL hybrids most people didn't realize the plug-in model would see a gain from too. But by using that button, you'll get labeled as a hypermiler... especially since the constructive Volt owners are now speaking out in disappointment from not having the same ability. The troublemakers thrive on bragging rights. So, you can imagine the resentment they feel about this.

4-06-2012 **12.1 Miles.** Some rechargeable batteries perform above specifications initially. That was indeed the case with my PHV. It hadn't occurred to me until I started to witness that. Then it was too late to take lots of photos. In fact, I never did at the highest. That was 13.1 miles. I actually saw 13.3 miles ever so briefly once, as I exited out of the bottom exit from the ramp from having recharged at the top. From my house, I was able to drive 14.0 miles with only EV taking the "Along The River" route, which only has a maximum speed of 55 mph... then ends with a step & curvy climb up at the 13.7 mark. So, I may have actually been able to go a little bit further. But all that's in the past now. 12.1 miles is what the "full" level has settled at, which is definitely above the 11-mile rating from the EPA. That takes me all the way to the on-ramp for the highway to cross the river... which just happens to be all downhill and I never even have to leave the merge lane, since I exit immediately after crossing. That means the engine is only lightly used then, allowing it to warm up quite efficiently. In other words, it was an rewarding morning commute today. I traveled 17.2 miles, which resulted in an average of 226 MPG. That certainly exceeds the 50 MPG from my previous Prius.

- 4-07-2012** **Oops!** The ability to preserve EV capacity for later use has proven quite valuable. So much so, it has become a source of irritation for Volt owners. Why didn't they get that ability here in the United States? It's provided with the European model. I push the HV/EV toggle button whenever I know there's going to be a long span of highway cruising followed by suburb driving afterward. Why would I want to consume the entire capacity on the highway? It depletes quickly when traveling at high speeds in any plug-in vehicle. Since PHV offers 50 MPG while cruising, it's an easy decision to switch over. The fact that EV capacity will usually replenish some during that HV mode travel makes it a no-brainer. However, there can be a penalty. In my case recently, I misjudged on 4 separate occasions... ending up with EV capacity still available upon reaching my destination, where I intended to recharge. Oops! Oh well. I plugged in anyway. This is why I included a decimal-point on my spreadsheet. I had anticipated partials. After all, why not take advantage of the opportunity? Even if it isn't complete, it's still an efficiency boost... which is the point. I'm sure I'll look back at this experiences quite fondly near the year's end, when temperatures plummet. Then, I'll be taking advantage of the engine for heat too. True, you'll still get super-boosted MPG even with the engine running. But again, why consume that EV capacity when you know it could better be used later during your drive?
- 4-07-2012** **Public Charging.** It's intriguing what the plug-in discussions stir. This isn't academic anymore. It's real. People are actually driving plug-in vehicles now. The future has arrived. So naturally, the perspective is somewhat different. Real money will be spent soon. We know what the circumstances are, but still struggle with recommendations about what could be most effective. Today, it was this comment: "*I think charge time might hurt big volume public charging.*" I interjected a dose of perspective which hopefully would stir even more discussion: Whether or not large-volume parking can adequately support public charging becomes an issue, it's not the same situation for smaller businesses... who are always looking for an advantage over the big guys. Coffeeshops are a great example. Restaurants are another. Owners of small lots leasing store space seek out ways to attract business too. Think about how some already offer parking discounts for patronage in areas with high competition. Working recharge appeal into the infrastructure of small businesses, which are seeking out new opportunities anyway, isn't too far of a stretch. Future patronage could include taking the plug into account. In fact, it could even alter the paradigm of location. And what about park & ride usage? Old school thinking just plain doesn't work anymore. New approaches will need to be tried. Some will catch on. Others will flounder. I find it very exciting to participate in the shift.
- 4-07-2012** **Old & New Memories.** I had a variety to share. It felt great being able to stir some old memories while making new ones at the same time. The first of which was my drive yesterday. I was delighted to see the 28 miles of EV on the drive-ratio screen. That's quite a return for just 2 recharges. Next was the capture of what excited me back in October. I was quite surprised to see the ramp at which I park for work installing 82 kWh solar-array. Then there was the bittersweet reminder of a horribly cold sunset I spent out on a desolate country road. It was the perfect setting for the very last photo I took of my 2010 Prius before getting the PHV. That was only a month ago. But it already seems like a distant memory. Lastly, I wanted to include something extremely new, to make that particular webpage complete. It's what you can see on the display while the PHV is recharging. All those photos can be found here... [photo album 174](#)

- 4-08-2012** **More Memories.** There's a photo of what you can see on the display while the PHV is recharging. I also captured the screens right before filling the PHV gas tank for the very first time. I took a photo to capture status at the end of the month too. Then with more highway driving, tank refilling a second time came sooner. So, I documented that as well. It difficult to actually know what's worthwhile still. No pattern has emerged yet. You drive a lot further with the same amount of gas from being able to augment with electricity quite often. All that certainly makes these initial days of owning a plug-in hybrid quite memorable. It's nice taking photos now that I'll be able to look back at years later. See what I mean... [photo album 174](#)
- 4-08-2012** **Slow Progress.** There was an op-ed article written for and posted exclusively on the big GM forum today. I was intrigued. It directly addressed the problems Volt has been struggling with. People seemed to be receptive to the comments made too. Perhaps seeing sales grow has changed attitude from always being on the offensive to being willing to listen first. It had become really bad. Volt was vastly superior, period. Now, some see a rethink is needed. It's progress, though painfully slow. My contribution to that open-minded thread was: I agree with that sentiment focus. Setting expectations different right from the start would have resulted in a very different outcome. The constant comparisons to Prius never made any sense, since supposedly the goal of Volt wasn't the same. Yet, there was a never-ending theme of matching purpose. Making Volt a premiere vehicle would have been a wise move. Treat it like a high-desired niche vehicle rather than something intended for mainstream penetration immediately upon rollout. Prius did not follow the traditional route for introduction of new technologies, it differed from history. It debuted with a sticker-price of just \$19,995. That directly aimed it at middle-market rather than targeting the high-end. Then when it was upgraded in late 2003, there were a variety of new high-end feature offered that weren't even available on Lexus vehicles. Prius carved out it's own packaging niche instead of totally recalibrating for the mainstream... which obviously proved a successful move, based on sales and the reaction from competitors. So what will happen with Volt now to broaden its reach? It's a whole lot easier to offer more than to scale down. Or should becoming affordable not even be a priority for Volt? What if the technology was expanded in low-cost form to a model of Cruze instead? Keep Volt for enthusiasts and create a new offering for high-volume sales.
- 4-08-2012** **Prius c Sighting.** There was immediate recognition, despite the distance. The deep orange color (called "Habanero") in the high-contrast lighting from the setting sun is likely what caught my attention. I looked vigilantly as it approached. Seeing that the car resembled a Prius and had a seemingly larger than usual blue Toyota emblem in the middle, its identity was easy to confirm. So, I made an effort to get a good look at it from behind as that smaller Prius passed by. It was sweet! I wondered what my first Prius c sighting would be like and when it would be. That was nice, on my drive home from spending time with the family celebrating Easter. It sure will be exciting to see them on a regular basis. Prius v is already becoming like that. I see them routinely already.

- 4-08-2012** **Brief History.** That thread about the op-ed has become strangely constructive. That captured my interest. The history of Prius came up several times. I provided the following, trying to address a number of the topics they had stirred up with respect to wanting to know more: Prius wasn't available on dealer's lots until May 2002. For the 1.5 years prior to that, it was direct-order quoted-limited long-wait sales only. So, actual demand was pretty much impossible to gauge. Of course, gas was only a third of the price it is now anyway. Only a tax-deduction available until 2006. That worked out to be \$300 to \$400 for the typical buyer. Sticker-Price was in the low 20's. Profit came from creating Echo afterward, a non-hybrid sibling. The engine was retuned for horsepower instead of emissions & efficiency and the power-split-device replaced with a traditional transmission. That was cheaper to produce, could easily be sold in high-volume, and would help fund advancements with Prius. The plan worked out well too. Sometime in the summer of 2003 several economies-of-scale kicked in to return a profit for Prius itself. Late in 2003, the Iconic model was rolled out and greeted with strong sales immediately, pushing it into the mainstream (60,000 annual) right away. By the time the first tax-credit was offered in January 2006, the reputation of Prius was well established. The purpose of that subsidy was to achieve deep market penetration quickly and stimulate the competition to begin offering their own high-efficiency technology. Toyota's approach was to increase efficiency along the way, keeping it priced for middle-market each step of the way. GM's approach is quite different, shooting for an ideal capacity immediately upon initial rollout, hoping the premium price will drop quickly. Needless to say, it will be fascinating to watch how the market responds over the next few years. Plugging in is new to everyone. Priorities vary. Wants influence purchase decisions. Choices are limited.
- 4-09-2012** **HV using EV capacity, observation.** This weekend was my first opportunity to find out what actually happens over an extended distance over a variety of roads. 60 miles of driving with only a single charge, the first 9 of which were at 70 mph. That meant using the HV/EV toggle button to preserve EV capacity for use later. After that initial highway drive, it slowed to 55 mph, then 50, then a very long stretch at 30. That's when my curiosity peaked. Would the system automatically take full advantage of the EV capacity available, even though I was still in HV mode? Turns out, it does... which is a wise design approach, since STEALTH mode is the most efficient use of overall resources. In other words, you can drive and drive and drive in the Eco-Meter's green zone with a seemingly endless supply of electricity, quite unlike the usual distance limitation of the regular model Prius.
- 4-09-2012** **HV using EV capacity, simple.** The request was made for a simple explanation, wanting to know why indentifying various states of operation even matter. After all, that is counter to the idea of ordinary vehicle ownership... since most people don't have a clue how an engine or transmission actually work. It is difficult enough trying to understand HV and EV when you look closely at the Eco-Meter and notice a variety of different indicators are presented. Now, we're pointing out what they mean when other efficiency-influencing factors like charge-level, power-demand, and outside temperature are included. So, I kept it brief with: When the engine is off, it depletes regardless of mode. When the engine is running and warmed up, capacity is retained & replenished. The term "*STEALTH*" came about to indicate when the engine is off, even though you aren't actually driving in EV mode, since the speed & power thresholds are different.

- 4-09-2012** **HV using EV capacity, awareness.** An excellent question came about from me posting my observation: "*What is the advantage of what you found in your test verses just leaving it in EV?*" Getting to point to aspects of the design, then answer what people ask about it, is quite rewarding. It's gives a good feeling to have a strong understanding of the system... which why I try to share that knowledge with others: You quickly develop a heightened awareness of when extra power is needed and prefer to have the engine warmed prior to that, especially when driving well beyond the EV capacity available. Leaving work, if I drive through the park, there's a very steep climb out of the river valley. But before it, there's a long stretch that's totally flat and only 30 mph. Firing up the engine then very efficiently warms it up. In other words, rather than losing EV from a rapid engine start, you actually end up gaining a little EV. Always keep the overall outcome in mind. Immediate power demand with a cold engine will result in EV capacity being used to compensate, since emission reduction is a primary goal of Prius. With an engine already warmed up, the request for power ends up resulting in a clean & efficient high RPM to both provide thrust and recharge at the same time. Gotta love that.
- 4-10-2012** **HV using EV capacity, documentation.** Inevitably, another one of the well informed had to step in with an explanation of why I would post such information. It concluded with: "*These posts are the documentation of that understanding.*" That brings back memories from over a decade, back when I was the newbie. Things sure have changed over that time. Here's what I had to say about the situation: That's it. Having driven 3 different generations of Prius over the past 11.5 years allows me to provide examples situations that could otherwise go overlooked for many, to appreciate the well thought out design. You could take advantage, of course. But that's true with any vehicle. The fact that Prius differs in subtle ways from other hybrids is extremely difficult to understand without knowing details like this. You'll also find the knowledge quite comforting later, like when Winter arrives. So rather than getting worried about the engine running for cabin heat, you'll feel assured that it's using that gas in the most efficient way possible. That means go ahead and play with the HV/EV button. You'll confirm that most of the time the system will make the best decision about how to use the resources available. So, you can try that at home. But the conclusion for many will in the end be what's been said all along: Just Drive It.

- 4-10-2012** **Repeat Buyers.** There was an article recently published. Same dance. Different song. It was basically a new twist on the old theme that hybrid premium is difficult to justify. I commented with: How is this different from the misleading propaganda we've dealt with in the past? The most obvious repeat is timing. In this case, the article didn't recognize the fact that Prius choices were just beginning to expand. Prius v wasn't available until fourth quarter and neither Prius c or Prius PHV were available until 2012. The next problem is all the Highway MPG advertising, which gives people the impression overall efficiency will be similar. In reality though, Combined MPG is much lower and City under that. Word about that deception only now beginning to stir. Then there's the lack of understanding about plug-in vehicles. It confuses consumers in a market which, unfortunately, includes some people who intentionally spread vague & outdated information with the hope of incorrect conclusions being drawn. Lastly, what if there really is a drop in interest for repeat purchases? There's nothing actually indicating that would be permanent, especially when next generation hybrids are rolled out. After all, look at how quickly people abandoned big SUVs as soon as gas hit \$4. Remember, with the overall quantity of hybrids being purchased now, each new one on the road changes what's considered the norm... regardless of who.
- 4-11-2012** **Another Infobit.** Here's another infobit to add to the awareness & understanding. PHV prefers not to leave EV capacity at full. So when I left home this morning, the switch to HV depleted a little bit anyway. To be specific, the "happy state" seems to be around 82%. Capacity was reduced from 12.1 to 9.9 miles while driving at 70 mph in HV mode. In other words, it has a battery longevity strategy similar to the regular model Prius. That's a good approach. Regen would be wasted if there was no where to store that electricity. The consumption of a small amount of electricity helps with emission reduction too, by allowing the engine to warm up more gracefully rather than a hard switch over. You still have an ample amount of electricity remaining anyway. And of course, normal hybrid system operation results in some recharging. That works out to a win-win situation, although that certainly isn't the impression newbies will get when they first witness the behavior.

- 4-11-2012** **Big Climb.** Today's commute was just a single charge. I got to my parking spot with 7.0 miles remaining. Upon the "big climb" on yet another route home, I had switched to HV and was down to 5.8 miles remaining. At the top, it had risen to 6.0 miles. And since this particular drive brings me higher than needed, there was rolling regen opportunity on the way down. 6.2 miles was the EV capacity by the time the ground had leveled out. Then after some suburb driving in EV, it was back to HV for some 55 mph cruising. Capacity was down to 3.8 miles. Stoplight a few miles down the road. Capacity shot up to 4.2 miles from braking regen. Another stoplight a mile down the road required brakes again. It grew to 4.4 miles. The light turned green, I drove a bit, then it was finally HV depleting EV capacity on a long 30 mph stretch. I thought that would be the end of the story. I'd leave the store I had just driven to in EV, using up the last of the capacity. Turns out, the most exciting hadn't happened yet... Right before I used up those final electrons, I pushed the HV/EV button one last time. It didn't make any difference. That 0.1 value vanished and I was back to ordinary hybrid driving... or so I thought. EV capacity returned and increased as I drove. Huh? I certainly wasn't expecting 0.8 miles by the time I had reached my driveway. Having pushed that button at the last moment had quite an effect. My 2010 most definitely wouldn't have generated electricity like that. 75 MPG overall from 36.0 miles of driving, with EV still remaining. That's fantastic from a 4.4 kWh battery-pack without recharging. Now I'm more curious than ever how the system will perform in the winter. The interplay between battery, engine, and motors is proving to be extremely well thought out.
- 4-11-2012** **Buffer Mode.** My conclusion is there's actually another operational state, as I've noted with this: Buffer mode is turning out to be quite an unexpected bonus. I drove another 15.5 miles through the suburbs with a variety of power demands. Nothing caused the system to let go of that final 0.1 mile of EV capacity. 3 times I watched it go from almost gone to 0.9 miles. The second half of my evening drive yielded an average of 59 MPG. That's pretty darn good without any electricity from plugging in. The amount of generated electricity being passed back & forth between engine, motor, battery, and road is impressive. Following an inevitable depletion, I had anticipated the same behavior my 2010 would have delivered. Turns out, PHV has been configured to take advantage of the bigger & better battery. It operates in a way we hadn't considered. Of course, weren't sure Toyota would even provide a HV/EV toggle option. Turns out they they did and it's surprisingly easy to take advantage of.

- 4-12-2012** **11 Mile Range.** When bragging rights dominate discussions, it should be obvious that a deeper look should be taken. Typically, there's some type of tradeoff involved. With the case of battery-capacity, that should be obvious... even among the division growing between Volt supporters. There's some who couldn't care less what the cost is. With others, they're deeply concerned about the high price and the approaching tax-credit expiration. What will become of that divide? Who knows. History tells us it likely won't be compromise that makes everyone happy. After all, you cannot have a halo vehicle that's also common. Those are fundamental opposites. Either it sells in high-volume or it doesn't. Prius is targeting at the masses. It clearly could have offered a larger engine, motor, or battery, but didn't. It could have been offered in a less practical shape too, but didn't. There's a balance of priorities which is able to draw sales, despite being portrayed as a negative by the competition. That's why I especially liked this quote posted today: *"Every time the PiP is criticized for its "11 mile range", my response is so what? A regular Prius has a 1 mile EV range, and look at what it can do, the success it is."* That sums up the situation well.
- 4-12-2012** **Argument Points.** Remember them? Most people won't. Newbies won't even realize certain things were even an issue. Antagonists will though. But there's not much they can do once an exploited misconception has been debunked. The first one that comes to mind for me is the monotonous "cold engine" claim. There were some Volt enthusiasts wanting to undermine PHV who went on and on about how once EV capacity was depleted, the switch over to HV would cause the engine to run at a very high RPM. That's bad when an engine is cold. Emissions cannot be cleansed thoroughly until heat is available. Turns out though, they were quite wrong. PHV always has some reserve electricity stored for warming up. The transition from EV to HV uses it, allowing the engine to run at a lower RPM at first. Knowing that now, the claim is now just a memory. A recent argument point was EV capacity, claiming only 6 miles was available. That originated from the EPA estimate, not real-world driving. They ignored 11-mile overall capacity, focusing solely on the first time the engine started up on that particular measurement. Complete disregard for how the test's purpose was a dead giveaway they weren't being constructive. But it took real-world data to get them to stop. They did immediately upon hearing some owners driving 14 miles before the engine started. Blended efficiency is one more strong argument point that suddenly vanished. No matter how many times I provided evidence of a MPG boost, they just kept dismissing it as an extreme example. But then when all of the new PHV owners began reporting the same thing, the false claim instantly stopped. The experiences reported from ordinary people driving their new plug-in Prius have made a huge difference, bringing many arguments of the past to an end. That's great!

- 4-13-2012 High-Volume Profitable Sales.** That daily blog for Volt is down to just random news events now, many of which aren't even about Volt anymore. The well known posters are almost all long since gone. But for the few who remain, they pounced today. The topic was just a repeat post of real-world Volt data compared to generalized estimates on how the PHV may operate, an opportunity some still holding on to the past year for. But knowing that the market & purpose are so different, what would that accomplish? My guess is it was just an attempt to retain the spotlight. So, I contributed my real-world data in response to a post pointing out their rehashing of assumptions. Within about an hour, there were already 7 negative votes from my spreadsheet with 2 graphs and this single comment: "*Real-World data tells a very different story.*" Predictably, there was one individual who personally attacked. I find that incredibly telling, not that it really makes a difference. Those few enthusiasts likely aren't representative of most owners anyway. For that matter, we know ordinary mainstream consumers aren't concerned with the details anyway. We know the purpose is to significantly improvement emissions & consumption. There isn't actually a goal to eliminate. Their bragging rights of most EV or most MPG don't address the reality of high-volume profitable sales. It's real-world data that makes a difference. There's a practical balance of purchase priorities you just can't overlook.
- 4-13-2012 Not The Same.** There has been a common theme on both the daily blog and the big GM forum. You mention Prius and they feel threatened. In fact, the fear has become so ingrained into their thought process, some have even come to calling it the "P" word. It's the continued false belief that you are somehow trying to prove it is the best. Pretty much no matter what you say, they think you mean something else. That's probably why so few remain, leaving only die-hard participants. The others got tired of the nonsense and simply moved on... especially due to the intentional provoking. All that bait routinely dropped with the hope of having the opportunity to argue "*vastly superior*" claims, gets old & repetitive. For the most part, I don't bother anymore. Just sticking to real-world data has been working well... extremely well, as a matter of fact. One of the outspoken troublemakers suddenly came to the realization that my providing of operational results from the PHV model actually proved that Volt is not the same. It's what I've been saying for years. But they were so scared of not market reaction they couldn't see the obvious. The moment he pointed that out to the others, all those negative votes vanished. Duh! Their trophy-mentality clouded judgment to the point that they ended up arguing against themselves. That analogy of a panicking animal desperate to escape a predator really fit. Thank goodness they finally see the situation. Unfortunately, there's still the reality of not meeting sales expectation, but we can celebrate this small victory.

- 4-13-2012** **Not Ready.** The early adopter mindset seems to be spilling over from enthusiast to automaker. This opinion pops up from time to time, more often now: "*IMHO, for now GM wants the Volt to remain a low-volume full-price specialty car.*" That's not the case for Toyota. This first year, rollout of the PHV model will be to 3 different markets at the same time... Japan, Europe, and the United States in limited areas. Next year, it will be all of the United States. In the meantime, the infrastructure for public charging-stations and aftermarket charge upgrades at home are being established. Ford will be joining in the end of the year too, with their one plug-in model based on a hybrid that won't even be rolled out until about June. A faster pace is what we need. Watching traditional vehicles compete for high-efficiency sales is a big problem. The opportunity to capture the mainstream shouldn't be allowed to slip away. Remember the "*too little, too slowly*" concern? It's playing out right now. Not being ready makes acceptance even more of a challenge. It's a moving target and getting use to paying higher gas prices is an unfortunate reality. As they say, strike while the iron is hot.
- 4-13-2012** **Electric Bill.** The previous billing period was for 33 days. It ended exactly 1 week prior to my first plugging in. This month's bill spanned 30 days, of which 3 weeks worth included PHV ownership. That meant at least 21 times. Doing the math, taking into account 3.1 kWh per recharge, it was reasonable to expect about 65 added to my regular household consumption. Instead, it was 30 less. Huh? Apparently, I'm not well aware of all the appliance draws at home. My guess is the natural-gas furnace was responsible for that. Long data collection may reveal some type of pattern. But then again, at 10.5 cents per kWh, it's not much of an expense. So for 30 nightly recharges, we're only talking about \$10 worth of electricity anyway. Looking that the gas consumption it offsets, using very crude estimations and guessing on gas price, I'm spending somewhere around \$35 less per month on gas. That's nice considering how much I drive. For those who don't drive 20,000 miles annually, they'll spend much less. The benefit is obvious no matter what your driving is.
- 4-14-2012** **EV mode EV, question.** The big question came up, what actually counts as EV miles? The tally on the Drive-Ratio screen isn't clear. Are miles driven while the "EV" symbol is illuminated in HV mode included? Should they be? Since EV mode is the default and you must push the button to switch to HV driving, that explicit choice is a decision not to use EV. So, it does tend to make sense to not identify any engine-off driving then as EV. After all, the HV mode is basically just regular Prius operation but with a Li-Ion battery rather than NiMH. Wanting to distinguish travel which take full advantage utilizes the system to the fullest is quite informative... and it does support future efforts. After all, the previous model of Prius had an EV button that didn't offer as much. Now, with this first plug-in, EV is improved upon. We are already aware of that CITY button not included in the initial rollout here. It offers the ability to push the electric ability even further, something markets with much higher traffic-density and low-emission restriction zones can take advantage of right away. Our current need here is different, especially due to the penetration barrier caused by consumer education and anti-plug propaganda... for that matter, the anti-hybrid push. So, I set out to answer the question.

- 4-14-2012** **EV mode EV, answer.** I figured a biking trip up to northern Minnesota would do the trick. It turned out to be 188 miles of driving, all in HV mode... none of which were counted as EV, despite driven several miles with the "EV" indicator illuminated. I even went out of my way and drove about 1.5 extra at the end of the trip without the engine ever starting. It made no difference. Being in HV mode means no official EV. Of course, you still get outstanding efficiency. But without the type of tracking having been established from this first PHV, how would advancements of the next be measured? With MPG varying dramatically from owner to owner, that really is the only simple system available for noting improved design. Looking at the big picture help, especially when in context of the approach having been taken over the past 12 years. It makes sense. That's why my initial gut reaction was what it ended up to actually be. I hypothesized the counting could include some HV operation. But that's too much of a short-term interpretation. The system will continue to evolve over time. As cost warrants, components will improve. The catch is affordability... something others still have a difficult time accepting. Just think what the EV range stated now will look like a decade from now, in the common car we encounter every day. There will naturally be niche vehicles offering far more, but that's not the purpose of Prius. By the way, the result of that 188-mile drive with the bikes on back was 46 MPG.
- 4-15-2012** **2013 Volt.** Things just took a very strange turn. Events like this are why blogging enthralls some people. You can document & read reactions to the unexpected, as they happen... and this one certainly qualifies. GM just released details on the 2013 model of Volt. What the heck? It's only April. How can announcing changes so far in advance be helpful? Won't that harm current sales? First thing I noticed was the removal of bluetooth for phone. Support for it didn't come until recently. It still had some quirks to be worked out too, quite unlike what Toyota has offered with Prius since 2003. Bluetooth also took money away from their OnStar pay service, since that was what owners had used for calls prior to being able to connect with their own phone via Bluetooth. Next thing I noticed was the introduction of the hold button for this market. Volt will be getting it after all. That put particular owners are in a difficult position. They had argued fiercely that having a feature which behaved like the PHV model Prius was useless. Yet, GM offers it in Europe now and will next year be offering it here too. Now they'll sound hypocritical and be missing a feature on their own Volt. Funny how things work out. Then of course, the big concern has been price. Will that heavy hyped drop finally happen? The answer appears to be no. Many of the features added actually rather nice, making it extremely difficult for anyone to argue that Volt isn't embracing the status of halo... becoming a well established niche rather than striving to be a mainstream vehicle. GM did make it look even more like a traditional sedan. That supposedly is a draw. The bottom part of the liftgate will be the same color as the vehicle, rather than the standout black it has now. Oh well, this makes the 2012 sales even more of a tale to tell later.

4-16-2012 The Aftermath. Situations can change quickly. That's certainly the case with the HOLD mode for Volt. Owners finding out about it are already sounding off, saying they hope the upgrade will be offered retroactively. We've even had real-world examples stated how that would be helpful. It's drowning out the rhetoric of the past. Those arguments from antagonists fiercely trying to keep Volt from being shown to have shortcomings are becoming an embarrassment. I hadn't expected humility to be an ally. That's nice. Suddenly, I have others on my side... who would wonder why in the world anyone could claim that the suggestion to offer that button here was really just an effort to promote Prius. They honestly thought that ability could somehow undermine. When they fear diversity, that's a sign something is wrong. Now it's out in the open. Obviously, I feel vindicated too. How could Volt not change? With the sales struggle, simply waiting for the market to change instead wasn't wise. Of course, there are still some who are dead set against the idea of change. But their voice is getting drown out by newbies repeating what I said last year. That means I don't have to say much anymore. The newbie desire to embrace sensible solutions overcomes the senseless arguments of the past. It still amazes me that it had got so bad, threads on the big GM forum were simply closed rather than actually addressing the problem. Fewer barriers now takes us another step closer to actually getting something affordable.

4-16-2012 Owners Prius Photos. On the big Prius forum, there was a long-running thread where owners would post photos of their Prius. It was very exciting to see them. Such variety exists, which people wouldn't be exposed to any other way. Routine addition of new photos to see was great. No one had started one for PHV yet. I stumbled across a fantastic opportunity to do exactly that, my escape up north. Along that 188-mile drive, I stopped at a public-landing along a river. This was the same location I took photos at over a decade ago with my Classic Prius. It was the ideal setting for the very first scenic photo of the PHV. Spring had arrived. It was a beautiful afternoon, 72°F and sunny. I had 2 bikes on the back, making the purpose of my long trip obvious. Unfortunately, the weather didn't go as planned. It rained all the following day. Heavy downfalls with blustery wind didn't make for good biking conditions, so we waited. It got colder. Overnight, the rain turned to snow. I woke up to discover my destination had transformed into a winter wonderland. Even though that was far from what I had hoped, it was a golden opportunity. 28°F with 3 inches of fresh snow blanketing everything was a dream come true for photo taking. So, I went nuts with the camera and started a new thread to share what I saw.

- 4-16-2012** **Below Freezing Temperatures.** When saying "below freezing", I mean a few degrees under 32°F. To think that even the meaning of that was twisted in those Volt battles of the past. But when desperate, certain individuals were willing to try just about anything to retain attention. It's too bad things got so ugly. But then again, my first experience with the PHV model Prius at a below freezing temperature was quite uneventful... not what antagonists were hoping for. I drove 4 miles in EV mode. Frequent stops always made photo sessions a bit annoying, since engine would have to run so frequently with the regular Prius. But with the PHV, having far more electricity available and a faster electric-only speed, the travel from location to location was quite pleasant. Being that cold made it even better. Some claimed that wouldn't be possible. I proved it clearly is, even when the Prius sits out in the cold all night. Knowing that will make the inevitable Winter conditions, which Prius already did better than traditional vehicles, even more pleasant to deal with. But looking outside right now and seeing all that snow still, I'm looking forward to Spring... which was here just a few days ago. Now, it's gone!
- 4-17-2012** **Brutal Opposition.** Looking back, it got pretty nasty. Volt owners were deeply angered by the idea of a HOLD mode. Anywho who brought up the topic was looked upon as suspicious, somehow having ill intent. I was amazed by that. Opposition to the idea of not totally depleting the battery-pack prior to starting the engine was brutal. It would make Volt more of a hybrid than an electric vehicle. The enthusiasts didn't like that at all... which is why they fought against it so much. Hybrid equals Prius, in their mind. Being associated with Prius was bad... since Volt to them was more a matter of bragging-rights rather than supporting a vehicle for the masses. After all, if Volt were to become as common as Prius, there wouldn't be anything to stand out anymore. It's a self-defeating situation... which has already defeated them. Newbies are sounding off. It's as if fighting last year never happened. Wow! Of course, that means a widened appeal and less focus on EV. In the past when a high-opposed situation suddenly took an abrupt turn, those who had been stirring the trouble vanish. It should be interesting to see what happens with this. I'm looking forward to constructive discussion. That propaganda of the past was unbelievable.
- 4-18-2012** **Attitude Transformation.** It certainly is odd watching the divide grow. The few remain antagonists continue to belittle & mislead about Prius. One such attempt yesterday was trying to state the recent update for Prius v was the very same problem as a recall for the Iconic model. He literally just made that up. No SSC number to verify his claim. No detail of any kind. Just a bogus statement about Toyota having repeated issues from not being properly fixed. This is the same individual who owns a Volt and uses "*pathetic*" when describing Prius, so he's basically a troublemaker who simply doesn't care. Thank goodness most are nothing like him. In fact, there are more and more Volt owners & enthusiasts who don't see a problem with offering a second more affordable model. They don't see a shift of priorities from capacity & power to being affordable for the masses. Old beliefs die hard. Remember the acceleration wars of the past? I sure am glad that nonsense is over. Having the attitude of former foes transform is the most telling. It hits you as strange to hear them agree now rather than argue. In other words, consumer needs are finally being addressed... even if the acknowledgement is only with an implicit reference to sales. Direct isn't necessary anyway. We are witnessing a change.

- 4-19-2012** **Smallest Capacity.** Doing more with less has been a high priority for PHV design. Not being affordable means not selling many. That's basic economics, a concept which continues to elude some. It's much, much easier to increase capacity than it is to reduce. Finding the smallest size that would be still be practical was a very big deal. As the price of battery-capacity drops, it will make the plug-in model more and more appealing. After all, you don't have to sacrifice any MPG after depletion. It's still an outstanding hybrid even without plugging in. Electricity supplied from an outlet enhances operation. Being rolled out mid-cycle is a reality always overlooked. No thought is given to implementation constraints... which is why the 2012 PHV is believed to be first generation. The prior two designs are almost never mentioned in articles and are summarily dismissed when brought up in comments afterward. Think about what the next generation of Prius will offer. Knowing that this PHV currently offers enough room under the false floor for an addition kWh, it makes you wonder what will happen next. A drop in battery cost could result in more capacity being offered, keeping the price the same. Or if it turns out that the current capacity is well accepted, it's physical size could shrink to offer even more hidden storage. That's thinking ahead. Toyota allowed themselves some flexibility to respond to market demand.
- 4-20-2012** **Never Happy.** It is somewhat tragic to step back and analyze the situation. You can't please all the people all the time. Yet, that's the standard to which some are held. I get that all the time. Every time it reminds me that some holding positions of power, especially elected officials, have to deal with that pressure constantly. No matter what they say, someone won't like it. Of course, then there are a few who are never happy. What they decided to endorse didn't meet expectations. You become the scapegoat, someone to blame for their misfortune because you chose wisely. My way of gauging success is when the count of those who oppose are a very small percentage. In the computer world, the goal is to deliver 90 percent of what was requested... since that final 10 percent is often extremely expensive to address initially... and more often than not, priorities shift upon using that first version anyway. I've seen that outcome repeat itself countless times over the decades. So, why would an attempt like Volt be any different? Reaching middle-market makes the need for adjustment especially important. After all, once the enthusiasts make their purchase, who's left? Mainstream sales down come from making them happy, not what an enthusiast wants.
- 4-20-2012** **Great Road Trip.** It was a nagging question with an uncertain answer. My first road trip left me wondering. The impression was efficiency would be equal to or slightly better than a regular Prius. But with the PHV not broken in yet and the freezing-point so near, patience was required. Over 2,000 miles on the odometer and warmer, it was now time to find out. 176 miles driven, using 9 miles of EV capacity, maximum speed of 60 mph, the temperature was 50°F. With the greatest of ease, the result was 62 MPG. Gotta like that. I sure am looking forward an ordinary Summer experience. Spring has given me a taste of what's to come. It certainly was a enjoyable destination. We went to the headwaters of the mighty Mississippi River, where it's nothing but a tiny stream flowing out of a lake. That's exciting to walk across. The incredibly efficient travel to get there made it even better, a great road trip.

- 4-21-2012** **Ugly Conditions.** Well, my PHV certainly is broken in now. Today's road trip was a demanding 194 miles. There was a steady and sometimes heavy rain the entire time. The temperature was 43°F, requiring both defrost & heat to continuously run. Two bikes were strapped into a rack on back, creating quite a bit of drag cutting through the air & water. There was no opportunity to plug in. The interior was stuffed with cargo (including a 3-wheel recumbent). That made for very ugly spring travel conditions. I wasn't exactly thrilled by the thought of what the outcome would be. Although this drive is really going to bring down lifetime average, it does provide real-world data in far from an ideal situation. Fortunately, even when Prius is challenged, it still shines. The result display was 39 MPG. What else could accomplish the same feat, especially without plugging in?
- 4-22-2012** **Horribly Vague.** There have been abundant examples of pointless comments over the years, so it's a big source of frustration to see that continue. This was the one posted today: *"People were predicting the Cruze's outright failure and boy have they been surprised. I predict modest uptake for the first year or so (as long as the diesel engine comes with good MPG, a slight price increase, etc.)"* Notice how there's no detail whatsoever. It's so horribly vague, the failure judgment is totally subjective. Nothing to actually measure was provided. Without anything quantitative, how can a proper conclusion be drawn? What sales count would qualify as successful? What is a good MPG to expect? What does *"slight"* mean with respect to price? This all comes back to stating goals. If they don't, you can basically say anything you want afterward. Leaving such an opportunity to spin outcome is senseless. Yet, that's what keeps happening anyway. When will they learn?
- 4-22-2012** **Being Trolled.** Someone started an editorial type thread on the big GM forum, attempting to address the topic of mainstream buyers rather than the usual *"zealot"* crowd (those who support a brand without ever questioning executive decisions). After all, there's good reason to take a better look at the market when vehicles like the Fiat 500 outselling Volt by a surprisingly wide margin (3,712 verses 2,289). The same defenders came to action. It didn't take long for the original-poster to be labeled as a troublemaker and for the compliant to be posted about being trolled. That's the typical response when they don't like the topic. It's Earth Day, so I felt obliged to join in the discussion: Just stick to facts then. What are consumer needs? If GM also delivers something else, that's great! Having choice is a definite plus. How long will it be until an affordable model of Volt is available? Many sources, including Lutz himself, have stated \$30,000 as the target price. If 2015 is the anticipated rollout, how will such a drop of cost be achieved? Remember, the \$7,500 tax-credit would have expired by then. Don't forget the competition either. And I don't mean that from Toyota or Ford. I mean from GM itself. The push of diesel & eAssist will make selling Volt even more of a challenge.

- 4-22-2012** **Oil Reality.** No matter what the spin is about waiting for technology costs to drop, the reality is that oil is expensive now and we are heavily dependent upon it. That "*too little, too slowly*" concern clearly wasn't taken seriously. Rather than building platforms to expand upon, there are haphazard shots at delivering a high-efficiency solution. Volt is obviously the poster-child for "*over promise, under deliver*". Changing that would be great. There isn't the luxury of time. Offering larger motors & batteries is nice, but definitely not required. That's a want, not a need. Ford is preparing to deliver a sensible new hybrid, one which will also offer the option of a plug. Hopefully, that will stir the market enough to focus attention on actual priorities rather than continuing with the propaganda. It's so annoying to watch time pass by without actually accomplishing anything. Traditional sales are a stimulant too, a clue that progress is more of a struggle than the hype would lead you to believe. Thankfully, the reality of \$103.88 per barrel pricing for oil this week is counter-balanced by a solution establishing realistic expectations. The PHV model Prius delivers the MPG boost it was intended to at a price within reach of middle-market today, not years from now.
- 4-23-2012** **14.1 Miles.** It had been quite awhile since my last opportunity to take the long way to work. It a more casual drive, the most efficient too. The slower road speeds allow me to enjoy every last electron of plug-supplied electricity. 14.1 is the longest distance I've seen... and I did again today too. Unfortunately, that end is midway up a very steep climb. So, there's no way to find out how much further I could actually go. Of course, other parts of the drive are far from flat too. But running out just before reaching a plateau is somewhat of a bummer. Then there's more climbing later. Following that is a very, very long decent... hence the best MPG on that particular route. However, what I find intriguing is that the maximum amount of EV travel isn't always the most efficient. That didn't come into play today though. My intent was to see how much I could squeeze out, especially when among morning commute traffic. Using the engine for heavy acceleration demands is actually better. But explaining how that's possible is quite a challenge. So, I'm starting with a footnote about capacity potential instead. Later, I'll get into when it's best to take advantage of that HV/EV button.
- 4-24-2012** **Chrysler Plug-In.** The automaker has begun delivering plug-in hybrids for data collection. Ultimately, there will be 25 Town & Country minivans and 160 Ram pickups. The cost is split between the automaker itself and DOE (Department of Energy) for a cost of \$26 million for the minivans and \$97 million for the pickups. There wasn't any detail whatsoever in the press-release. It was just a generic "look at we are doing" type article for Earth Day. Supposedly, the technology being used is Two-Mode still. But nothing about motors or battery was mentioned. Heck, there wasn't anything said about MPG either. No date. No price. No expectations of any sort. Oh well, at least you can't accuse them of hype.

- 4-24-2012** **55 @ 110.** Today's driving around came to a total of 55 miles. I started with a full charge at home, then recharged entirely at work. The result after the commute both ways and side trip to walk the dog was 110 MPG. That's great! I wish all days could be like that. Some are actually better, but more aren't that good. My expectation of averaging around 75 is still quite realistic... at least enough to make the MPG boost obvious. My influence of long highway trips and the depths Winter here in Minnesota make overall efficiency uncertain. But you get the idea. The fact that adding 2.8 kWh of capacity plus a plug (along with the switch to lithium) could results in such an improvement is the point... especially when so much importance was put on cost. There was a clear priority of configuring the design in a way to reach a very wide market. Real-World data like today's clearly confirms that choice was a wise one.
- 4-24-2012** **Vague & Ambiguous.** It's hard to believe the same old nonsense continues. This wasn't much of a surprise though. GM launched a new Volt promotional website... which included a "*Total gallons of fuel saved*" value. No detail was provided though. A footnote buried within a link at the bottom of the homepage only made reference to "*Official MPG for US passenger cars*". Upon digging for the actual value from other internet sources, we found out the official value was just 27.5 MPG. It was a great example of how standards have been lowered. Why wouldn't they just compare Volt to itself, stating how much the battery usage offsets engine usage? After all, that's what PHV does. Of course, Volt comes up way short of the 50 MPG delivered by PHV after depletion. Naturally, electricity consumption was disregarded entirely too. Even the charging-station reports available online provide kWh information. Why doesn't GM? Isn't the point to give a clear representation of what the plug-supplied electricity accomplishes? Their data is cherry picked, presenting only what advertises well rather than supplying enough for consumers to draw their own conclusions. Arrgh!
- 4-25-2012** **Short Replies.** The attempts to stir debate have dwindled to almost nothing. The Volt supporters enjoyed heated exchanges with PHV supporters. But back when real-world data wasn't available, it was a very different situation. They could still mislead without much consequence. They'd just pretend the topic lacked evidence and was only speculation. Now, it's fact. They've run out of excuses for struggling sales too. It's a waste of time responding anymore. The debates had actually be constructive last year, since they exposed argument points. But now that those are well known and there's plenty of information available to eliminate doubt, what purpose would rehashing serve? It's over. So, I don't bother. To one provoke, I posted this: "*No concern for middle-market buyers or business-sustaining sales.*" And to another, it was just this short reply: "*Time is not a luxury.*"

- 4-25-2012** **Range Estimates.** These are my most recent recharges, in the order as they occurred: 11.6, 11.7, 11.8, 11.9, 12.0, 12.1 Clearly, the system is estimating based on previous drives... since I went from only recharging 3 times over the course of driving 600 miles to recharging very frequently, twice per day. Leaving for work in the morning means using the entire capacity and a very small amount of gas. Then after lunch, I plug in so I can drive home using the entire capacity again. That won't be the norm, since I travel elsewhere in the evening and weekends. But for the sake of collecting real-world data now and enjoying the departure of Winter, why not? It revealed the range estimate drop I had been seeing wasn't actually from the battery itself. In fact, today and yesterday I was able to drive 14.1 miles in EV before the engine started. That's well above the estimates which had been displayed on the screen.
- 4-26-2012** **MPG Marketing.** Now that hybrid choices are diversifying, what effective method of marketing is there? The PHV owners have happily discovered that the "*only gets 11 miles of EV range*" argument holds little to no merit. All you have to do is quote your recent MPG to screw up their attempt to undermine. In fact, that's so remarkably effective, it could be a big reason why antagonist activity has almost completely vanished. I'm thrilled how quickly that rhetoric has ended. It certainly didn't dragged on as some had feared. As soon as the real-world data from Prius owners who were now plugging in was posted, that brought a profound wake-up call. As if overnight, the shift had taken place. Discussions of PHV intermingling with posts from those who didn't have a plug were welcomed. There was no divide, quite unlike that of Volt. Each Prius owner proudly shares there MPG experiences, knowing others get different results. That coexistence is priceless. Just let consumers spread the word by sharing experiences among their peers, who can relate directly to the circumstances. Getting 80 or 90 MPG from a PHV is easy to understand. Efficiency is enhanced from a plug. That MPG boost is simple to convey. It makes the marketing effortless.
- 4-26-2012** **Hybrid Vendetta.** You never really know what someone's purpose truly is. But with a quote like this, it's easy to guess: "*After 1.5 years and 13K miles, I've had it with the 2010 Prius. What a pile of junk, I'll never buy another Toyota again, ever. I've bought a new 2012 Ford Mustang, 305HP V6 with 31.5MPG customized with Ford Racing components from the factory.*" With 305 horsepower and a MPG clearly not real-world (the combined estimate is only 23 and city is 19), you know the person wouldn't be satisfied from anything type of middle-market. In fact, there are probably a hundred different vehicles that could fall into the same category. We'll never find out if that was even a real owner. But then again, someone looking to stir trouble typically isn't that blatant. Of course, there's always that mid-life-crisis situation to consider. I find it amusing how such a non-constructive thread could even be started. What would the poster hope to achieve? Perhaps there was a vendetta against hybrids manifesting itself. After all, it's very difficult not to encounter a Prius on a routine drive anymore. They're everywhere now!

- 4-27-2012** **Repeating Mistakes.** Believe it or not, the hype is beginning again. It's exactly like Two-Mode. With sales struggling and excuses exhausted, focus shifted over to something else. In that past, it was Volt. In this case, it's the Cadillac ELR. This is the successor to Volt; however, it's a more expensive model. Talking about going in the wrong direction! It's amazing such senseless decisions are being made. Counter-Balance with a less expensive choice would be fine. That's not what we are seeing happen though. But with Volt getting almost nothing for attention during Earth Day news and upcoming uncertainty about demand, the market was beginning to look at other offerings... like PHV. Like last time, silence comes. There aren't any heated arguments anymore. There aren't even new discussion threads started. The topic simply dies. This is a repeat of mistakes we saw before... nothing learned. Rather than addressing what the market actually needs, focus continues to be on want.
- 4-28-2012** **PHV Operation.** It's exciting to read questions specifically about the plug-in model from new owners. The heightened awareness & curiosity is a win for everyone interested in Prius. Today, one wanted to know what happens if you wait until the last minute to start the engine when it's still cold, like as you are accelerating up a ramp onto a highway. This was my response: No matter what you do, the engine will always warm gracefully. The system is very well thought out, always taking emissions & longevity into account. Watching a ScanGauge, it's easy to confirm that. I see the engine running at a lower than usual RPM while the coolant temperature is still low. Watching the EV capacity, you'll see it drop initially... dipping well into the HV capacity if EV is already depleted entirely to ensure the engine isn't worked too hard. So regardless of speed, power, or temperature, when the engine warms, it is protected from wear... much like it has been for startup itself for over a demand. The battery-pack is taken advantage, rather than putting stress on the engine.
- 4-28-2012** **Cost Savings.** I like when this question gets asked: "*Am I missing something from the PIP?*" He had only listed the two extremes, use of EV exclusively & entirely and driving very long distances. Listing nothing else was a bit odd. But then again, that is sometimes a good way to start a discussion thread. I chimed in with: Yes, those points were an oversimplification. As already mentioned there's a major benefit to short-trips, something commonly overlooked. Focus on the resulting MPG instead, which was also mentioned. For me, my current tank is just a little over 300 miles with an average of 114 MPG. Lastly, how do you put a cost on reduced emissions? My electricity comes from natural-gas and solar, which is clearly better than coal. Using even less gas (oil) is a benefit too... for both emissions & dependency. What's the value of that? Let's not forget about your contribution to a better future as well. Each generation of plug-in will get better. The children will appreciate that.

- 4-28-2012** **Panic Reports.** Paying close attention can make a big difference. It allows you to identify patterns. That can be really helpful. In this case, it provided me with a response others hadn't expected. I noticed something that hadn't even crossed their minds. There were numerous reports recently published, all based upon a survey. The topic was repeat purchases by hybrid owners. I was suspicious. The results seemed too good of a source of new argument material for antagonists. Though vague, the content itself didn't seem too bad. Then I thought about the timing. Publishing that just before Earth Day makes you wonder. Then I stepped back to consider the big picture. Ah ha! It reminded me of the panic 3 years ago... when there was a panic about the imminent next generation Prius rollout. The competition came up with a bunch of reports that made Prius look bad... with the hope consumers wouldn't realize the choice was about to change. The same thing is happening now... quickly reporting information before the word spread about new Prius models becoming available. The survey was legitimate when taken, those hoping to undermine simply won't mention it being outdated already. People will just assume the newer models were included. We've seen that type of misleading before. It's an unfortunate reality we have to deal with it. Fortunately, some of us are aware of the circumstances.
- 4-28-2012** **Brainless Observations.** Since the very beginning back in 2000, there has always been a dead giveaway to confirm that the reviewer has no clue how the system actually works. When you come across one, don't let it bother you. Until recently, it was always the fastest speed you could travel with the engine off. They'd notice acceleration from a stop, then never do any further observation. So, you'd get a quote stating the maximum is around 12 MPH. There was no effort to find out if it was different for other circumstances. They simply didn't bother. In fact, you'd sometimes wonder if they even drove the car at all. Now, the claim with 6 miles of EV for the PHV is just as brainless. That's why most of the writers are only called reporters, not journalists. There's lots of disappointment on the way if you're expecting well researched reviews. Those that convey accurate & thorough information will be extremely rare. Cherish them.
- 4-28-2012** **Recharge Measurements.** Accessing my charging account online, I got this report of kWh values: 2.989, 3.129, 3.125, 2.986, 3.032, 3.109, 3.110, 3.201, 3.117, 2.947, 3.067, 3.136, 3.126, 3.088, 3.022, 3.021, 3.081, 3.117. That makes 3.1 kWh per recharge a reasonable standard value to use. (I believe that one with 3.201 was from my remote A/C test, where electricity used to cool the vehicle interior comes directly from the plug rather than the battery-pack.) Having a sampling of that size readily available sure was handy today. Some were beginning to assume other values based upon just a personal observation or two using inexpensive aftermarket devices. Values measured from commercial-grade charging-stations specifically designed to capture that detail is much more likely to give reliable & consistent results. Needless to say, I too wanted to know with a high level of certainty. Then all I have to do is count recharges and multiple that standard 3.1 to get the total kWh value.

- 4-29-2012 Sales Results.** This particular month is an important one for sales. We'll find out what the results are in two days. Expectations for PHV are for roughly the same as last month, since pre-order delivery is still taking place. You can imagine the quantity getting media spin regardless of what it is. Less would supposedly mean weak demand, even though you can't buy them directly yet. More would supposedly mean weak growth, not meeting whatever expectations antagonists arbitrarily come up with. No change would supposedly indicate a pattern of something bad. You know how it is, there's no way to actually "win" when quarrelling with those who thrive on hype. In other words, April will provide the slow progress forward we have anticipated. May will bring about the beginning of dealer sales, but only in 15 states. Being able to purchase without pre-order will be a big deal, regardless of where. That will be very interesting... especially as PHV owners continue to share real-world data. In the meantime, there's Volt. What the heck are the expectations for that? Sales of 3,750 per month was the revised goal, dropping the 60,000 hope in this market to 45,000. But last month's record sales of 2,289 fell way short. That's not even 1 per dealer. There are 2,600 in the United States who offer Volt. So, you can imagine the internal competition from Cruze & Malibu being far more of an influence than PHV... with price the major factor. It's too bad the priority of affordability wasn't taken seriously. How will mainstream volume be achieved otherwise? Traditional vehicles will continue striving for sales, making it difficult for hybrids (with and without plugs) to gain marketshare.
- 4-30-2012 Daily & Monthly.** I like to collect real-world data. Having lots of it available helps to prevent the intentional misleading we have to routinely deal with and it conveys realistic expectations for those considering a purchase. With that, you get a variety of reports from me. Here's the one from today: Ugh! 70 miles today, from a variety of driving. 2 recharges, I thought would be well used. But no. I ended up pulling into the garage with a warm engine and 0.1 mile of EV left. Unused electricity. That's terrible! Oh well. 78 MPG is hardly anything to complain about. For this month, which includes my snowy & rainy 636-mile trip up north, the total distance traveled was 1,828 miles. By tracking plug-in activity and using 3.1 kWh as the per-recharge quantity, 128 kWh of electricity were consumed. Based upon the values shown on the display each evening, 27.5 gallons of gas were consumed. That calculates to an overall average for the month of 66.5 MPG. I can't wait to find out what next month will bring.
- 5-01-2012 Production Here.** That was the big rumor today. It was pretty much a given though, hardly a surprise. The industry fallout in 2008 clobbered the plans to begin production here with the third generation Prius and it's not money well spent setting up mid-cycle. Planning for the fourth instead is a sensible move. That likely means late 2015 for the 2016 model-year. Where isn't even speculated. The location that was under construction, then halted abruptly when cash became scarce, resumed with new plans for Corolla instead. And that is indeed what's produced in the Mississippi plant now. Kentucky is where Camry is built, including the hybrid model. But there's no guarantee it will even be in that area of the country. Whatever the case, it was a good sign hearing about this again. The recovery from the fallout is becoming apparent now... and efficiency is much more of a priority. Looking back, it makes sense that the highly profitable SUV market would have to collapse... since the automakers certainly didn't want to miss out on that lucrative opportunity. But now that guzzling is no longer acceptable, production of responsible choices is getting lots of attention.

- 5-01-2012 Sales Silence.** It was downright creepy today. The GM supporters didn't want to say anything about Volt sales for April. The previous month's record included clearance 2011 models. Disregarding that one-time gain was a setup for disappointment. No discounted prices for new inventory wasn't a reality they wanted to face. And of course, the inevitable happened. Sales were indeed lower as a result. The problem is, they were way too low to spin. With excuses exhausted, maybe the time to be constructive is near. There's hope. Anywho, only 1,462 Volts were purchased. That's significantly lower than the Buick LaCrosse eAssist, of which 4,311 were purchased. The new model of Chevy Malibu with eAssist also did well, with 3,324 purchased. Competition from within continues to be a serious problem... especially when you consider Chevy Cruze had a total of 18,205 for the month. GM is it's own enemy... quite unlike Toyota. Again, Corolla was beat by the Prius family. Not by much. But with numbers 24,804 and 25,168 for April, neither is actually in jeopardy. Sales of 36,820 Camry made it quite worthy of attention too. For the plug-in portion of Prius sales, there's no way of gauging PHV demand yet... since pre-order deliveries are still in progress. But you know the 1,654 new owners in April made for more than enough reason to affirm the reason for silence.
- 5-02-2012 That New Button, tried it.** Whoa! I had no idea the difference would be that obvious. Yesterday, I took the "along the river" route to work. It's 17.2 miles long with a top speed of 55 mph on some roads that are quite scenic. The purpose of that particular drive was to go as far as I possibly could as far as I could using only EV accelerating as fast as possible. That extra push from the battery resulted in a drop of maximum range from 14.1 to 13.0 miles. But that electricity sacrifice prevents you from holding up any traffic. You accelerate at the same speed as everyone else. When reaching the depletion point, the engine started. It's not the ideal, since using the hybrid system can be more efficient overall than electricity-only driving... especially with a battery-pack that's 4.4 kWh. The result was 250 MPG. Today, I took advantage of the HV/EV button. Taking the same route, I fired up the engine when the first need for acceleration came up. I briskly accelerated, knowing the engine running optimally will end up recharging the battery-pack a little bit as a result. After all, that's the point of a FULL hybrid. The system focuses on overall efficiency, not that of the moment. Once warmed up, I pressed the button again to shut the engine off. It was now available for a quick on & off later. That came when a steep hill climb was needed. Then things got interesting. MPG will unexpectedly high, close to 250 and there was plenty of EV available. Later when I arrived at my parking spot, there was 1.3 miles still remaining. And to my delight, on the display it said 310 MPG. The HV/EV button allowed me to use less electricity and less gas. My expectations weren't to see so much of an improvement. That was amazing!
- 5-02-2012 That New Button, advice.** It's to fire up the engine to take advantage of the hybrid system when you are driving beyond the EV capacity available. Once the coolant warms to 130°F, the engine on & off is surprisingly quick and you gain a little bit of EV in the process. Today, I pushed the button to start the engine, then drove the warm-up distance while in HV mode. Tomorrow, I'll push the button, but only stay in HV mode for a few seconds. Switching back to EV mode right away will draw from the battery more, which is ok for me since I ended up at my destination with unused EV today. That should result in higher MPG. Keep distance & speed in mind. Like any efficiency driving, planning ahead is key. But when on your daily commute, the routine should make observations easy. The system will automatically squeeze out great efficiency anyway. But it couldn't hurt to start up the engine sooner if you know the EV would be better used later.

- 5-03-2012** **That New Button, quick switch.** As planned, I used the button today to fire up the engine, but then switched back to EV mode a few seconds later. That left the Prius in "enhanced HV mode" until the engine was warmed up (130°F), then it automatically because electric-only driving. It was a "*just drive it*" experience, making no effort whatsoever to keep the engine from starting back up, even when climbing up the long steep hill. Turns out, that wasn't necessary. There was no need for that much power. In fact, I was a bit bummed when I finally reached the river crossing. Merging onto the highway, I dropped the pedal to the floor to start the engine. Turns out though, traffic was only traveling at 52 mph and it was downhill. So, that was likely wasted gas. Upon reaching my parking spot, there was 0.2 miles of EV capacity left... and to my delight the efficiency was higher. The result today was 320 MPG. That's only a difference of 0.0017 gallons of gas (from the 310 MPG yesterday), well inside the margin-of-error for measurement. So, far more sampling would be needed to really nail down the improvement. But that's rather pointless, since even getting just the 250 MPG from never using the button is great anyway.
- 5-03-2012** **No Resistance.** There hasn't been any aspect of backlash. Nothing has become of falling way short of the revised sales expectation for Volt. Scaled back from the much hyped 60,000 for the second year, it was recently changed to 45,000. That meant 3,750 per month. But rather than acknowledge that April's count of 1,462 didn't come anywhere close, the response was: "*Volt has third-best sales month yet.*" How is that constructive? Odds are quite good the reason for silence from the once very vocal antagonists is that the new plug-in model Prius is doing much better than they had anticipated. Remember, these are the same individuals who absolutely insisted that engineering alone was all GM needed to succeed. Their blatant disregard for business & consumer need supposedly just a twisted perspective ploy by those hoping to kill Volt. That refusal to deal with economic realities was an endless source of astonishment. Those pointing out the necessity for high-volume profitable sales quickly weren't trying to make production come to an end; they were trying to prevent it from becoming a niche. Getting stuck at that status is extremely difficult to overcome later. Yet, despite major examples of the past (like Two-Mode), they followed that same path anyway. What a waste. So much potential lost. I guess that explains why there's no resistance now. How could you respond without sounding hypocritical? Needless to say, on the thread in the big GM forum linking to a sales article highlighting the recent Prius sales, no one responded to the original post or my addition to it which followed later in the day: Here's the individual US sales counts for April: 15,661 = regular; 4,006 = c; 3,847 = v; 1,654 = PHV. Note that sales of the regular model were not lower as a result of other choices being offered. In fact, quite the opposite happened of that prediction. For the PHV model, all sold are still pre-order deliveries and only in the initial 15 states. So it's there isn't any way of gauging actual demand. In March 911 were delivered. On February 28 & 29, the only days in that first month, 21 were delivered.

- 5-04-2012** **Best Tank?** I wonder how thing will change as Summer approaches. The real-world data I just collected may be unlike what I see going forward. This is uncharted territory now. It's very exciting. None of us know how things will ultimately play out. So, celebrating small victories is ok. That's what I'm doing now. Technically, this is my best tank anyway. Will it remain that way? Here's the detail and my thoughts at the moment: 96 MPG measured at the pump last night. 7.314 gallons of E10, from traveling a total of 701 miles. 78.1 kWh measured at the plug (25.2 recharges @ 3.1 kWh each). I suspect that will be my best tank for a very long time. Biking season has begun, so lots of long-distance highway cruising is in store. Carrying 2 kayaks on the roof will obviously impact efficiency too. Of course, the biggest news is that I will have to begin sharing the plugs at work. Eeek! It was nice having that entire area all to myself. Not being able to plug in anytime I want will obviously influence results. But then again, that area was designed to support additional charging-stations later. It sure would be exciting to see the demand for more emerge right away.
- 5-04-2012** **A/C Use Data.** To stimulate new PHV discussion, I tried something completely different. Nothing had been mentioned about A/C usage yet. It's not warm enough yet. So, data has been non-existent. Unexpectedly, it got "hot" here... that means low 80's in Minnesota in the Spring. I had my Prius facing the sun parked in the open lot. That was enough to make the interior a bit uncomfortable. It was the excuse I needed to give the new feature a try. I took advantage of the remote A/C, via smart-phone, but I bet the via FOB works the very same way. Watching the real-time data the ChargePoint app offers, I saw exactly what happened when clicking the "*Turn On Climate*" button within the Entune app... after the battery-pack had been fully recharged. It showed the rate at which power was being drawn through the 240-volt plug connection to run the A/C, which confirmed the battery-pack wasn't being used. More importantly, it showed how much energy was used. For a 10-minute remote run cycle, 0.25 kWh were consumed. That's worthwhile data. It was fun to collect too.

5-04-2012 **Final Proclamations.** The last of the Volt comments are being made. The audience has left. Very little is posted about it on the big GM forum anymore. It's just like Two-Mode, following that same history of being far too expensive to appeal to the mainstream and struggling with sales as a result. Those few who remain loyal seek out something to blame. PHV is an obvious target. Today, there was this: *"It's just amazing, for \$3k more PIP buyers could have had a Volt with lots more range and much better mileage (before it switches to the hybrid mode)."* Curiosity got me more than being compelled to respond. Feedback of any type is hard to get now. I wondered if anything constructive was even possible. So, I tried: Keep in mind that tax-liability isn't high enough for some to collect that entire \$7,500 credit for Volt. The range/mileage assumption very much falls into the YMMV category too. Think about how different weekend travel can be from weekday commutes. Looking forward, it's easy to see how Toyota configured their first offering for the "affordable plug-in" market. That most definitely isn't the approach GM took with Volt. Trying to squeeze out very high efficiency from a battery-pack only around 5 kWh simply wasn't a priority. Instead, the was focus on EV driving... which is clearly more expensive and heavily dependent upon tax-credit money. My most recent tank measured 96 MPG at the pump & plug (7.314 gallons of E10 and 78.1 kWh of electricity for 701 miles of travel). Since automakers require a high-volume profitable vehicle to sustain business, something for middle-market is required. What are those consumers actually looking for? There's nothing wrong with continuing to offer Volt's current configuration as a niche. But recent sales certainly don't support the argument of it being a primary product. Something else is needed to attract those would otherwise purchase a Cruze or Malibu. Notice how sales of Prius are now eclipsing that of Corolla here? That overtake happened years ago in Japan. Fuel efficiency has become an important purchase factor; however, sticker-price is still paramount.

5-04-2012 **PHV vs PIP.** There are a variety of terms that can be used to identify the most efficient model of Prius. Some are descriptive simply by recognition of the acronym. Some are abbreviations of somewhat arbitrary references. The ideal would be EVHV, but that hasn't emerged in discussions. Perhaps it's because *"Electric Vehicle"* combined with *"Hybrid Vehicle"* is self-explanatory. What has is limited to particular audiences. On the big Prius forum, like like "PiP" as shorthand for the *"Plug in Prius"*. I don't care for that, due to its scope only applying to a single vehicle. In Japan, the emblem on the vehicle itself is "PHV". It represents the same as PHEV, but don't have the redundancy of plug & electricity describing the same thing. To stimulate discussion, with the hope of stirring ideas I can use in documentation later, I started a new thread with the following: PHV means *"Plug-In Hybrid Vehicle"*. It's the universal standard established to identify all plug-in hybrids. It will become quite useful over time, as other automakers offer their own models. That's a much better way to distinguish the difference between the plug-in and the regular model than an abbreviation unique to each hybrid. In other words, I haven't been and have no intentions to support PIP. Past experience has made it overwhelming clear that newbies have no idea what the heck you are referring too, since the same convention was used to differentiate traditional models from hybrids and it was quite ineffective. Keep your audience in mind. PIP means *"Picture In Picture"* for anyone familiar with television. PIP also already refers to the measurement of fuel on the Prius gas gauge. PHV is distinct, yet can be used across the industry. Any hybrid that offers a plug as a package-option needs some type of simple identifier. PHV will work well for that.

- 5-04-2012** **\$98 Per Barrel.** The price of oil dropped below \$100. It's been a very long time since that was the case. Expectations of gas prices dropping are realistic now. In fact, the influencing factors of higher prices are gone. It looks like peak has already passed, that the Summer struggle won't actually happen now. It's bittersweet for those counting on expensive gas to help sell vehicles new traditional vehicles with an efficiency emphasis. Prius is also green (low smog-emissions) and still remarkably practical, being a hatchback and now a wagon. The plug-in model of Prius doesn't depend heavily upon either monetary enticements or the absolute of no gas. Keeping gas below the \$4 per gallon mark is a major priority for many, in multiple industries. This is where vehicle design balance is so important. It must be able to deal with changes in the market. Remember how people started buying guzzlers again, right after the scare of \$4 gas had passed? Having something already a common sight on the road when efficiency favor swings the other way is really important. That means achieving mainstream sales now. Delay is missed opportunity.
- 5-05-2012** **Plug-In Newbies.** Hearing from new PHV owners is very exciting. They're emerging everywhere. On the big Prius forum, the first clue is by looking at their post total. New members only have a very small count. Watching their messages, you find out pretty quick whether or not their previous vehicle was a Prius. For a large majority of them, it wasn't. They found past Prius interesting, but not enough to purchase until the option of a plug was offered. Being able to effortlessly achieve over 60 MPG is quite a draw. Knowing that not driving far or recharging at work will result in even higher MPG makes it more compelling. I'm delighted with the efficiency I've seen so far with mine. So what if the engine runs at times. That's the point of being a hybrid. You get greatly improved design over traditional vehicles without a major price premium. Keeping the battery-pack so small was a brilliant decision. Newbies obviously figured that out too. Their comments on the forum and in automotive blogs make their acceptance & understanding quite clear. It's very uplifting to see proof of market expansion like that.
- 5-06-2012** **Downplay, the end.** Confirmation of having arrived at the end of "rollout" is easy to see when all the excuses have vanished. What a relief. Phew! Many of us were hoping the unmet sales expectations of Volt wouldn't interfere with the introduction of PHV. The plug-in model Prius was intended to establish itself within the first year, so nationwide rollout the second year would be a natural step... quite unlike the struggle we've seen with Volt. Downplay of expectations, though hypocritical of enthusiasts, was the answer. They had to decide to change stance though. Anything from Prius supporters would just be dismissed as spin. And of course, they'd never admit to such a paradigm shift. Sales were to meet the mainstream level (5,000 per month) beginning the second year. Now, they're saying we must be patient and wait for the next generation design instead. All the current owners are only "early adopters" rather than middle-market consumers as originally planned. Whatever. Labels don't mean much anyway. It's all about sales... which is why they were totally silent about April results until I finally chimed in.

- 5-06-2012** **Downplay, validated.** Disregarding business need became the theme awhile ago. Whether it will ever be acknowledged or not, the "*too little, too slowly*" concern has been validated. That's why the plug-in Prius won't be liked regardless of what's posted. A quick look at the specs makes you wonder why the heck a 60 kW traction-motor was used, since many of the other hybrids use only 10 & 15 kW. Such a big difference should have made it obvious that being able to take advantage of a larger battery-pack later was already built into the design. But instead, there's just spin claiming the plug was an after-thought. None of the excuses or downplay will cover up the reality that consumers have shifted priorities, making efficiency an important purchase factor. That means each automaker must somehow fulfill that demand; otherwise, the opportunity is lost to traditional vehicles... as we are now witnessing.
- 5-06-2012** **Downplay, pattern.** The final sign is how quickly the rhetoric ends. That previous entry was my last post on that thread. They ran out of argument material so quickly, there wasn't anything remaining to say. I just provided a summary of the situation and moved on. Their focus on bragging-rights falls on deaf ears now. Very few participate in that nonsense anymore. The MPG boasting is as weak as 0-60 acceleration was a decade ago. It faded away as need was exceeded. Want is difficult to appeal to in this new economy where gas is expensive and financial risk has harmed the well being of so many. Priorities have become more balanced. Purchases are occurring now, not waiting for a next generation years from now. They know it too. This is how an enthusiast becomes an antagonist. They realize goals were met by a competitor and not by their preferred automaker, so they do everything they can to undermine the competitor's progress. Watching this same pattern of behavior play out again is fascinating.
- 5-07-2012** **Downplay, greenwashing.** As anticipated, their efforts totally fell apart. There's nothing left to argue about. There was an attempt to spin the "*6 mile EV*" measure as absolute, but no one wanted to contribute to such blatant greenwashing. Why participate when obvious misleading takes place? It served no purpose. Selling vehicles to middle-market is very different. The response has left them dumb-founded. The final line drawn by a flurry of insults about Toyota and Prius buyers wasn't worth it. That was sad to witness. So as had been done years ago, it is best to simply wait. Each month of meeting sales expectations reinforces statements already made. No need to repeat them. The reverse is true too. Each month of missing sales expectations confirms what was said about want verses need. No amount excuses can change that. The best they can do now is downplay.
- 5-07-2012** **Downplay, traditional.** For over 5 years, I've been reminding Volt enthusiasts that traditional vehicles are the enemy. Yet, all they heard was Prius. That complete disregard for such apparent facts was very frustrating. Why would a new vehicle fight a well-established one if the goals were the same? Unfortunately, they really did believe Volt was going to leap-frog Prius immediately upon rollout. It was going to be a slaughter. The leader of high-efficiency sales would be dethroned. Volt was destined for rapid mainstream acceptance. The invasion would begin November 2010. But when that time actually came, the signs of trouble were already too big to ignore... hence the start of the downplay. Price was a major problem. It wasn't compared to Prius price either. It was that of traditional vehicles. Cruze was only half the price and available immediately on that same Chevy dealer's lot, with many colors & packages to choose from. How could they not have seen that competition, despite the endless stream of warnings?

- 5-08-2012** **Downplay, promotion.** It's advertised as being an EV. It's promotional information focuses on MPG. Talking about downplay! It's quite frustrating to not get kWh data. With electricity being the primary, you can just leave out that detail. All we get is "*gas saved*" references. The usage of gas in a vehicle that also uses electricity makes it a hybrid. Yet, there is fierce retaliation toward anyone who points that out. Neither GM nor the Volt enthusiasts take the situation seriously. The hope is consumers will embrace it just as they did Prius. Trouble is, they don't understand the history of how that happened. That's why references are often vague. It's also why some quite angered when you point out examples from the past. They just hoped for the best and allowed hype to flourish. Clearly, that wasn't the correct approach. They missed the effort supporters put forth to gather feedback and make sure those making decisions acknowledged the need. Promotion alone is far from enough.
- 5-08-2012** **Self-Drive.** The vehicle Google has been testing for years, equipped with sophisticated hardware & software to enable the vehicle to drive itself, has officially been granted permission to be used on public streets. This is the first time ever any state, in this case Nevada, has approved such a request. And you guessed it, the vehicles (there are 3 of them) are Prius. The license for this identifies them as "*autonomous*". The plates are red and have an infinity symbol on them. It's fascinating to watch the video. Driving without a driver raises many questions & concerns. But like what has come from other innovations, you really don't know the outcome until it's tried. How will the technology be used and how it will be implemented starts with real-world data collection? We've seen that already from Prius. The earlier models provided a wealth of insight, revealing how efficiency could best be delivered... some times in support of what had been originally suggested and other times proving the attempt or hypothesis insufficient. I look forward to hearing more about what develops. There's definitely near-term opportunity for things like safety improvements to come from this... not to mention the ultimate goal of letting the vehicle drive you to your destination entirely on it's own... especially if it's a Prius!
- 5-08-2012** **RAV4 EV.** The price was announced today, an MSRP of \$49,800. That was about what had been expected for this newest EV, since it is expected to be rated with a 100-mile range and features 6-hour recharging. With lots of cargo space, offering plenty of features, and being surprisingly quick, it will be fascinating to see how consumer perceive it. There's a very small market and that niche isn't expected to reach out beyond the initial CARB market. But it does support the movement toward electrification as a whole. The much smaller battery-pack in PHV becomes even easier to embrace when you see what implementation with greater capacity can offer. After all, the design of hybrids like Prius is to provide a best-of-both-worlds approach. That means seeing what EVs can deliver is quite supportive. In fact, that's what diversification is about. Most people will seek out the balance... not everyone though, which is why having a choice is so important. This RAV4 is for them, late this Summer.

- 5-09-2012** **KISS HV/EV.** Finding the most simplistic use of the HV/EV button has been the focus. Today was the "along the river" route again. This time, I pressed the button a few seconds before turning onto the 50 mph thruway, then pressing it again as soon as my merge was complete. It was 50°F outside. So, it took a stoplight and about a mile of travel for the coolant to reach 130°F. When it did, the engine automatically shut off. The engine wasn't needed again for 18 minutes. By then, the coolant had cooled to 82°F, I was about 1 mile from work, and there was only 0.1 remaining of EV. Warm-up brought the EV up to 0.3 mile, just enough to reach my parking spot with only electricity. And I did. The resulting overall efficiency (using 3.1 kWh of electricity plus a little bit of gas) for 17.2 miles of driving was 271 MPG. Simple with great results. Gotta like that.
- 5-09-2012** **Newbie Questions.** I enjoy when they share their thoughts, especially when a question emerges about PHV. You never know where ideas come from or how attached they are to a particular theory. But there's no to get feedback without contributing yourself. So, I jumped at the chance after reading this: *"If the car is in full EV mode and then gets on a freeway, the car's ICE will wear prematurely. I'm sure Toyota engineers took some precaution by increasing EV boost but basic driving rule is don't get on a freeway with a cold engine."* That reminded me of the questions way back when about the engine restarting so frequently. To think how much of a concern that was back then and how much of a non-issue it is now. The same thing will happen with the plug-in hybrids too, given some time and some sharing of observations. This was mine: Those attempting to mislead about PHV and undermine its progress have been spreading that belief, since it builds from a reasonable assumption. Don't fall for the greenwashing! That absolutely is not the case. When you accelerate hard with a cold engine, the battery-pack is called heavily upon regardless of charge-level. I did that specific verify just yesterday. The engine RPM only got up to 1532, despite a demanding acceleration up hill onto a 70 mph highway. That is a truly remarkable RPM, way lower than anything you'd ever expect for such a situation. The engineers designed a system that already takes cold starts into consideration and protected against engine stress. There is nothing to worry about. Just drive it.
- 5-10-2012** **Still Climbing.** The estimated EV distance shown after a full recharge started at 13.1 miles for. It ended up going down to 11.2 miles from my trip up north with lots of highway driving and little opportunity to plug. It's been climbing since then, now back up to 12.8 from being able to recharge at work and not having taken any lengthy trip lately. Others are seeing the same type of behavior, the computer utilizing their recent driving results to calculate EV potential. None of us know for certain what the circumstances truly are, like if there's any battery pre-conditioning or break-in also included. But patterns can be identified from lots of owner observation. So, that's what we've been doing with an online poll & discussion. I suspect mine will be returning soon to that original 13.1 miles. Going above could happen too. Others have seen that. Of course, it really doesn't matter. That value is only an estimate anyway. I've driven beyond that without the engine starting several times now. But it's always nice to know how the system works, since newbies always ask lots of questions when something unexpected happens.

- 5-11-2012** **Oops!** I unintentionally blew past the high-end on the measurement scale. Being a Friday morning, commute traffic was rather thin and I was able hit a few of the lights green which I normally have to stop for. And since acceleration from a stop consumes far more electricity than just maintaining a steady cruise, I was looking at the potential for an unusually good result. I certainly wasn't expecting this though: 563 MPG. That's a "huge" improvement over the 271 MPG from the very same drive the other day, using the button just once to start the engine then quickly switch back to EV mode. Realistically, that's only a difference of about 0.03 gallons of gas, but it's still exciting to see. The supply of electricity is consistent, since it is used entirely. It's the same amount each recharge: 3.1 kWh. What varies wildly are the traffic conditions, which consequently influences the amount of gas required to supplement the journey. This is why large sampling is needed to accurately determine the true efficiency. That means several months of real-world data collection is needed just to get a general idea. To really be thorough, you need to document each season several times. Fortunately, I have. So, that's a great basis of comparison... much better than relying upon an oops to serve as an example. Though, it certainly is fun to experience results like that!
- 5-12-2012** **Looking Back, moving on.** We've reached the point where hype & perception of the past doesn't matter much anymore. People just claim you misunderstood or were poorly informed, especially those who didn't participate in that history. It's always different when you look back. That's why the blogs are so valuable. They tell a very different story. Volt was intended to leapfrog Prius in every way, including sales. Remember all the hope for 60,000 the second year and as much as double that the third? Those setting expectations now certainly don't. In fact, they embrace the "early adopter" mindset as the obvious, completely dismissing any possibility of downplay having occurred. That's why arguing is pointless. Their disconnect from the past makes it a moot matter. It is what it is now. After all, who would admit falling so short of so many goals anyway. Focus on the future instead. Stay focused & productive rather than dwell. That's why I'm noting what actually happened. It makes moving on much easier.
- 5-12-2012** **Looking Back, sales.** With a comment like this, how would you respond: "*Volt sales are much higher than you and those --- news guys were whining about. It's a first generation car.*" We all know that "first" is a weak identifier. Many aspects of EV1 and Two-Mode are readily identifiable. Heck, even some of the same engineers & managers were part of Volt development. But none of that has anything to do with sales expectations we had been told. The count is much lower. So, I posted: Not even close. Much has been forgotten and changed. All along, Volt was promoted as a vehicle for the masses. Sales were to become mainstream the second year, not the second generation. The hope abruptly shifted upon learning what the price would be. Then it really got ugly when the EPA revealed their estimates. There's a drastic difference between early-2012 and early-2010. You have to choose a point-of-reference for expectations claims.

- 5-12-2012 Looking Back, when.** The time has come to leave this behind. It was confirmed. Saying more doesn't accomplish anything. Focus should switch to asking what comes next. Push for details, preventing hype to build again. Don't let them take vague comments and make wild assumptions with them. It certainly don't tolerate any more "*vastly superior*" claims. That obviously didn't pan out either. I stated it this way: The concern was "*too little, too slowly*". Watching Cruze & Malibu become strong sellers without Volt, as consumers embraced fuel efficiency, wasn't part of the plan. That was a change which came about after rollout. Having to wait several more years for something that still may not be competitive and settle for vehicles with combined estimates in the low to mid 30's for MPG in the meantime validates the concern. Profit is now being made from vehicles that don't actually meet intentions.
- 5-12-2012 Looking Back, replacement.** It has always been about replacing traditional vehicle production with high-efficiency choices. Remember Toyota's goal of 1,000,000 annually by the end of 2012? Unfortunately, impact of surprise scandal & disaster seriously hindered the effort. Despite that, there were **252,528** Prius were sold in Japan and **136,463** in the United States last year. And with the popularity of the new models, achieving two-thirds of the original goal worldwide by the original deadline is still realistic. Those are actual numbers, not some vague hope. We still have no clue what to expect from Volt. To make matters worse, we see GM investing in eAssist & diesel along with a push for more small car sales. What kind of future is that?
- 5-12-2012 Looking Back, survival.** We've heard countless reports of people supposedly trying to kill Volt, but none of them appeared to like green vehicles anyway. I want to know who in support of plug-ins actually said Volt wouldn't survive... because it's often implied they were the ones. People like me were saying the current configuration of Volt is far too expensive to reach middle-market. Even with cost reductions, it would still be far from competitive with GM's own offerings. How long must we continue to wait and for what specifically? We never saw Volt going away. It was always a matter of having to realign to actually met the mainstream needs. The niche appeal would force the offering of a model with a balance similar to other high-volume vehicles. It's how many, not if.
- 5-12-2012 Looking Back, foes.** It's fantastic that so many have totally vanished. They made unfounded assertions about either PHV or Volt. Then upon being proven quite incorrect, their posts abruptly stopped. Looking back through my documenting of what they actually said, it makes me wonder if they were blindly hoping, poorly information, or just flat out lying. That last one comes with denial, since presenting data to disprove the incorrect claim continued right up until rollout fell on deaf ears. They sliver of doubt gave them the opportunity to believe it was just speculation rather than fact or could possibly be different with the final production model. Now that those plug-in vehicles are now on the road, it's all over. That's why 2012 is such a pivotal year. No more hype. The wild optimism has been replaced with a healthy dose of reality. And for those foes, the barrier they put up to impede progress is gone.

- 5-12-2012 Looking Back, goals.** A big part of the problem has been the reality that Prius PHV did indeed achieve the goals Toyota was determined to deliver. Seeing such a huge MPG boost from such a small battery-pack provides the basis for some serious market penetration, quickly. There's no good way for those supporting other plug-in vehicles to address that. How do you deal with a situation which draws so much attention and has so much risk? Of course, that is why the request for goals was made countless times prior to rollout. Each was responded to with efforts to avoid detail. None wanted to state anything definitive with respect to cost or need. It was always the appeal to want and hype about immediate strong demand. Looking back, that was unwise. Looking forward, we wonder what comes next. What are the goals now?
- 5-12-2012 Looking Back, confusion.** The unfortunate reality of having allowed the hype to get out of hand is showing its ugly face now. Just imagine how different things could have been if expectations were better managed prior to rollout. To make matters worse, those who warned about that all along are now belittled for even just suggesting that such a thing ever happened. It makes constructive discussion difficult, for Volt anyway. Choices like upgrading from a regular Prius to a plug-in are still a challenge though. I like to point out that the kWh of electricity are used regardless of speed or distance. Your travel will improve from the plug. How much varies quite a bit depending upon circumstance. But there is a still less gas being consumed. As time goes on, the choice will become easier... especially once the tax-credits expire. Reports of real-world MPG help a lot too. For now though, good luck with the decision.
- 5-12-2012 Looking Back, forgetting.** There was that never ending "*Why are you here?*" question. The antagonists would continually ask your purpose, even though you posted it on a regular basis. They wouldn't even claim to forget it either. You were always grilled as if it was the first time. That was a dead giveaway they couldn't care less what you posted. They knew, but simply didn't like your answer. Cooperation among plug-in supporters was unacceptable. Superiority was all they've ever known. Having a common enemy was regarded as suspicious. So, it's been terribly unconstructive. It's finally changing. To what is quite uncertain though. All that's clear is those enthusiasts of the past were rude & insulting, sometime downright hostile. They want to forget all that. It's why those who remember are now treated so harshly. Referring back to the old posts is a genuine fear. They made statements which are now rather embarrassing and assumptions that are quite incorrect. Can I forget that? Sure. But it requires some type of effort on their part to be constructive now. Let's not forget how much can be learned from looking back.

- 5-12-2012 Looking Back, sparring.** The biggest takeaway from the past was the experience from all the online debates. It was a full-scale shakeout well in advance of when that information would actually be needed. I found out the perceived weaknesses of PHV that people would argue long before and had plenty of time to come up with concise rebuttals. Being concise is important, since there are so many assumptions & misconceptions at play. Remember, this is in response to what people believe, not necessarily anything supported by fact. So, posts containing real-world data are simply dismissed as some type of misleading. I looked upon those opportunities as sparring. You learn moves of the opponent. They throw countless red-herrings at you, hoping you'll waste time & effort following them. From that, I've learned to stay focused. Remaining on the point makes a huge difference. They provided lots of practice for that. I feel well prepare... and those enthusiasts spreading hype ended up contributing to their own struggle.
- 5-13-2012 Weekend Hatchback.** I certainly am using my PHV as if it was a regular Prius. Both this and last weekend were major Spring cleaning efforts at Mom's, years of things stored away in the sheds to finally sort through. That resulted in stuffing the cargo area with junk to get rid of. I certainly did. Some of it was pretty old & nasty too. But with a large & heavy tarp, you can easily protect the vehicle interior rather well. So, I loaded up the Prius... despite the moist, muddy, and rusted items. That was quite effective, but looked terrible to have that much garbage inside of such a high-tech vehicle... especially when you consider it is very likely still the only advanced model in Minnesota. But the utility aspect is a selling point, and I was definitely taking advantage of it. Owning such a practical vehicle that's also extremely clean & efficient is marvelous!
- 5-14-2012 Surprise!** This morning's (Monday) commute provided an unexpected surprise. Traffic was heavier than that last Friday (the Oops! from 3 days ago) and I did end up having to stop for some of those lights I had been able to sneak through. Despite the extra acceleration draws, the efficiency was still remarkable... strangely, it was nearly identical: 562 MPG. There was an extra surprise too. I ran out of EV about 150 feet from my parking spot. But when it switched over to HV mode, the engine remained off since draw from the battery-pack was below the usual threshold. I wondered if warm-up was triggered by draw or simply running out of EV. Now, I know.
- 5-14-2012 Late Groceries.** I finally had the opportunity to try what I had been talking about ever since I drove an early model plug-in Prius, way back in August 2010. After the usual work day, I came home and ate dinner. Then after doing a few chores, there was time to play. With a few hours of light remaining and it warm enough for a Summer activity, I could go biking. But before escaping, I plugged in. Later when I got home, it was time to run an errand. I needed groceries. Wasting precious daylight was out of the question. Now the sun had set and the Prius fully recharged. It was a delight driving to the store and back... using only electricity. With a maximum speed of 45 mph here in the suburbs, I had a variety of locations to choose from too. That no-gas-required really changes your outlook on chores. Late grocery shopping hardly felt like an effort. Usually you have to convince yourself to go out to do tasks like that. Now, it's an excuse to drive... especially short distances, which had been a MPG killer... but not anymore.

- 5-15-2012** **Shrinking Thread.** It's interesting to interact with Prius owner who is now leasing a Volt. That perspective is rare, especially when Volt hadn't been closely watched until rollout. Not having that history, things look different. Not following the discussions closely either, adds even more to the perspective. So, I wanted to know more from him before the shrinking threads no longer stirred. The rhetoric is clearly coming to an end. But this deserved a final poke: *"Restating vague and undefined terms won't do much good. If you have defined them more explicitly I apologize. A link would be sufficient..."* Just 2 days earlier in this very thread, I provided specifics. Keep in mind that 2 years ago, the Volt enthusiasts were standing absolutely firm on Volt selling 60,000 here in this market the second year, demanding we must all wait then until before drawing any conclusion. Now, those specific individuals deny that ever happened. So, I apologize for being brash sometimes when asked to repeat what I have already posted literally a hundred times. It's difficult to interpret intent. Long story short, Toyota has been quite specific over the years, setting very clear goals for market penetration. Having that level of detail from them set the expectation of the same from other automakers... especially any who are depending heavily on tax credits. The first goal I remember from Toyota was the 300,000 total. It seemed so far off, knowing it would take years for that many too be purchased. Has that ever changed. As for profitability, a design must be configured to make a profit. Whether it does initially or not is a separate matter, since a buffer (like tax credits) can be used to help initial rollout... which begs the question of when that should expire. Volt depends upon an expensive system. Motor, Engine, and Transmission alone are very costly. Just look at the struggle Two-Mode has had with that. Then there's the battery. Using 16 kWh is a killer. At currently just under \$700 per kWh (excluding support components), it dooms the vehicles to sticker-shock. What does having a showcase vehicle, but selling mostly Cruze accomplish? When will favor shift? Notice how Corolla has been dethroned as #2 in Toyota's line up, replaced by Prius.
- 5-16-2012** **Gauge Confusion.** The aftermarket gauge I have works fantastic for conveying coolant temperature information. Knowing that reveals a lot about how the system works. It's quite educational. But when it comes to MPG information, my experience with it today didn't go so well: The merge onto the highway this morning was with the usual 1500 RPM maximum, dramatically increasing MPG from the usual 30 to 90 by taking full advantage of the plug-supplied electricity. Upon settling down to a steady cruise at 70 mph with an engine RPM at only idle speed, still drawing heavily from the plug-in battery-pack, I noticed the instant MPG on the gauge. 21.7 MPG! Huh? The instant MPG on the Prius speedometer was spiked at 100 and so were the minute-summaries on the Consumption screen. The gauge MPG value kept jumping from a low in the 20's to the 80's & 90's. It clearly didn't understand what was happening. I wonder if anyone else seeing older devices struggling to properly report data from new technology. There are bluetooth connectors now, which interface with smartphones. That would provide the ability to easily upgrade software. But for now, it still pretty early for plug-in hybrids. Aftermarket device confusion will likely take awhile to remedy.

- 5-17-2012 C-Max Detail.** As expected, this new hybrid from Ford is a close match to Prius v but has components a little larger. Of course, the only actual specification we got was the engine would be 2.0 liters. The battery for both the hybrid and the plug-model are just said to offer more capacity, no detail. The press-release just generically said it will have a faster maximum electric-only speed for the hybrid. But since rollout won't begin now until this Fall rather than next month as anticipated, there's plenty more time to unveil small bits of information to build interest. Price of the base model was revealed. It will be \$25,995. That's about \$500 less than v's base but obviously quite a bit more than the regular Prius and the c model. It likely means the plug-in base will be more too. Odds are it will be a popular vehicle, since it's traditional-counterpart available in Europe is. Here in the United States, it will only be available as a hybrid. With the price of gas going down and people growing use to paying more to fill the tank, it would have been nice seeing C-Max on the road sooner. Oh well.
- 5-17-2012 Turning Tides.** Things change. Those who had incorrect assumptions in the past are faced with how to respond now. Many simply go silent, mostly to avoid being labeled as hypocritical or needing to apologize. Some also fear retaliation through spin, knowing how easy it was for them to twist facts. A few rare individuals actually follow their principles and concede. They begin ignoring the technology which they had previously endorsed and pay more attention to what you have to say instead. That's when you know the tide had turned. Blinded by brand loyalty themselves, they had just assumed you were doing the same thing... never actually looking into the detail you had provided all along. I've witnessed that phenomenon in the past, dating all the way back to the original Civic hybrid. Throughout the years, others came and went. But for Volt, it is especially noteworthy... since no other high-efficiency had been so hyped. Ironically, they played right into the "*over promise, under deliver*" self-fulfilling prophecy... despite being warned of how that happened in the past. Thank goodness the direction has changed. The flow is going in the other way now. Resistance before may not be anymore. In fact, those who had opposed may even become supportive. These are interesting times.
- 5-17-2012 Estimated EV.** That start at 13.1 miles when I first got my PHV two months ago quickly shrunk. It was based upon the assumption of lots of EV driving. Instead, my driving has been heavy on the HV... especially as a result of that trip up north. It dropped down to 11.2 miles. Of course, that's just a range estimate. The computer uses prior real-world data to approximate potential. The value has no actual bearing on outcome. I've hit 14 miles of EV a number of times, despite seeing lower numbers on the computer upon starting the vehicle after recharging. Plugging in at both home & work has helped bring it up. The estimate EV climbed to 12.8 last week. This week, I watched it return back to 13.1 miles. Yesterday morning, it hit 13.2 for the first time ever. Yesterday afternoon, it was 13.3 miles. Today, both recharges were 13.3 too. Knowing that others get values in the 14's and 15's, I'm quite curious what mine will end up at. Summer driving trips should have a heavy influence... downward. Winter will be even worse. It doesn't matter much. Efficiency is absolutely outstanding. At this moment, my current tank at 675 miles is showing an incredible 107 MPG.

5-18-2012 **GM Stock.** It's extraordinarily difficult to have constructive discussion when it comes to the financial outlook for GM. That's why Volt comments were often taken as confrontations, believed to be undermining efforts. The situation became polarized. With no opportunity for analysis, you were doomed to the "Anti-GM" label regardless of what you posted. Only cheerleading was acceptable. My approach has always been the grading method, identifying progress and by pointing out potential. There's no outright failure. Of course, when it came to Volt, the homework assigned wasn't what was actually turned into the teacher. So, enthusiasts were always angered by not giving it an "A" based solely upon engineering accomplishment. It didn't matter to supporters that the business aspect hadn't been addressed as instructed. Whatever. That could go on and on; however, there's no need anymore. Reality has come crashing down. Last week, the United States Treasury issued a report on their 26-percent stake in GM. The \$49.5 Billion spent on reviving the automaker back to profitability, unfortunately, continues to be a struggle to recover. The short-term profits have been fine. But for actual monetary payback of the 500 million shares still owned by the government, it's a big problem. At the time of the report, stock was trading for \$22.54 per share. That's well below the \$33 each they were purchased at. Today, the stock closed at an all-time low of \$21.18 per share. The hope for a net gain, to help cover taxpayer expenses, isn't going to happen. GM has expressed frustration from delay of selling that stock. They don't like such a large outstanding liability, which contributes heavily to the "Government Motors" references. The Treasury department doesn't want to accept such a massive loss. Those who argued there's plenty of time, that the "early adopter" stage of Volt isn't too slow, are growing quiet. Consequences of not having addressed the business aspect are making themselves quite apparent.

5-19-2012 **Next-Gen Worry.** The talk of next-generation design for Volt has evaporated. It had been a strong reason stated often for patience. But that delay only made sense if you assumed the competition wouldn't be improving their designs within the same time period. Turns out, Ford is in the process of doing that now and Toyota will be roughly when Volt gets an upgrade. Knowing battery-tech and engine-efficiency will both be improving for them, any argument for Volt becomes moot. The moving target is obvious. Enthusiasts see this and have noticeably backed off as a result. They are worried that GM will always be struggling to get ahead, that leap-frog hope depends heavily upon a dramatic cost-reduction. Without that, they will have to settle for "*direct competition*" rather than being "*vastly superior*" as long hoped. To them, the word compromise means "*failure*". For the rest of us, it means "*balance*". That's why they worry. Trading off power & capacity for affordability is unacceptable, in their minds. Of course, so is having a vehicle which doesn't stand out. Being an ordinary family car doesn't draw attention. That type of success is actually a conflict of interest... something else to worry about. In the meantime, there are PHV owners like myself who are thoroughly enjoying the plug-in boost.

- 5-19-2012** **Goodbye \$100.** It looks like seeing that for the price of a barrel of oil is gone. Pressures have finally subsided... allowing the closing price for the week to drop all the way to \$91.48, making it the lowest we've seen for a very long time. That means the concern of \$4 is gone too. Fortunately, that doesn't seem to be having a negative on the interest in fuel efficiency. It appears as though higher MPG is a priority now among most consumers. To what extent is the question. This is a great opportunity to establish PHV in the meantime. The expectations for plug-in hybrids are all over the place. Being able to supply lots of real-world data prior to the next inevitable climb of gas prices should be quite helpful. What are the assumptions now? With all the hype from Volt over, it's time to find out if there was any collateral damage and deal with it quickly. Would any of that even have influenced consideration of a plug-in Prius? What about Ford's upcoming plug-in hybrid? Less expensive gas may actually benefit EV rollout as well. Establishing networks of charging-stations and lowering of battery cost requires lots of time. PHV supports rapid acceptance without dependency upon it. Tax credit expiration isn't a problem like it is for Volt. That pressure still very much exists. In fact, it will probably struggle more with the price of gas lower. These are definitely interesting times.
- 5-20-2012** **Discovering C.** This series of quotes was from a delighted new owner: *"I had always wanted a Prius, but never thought I could afford one... I sat in a car labeled Prius... I thought it was the traditional Prius... I had no idea there was a new model out... Then I saw the sticker price and I was sold!"* His thrill was clearly expressed in his introduction and follow up posts. It was fantastic hearing from someone who discovered Toyota's newest hybrid, quite unexpectedly. It was a natural choice for him. No pressure. No doubt. Of course, now behind the wheel of one, he added this: *"I can also see why the whole mpg thing becomes an obsession - the car kind of makes you want to do better."* That was great to read. I articulated my feelings with: Hearing that you didn't know a new Prius was available is very exciting. It means there's untapped demand, a juggernaut waiting for more showroom discoveries.
- 5-20-2012** **Gallons Saved.** I was quite intrigued when this newest advertising campaign from GM featuring Volt was launched. It's been 3 days. Comments online about the *"2,130,000 Gallons of Gas Saved"* have been mixed. The most obvious talking point came from what they were comparing to. That wasn't stated. Being vague allows you to assume it's in comparison to the high MPG choices that don't offer a plug. But in reality, it looks like they are still using the 27.5 MPG average for the United States. Naturally, there wasn't anything stated about how much electricity was actually consumed in its place either. Knowing there are over 1 million Prius on the roads here, that's rather frustrating to see such lack of detail proliferate. It certainly is nice to see gas dependency getting attention. But that's leading to an increase in downsizing purchases of traditional vehicles, not a strong demand for Volt. What will the situation be like 2 years from now? Next year? In the Fall, when Ford's plug-in becomes available? As the biggest guzzlers disappear, what draw is there to purchase a much more expensive vehicle like Volt when you can just get a Cruze, or Sonic, or Malibu ECO instead?

- 5-20-2012** **100 Miles Less.** It will be fascinating to get averages from PHV owners, especially since travel distance can vary so much. In that recent press release from GM, it stated: *"Typically Volt owners drive an average of 900 miles between fill ups at the gas station."* That's 100 miles less from the press release 1 year ago. Remember all that publicity that provided? Did it make a difference? What are consumers really looking for? What is there purchase criteria? How much is the right amount? I'll easily get 750 miles from my current tank. That's well above industry average. Will people really want more? After all, it doesn't actually matter, since that isn't a factor of efficiency. And how will the other automakers respond? Will the ability to plug in be at the forefront of promotion? If so, how often will the owners typically be plugging in? Numbers like this don't have any sort of reference yet. There's no plug standard. Heck, there isn't even a no-plug standard. In fact, there isn't a traditional standard either. So basically, in this new age of efficiency focus rather than power or speed, change is extremely difficult to interpret. Each number raises new questions.
- 5-21-2012** **Sloppy Reporting.** Reading an article with this opening line will make you immediately check when it was written: *"Up until just recently, hybrid models were not moving off dealer lots and most buyers didn't really understand the new technology. But as gas prices have risen to \$4 per gallon, sales of hybrids have skyrocketed."* Bizarrely, the date was yesterday and its focus was Prius PHV. Huh? Since when is hybrid technology new? Did he actually mean plugging in? But gas was first \$4 per gallon 4 years ago, so what does recently refer to? Then things got even more confusing with: *"But the small hatchback is really designed for city driving and that is where it feels most at home. It is great for zipping in and out of traffic and is easy to park because of its size."* Did the writer get mixed up, confusing the c model with the plug-in model? None of the specifications, including price, were wrong. In fact, even c was mentioned. Then it stated: *"The biggest drawback is the Prius plug-in Hybrid has a limited electric range of 15 miles before the battery is depleted."* That gave the impression in might be a covert promotion for Volt. But then this was included: *"The similar plug-in Chevy Volt can travel 25-30 miles on a single charge."* What the heck? That's a sad excuse for journalism, especially from an automotive publication. At best, it's sloppy reporting.

5-22-2012 **Hypermiling.** It's always intriguing to hear the different perspectives on this. The origins can be traced back to that "*Up To The Chore*" saga. That heated debate was intense and lasted an amazing year and a half. The person who coined the term came up with it in response to something I had posted. He was doing a variety of things to squeeze MPG from a Corolla, claiming there was no benefit to the hybrid technology. Of course, he later discovered P&G (pulse and glide) could take Prius to a whole new level of efficiency... but that had some negatives, leading to conflicts of what was considered acceptable and the variations causing confusion... which years later, brings us to the uncertainty now. I posted this, providing some history: The term "hypermile" has been around for a decade. It originated from traditional vehicle comparisons to the earliest hybrids. Then the hybrid drivers began doing their own modified version of how to squeeze out higher MPG. Over the years, the recommendations of what to do changed. Then the next generation designs introduced new twists on it, making the meaning quite unclear. Now, we have plug-in hybrids. For Volt, there's the suggestions of shifting to L and taking advantage of MM. Next year, there will be a HOLD button introduced. For Prius PHV, there is an HV/EV button. Plus, there's the obvious benefit recharging at work provides. In other words, what does "normal" driving mean? Think about how informative the real-time efficiency screens are to the driver. Responding to the data being presented could be considered hypermiling; however, those screens are a standard part of the vehicle. It's normal to have them. Ignoring them would not be normal behavior. It would be like disregarding what a tachometer tells a manual transmission driver.

5-22-2012 **4 Million Sold.** It was way back in December 1997 that sales of the Original Prius began. Then in August 2000, the upgrade was rolled out. It was the Classic Model and we here in the United States got it first. Mine was delivered a few weeks later. Crown & Estima were then introduced. The race was on. There wasn't much competition though. Most of the attention came from anti-hybrid efforts. Thankfully, Toyota pushed on. New hybrids continued to be introduced and the system itself was enhanced. I upgraded at the first opportunity, becoming a pioneer again in October 2003 with a new Iconic model. In a flurry of success, lot of real-world data provided great endorsement for the technology. The ownership count grew. I remember 500,000 sales being reached. Then 1 million. The third-generation design, as it is now referred to, was introduced. I joined in, upgrading again. It was fun being part of that. There were lots of owners. Hitting 2 million sales for Prius and 3 million for Toyota hybrids overall came quick. It was the kind of growth needed, finally realistic. Mainstream status could no longer be questioned. Today, it was announced that the 4 million overall mark had been reached. Yeah! It's so nice knowing progress continues. Several new models of Prius, including a plug-in are now contributing to the market penetration. Hopefully, all that will serve as inspiration to the other automakers. We hear about their efforts. There are plans being made. But at the same time, traditional vehicles march forward.

- 5-23-2012 PHV Data.** We're into uncharted territory now. There's an ample supply of material to make a mind wonder. So many variations to ponder leads to a welcome loss of perspective. A commute back & forth to work along with a stop along the way, even with just a single recharge, will result in MPG above 80. That's what had been predicted. Now, it's a reality. Those who don't have to drive as far or like me who can recharge at work will see efficiency even higher. I'm absolutely delighted. Summer biking trips are soon about to result in lots of HV driving. Far more of those miles than EV will cause my average to drop. But that low will still be well in excess of what a regular Prius delivers anyway, which in itself is impressive. It's an enjoyable experience. Winter will even bring a thrill, which I'll document every aspect of. Having plug-supplied electricity available improves efficiency regardless of the situation. Witnessing results firsthand is rewarding. This is what I posted online for yesterday's gas purchase, contributing to the collection of statistics owners have been sharing: Still one pip showing, but it was close enough to need a refill. **DISPLAYED:** 848 miles total, 454 miles EV, 393 miles HV, 111 MPG, 92 kWh. **CALCULATED:** 104.9 MPG, 103.2 kWh. **MEASURED:** 33.3 recharges, 8.077 gallons. That was a very exciting tank; though, waiting 2.5 weeks for the real-world data was an exercise in patience. It takes a long time to drive far enough to need to visit the gas station.
- 5-24-2012 Finale & Epilogue.** The thing which has caught my interest recently is Volt supporters also seeking closure. A grand finale is their approach on the situation... wishing Volt good fortune and seeing no reason to for any other action beyond patience. The PHV supporters are pursuing closure too, but how is quite different. They provide an epilogue... finally putting to rest the unfulfilled hype for late 2010. It would be nice to move on, even if the reasons for doing so vary. The comparisons of Volt to Prius aren't attracting attention anymore anyway. Increasingly apparent is the view of GM's own production, that the issue is within the automaker itself. Toyota is really only the distraction. That's becoming easier and easier to see. There isn't an effort to kill GM or Volt. It's really a push to not waste more opportunity. Too much has been lost already. That meritless hope of the past should have been a warning about trouble to come. No more excuses either. Set a clear & concise goal, then stand by them.
- 5-25-2012 Lost Opportunity.** Repetition is the sign. Today, it was: "*Spin! Spin! Spin!*" We've seen that over and over again. It's quite refreshing for GM supporters to grow tired of the same thing. Moving on requires that step of recognition. They don't want to see anymore opportunity lost either. I added: That's a good assessment. It's the same old meritless statements. Prior to rollout, it was: Hype! Hype! Hype! We all know middle-market vehicles have different priorities than what Volt initially delivered. The catch is, it's still promoted as if it the current configuration was designed for the middle. It's that misrepresentation which rubbed people the wrong way, especially the disregard for market need. That has been changing. Calling this stage "early adopter" is an acknowledgement that mainstream will be achieved by the next generation instead. Understanding the system by clarifying vague claims of the past with real-world detail is how progress will come about.

- 5-26-2012** **Actual Issue.** Stepping back to look at the actual issue, it's the mixed messages coming from both Volt owners and GM itself. Sometimes Volt is an EV. Sometimes it is a hybrid. That's the inconsistency... which is very frustrating for some of us. PHV is always a hybrid. There's no issue with the engine running briefly. It's not promoted as an EV. The plug provides a significant MPG boost. True, sometimes it doesn't use any gas at all. But even when depleted, MPG is still above what traditional vehicles deliver. Emissions are cleaner too. The purpose is deep market penetration and high-volume sales quickly. Within the next few years, when the next generation of Prius is rolled out, the PHV will naturally just be part of it. That package option offering a plug will be a regular offering. It's such a natural next step, it's easy to embrace. For Volt, we're still scratching our head trying to figure out purpose. The issue of not knowing is a big deal... often overlooked by the petty squabbling common when plug-in owners attempt to have constructive discussion. Ask yourself what the problem actually is when you encounter a heat exchange of posts. It may not be what is getting the attention.
- 5-26-2012** **Bottom Line.** It's interesting to read the perspectives of others. They vary dramatically depending upon when they began observing the automotive industry and how much business background they have. The enthusiast typically is quite new and focuses solely on engineering. So, you know how pointless those discussions are. They turn into meritless debates rather quickly. What stands a chance at being constructive is what I'm trying to spend more time on now. I liked & appreciated reading this today: "*Bottom line - GM didn't do their homework on the Volt as compared to the PIP, or regular Prius on the design concept, approach, and execution of their hybrid.*" My response to that was: Actually, they did. However, results of those studies didn't fit well with what they wanted to deliver. It's the SAAB story... ironically, GM not taking the very advice they gave them. They knew it was a bad idea disregarding sound business strategy and went with their gut instead. After all, a powerful electric motor does indeed deliver a pleasant driving experience. But then again, so does a gas engine with lots of horsepower. Cost comes back to haunt and middle-market vehicles aren't exciting to executives & enthusiasts.
- 5-26-2012** **Still?** I remember dealing with this same thing: "*Had my Prius for a week and I lost count each time someone asks me or makes a comment about "needing" to plug in my car each night to recharge the battery.*" That became really annoying back in 2000... 2001... 2002. It subsided, then almost went away entirely. But now that Prius is penetrating deep into new markets. It's back! My guess at the best response would be to simply reply that you didn't get the plug-in model... and not provide anything else. Make them ponder that on their own for awhile. At some point, curiosity will get the best of them and they'll ask for more information. You can trick them into intrigue, perhaps even open up the door to opportunity for showing them your Prius. Then they'll be hooked.

- 5-27-2012 Gas Prices.** One political party wants to improve efficiency technology. The other wants to lower gas prices. Which makes more sense for our children? Which is more likely to get that politician re-elected? It's so frustrating to the price of gas taking precedence over the consumption of it. People carelessly guzzled for years. They mocked hybrids. The technology was misunderstood. Greenwashing flourished. Are things better now? The technology continues to advance. Support of it is quite limited. The heavy dependence on tax-credits is a warning sign that a struggle is about to come. Much needs to be done before that opportunity to collect expires. And worse, what if the automatic budget-cuts next year impact that funding? The price of gas being lower doesn't help advance progress. It sets up false expectations, leading people to believe there's plenty of time still. How much longer can we really afford? For that matter, how much longer do you want to continue driving a vehicle that depends upon low gas prices?
- 5-27-2012 100 MPG, part 1.** What is compelling? The auto industry clearly lowered standards. They had emphasized the importance of reaching 40 MPG for many years, then abruptly backed off when gas hit \$4 per gallon. All of a sudden, 30 MPG became the focus. Sadly, it was what came next that was worse. They switched from advertising city/highway/combined estimates to highway-only. Not having anything efficient to actually sell and the revision of the EPA measurement system obviously put them in that position. But what does that mean now? At what point does the reality of diminishing returns influence consumer purchase decisions? The efficiency value which comes up far more often than any other is 100 MPG. How many miles you can travel on a single charge before dropping below that mark would be a new way of promoting. It could be quite effective too, since the EV estimate is inherently misleading for a plug-in hybrid like Prius. Real-World data is far more of a draw than rating measures. Prius has overwhelmingly proven that. Knowing you'll go around XX miles before dipping below 100 MPG, regardless of how you drive, would be a powerful bit of information owners have yet to share. Most of the time, I plug in with the MPG still well above 100. So, I really don't know. My very limited data hints that it's somewhere around the 20-mile mark. Anyone care to guess where that average threshold will be for PHV?
- 5-27-2012 100 MPG, part 2.** That idea of paying close attention to what distance achieving 100 MPG is effortless came from a "discussion" with a Volt owner. He was trying to be helpful, but the responses were so vague, it became frustrating. His effort led to suggesting some arbitrary numbers. So, I'll give credit for that. Unlike other confrontations, that one exhibited some merit. Trouble was how to apply random observations to something effective for promoting plug-in hybrids. It's far too easy to tell people numbers they cannot relate too. After just 2 months of driving a PHV, it's easy to see the EV range estimate is quite misleading. People have no idea what to expect following depletion. They hear "*then it runs just like a regular Prius*" but don't understand what that means in terms of MPG. So rather than continue to focus on the two distinct modes and continue to neglect blending, why not convey a measure which highlights it? But rather than a fixed distance, we'll use a fix MPG instead. I'll note whenever my MPG drops below 100 following the depletion of a single recharge. Eventually, a pattern will emerge... without any need to refer to EV. It will be a measure for people to consider when they know they will drive beyond the battery-capacity available... something no one has actually addressed with anything beyond just random observations. Watch my spreadsheet. And of course, be patient... since my MPG is often well above 100 and I often recharge at work.

- 5-27-2012** **100 MPG, part 3.** This morning's errand running was only 18.4 miles of driving, which meant MPG only dropped to 142. I was back home for lunch. There wasn't any need to use the Prius until late in the evening. So, I set the timer and plugged in. That drive was just 11 miles. Capturing data-points for when 100 MPG is hit will likely continue to be quite a challenge. Despite my annual average of 20,000 miles, plugging in is too convenient for me to let the opportunity slip by. That particular situation doesn't happen often for me. The thought now is to see if there's some type of normalization available from the daily information I document. With so much larger of a sampling, the trends would be easier to see. Remember, we're not looking for any specific value. We're hoping to identify patterns based on each of the driving scenarios we encounter, especially the routines not well understood... like Winter commuting. For just 2 months of driving a PHV so far, I'm pleased with the way data-collection has been proceeding. Real-World reports are very worthwhile, quite a help when conveying expectations to those unfamiliar with efficiency influences.
- 5-28-2012** **Rewriting History.** Just hours after Toyota presented their vision for the future, some GM supporters began to spread a different interpretation of what was actually said. So all these years later, trying to convince a Volt owner they were intentionally mislead would be an exercise in futility. It's really unfortunate when greenwashing is effective. Toyota stated it wasn't possible to deliver a plug-in vehicle for the masses that was affordable. Those hoping to rewrite history simply left off the "affordable" part. Now after all that time, we have Volt owners celebrating with comments like this: "*While Toyota said for years that plug-in would not work, GM proved them wrong and now its Toyota's turn to have to catch up.*" That cost problem is the very reason why PHV uses a battery with a 4.4 kWh capacity. And of course, there are now a number of problems arising from the antagonist nonsense. The "*vastly superior*" gloating has pretty much faded away, but we do still hear this: "*The Volt leap-frogged the basic HSD design.*". The engine in Prius is more efficient already and there are thermal improvements on the way. The hybrid Camry uses an electric motor very close in power to that of Volt (105 vs. 111) and it's more efficient. The clincher though, coming from that same individual yesterday, was this: "*So you want to invent yet another metric? I think this one is silly.*" Recognize that? We've seen data-withholding efforts before. When has that ever been helpful? Providing data to let consumers draw conclusions on their own has always been the better approach.

5-28-2012 **Moving On.** This month is coming to an end, the first which Prius PHV is available (in the 14 initial launch states) to consumers who hadn't pre-ordered. That should make things interesting. The Volt downplay & denial was beyond agonizing. Not accepting the reality of price has been a big problem that won't be overcome anytime soon. So, the results from Toyota will be looked up with great scrutiny... since their plug-in was designed to be affordable. They targeted middle-market right from the start. GM won't address those consumers until the next generation, falling well short of expectations. Remember the ultimate plan for tax-credit money, to have 1 million plug-in vehicles on the road in 2015? Toyota should be able to meet the mainstream minimum rate of 5,000 per month sometime next year. Ford may be able to meet that the following year. Toyota's next generation Prius should be available for that final year. The new PHV will likely play a major role in the race to fulfilling that goal. Only a well-established plug-in could accomplish the high-volume numbers hoped for, for that matter, needed. Production then is expected to be domestic too, which is another intended benefit from the monetary incentive. What's realistic from the other automakers? What will Nissan end up doing? What about plug-in vehicles from Hyundai & Honda? How will VW react to the changing market? For that matter, what will Volt end up becoming? With the only certainty being a growing demand for gas, simply due to population growth and greater congestion on road, how seriously will the efficiency goals be taken with respect to plugging in? We know hybrids like Prius without a plug will prosper due to the upcoming CAFE requirements. But what will the reaction be to owners like me reporting an average over 75 MPG from a vehicle with a price of about \$30,000? That's what my thoughts are moving on to. The crazy hype of the past is quickly fading. What others had hoped for didn't happen.

5-28-2012 **100 MPG, part 4.** Collecting that data could be much more difficult than expected. In real-world conditions, efficiency simply doesn't drop that low for me. After 27.1 miles of driving around today, my errand running was done early in the afternoon. I wouldn't need the car again until sometime in the evening. There was plenty of opportunity to recharge in the meantime. The display showed 110 MPG... and I had no interest in driving around just for the sake of seeing how much further it would need to dip below 100 from just that one charge. It was already enough to support the thought of being able to go well beyond 20 miles. Will those curious about PHV understand that though? Without lots of data to illustrate that, greenwashers will just say whatever they want. There's pressure building. Other plug-ins struggling for sales will put Prius, which has only been available for a few weeks and only in rollout states, in a position of attention. When is the question. Soon is likely the answer.

- 5-28-2012** **HWFET.** I never looked closely at the "Highway Fuel Economy Test" procedure. We just knew there was a hard acceleration involved, that would cause the PHV engine to start. But we also knew after warming was complete, it could shut off immediately upon speed dropping to 100 km/h (62 mph) or below. So, there wasn't ever any pressing need to look at the detail. Today, someone brought up the graph of the speed & duration of that particular EPA test measure. Sure enough, right around the 6-mile mark was that acceleration. It visually explained perfectly why the window-sticker states 6 as a point of significance. Antagonists have used that to mislead, claiming the battery-pack is depleted at that point and totally disregarding the 11-mile rating. They claimed the remaining drive was in HV mode. With the speed on the graph clearly showing values in the 50's, arguing the engine doesn't shut off then would be an act of desperation... especially knowing owners like me have reported driving 14 miles before the engine started for the first time. One individual actually insisted that the battery-pack was totally depleted after 6 miles. I bet he was frightened by the EV-boost mode. Driving at 65 mph, I pushed the button. Switching from HV to EV-boost increased efficiency from 50 to an amazing 150 MPG. Seeing that was quite vindicating.
- 5-29-2012** **Backlash.** Watching new articles pop up about EV sales, it pleases me immensely that Volt wasn't actually marketed as a plug-in hybrid. Enthusiasts pushed hard to it to make it stand alone. That contradictory approach of wanting it to be popular selling niche was doomed from the beginning. How can you have something common yet be uncommon at the same time? They'd shun Prius, then strive for what it represented. Ugh! At least Nissan understood the importance of being affordable. Unfortunately, the economic realities of delivering a 24 kWh battery-pack caused the price to go up. Perhaps this is why there's so much emphasis on gas usage now, without mention of plugging in. It could be a scramble to disassociate, knowing the EV is becoming looked upon as "*plaything for rich environmentalists*". Success requires acceptance by the masses. And that doesn't mean the disingenuous reactions we all see at autoshows, where they love the idea but wouldn't actually purchase it. This is how PHV differs. While those enthusiasts mocked, ordinary consumers took notice. Now just on the verge of a backlash, where traditional vehicles gain attention for fuel-efficiency again, here comes an affordable plug-in choice from Toyota. Timing is difficult though. What happens now is critical. Sharing lots of real-world data will help keep the building of political tension from getting out of hand.

- 5-30-2012** **Improving EV.** The range estimate value is beginning to make some PHV supporters feel a bit lost. They aren't sure what to do for newbies who see it abruptly drop. The obvious suggestion is to provide information about improving EV. That sounds like a good approach, if the system only had an EV mode and a HV mode. But it doesn't. There's that one in between. So, you cannot easily define EV range or even identify the factors which contribute to the estimate value. I sounded off with: "EV-boost" confuses matters though. Depleting from the battery-pack while the engine is warming up and while cruising at speeds faster than 100 km/h (62 mph) provides remarkable MPG. That mode is great for efficiency, but doesn't count as EV miles. It's considered HV, since the engine is running. The fact that MPG is spiked at +100 on the display shouldn't be excluded from discussions. It likely will reduce the EV range estimate as well. New owners will be concerned pretty much no matter what information we post. But that's not necessarily a bad thing, since knowing there's a lot to observe enhances the ownership experience. You feel like your purchase is well thought out, when so many factors are already accounted for... and you get incredible results no matter how you drive it.
- 5-31-2012** **Measured, part 1.** For an entire decade, we were told price was a major purchase priority for any new fuel-efficiency technology to be accepted by the masses. That's how the \$3,000 to \$5,000 plug-in premium come about for Toyota and the \$30,000 target for GM with Volt. Then came the fallout, when Lutz started campaigning for heavy government subsidies and the \$40,000 base price was finally revealed... which is how I became so outspoken, asking "*Who is the market for Volt?*" Then came the range (40 mile, all conditions) and engine (50 MPG, combined rating) expectations not being met. So, physically checking out the car itself became pointless. After all, those endorsing the "*early adopter*" perspective said to just wait anyway. But today with another long-time Prius owning friend, we stopped at the local Chevy dealer. A salesperson escorted us over to an open Volt to check it out, though somewhat irked knowing I had absolutely no intention of buying one... since I had come there in my PHV and openly said I was there just to measure the interior. Wow! I had no idea Volt was that much smaller inside. I'm average height for a man (5'8"). So when my head touched the ceiling in back, it only took a moment to realize it would be difficult to remain objective. In the driver's seat, it was clearly shorter there too. I measured, though it was obvious just by sight. There is 2.25 inches less headroom. The cargo area is smaller too. The sunken floor would make loading large cargo a pain, not flush as with Prius. My 3-wheel recumbent bike simply wouldn't fit either. When I asked about carrying bikes on back, wanting to know if anyone had figured out how to use a strap-on rack even though Volt doesn't have a back bumper for it to rest on, I only got a hitch suggestion... which made me wonder how often that would scrape considering the lower ground clearance. That salesperson and the other who came to answer questions when we stepped inside were polite & helpful, but clearly didn't like Prius at all. We already knew legroom in back was less and there wasn't seating for a fifth person. But now finding out about headroom and confirmation about the cargo area, more than ever I have to wonder who the vehicle was intended for. With PHV having a base price of \$32,000 and offering a larger interior, I see it appealing to a much wider base of consumers.

- 5-31-2012** **Measured, part 2.** Size difference was an unnoticed issue with Insight all those years back too. The subject was simply avoided. Not being mentioned allowed the belief of equal size to persist. Whatever. It's pretty easy to notice Prius is larger once you see both. As for the rest, the debate is over... done... dead. How they disregarded such an important aspect of vehicle preference is only just a topic of wonder. Was there such intense dislike for Prius that would endorse anything offering greater EV capacity? Think about how the "complexity" argument has come full circle. I can easily imagine frustration arising from seeing Prius in such large quantity now. They're everywhere! It's great for someone like me, who has always sought out a solution for middle-market. Their desire to justify a higher price in favor of raising performance clouded logic. Simply delivering higher efficiency with a vehicle similar to what people currently drive was a better goal. The emission & consumption reduction was worth paying a modest amount for, but not a huge premium like Volt requires. Keeping price in check was what contributed significantly to Prius success. Engineering for maximum EV isn't enough, as they are now learning the hard way.
- 5-31-2012** **Measured, part 3.** I'm glad it has come to an end. Setting such high expectations on hope was never a good idea. Seeing all that former hype gone now is major relief. Today is the last day of the month. Sales results for May will provide a big dose of reality. Major growth had been expected for June, but barely squeaking by up to then won't be a good sign. Perhaps that will keep things from getting out of hand going forward. Lessons of the past with Two-Mode clearly weren't recognized as repeatable with Volt. However, now that the history has indeed repeated, there should be some type of trepidation about what comes next... rather than just accepting hearsay without question. They didn't believe it could be this bad. But with oil at just \$85.92 per barrel, that certainly isn't providing any encouragement. Gas staying at \$4 wasn't reasonable. Slow recovery of the economy combined with unwillingness to accept financial risk should have been sensible consideration too. That didn't happen though. There was a very heavy dependency on tax-credits and the belief of rapid acceptance. The smaller capacity of PHV was just a joke to Volt enthusiasts. They mocked & taunted. Looking back, do you think some of them now regret not at least taking the advice of diversification? They laughed at the idea of a second model offering a smaller capacity. Violating such a fundamental rule of business doesn't appear to have been a wise decision. What the heck were they measuring?
- 6-01-2012** **Expectations.** The morning started with this, still hours before May sales numbers would be released: It's been the same old game ever since Two-Mode was first conceived. GM says something vague & ambiguous, then allows hope to build without clarifying incorrect expectations. Then the executive who made the comment moves on, allowing hype to propagate without recourse in blogs & forums. The most recent example is the mention of a plug-in Equinox. Who knows what will become of that. But without accountability, you're fighting an idea, not a promise or actual goal. To complicate matters, people forget what happened when. That makes it really easy to be misled, simply by missing vital pieces of detail. That's why it boils down to sales. The debates about expectations are over.

- 6-01-2012** **May Sales, initial counts.** With the price of oil closing this week at \$83.23 per barrel, it's interesting to see sales numbers for Prius holding. Both PHV and the c model have been in very short supply too. To complicate matters, PHV will only be available in the following states this year: California, Oregon, Washington, Arizona, Maine, Massachusetts, Vermont, New Hampshire, Rhode Island, Connecticut, New York, New Jersey, Maryland, and Virginia. So even though the preorder deliveries were completed this month, there's waiting still. 1,086 PHV were purchased. So of course, the sales of 1,680 Volt were celebrated as a major victory... even though it is available nationwide and gets an additional \$5,000 of federal tax-credits and it is heavily advertised. That's well short of the revised goal of 45,000 that GM set for the year and a major reason for having stepped away from the rhetoric. What a mess! Anywho, the other Prius numbers were 13,053 for the regular model, 3,693 for c, and 3,645 for v. Those counts can be considered steady and on track for the year. Camry & Corolla on the other hand, whoa! They've both taken this market by storm. An amazing 39,571 for Camry and an impressive 31,847 for Corolla. The report of that over-shadowed Detroit recovery reports. Toyota surged way further ahead than had been expected. That's a head-scratcher for what it means to Prius. That most definitely reinforces the claim that traditional vehicles are the true competition, not other automakers. Each will have their own challenges for offering high-efficiency choices. 2012 is becoming quite a year for history books.
- 6-02-2012** **Switching Over.** When a revised goal from just 6 months ago is denied, you know switching over to other tasks will be without fallout. The original DOE goal (hence the tax-credit subsidy) for Volt in 2012 was sales here of 120,000. That was later revised by GM, lowered to 60,000 for 2012. Then when the revised goal from 15,000 to 10,000 wasn't even made for 2011, the new goal for 2012 became 45,000. Needless to say, the expectations for making that recent revision are quickly growing dim... so much so, none of the enthusiasts seem to remember any of those numbers anymore. Their downplay has taken hold. For me, I've switched to Prius. Sales speak for themselves. No need to spend time anymore discussing what could happen. Today, was my first test-drive with a c model. It reminding me of my Classic model, but with an enhanced system. I finally have enough material to update the User-Guide. The one for the 2010-2012 was quite different from the Iconic from the beginning. Now, it's going to include lots of PHV information as well. That means lots of new photos to consider and data to continue to collect.
- 6-03-2012** **That 100 MPG.** Knowing I wouldn't have an opportunity to recharge during the day with so much running around to do, it was a matter of deciding when to deplete the plug-supplied electricity I currently had available. The short drives on the highway were the best candidates... though I really enjoy taking advantage of the battery-pack at high speeds, seeing continuous +100 MPG despite the engine running. Capturing data for that new metric was the hope. Today wasn't working out though. MPG was only in the low 90's the entire time. Yes, I know that is absolutely outstanding efficiency. But not reaching 100 caused a rethink. For driving a little over 39 miles using only the overnight recharge, who would actually ever complain about results like that? Those real-world experiences sound great even on paper. The arguments against having a 4.4 kWh capacity just aren't stacking up. For the affordable price the package upgrade requires, you get a great return... regardless of how far you drive. It significantly reduces emissions & consumption. Isn't that the point?

- 6-04-2012** **No Mention.** Not having anything to respond with makes shooting the messenger extremely difficult. That's what the Volt enthusiasts have recently discovered. No mention of PHV anymore, focusing on GM's own inventory now, prevents accusations of Toyota defending. Traditional vehicles like Impala & Malibu selling well and no high MPG hybrid being offered, they really don't have much to say. Volt was suppose to easily achieve the 60,000 level this year, to the point where it was deemed an insult to even consider the possibility of that not happening. No, there's never any mention of that anymore. In fact, even the 45,000 level is being avoided now. The only discussion related to time is that of patience, instructing us to wait for the next generation... that those who expected 1 million to be sold the very first year were out of our minds. They use exaggeration to obscure. But there's no need. We're done. Hype allowed priorities to be misplaced. Now there's an effort to convince people using less gas is more important than being affordable... which is falling on deaf ears. Consumers in middle-market are buying lots of Prius. Some will seriously consider an upgrade to the plug-in model when it becomes available. PHV is a package choice, not an entirely different vehicle with a huge price difference. Ugh! Arguing business sense with those who focus primarily on bragging rights is rather pointless. I guess there's no need to mention that anymore either.
- 6-05-2012** **Reality Check.** It sure is nice not having to listen to all the hype anymore. The only thing left keeping the plug-in market from settling is the stir about Volt sales last month. Supporters simply disregard the reality that there was such a difference in availability compared to PHV. But that doesn't actually matter. They know all too well when the HOV sticker supply runs out, the tax & state credits expire, and the advertising campaign ends, Volt's competition is really the other vehicles GM offers. That trophy-mentality continues to influence comments though. Bragging rights dominate. Rewriting history is popular too. Prius was never a halo, since the definition indicates a lure of one vehicle resulting in the purchase of another. Lots of Prius were actually purchased, pushing it well beyond that minimum of 5,000 per month. In fact, it was quite normal to see sales more than double... and that was long before gas hit \$4 per gallon or any tax-credits. So, there's not a parallel as they insist on claiming... to Prius, that is. We had see the familiar pattern of Two-Mode until recently. That obviously didn't qualify for HOV privileges. The divergence now makes it unique... requiring a step back for a reality check.

6-05-2012 **May Sales, big picture.** The biggest "*haven't noticed yet*" news is that the second-generation BAS system from GM called eAssist is selling fairly well. Malibu came to 1,640 for the month, which was just shy of Volt's 1,680. There was 1,202 for Buick LaCrosse. The other Buick, Regal, was really off with 174 though. Not sure what the deal was for that. But with all the models of Two-Mode combined coming to just 223, there are other issues to consider. What should we be expecting? 683 for Ford's Fusion hybrid was a bit underwhelming. Could that be the result of the upcoming C-Max hybrid? But then again, seeing 4,403 for Camry hybrid does make you wonder. 480 for Lincoln MKZ hybrid raises other questions. Looking at Honda's Insight, the 512 may have been reasonable... since Civic is the dominant hybrid. But then again, those 708 don't stack up to the similar sized c model Prius, with 3,693 sold. For the v model, there were 3,645. The one I'm most familiar with is the regular model (often referred to as the "*liftback*" model now) saw 13,053 for sales in May. That is a good number, showing steady & strong quantity... easily providing a self-sustaining business product. We know that 1,086 for PHV doesn't tell a complete story. When availability spans to nationwide, then we'll get a decent idea. Currently, I wonder who even knows there is a plug-in model. How do people find out about new offerings like that? For electric-only vehicles, Nissan's Leaf had 510 purchases. Ford's Focus EV is brand new, with only 6 so far. Looking at diesel, the top-selling automaker here for them continues to be VW by far with 7,843. Jetta was the most popular, drawing 4,644 sales. Other noteworthy activity for May was the often overlooked Hyundai Sonata with 1,869 sold. Hybrid SUVs are rarely talked about anymore. In fact, the discontinued Escape shrank to 206. What does that mean for Highlander at 506? I understand it's AWD and 3,500 are genuinely useful for some, so a small market makes sense. Then you look at the RX from Lexus with 1,011 and take notice. 1,549 for the CT from Lexus (luxury hybrid sedan) is another. Long story short, the market has been stirred, there's lots more to report about now.

6-06-2012 **Who?** Got the answer! Finally!! That long asked but never answered question got some acknowledgement today. "*Who is the market for Volt?*" turned out to be a challenge of how to avoid providing a response without making it evident that the words would provide a change of context... and draw attention to those who were doing the avoiding. Anywho, the reply came under the guise of providing education for the sake of spreading information. In other words, we got more downplay. Thank goodness this nails the coffin shut. How doesn't matter anymore. And technically, Volt really did die. They just never wanted to admit how different its successor really would be. This current generation is only intended for "*enthusiasts*", not ordinary consumers as the "*early adopter*" label intended to imply. But the buying patterns have become too obvious to deny anymore. There are those who thrive on the efficiency and those who bought the car just for the sake of getting in the HOV lane. The middle is missing. The lesson learned is hype leads to pride. Overcoming pride is a major obstacle, one requiring a great deal of persistence & patience. Phew! Sure glad the obstacle itself is now so easy to see. Ironically, they'll probably really like the next generation, even though it will compromise their own standards. It's just so unfortunate it will take so long. Heck, just getting an answer to the question took years!

- 6-06-2012** **Figuring It Out.** It's always exciting to help out the newbies. Though, it can be quite challenging without really knowing their background. You give it try. Today's question that caught my attention was: "*Now if I could just figure out how to use the electrical motor the correct way????*" Coming from a thread already filled with attempts to explain, I tried to carefully word the response: Engine only is inefficient, hence the hybrid approach. The addition of an electric motor allows the engine to run in a less wasteful manor. That's what you want. Using the electric motor exclusively consumes your limited supply of electricity quickly. On the Eco-Meter, you can see that. The energy-bar is much larger for acceleration than it is for simply maintaining a steady speed. That's why you want to share the burden with the engine during times of high demand. Also, keep in mind that there's a second electric motor. While the engine is running to provide thrust, it will use that to generate electricity at the same time. This allows the engine to run at a more consistent RPM, which is more efficient. This recharges the battery-pack along the way too. Intentionally using the engine is counter-intuitive. New owners tend to fight it, not realizing they are preventing the system from doing what it designed to do... causing lower MPG. Enjoy electric-only when not much power is needed. The electricity is better used that way. When you do need power, don't be afraid to let the engine start. It shuts off quickly afterward anyway. And interestingly, that applies to the plug-in model as well. You have more kW & kWh available, but there's still just a finite amount. So, you want to consider when to consume it. Typically, when lots of power is needed, take advantage of the engine.
- 6-07-2012** **Routine 200's.** I've grown quite use to seeing that. The commute has ended that way frequently lately. I drive to work starting with a full charge and leave from there the same way. This week, I've been taking the 70 mph highway to work due to road construction on the route along the river. It doesn't offer the 400's and has quite a bit more traffic to deal with, but it's fairly nice. I can still take advantage of the extra electricity. And the difference between the two is roughly just 0.04 gallon each way. I'm into that efficiency range where gas is measured in tiny amounts, quite unlike what traditional so-called efficiency vehicles offer. It's a great example of diminishing returns. Higher MPG wouldn't result in much of a difference. Heck, vehicles without a PZEV emission-rating end up losing tiny amounts of gas from evaporation. Most people don't even realize vehicle pollution can come from something other than the engine itself. Anywho, with seeing that level of MPG becoming routine, I'm more curious than ever what Winter will end up bringing.

- 6-07-2012** **EV-BOOST.** It's a new concept... and exclusive to PHV. Combining gas & electricity at a more balanced ratio allows for greater efficiency, seeking opportunity otherwise lost by depending primarily on electricity or the engine. Think of normal HV mode, like this at 70 mph: 90% engine, 10% motor. Then consider a reduction of the one and an increase in the other, a more balanced approach, like this at 70 mph: 50% engine, 50% motor. EV-BOOST works something like that. You get the choice of how to consume the electricity. It's not just one extreme or another. And when it comes to non-propulsion needs, like heat in the winter, that choice could provide quite an efficiency gain. I'm looking forward to exploring this mode more. In my brief experiences with it before, I've cruised at 70 mph watching each 1-minute bar on the Consumption Screen display at 100 MPG. Too bad the scale doesn't go higher. I can see on the ScanGauge it wavering, going all the way into the 300's at times and dipping into the 90's at others. Even minor hills cause the value to fluctuate. There's no such thing as a truly flat stretch of road around here. It averages out to over 100 every time though. More to come. Stay tuned.
- 6-08-2012** **Now, They'll Like It.** How do you respond to this: "*Now, they'll be spinning it as a good thing.*" We all remember how the suggestion of a hold button was a horrible thing, that nothing good could ever come from intentionally starting up the engine... Since not hearing the same old rhetoric over and over again is a good thing, this was treated that way too with: It's frustrating when they conveniently forget that previous stance. We've seen their refusal to address the past already. But realistically, there's no reason to dwell anyway. Witnessing the change is confirmation of being correct all along and a step forward has occurred. That's a measure of progress. Accounting for the wide variation of real-world conditions takes time. The snap judgments we've been seeing lately are red flags, dead giveaways that generalizations are being made and/or some type of defensive response is at play. Efficiency is a balance of resources available. With speed, length, time, temperature, traffic, etc. altering on a regular basis, it simply doesn't make sense claiming that the restriction of choice is best for every situation.
- 6-09-2012** **Stirring The Pot.** The publishing of my most recent batch of personal logs came with the anticipation of rubbing someone the wrong way... almost inevitably, a Volt owner. Most have embraced the "*it's going to take a few more years*" outlook, that nothing else needs to be done except wait. Sound familiar? It's the pattern repeating, again! However, this time, there's just some "*here's what to watch out for*" comments. I'm already well into moving on. Taking those new photos for the User-Guide is great. I'm having fun doing that. It requires me to really think through the circumstances needed for each scenario. After all, you've got a limited amount of electricity available, the engine warms up mighty quick, and the lighting conditions required to capture a moment with the camera presents challenges. So, I've been devoting quite a bit of time to that. But knowing June brought the long-awaited upgrade to Volt, there was still some attention lagging. Turns out, the battery-pack chemistry was improved. That will provide another half of a kilowatt-hour of electricity for propulsion, raising the overall capacity to 16.5 kWh. No price reduction, though. The theme now is just to accept what they believe cannot be changed. Makes you wonder if they'll ever figure out how much influence they could have on the design. Prius owners discovered the power of their input long ago.

- 6-09-2012** **Wrap Up.** This worked out well. I ended up getting called out by a Volt owner and accepted the criticism with: How would you suggest getting it back on track? Isn't the purpose to replace traditional vehicles? The suggestion of a second model, one actually configured to be affordable, continues to fall on deaf ears. It's very disappointing to see the performance aspect being used as justification for purchase, rather than actually having something for middle-market. Step back and look at the other rollouts which were also niche vehicles, ones that didn't do anything to help mainstream consumers. You can disregard them or push to make them better. Also, keep in mind what you don't see. Those of us active on the blogs & forums prior to rollout are well of aware of the disenchantment. Enthusiasts of Volt left in droves once they found out about the price, range, and engine efficiency... leaving only the truly loyal remaining, who as a result took a very defensive stance.
- 6-09-2012** **Newbie Posts.** When a new Prius comes out, I tend to back way off. That gives the newbies an opportunity to develop a sense of community unimpeded by veterans. Letting that take form on it's own is empowering to them. When I post something, it will sometimes kill the discussion... since I have lots of real-world data to support whatever they were speculating about. Allowing them to think through those scenarios themselves is rewarding for them... and priceless for me, since that's how I get ideas for the User-Guide. Their non-interfered with comments provide an insight to their perspective... something I have difficulty seeing with 12 years of hybrid study. After all, the market continues to evolve. Think about how many people have smart-phones now. That places different expectations on what information a vehicle should provide, especially one like Prius. Of course, this leads to a perception problem. It gives the impression I'm not being attentive to them anymore. But then again, this is the same transition we've been through before. However, it was only 1 new HSD hybrid at a time... not 3 all at once!
- 6-09-2012** **Too Little, Too Slowly.** How does one summarize what has happened over the past 3 years, since that concern was first stated? I've used the grade analogy. This stresses constructive criticism, allowing you to suggest opportunity for improvement without it being taken as patronizing or condescending. It seems to be fairly effective too... since their had been many supporting Volt how immediately assumed anything negative was an implication of failure. Thank goodness that's changing! They've even accepted the timing some of us struggled to get them to understand from the start. Expecting all those goals to be achieved by the end of 2010 was absurd, hence the vaporware nonsense. That's over now. Phew! The complexities of delivering so much should not be taken so lightly... especially when the competition (traditional vehicles) continue to improve. It's a moving target they nonchalantly dismiss. It doesn't get easier. New challenges emerge at the entire industry advances. It's really unfortunate they don't see that yet. Without a constant push, the pressures of for-profit business gobble up opportunity. You can't just hope for the best.

- 6-09-2012** **Review Ratings.** They're a mess. The hullabaloo from a report about Prius *c* getting a "*we cannot recommend*" rating has stirred the pot far more than any of my ramblings ever could. Naturally, their measurement of efficiency was what provoked the outcry more than anything. Prius is no stranger to this topic. Remember the nightmare when the Iconic model was rolled out. All reviews published in the dead of winter reported terrible MPG observations... none of which were ever followed up on when the weather warmed and owners saw their MPG increase dramatically. It was quite controversy. They didn't want to admit having made such a terrible mistake. That's embarrassing and harm's reputation. Needless to say, we are quite intrigued how this will play out... since the situation is much more complex now. I contributed to the venting of feelings with: What else can be said? The topic of fuel-efficiency measure has been controversial for years, but limited to certain markets. Now that Toyota has penetrated into the lower-cost realm in large enough numbers to draw attention, the pot is getting stirred even more. To make matters even more complicated, adding a plug adds an entirely new dimension to the already confused comparison scales. How will middle-market consumers make sense of so much variety? Each design differs well beyond the typical understanding of what's under the hood. Trying to apply that to your own particular driving circumstances is a fruitless effort, even without considering seasonal change. Automakers will provide specifications. Publications will state their observations. But like in the past, it will be owner word-of-mouth endorsements contributing heavily to sales.
- 6-09-2012** **Tried Something New.** With EV capacity quickly running out, I wondered. Hmm? What would happen if I intentionally accelerated hard at each stoplight, just for a few seconds? The engine was already warmed up and I had several lights in a row coming up... which almost certainly would all be red. So, I tried it. Each time, the engine fired up briefly to assist. It shut back off just seconds later. But to my surprise, that short amount of time was enough to bump up the capacity. At each red light, it had climbed higher... despite the fact that I was still driving in EV between them. Normally, the stop & go situation is maddening. Now with the PHV, it becomes a game. I was taking advantage of the engine to get going and ending up with a little bit more driving with the engine off opportunity. The thought hadn't occurred to me. Making the best of limited resources is what Prius has always thrived at. This is yet another example. Instinct tells you using the engine is wasteful. Reality reveals that's not the case. The flexibility and rapid energy-flow change of the PSD can be utilized to squeeze out efficiency opportunities otherwise missed.

- 6-10-2012** **Finally.** I liked reading this: "*You're actually the last person I ever imagined defending the Volt to.*" It's confirmation of the paradigm shift. I responded with: You should have spoke up a hell a lot sooner. Having someone like you at my side to work with would have made things much, much easier. There was no open dialog. The other forums made outsiders feel very unwelcome. That allowed the constant comparisons to get way out of hand, since there was no venue available for input. Volt was promoted very differently until late last year. We kept hearing sales would pick up significantly in the second. Now, the perspective has shifted to a wait for it to evolve outlook. If expectations would have simply been stated like that in the first place, all that previous strife could have been avoided. Have you noticed how much GM's advertising has recently changed? The "*230 MPG*" and "*Gas Free*" campaigns of the past were very misleading and they did nothing with respect to informing how or when. Consumers got the impression it was a new revolutionary technology ready for mainstream penetration. That ended up contributing to the fallout we've been dealing with. Remember my recent complaints about mixing of present & future? I was reaching out, hoping for someone to finally step up. You did. So, what's next?
- 6-10-2012** **Take Away.** What can we take away from all the craziness? It stemmed from the setting of unrealistic expectations. Volt was hyped as the vehicle that would be "*vastly superior*" to Prius... back in late 2010, not a second-generation design years later. And now that so many supporters have accepted the "*early adopter*" perspective, it makes those of us who saw this coming seem like we were on some vengeful quest... rather than pointing out that what's been committed to is far more than just a future upgrade. The theme has overwhelming been to show some patience, please wait. That probably wouldn't have been so bad if they didn't continue to imply that other designs couldn't accommodate larger battery-packs or more powerful electric-motors. They can advance too. That constant misrepresentation had fed the fire for quite awhile. But now, even the MPG claims are falling out of favor. Cost has increasingly drawn attention. Embracing that shakes off the "*niche*" label, redefining it as just a delay instead. This could very well be why the "*pathetic*" label seems to have recently been abandoned by Volt owners flaunting MPG over Prius. If they really are willing to stop with the taunting and move on to constructive discussion, we can begin to deal with the big problems... like those against vehicle electrification of any kind.
- 6-10-2012** **Turning Point.** That's what I see this as. Things look quite different afterward, but are very uncertain right up until the moment they actually happen. That past is well documented, capturing the feelings & beliefs well enough to provide a basis to look forward with. Of course, we'll still remember all times EV range and MPG were brought up despite such blatantly obvious battery-capacity differences. But clarity allows us to finally to a step beyond the discord. And now that there is an effort taking place to move on, suggestions about what to do next should be the focus. Not stating goals has always been a major source of contention, so stating them now is my suggestion. It's really hard to argue particulars when it's clear that purposes aren't the same.

- 6-10-2012** **Eco-Meter Photos.** Some of us refer to the "Hybrid System Indicator" by that name instead, since it does much more than just indicate. Though, the newest version does actually have an indicator which is quite informative. The 2012 model introduced a "stealth" mode indicator. It's a small EV symbol that illuminates when in HV mode. That's nice to know with both the regular model and the plug-in. But I didn't have any photos of it available. And knowing how much stuff like that gets asked about, it was an essential thing to add to the User-Guide. Now, I've got a number of samples to work with. The bigger symbol for EV mode itself was obviously another I needed, especially what it looks like while the engine is warming up or you're traveling at faster than 62.1 mph (100 km/h). Of course, the part that varies a lot and often is the energy part of the Eco-Meter. That bar has colored zones. You can never have enough samples of that. The battery-capacity is the most intriguing though. When EV is plentiful, it's solid. When you get down to about the last mile, it fills up again but has divider-lines, which is something I'll have to explain in detail. It goes both down & up while you drive. Anywho, I captured a variety of new photos and just put them on this webpage... [photo album 176](#)
- 6-11-2012** **Somehow.** I wonder what will become of these thoughts I posted online today, in that rather abrasive thread: The post-rollout perspective of PHV is very different from what we had to deal with prior to availability. There's no reason on anyone's part to feel troubled by that. It's just what happened and there should be an effort to raise awareness showing how different things are already. It is frustrating though, that some just outright dismissed the early model data we had and intentionally raised concern on operational aspects we already knew were non-issues. But that's in the past now. We really are attempting to establish constructive discussion. It's unfortunate that the ally we sought years ago in the effort to promote plug-in vehicles is only now accepting of that olive branch. It was misunderstood for far too long. But hey, gotta start somehow.
- 6-12-2012** **Unaware.** It's amazing to witness the turnaround, when someone didn't realize they there was more to the story. That unaware factor has been a substantial obstacle with advancement of a hybrid like Prius. In fact, just today there was a renewed effort to keep the old debates from coming to an end. Some declare their postings as an endeavor to educate. A growing number of us see it as an intentional holdback. This is the same "raising doubt" undermining of the past. Don't let the conclusions from being draw, at all costs. Remember the argument against collecting that "100 MPG" data recently? Looking back, it has already becomes clear that was an effort to suppress information. Geez! Of course, being so obvious makes that easy to conclude. Confusing with red-herrings only goes so far. Focusing on power too much reveals misplaced priorities. They stall, waiting for the next big news event. In the meantime, people keeping buying more Prius... and studying the history. Reading blogs reveals much about what actually happened verses what some claimed happened.

- 6-12-2012** **Any Benefit?** I decided to try something new today. I modified my commute to work. Rather than jumping on the 70 mph highway just 3 blocks from my house, I drove roughly 4 miles in EV first. Would getting on later make a difference? Turns out, it did. But rather than being a benefit, the resulting MPG was the same but I completely depleted the battery. Jumping on the highway right away instead, I typically end up with a little bit over 1 mile of EV capacity still available. So, it was a net loss. That tends to make sense, since you only have to get up to speed once. Maintaining it takes far less electricity than having to deal with frequent stops. So, I tried another variation on the way home. I drove 11 miles of my 17 mile trip with EV only, before jumping onto the highway. That 3 miles of EV capacity I had available for the high-speed travel was consumed quickly. I watched my average drop slightly below what it would have been if I had just traveled on the highway from the start. In short, neither of my attempts to use more EV actually resulted in a benefit. I was better off doing the "*just drive it*" approach instead. Isn't it fascinating how counter-intuitive hybrid efficiency can be? That's why some of those arguments persist for so long. Assumptions don't match implementation.
- 6-13-2012** **Display Photos.** I've taken quite a few lately. There's a lot of variety needed for the User-Guide and it isn't easy encountering those situations, especially when there's good lighting and little to no traffic so I can use the camera. That has limited much of the photo taken to late in the evening. I'm getting there though. Enough source material now exists which I can build upon. After all, the User-Guide is a constant work in progress anyway. Looking at all those photos, I can't imagine where a newbie would start. There's just so many different indicators that individual photos don't portray well. It makes sense in action, watching the changes. But that requires video, which is my next capture challenge. Here's what I have so far... [photo album 176](#)
- 6-14-2012** **Pathetic.** Comments like that from the past causing new Volt owners to cringe is quite redeeming. They wouldn't say anything as offensive as "*pathetic*", so it's embarrassing to discover such declarations from enthusiasts back then... which is why I included those quotes so often in these personal logs. Humility can be an effective tool for overcoming major obstacles. They kept pushing the "*vastly superior*" attitude, to an extreme which is quite difficult to believe now. Not having any idea we had to deal with nonsense like that clarifies the stance we took. I remember having to tolerate the "*anemic*" claim for years. There was an intense effort to belittle & mislead about the plug-in Prius, something only now being exposed. Understanding comes from learning about origins. More importantly, it prevents those same mistakes from repeating. The goal is to penetrate the mainstream, not showcase a performance vehicle. Hype dominated. Expectation management was a joke. Attempts to be constructive were labeled as undermining "*spin*" and the threads either overwhelmed with red-herrings or just outright closed. It sure is nice to have finally moved beyond all that.

- 6-15-2012** **Greatest of Ease.** Driving the same roads as with my 2010 Prius, which I filmed myself doing not too long ago, brings back incredible memories already. The engine shuts off sooner with the PHV model. The power threshold for electric-only is quite a bit higher too. With the greatest of ease, I travel those driving experiences with a new perspective. That's exactly what I was hoping for. My expectation management was well researched. I knew that the 60 kW traction-motor was being under utilized, that more could be returned from the same system simply by having more electricity available... and the supply the plug-in battery-pack provides certainly does that. It's great, though odd. Watching MPG drop below 100 comes with a brief moment of trepidation. You tend to lose perspective. That's well above the usual 50 MPG still. What's interesting is that I find myself using the engine more often now. Seeing that it adds some EV distance when used and knowing how quickly it shuts back off afterward, why not? Overall, that works out really well for travel beyond the capacity available. In short, it's becoming remarkably easy to promote the "*Just Drive It*" motto.
- 6-16-2012** **40 MPG Challenge.** This new article was an interesting read. That perspective is really beginning to be out of touch with the big picture. This was my favorite quote: "*After all, a hybrid might easily get 40 mpg, but it customarily carries a sizable cost mark-up to pay for its exotic technology.*" Since when is a well-established hybrid like Prius exotic? In fact, it's easy to consider the 6-speed, automatic, dual-clutch traditional systems more complex. And when 5 of the 6 vehicles they tested were in the same price category as Prius c, you have to wonder about the price claim. Naturally, there wasn't any mention of emission-ratings either. I was particularly amused by the calling of 40 MPG for fuel-efficiency as "*lofty*". With plug-in hybrids entering the market featuring battery-capacities with affordability in mind, you have to wonder how long they'll be able to keep up the avoidance. I've been averaging 100 MPG over the past 2,000 miles from mine. How does that influence their challenge? They asked a final question: "*How much money will you save when you pick one of these fuel sippers over another?*" Think about how much pressure the traditional market will put on anything offering a plug, especially with the current disregard for hybrids. At what point does the reality of diminishing returns come into play? This is a very important question when it comes to plug-in vehicles offering larger capacity batteries? People are growing accustomed to pay \$4 for a gallon of gas.
- 6-16-2012** **Upgrade?** 54 miles for the daily commute, round trip. Is it worth upgrading from a 2006 model? Trade-in value is decent, but not being able to plug in at work raises questions. It can be a difficult situation to consider. Hopefully, some real-world input will be helpful. Here's what I contributed to that discussion, following someone else's comment that results may be disappointing: That's a matter of perspective. Realistic expectations make all the difference. It depends on whether or not effortless 70 MPG is impressive. I didn't get a chance to plug in at work the other day and drove close to that distance with only a single charge. Evening errand running is quite amazing if you plug in after returning home from work. My late night runs to the store are typically all EV. Seeing that 999 MPG, especially on short trips, is a dramatic upgrade from 2006 model. Don't forget that you get to choose when & how to use that electricity too, with the HV/EV button.

- 6-17-2012** **999 MPG.** Today was my very first with the PHV. Ending the day that way wasn't the plan. I wasn't even trying. It was just unusual circumstances that prevented the need to drive too far. One trip in the suburbs isn't enough to use up the entire supply of electricity. Traffic around here is quite reasonable. There's hardly ever a the need for lots of power. It's nice being able to drive around without the engine ever starting, but that's not an expectation. I don't mind when it starts, since so little gas is used anyway. It shuts off quickly in the warmth of Summer. Come this Winter, the warm-up should be interesting. Since I'll intentionally start the engine for cabin warming in those much colder temperatures, the option of rapid on & off for acceleration will be enticing to take advantage of... since then the engine won't have to come on as soon for more heat. It's an excellent balance of resources. Observing the dynamics of the system makes first-year Prius ownership experiences quite rewarding. The PHV is certainly no exception. Anywho, it was all electricity today.
- 6-18-2012** **Drive-Thru.** That was sweet! I pulled up to the drive-thru window and the guy there greeted me with: *"I love that sound. Every time I hear that..."* He was referring to the proximity warning, a subtle artificial sound made by the car when you drive slower than 15 mph. It's intended to warn pedestrians of the car's presence. In reality, many aren't even attentive to headlights when you are right there behind them in a parking lot. Unfortunately, the noise of a shopping-cart or the preoccupation of a phone conversation makes them oblivious to their surroundings. But at least the sound will help a few... and it turns out to be quick entertaining for people working the window... especially this time. He assumed it was just a Prius in EV mode. I know that, because when I pointed out my Prius was a plug-in model, his face lit up with excitement. His reaction was great! I then proceeded to share current MPG statistics. He gobbled up every bit of info I could quickly through at him. Want to bet he's even more attentive to that sound now?
- 6-19-2012** **Carbon Reality.** I watched a new special on television today. The evidence of climate-change is overwhelming at this point, especially with record temperatures and drought becoming so prevalent. The major contributor is the carbon increase in our atmosphere; that's very difficult to deny now. The source of that is still wildly under debate nonetheless... much like smoking was in the past. You know nothing good comes from certain consumption, yet there are plenty of excuses to not change your habits anyway. It's seem absurd at this point not to try. We have the technology. What the heck we will tell our children later... we suspected it, but didn't bother. Yeah, that will make them feel wonderful about the prior generation. Thank goodness hybrids are well proven now. Prius has become such a normal part of everyday traffic, it's basically flat out denial that it's not realistic... especially with plug-in variants now entering the market. Long story short, the program I watched provided new detail. It followed up on some of the things we had considered a warning sign in the past... confirming those fears. To think that some people see absolutely no need to embrace motor & battery use. They insist the combustion engine alone is improving enough for use not to be concerned about carbon emissions. That goes to show you how short-sighted they are. Even if that was true, our children will see the end of abundant oil. Then what will they do? Totally disregarding what electricity has to offer is not a good plan. It's like we're living in a modern version of the dark ages.

- 6-19-2012** **That Splendid Drive.** I finally had the opportunity to drive that memorable route with the PHV. It was indeed splendid too. The story had been retold many times over the past 2 years. I drove from my house to McDonald's and back in EV mode. A surprising number of Volt enthusiasts denied it was possible. They claimed there was no way a plug-in Prius could do that journey using only electricity, especially since it required a climb out of the valley at 45 mph. That never happened, period. It was infuriating, for me. It was outright denial, for them. Heck, even the blog moderator got involved. When I pointed out the power output from the electric motor increased from 27 kW to 38 kW, he hid the post "for review" later. As expected, it remained hidden. That's when I knew things had gone from bad to worse. Nothing good comes from facts being suppressed. They just plain didn't want to believe the PHV was anything more than a Prius with a bigger battery and a plug. After all, admitting the components in the current model are under-utilized means acknowledgement that Toyota planned for this long ago... rather than scramble to compete with Volt as they had been claiming. Needless to say, it was a delight getting to recreate that drive again.
- 6-20-2012** **Now Silent.** The big stir a few weeks ago dwindled down to nothing. It was an "*all bark, no bite*" situation. The antagonists made a huge ordeal out of something, complaining about this & that, yet never actually provided any suggestions for change... hence the way they have been and continue to be identified. It fit the recognizable pattern all too well. In this case, that served as confirmation of finality. Though frustrating to experience, seeing nothing was ever delivered reveals it was really just a desperate attempt to retain attention. They know the market has seen Volt and is moving on. It's been written off as too expensive for now and won't get another look until the next generation is presented. Ironically, that is logical outcome of promoting as an "*early adopter*" rollout. They didn't think through the entire situation though. That outcome is undesirable. Oh well. Stating goals could have avoided this. The silence now is good; however, I am rather bummed the reach out for constructive discussion didn't result in anything. It sounded hopeful, especially from the one outspoken individual. Oh well.

6-20-2012 **Review Audience.** The uncertainty of who is growing as attention slowly shifts over to PHV. With the spotlight no longer on Volt, you have to wonder who the plug reviews are actually for. The vague rollout of Volt confused everyone... the very problem we attempting to prevent. Oh well. The damage wasn't too bad. But it does beg for some answers to questions emerging as a result of that. On a thread featuring a teaser review (brief hint of what will be in the next issue) of PHV, my thoughts were: Who is the market for Volt? That question was asked countless times prior to rollout. We knew the consumers who would be interested would not be the same as those who Prius targeted. It's like trying to sell a plug-in Camaro to someone that was looking for a fuel-efficient Cruze or Malibu. Yet, enthusiasts refused to acknowledge that. When they said "leap-frog Prius", it was implied as direct competition; now the claim is quite different. So, we move on to discussion from other sources, now about what Toyota is offering. How will popular rating publications portray the plug-in model Prius? The "*you can't drive it completely gas-free*" comment really makes you wonder about market. Who's needs are they addressing? Why would that matter to someone who was considering a different model of Prius, a Corolla, or a Camry? Would any of those consumers really have a priority of no gas whatsoever rather than just a significant MPG boost? The beauty of PHV is that it is package option, an upgrade choice. It's an enhancement to a vehicle people already know and like. There's no paradigm-shift required. You're not buying something fundamentally different. There's a major improvement to efficiency & emissions. Simple to understand. Easy to sell. A small decision to purchase.

6-21-2012 **More 999 MPG.** The unusual circumstances continued. I had 4 days in a row of electric-only driving. Today, road construction ended that. Trying to cross a road with very heavy traffic funneled down to a single lane resulted in me simply dropping the pedal to the floor for maximum power. Though probably overkill and knowing it would cause the engine to start, I did it anyway. Taking advantage of what the system had to offer was a wise choice. You never really know how frustrated or confused others dealing with all the traffic are. So when it was my turn, I did as seemed best. That was in the morning. Late in the afternoon, I ended up needing to run an errand further than the EV range available. So, the streak would have come to an end anyway. It was interesting. Feeling the engine come back to life provided assurance that extra power was about to be provided. That certainly isn't the way antagonists have been portraying such an experience. They spin it as a negative, sighting how it prevents you from being "*gas free*"... which makes no sense, since any vehicle with an engine will have to run it from time to time for longevity maintenance. I obviously don't believe in absolutes.

- 6-21-2012** **\$78.20 Per Barrel.** That was rather interesting to see. The price of oil dropping well below expectations sure adds to the challenge of selling vehicles that offer high MPG, when expensive gas is the primary influence. I see this as yet another reason in support of the configuration for PHV, where capacity was carefully balanced with cost. There isn't dependency on what happens with oil. People will consider the purchase even without the pressure at the pump. That's important when it comes to deep market penetration. The raising of CAFE standards is a change for the entire fleet. The technology must be well established and well accepted to sustain high-volume sales. That's means no dependency on tax-credits either. How each of the automakers will deliver, especially if the efficient choice is expected to be green as well (SULEV emission-rating or better). With the economy having fallen into such a deep recession, the need to have well-balance choices available is more important than ever. We cannot just hope for the best as so many had done in the past. Seeing \$3.39 now for a gallon of gas certainly makes a person think too.
- 6-22-2012** **Info Omissions.** A new 10-minute video provided by an automotive publication motivated me to post this as a response: The review begins with this introduction: *"If you're looking for a commuter car that doesn't just get good, but exceptional fuel economy, there are two standout options."* Then it goes on to point them out, the Jetta TDI and the regular model Prius. What the heck? You know VW supporters would complain to no end if they had compared a regular Jetta to Prius. Yet, this brand new review published today made no mention that a plug-in model even existed. Had there been some disclaimer, like an "another category" or "at a later time" reference, that would be understandable. There is simply no excuse to for a professional automotive organization to totally ignore. People expect them to be well informed and comprehensive. An omission like that is misleading. And since the introduction put focus specifically on fuel economy, that could qualify as greenwashing. That being said, the sticker-price of the base model Prius PHV is \$32,500 and it easily delivers double the MPG of the Jetta TDI. It's significantly cleaner too. The review itself was actually fairly good. It featured a mix of priorities with a variety of opinions and seemed reasonably objective... but makes you wonder how much longer excluding models will be able to continue without backlash.
- 6-23-2012** **Who Said What?** From time to time, I've stumbled into arguments stemming from quotes I never actually said. Someone else did, yet I got blamed. It's very frustrating to be trapped in that situation, where they truly believe you changed your stance... because you are now saying something different from what they remember. It's very easy to disassociate, especially when there's strong emotion involved. They're totally unaware of it taking place too... or at least were until recently. I don't know if some are making an effort to read my personal logs or search through old forum posts, but a few unexpected apologies have emerged. That's quite a surprise. I hope I am properly acknowledging them too. It's easy to sound condescending or patronizing in broken discussions like this. Fortunately, some of the tension itself is instantly relieved upon the revelation of having mixed up who said what. It's makes starting fresh threads easy. There's a desire to move on coming from multiple sources now too. After all, the hope for late 2010 is well beyond the "please wait" stage now.

- 6-24-2012** **13.5 Miles.** After driving a PHV for awhile, you focus on the overall results rather than observing individual drives experiences. Today was different though. To my surprise, I traveled beyond the usual EV estimate range without even trying. The engine simply never started. I went 13.5 miles with just electricity alone. I've went further before, but not effortlessly like this. The feel of the driving is obvious becoming natural. It's like the way automatic transmission drivers just naturally avoid both hard downshifts and wheelspin. They just do without any thought. It becomes habit... one that's a challenge to break when you tell new Prius owners it's perfectly fine to drop the pedal to the floor, since the system controls the wheel movement for you. They don't even realize it was something they were avoiding. Anywho, it's fun experiencing what I've looked forward to for so many years... especially something so easily understood by other Prius owners.
- 6-24-2012** **Change.** It's nice seeing it happen. Raising awareness about bad practices still "stirs the pot" though. Some unknowingly continue to greenwash feed. Bring that up results in responses like this: *"Your first post here was trollish though."* I understand their upset from being pointed out and am thrilled to observe their change following that. It's a slow process. But if sincere, overcoming that is totally realistic. This was my reply: That comes with taking a "pushy" stance. Wanting to move on means not letting the rehash of old information dominate anymore. Unfortunately, that desire for progress appears to others as "rocking the boat". And sadly, the approach has been to welcome "cheerleading" and shun those attempting to have more than just the repeating of particular points. Think about what still hasn't been addressed yet, items we don't stand a chance at discussing while the rhetoric continues. It's been a heck of a challenge trying to get any real-world data about winter performance. It's a topic that is simply dismissed whenever brought up. That makes a topic like recharging in winter a daunting challenge to even just acknowledge. Are people of the fact that charge-rate can be reduced in sub-freezing temperatures? Think about the influence that could have on capacity discussion. Many haven't, yet pounce on those who attempt to bring it up. Thankfully, we are beyond the paranoid stage. In the past, when a Prius supporter would bring something like that up in a discussion about Volt, it was immediately assumed to be an effort to undermine Volt. The enthusiasts were in a state of panic, blindly lashing out in fear of anything that could tarnish reputation. I sure am glad that isn't the case anymore. Phew!

- 6-24-2012** **Improvement.** You can see hints already. The plug-in hybrid and EV are moving forward, people just beginning to become aware of differences from impressions of long ago. I find it exciting, since I've been paying close attention. It's intriguing how so many seem to overlook (or more likely don't even notice) just how many angles of attack Toyota is actually taking. The process is slow, but the variety of choices to become available as a result will shift the entire product line. The partnership with Tesla is an obvious example. It's a win-win situation for both. It's not a "let's try this" approach. It's a "here's what we are going to do" strategy. That makes it matter of when, not if. That's why questioning the PHV model seems so pointless. A diverse offering in the future means providing a low-cost plug-in option for the mainstream. Toyota is already well on the way to doing that. The design brilliantly enhances the existing hybrid system. Consumer willingness to spend more means the choice of increased capacity & power. It's not required for great efficiency & emissions though. The start with PHV demonstrates heavy dependency on tax-credits isn't necessary either. Replacement of traditional vehicle production shouldn't be taken lightly. Viable solutions are needed soon. That shouldn't be argued against. We all know the risk attached to consumption & emissions. A small quantity of token vehicles or just mild improvements are far from enough.
- 6-25-2012** **No Politics.** That was today's declaration. It is the formula prescribed for moving on. That sounded really good, until asked the question of how tax-credits were still ok to discuss. That obviously argued a few. I found it quite hypocritical. It was yet another example of cherry-picking. That's frustrating considering the level of vague surrounding what the next steps should be. I've stopped referring back to the past. They totally disregarded that, jumping on me for asking what the "*no politics*" actually referred to. Fortunately, these small attempts to reignite passion of the past, quick before month-end results are posted, don't seem to be accomplishing anything. It's the harmonic nature of progress. There will always be some residual resistance. That's following the familiar pattern we've seen before. So, this will likely work out fine. Advancements include scuffles, but they fizzle out and are commonly forgotten afterward... which I'm really looking forward to.
- 6-26-2012** **Reduced Again!** Here we go, again. Prior to rollout, the Volt enthusiasts were appalled if you were to even just consider the possibility of not meeting the 60,000 sales goal here in the second-year. They were quite adamant that there was no need to question the quantity. It would happen, period. Then came first-year sales well under the rate needed, so the goal here was revised to 45,000. Of course, some spun that to say that was the goal all along, that the 15,000 for the market in Europe was always included in that amount. Whatever. Those having paid close attention all along knew that wasn't the case. But no need to dwell. The effort has been to move on, accepting the revision as-is. Fine. That didn't last long though. Now, the expectation has been lowered to 20,000. It's enough to make you crazy. If you even just mention that change, you get catechized. So, I won't bother. The numbers will speak for themselves anyway. By the way, the number for Europe has been reduced too; it's now 10,000.

- 6-26-2012** **Avalon Hybrid.** The future of this model of car offered by Toyota was always a bit uncertain. Only here in America was there demand for such a large sedan. Would that continue? We'll find out. The upcoming redesign later this year will include a hybrid system, the FULL type like Prius uses... but bigger. Getting a major efficiency improvement, unlike the modest increase from a domestic automaker, will likely be the draw for consumers who still want the size but cannot tolerate guzzling anymore. The expectation is 40 MPG. That's quite a bump up from the current 25 MPG. It's always exciting to see how well the system scales. This is yet another example of the flexibility with engine, motor, and battery possible. Variety is very important for business. In fact, lack of diversity is what has crippled other efforts of the past. One size does not fit all. This newest offering takes Toyota another step further toward ending the production of traditional vehicles. People will just naturally transition over to the hybrid options.
- 6-27-2012** **Drawing Conclusions.** Just as we saw in the past with previous struggling new technologies, there were statements like this about the more successful competition: *"Certainly the Prius PHV looks like it has a battery that has too small a capacity for the market, which makes the rumors that the battery capacity increases likely."* That's the rumor Volt supporters are trying really hard to spread. It appears as though their attempts to belittle based about the top EV speed aren't drawing the attention they hoped. They've discovered the EV-BOOST mode is remarkably efficient. Arguments claiming sustained efficiency above 100 MPG aren't finding an audience. So, they've switched to capacity... quickly, before proof emerges that the conclusion they are drawing doesn't have any actual merit. According to who? This is why I asked the market question for years. How could typical mainstream consumers already be saying that? Based on what? As for the capacity increasing, that's a rather pointless thing to say. Of course it will. Generational improvements are a normal expectation. Each gets progressively better. That's the way battery technology has been for decades for portable devices. Why would it be any different for those used in vehicles? I find it amusing how after only 3 months on the road, with very little real-world data available yet, they can make a blanket statement about the market with complete disregard for cost.
- 6-27-2012** **Recharged Twice.** Traveled so far 38.1 miles. Displayed average 118 MPG. Remaining EV distance 7.9 miles. That made for a very interesting commute. The slower, longer, more enjoyable route finally opened up again. Construction season is causing lots of detours. Prius makes dealing with the unexpected much easier. I had no idea a return back to the usual would yield such great results, especially switching to A/C halfway through the return home. The evening included some time to relax and do some blogging. On my journey out, I didn't use EV much. In fact, the use of HV mode bumped the EV range up to 8.2 miles. At 47 miles total for the day, the average had only dropped to 99 MPG. That made me especially curious what the outcome would be. After traveling 55 miles for the day, it ended up coming to 117 MPG. Easily staying above 100 is great. That's the boost many supporters have promoted for years. Of course, they envisioned a much larger and more expensive battery-pack. I did that with a small one, just recharging twice instead. But then again, my daily driving is further than the typical person.

- 6-28-2012** **Where?** The final arguments from Volt owners antagonizing PHV are falling on deaf ears now. The realization of not having anything for middle-market is beginning to provide the rebuttal for us. Simply reading about experiences from new owners plugging in their Prius depicts a situation quite different from what they are familiar. It doesn't resemble what you'd expect from an early adopter. There's no sense of having something to prove. As far as they're concerned, the technology is already established. These are ordinary people just trying to figure out how to get the most out of having a plug. I posted this as a synopsis of their last attempts: Lowering expectations is exactly what the auto task-force warned about. Remember the "*too little, too slowly*" concern? Why should we just settle for something out of reach for mainstream consumers? Remember back when we used to strive for ambitious goals? Now there is trepidation about even just stating goals. You know the recent backlash & downplay is due to the sales falling way short. It wouldn't be so bad if the overlooking of PHV the belittling finally ended. But those who speak out get catechized. Where's the choice for the masses?
- 6-29-2012** **Forum Trolls.** A thread from 3 years ago was bumped back to life today on the big Prius forum. It was interesting to revisit it, especially due to the timing. That was back when the newest generation was first rolled out. Obviously, there were strong feelings about that from those who supported the competition. I added to the discussion with these recent observations: Sadly, as a forum matures, some members go rogue. They thrive on the lively debates and drop bait to entice responses. Newbies often bite, unaware of what's happening. There hasn't been a term coined for that yet either, because the identifier of "troll" is defined as an outsider joining to stir trouble. When a well-known member does it, that really becomes a problem. The sign to watch for is the "invitation" post, something that clearly isn't correct or constructive. There's often a strong opinion included too. But because that person has been around for years and typically have thousands of posts, no one calls them on it. That became a huge problem on the big GM forum awhile back. Finally, the moderators declared a clean-up campaign. It was better to callout the activity of those well-known members rather than allow the reputation of the forum fall apart. It was a fruitful effort. They watched their posts for intent. The "provoke" is easy to spot when you're looking for it. That worked well. Some popular names quickly vanished, never to return. Being constructive is the key. Arguing for argument sake isn't productive. What is the purpose of the discussion? Do they simply contradict or is there actual substance to replies? Will that information benefit other members or is it a desperate attempt to keep a thread active? And of course, what does it have to do with Prius?
- 6-29-2012** **Yellow Skyline.** The cityscape I see when taking the scenic route to work looked absolutely awful today. The dense morning air kept the pollution from blowing off into the country as it usually does. Knowing that is normally passed on to others by the wind makes it even more disgusting. But you usually cannot see it, especially up close. Being about 15 miles away, the distance allows you to easily notice it. Emissions from our vehicles contribute heavily to that. Those who point out the problem get labeled as a "treehugger" or the driver of a "greenmobile", insults that are commonly accepted still. Far too many guzzlers populate roadways, making the attitude easy to share. The yellow color of the sky is dismissed as contributions from vehicles long ago. They claim emissions are much better now, providing an excuse to consider newer vehicles good enough. Why bother with a SULEV or PZEV rated vehicle? That's sad.

- 6-29-2012** **New Own Panic.** The EV estimate, the range of miles displayed upon completion of recharging the PHV, has been the start of new threads lately... coming from owners new to the forum expressing their feelings in a heightened emotional state, with the insistence upon contacting the dealer right away. It's been quite riveting to witness. There's passion about this topic from all involved. This was my contribution to the one today: I watched mine decline as I drove more on the highway in HV mode. It gave the impression capacity was somehow being lost each recharge. In reality, it was just the EV estimate value influenced by previous driving data. Now mine is up higher than ever, not having taken a long trip recently. Actual EV driving distance hasn't actually change. It's been consistent throughout, despite the estimate going up & down. It reminds me of the reaction Prius owners had throughout the Iconic years. When the battery-level dropped to 2 bars, that change to pink on the screen made them panic. They truly thought something was wrong. A few even took desperate measures, not realizing that was perfectly normal. Everything is fine. They certainly don't feel that way seeing it though. This is unquestionably the "panic" situation for new PHV owners.
- 6-30-2012** **EV modes.** There are 2 different modes available while driving faster than 62 mph (100 km/h). Regular HV is when you explicitly push the button to halt EV depletion. This causes the Prius to revert to the usual 50 MPG hybrid driving. If you don't push the button, the default EV mode transforms to EV-BOOST mode. This causes the system to take advantage of the plug-supplied electricity, which results in efficiency above 100 MPG. When the EV symbol is small and the Eco-Meter has a center-divider to indicator a white zone, that's HV mode. It will remain that way until push the button again or shut the power off. When the EV symbol is large and the Eco-Meter only has a green zone, that's EV-BOOST mode while driving fast. It automatically turns into EV mode when you leave the highway and changes back to EV-BOOST when you exceed 62 mph... or you acceleration hard... or the heater cycles back on.
- 6-30-2012** **Rollout Progress.** The antagonists pounced before much real-world data about PHV became available. Focus was concentrated on those who had already begun to draw attention to choices for the masses. With a plug-in like Volt, lots of time is still needed for significant cost reduction. Seeing the rollout progress of PHV poses a very real threat. I doesn't take much to confirm their fears either. Reading new owner posts reveals the appeal of the simple approach. The plug is offered as a package option. You get a Prius with added battery capacity, expanding upon the abilities already offered. Instead of a little bit of EV as the regular model provides, you get a whole lot more. There's no paradigm shift, consisting of an entirely new vehicle. It's the next logical step. As a result, progress is rapid. There's no resistance. There's no hype either. It's just a soft build up of interest. By next year when national availability begins, sales will highlight the natural acceptance those of us very active online are observing now. Ford will be offering a plug-in hybrid too. The antagonists are well aware of the pressure building, where the expectation is for growth. Low sales are bad enough, flat is even worse. Watch what happens in states without local tax incentives or HOV privileges. That will be telling about what's to come. Remember, there will continue to be a MPG push from traditional vehicles, making sales of hybrids & plug-ins even more of a challenge.

7-01-2012 **Branding Choice.** Ugh. The past has many, many examples of vehicles rebranded. The automaker would choose to offer a cosmetically different vehicle that was virtually identical under the hood. Volt appears to be taking that approach too. Cadillac ELR will be the next GM model delivered. It is expected to be the first to offer what the next Volt will include. So, we are looking at a nicer class interior, sound-proofing, and suspension, but not much else different. It could be the first step to downgrade Volt to being more representative of what Chevy usually offers. That's good. But no change to the propulsion system means it will remain very expensive. So, what's the point? Why didn't GM just do that in the first place? I posted this in that discussion on the big GM forum today: Yes, GM would have done well choosing to offer Volt as a nicer class of vehicle first. It was configured to appeal to buyers of that price-point anyway. Much of the flack & comparisons could have been easily avoided that way too. The vehicle simply would have been paving the way for an affordable model later without any conflict of approach or even expectation. Instead, the decision was made to make it a Chevy... which contributed heavily to the hope of mainstream sales within the first generation, feeding hype that could have been prevented. However, there is the constraint of time and the reality of the technology not scaling as promoted. What resources will be expended to offer something other than a compact? How will aspects of price & performance be affected? When should we anticipate that? Think about how price has already pushed Volt interest over to other GM choices. The growing pressure from CAFE standards means competition from within. More affordable options from other automakers doesn't help either. Can people be convinced to just wait in the meantime, as the technology improves? If so, what will they be waiting for? Long story short, we're beating a dead horse unless someone provides a new set of expectations.

7-02-2012 **Prorogation.** It would be nice for the current backlash/fallout/downplay to truly be concluded. The Volt owners who launched an offensive on the big Prius forum have grown quite quiet. In fact, the one who made a huge deal out of my stance, who said he'd help out with the effort to share information, has vanished. But looking at his past, there was only a single post last year and none before that for an entire year. So, it's not like he was contributing anyway. Everything was about keeping Volt in a good light still. That meant belittle Prius and turn a blind eye, denying that was happening. It was so obvious they were not being sincere. But that was a fantastic way to find out what each individuals purpose was, since they'd never just outright say it as I do. That approach worked. Of course, one particular individual took to the old antagonist technique of changing a definition. He attempted to spin "*too little, too slowly*" as a reference to Toyota. It was a desperate effort to conceal the reality of it meaning something must be delivered to the masses soon. That was said back in 2009 as part of the GM bankruptcy recovery plan. 3 years later, we are now being told it will still be another 3 years before something could possibly be available as an affordable mainstream choice. It's a sad statement, but closure nonetheless. Meanwhile, Toyota is rolling out several options for middle-market buyers. My favorite is the PHV model.

7-03-2012 kWh Gauge. That idea has been tossed around quite a bit over the years. Currently, we have an analog representation of percentage and an estimated distance. Neither of which give you a clear understanding of what the outcome would be. kWh measure for EV really wouldn't either. But the thought is that could be more informative, especially when used in conjunction with the other displayed values. I've always liked Toyota's KISS approach. The simplicity has proven to attract mainstream buyers too. Is having a plug different? Would introducing that be too complex? Would it contribute to new assumptions or help dispel misconceptions? At this point, no one knows. These are my thoughts I posted: Unfortunately, a kWh gauge wouldn't work either. 14.1 miles had been my record EV distance until recently, when the hot summer mornings arrived. Although the EV estimate stated 13.7 miles yesterday, I actually traveled 15 miles of EV with 2 miles remaining when I arrived at work. It was 84°F degrees that morning, quite a bit higher than the usual mid-60's. Today, it was 77°F and I was curious as heck how far I'd be able to travel in EV. So, I refrained from the usual HV button push to warm-up the engine during the most efficient portion of my drive. 17.2 miles later, I was in the parking ramp with 0.3 miles of EV still left. The entire commute was with electricity, even though the EV estimate stated only 13.7 miles were available. In short, YEVWV is the new term we'll have to learn to accept. Your EV Will Vary, based upon acceleration demand, cabin comfort, window clearing, and outside temperature. There's simply no way to accurately depict expectations.

7-03-2012 Sales Spin. We all saw this coming. Televisions commercials for Volt have been abundant. Promotion of zero-percent financing, state & federal tax incentives, and HOV privileges was heavy. Constructive discussion never emerged, despite efforts to establish. There was hope without anything to actually support it. A popular Detroit publication took month-end results and titled that report with "*sales rise*". In the article itself, there was this quote to peek interest: "*The company abandoned its 2012 U.S. sales forecast of 45,000, saying it would instead match supply to meet demand.*" And it did too, I was quite intrigued to read on. The remaining half of what had been written was all about how much lower Nissan Leaf sales were. Why acknowledge the 31,402 Malibu, 20,793 Equinox, 18,983 Cruze, or 6,785 Sonic of GM's own offerings when you can draw attention to an unrelated vehicle from a competitor instead? Needless to say, the Volt quantity sold was much lower: 1,760. That's below the number to even make the newest revised goal. Unfortunately, there isn't a breakdown available for Prius sold with a total of 19,150. Fortunately, it still holds the third position behind Camry's 31,107 (including the hybrid model) and Corolla's, 26,647. The goal of diversification is clearly being addressed by Toyota. It will be interesting to find out how PHV did, being available only in select states still. Meanwhile, the article stated that 5,300 Volts are available for immediate purchase as of the end of June. So, the supply meeting demand question has clearly been answered. Reading the comments, it was very clear that people are worried about the politics and slow progress... seeing the situation very different from what Volt supporters have been saying.

- 7-03-2012 PHV Sales.** It didn't take long to find out the tally for the United States. June was the first month of open availability, but inventory wasn't stocked with more than just a very limited selection until last week... and that's only in California. So if you didn't want what they specifically had and wanted one that wasn't a demo model, you were out of luck. July should be different, the first to offer a hint of actual demand. Neither March nor April did, since both were pre-order deliveries. May was a mix of pre-order and pre-sold units. But those facts won't stop the antagonists. Here's what I posted on the big GM forum, hoping to at least present some facts before they start their Volt spin: 695 sold from the 14 states it is currently available (California, Oregon, Washington, Arizona, Maine, Massachusetts, Vermont, New Hampshire, Rhode Island, Connecticut, New York, New Jersey, Maryland, Virginia, and Hawaii) in June. It sure will be nice when nationwide happens. But then again, people still await real-world data to make their purchase decision. Warm weather has been making quite a difference with mine. Today I drove my morning commute, that's 17.2 miles, entirely with electricity. In fact, I ended up with 0.3 left in the parking ramp. That's well above the EPA's 11-mile estimate. My current tank is just under 900 miles, averaging 120 MPG. So, I do indeed see it as a better compare than a pure EV like Leaf. I still wish there was a more affordable model of Volt available. Diversification is needed anyway. Offering a choice of a smaller pack with a system tuned more for HV efficiency would be a win-win for both automaker & consumer.
- 7-03-2012 Sales Breakdown.** The impatience and self-defeating mindset of monthly sales hit Toyota hard this month. There are people waiting for c model delivery. PHV availability is very limited as well, even within the states it is currently offered. The number-crunchers don't care though... and neither do those yearning for an opportunity to claim falling demand. Guess what happened. Yup, the resulting 695 sales of the plug-in model for June were indeed spun as market interest dropping already. That's so hypocritical. With all times we were told by Volt enthusiasts to be patient and wait for the second-year, not doing the same now is the ultimate show of disingenuous intent. Of course, when we did wait, they made excuses to wait until the next-generation model rollout instead. Thankfully, the short-sighted nature of these reports makes it easy to focus on year-end results later. For the month though, there were 11,514 of the regular model here, next with 3,657 for the c model, and 3,284 for the v model.
- 7-04-2012 EV with A/C.** The holiday was going to be a hot one. We were all planning to do some shopping around town. That meant driving EV with A/C. It was an opportunity to observe firsthand the punishment those down south have to routinely endure. Seeing triple-digit temperatures use to be rare up here in Minnesota. Now, it happens routinely... a few days here and there. I cannot imagine what that would be like all the time. But then again, I bet that's exactly what they say about sub-freezing conditions up here. Anywho, I looked forward to the day's travel. We had 4 stops. Each was long enough to allow the car to heat back up when we stopped. I was generous with the A/C, curious if the draw would cause the engine to run at some point. It never did. EV driving through the suburbs was no big deal. I was very pleased with those results. Errand running is quite pleasant with the plug-in model Prius, exactly as I had hoped it would be.

- 7-04-2012** **Competition.** I provided the sales numbers for Malibu, Equinox, Cruze, and Sonic. This was the response: "*Only in your mind is that the competition for the Volt. Unbelievable.*" It boggles the mind how greenwashed GM supporters have become. It's a game and a race to them, but only Volt, Leaf, Focus-EV, and Prius PHV are competing. To them, nothing else matters. They don't see the rest of the market or any pressure to become affordable quickly. Sales lost to those other vehicles don't matter, as long as their own category of vehicle has Volt on top, all is well. Thankfully, not all feel that way. But the majority participating online certainly don't see any problem with GM having dropped sales expectations for 2012 again. That's so bad, it seems pointless even bothering to point out the limited inventory of PHV still. I'm better off just waiting for stock delivery and distribution to the other states. In the meantime, interest will build from forum posts and website updates. Currently, the typical person isn't even aware that a plug-in Prius has been rolled out. That's quite a drastic difference from the heavily advertised Volt with television commercials. My follow-up post was with this: The "game" is traditional vehicle replacement. The "race" is mainstream penetration. To achieve those high-volume sales, you can't just disregard the other choices available.
- 7-05-2012** **Dual Sighting.** I spotted a Prius c up in the distance. It was that Habanero color (the vibrant orange), very hard not to notice. I caught up to it at the next intersection. Me getting into the left turn lane meant pulling up next to it on my side. I looked over to check it out. The owner was obviously use to getting the attention from what she was driving. She just passively looked over at me, then my car. You could see her expression suddenly change to bewilderment. She had obviously noticed the "Plug-In Hybrid" emblem and was in the process of recognizing what that actually meant. The expression transformed to a smile. We had just checked out each others Prius. It was quite an unexpected experience. That adds even more to how Prius makes waiting for a light to turn green a more pleasant event. I cannot wait until I finally spot another PHV on the road. Here in Minnesota, it could be a very long time still. Rollout won't hit this state until next year and it's rather unlikely many will pounce on the opportunity in early January... the dead of Winter.
- 7-05-2012** **First Mega-Regen.** The result of 87 miles of driving, using only the electricity from overnight recharging, was 71 MPG. That was quite pleasing, especially considering this drive to a remote bike-trail included use of the A/C. On the way back, it was late in the evening. Open windows did the trick that. Of course, that cooling reduces efficiency too. The most exciting part of the journey though was a long decent downhill. That was my first opportunity with the PHV. In the past, I had used "B" to avoid over-charging the battery-pack... since the 2010 didn't have enough capacity to hold that much electricity. This Prius does. So, I was quite curious what would happen. Down the scenic valley road I went, watching the charge-level climb. When I got to the bottom, there was 1.4 miles of EV now available. That was the kind of result I was hoping for. With MPG having been so great up to that point, I was reassured the return trip up wouldn't be much of a penalty with that much electricity to help out. That indeed ended up being the case too.

- 7-06-2012** **Entune Updates.** Toyota has been delivering updates to their in-car information/entertainment systems to customers via postal mail. With such a variety & quantity of vehicles, many more than just Prius, getting something at home is much more convenient than having to come into the dealer... especially when it has nothing to do with vehicle operation itself. That means most owners are discovering a USB memory-key in their mailbox. You plug it into the port somewhere inside the vehicle, then accept the update prompt on the screen. For advanced plug-in owners, like myself, the process is different though. I didn't get anything in the mail. The update was broadcast to me wirelessly via my smart-phone over a bluetooth connection. That's happened twice now. I pull up the screen in my garage and discover an update is available. Clicking YES, the software is updates. It only takes a minute if you have a fast internet connection too. Someday, most everyone will likely get updates that way. For now, I'm among those helping to verify the wireless method works well.
- 7-07-2012** **Signs Of Hope.** The bait dropping got quite intense lately. They missed me on the big GM forum. All the provoking & taunting to get me to post something was very amusing. It's like they have no idea that forum is a fanboi venue, not having any reflection on what ordinary middle-market buyers are interested in. Other websites focus on what you get for what it costs instead. They thrive on bragging rights, not caring at all about business objectives. With the price of a barrel of oil currently in the 80's and gas around \$3.49 per gallon, it should be clear that efficiency is a higher priority for buyers now... but not the highest. Price of the vehicle itself is having a major influence on sales. That target of "*nicely under \$30,000*" is still a major goal. Oddly, that message is getting through. Fewer and fewer antagonist attacks prevail. They simply aren't drawing attention anymore. With 39,970 regular model and 28,736 c model sold last month in the US and Japan, it's not much of a stretch expecting growth for the PHV model. Everyone knows it too. The Volt rhetoric is dying down.
- 7-07-2012** **Missed It!** Someday I knew it would happen. Stopped at the light today, I was taken by surprise when a subtle vibrating sensation grabbed my attention. It was the engine warming up. For the first time with my PHV, the transition from EV to HV was totally overlooked. There's was lots of traffic at the time and I had just climbed a very steep hill amongst all those vehicles. Running out of electricity at exactly the right moment prevented me from noticing. That was cool. I figured not focusing on the screens so closely would allow that automatic mode switch to occur without drawing attention. After all, the engine runs at a low RPM and the pumping cycle makes it faint in comparison to traditional vehicles. The startup process itself is different as well, far less strain on the engine. The system waits until oil-pressure is established and spins the engine up to idle speed instead. Long story short, I missed it!

7-08-2012 **New Advice.** Actually, it's the same old advice of the past. But now we have a new audience. The nature of online forums is a dynamic with much uncertainty. PHV doesn't make expectations any more clear. It's a little better though. The big warm-up penalty of the past has been reduced rather significantly. The hybrid system is taken advantage of even more. Nonetheless, we still have lots of emotion to deal with when it comes to the purchase of unfamiliar technology. I put it this way: I have a feeling it's going to be common hearing complaints about EV range. It's a sad reality that people will seek out a venue when they're upset but remain totally unknown when pleased. What's worse is the disregard for purpose, which is to boost MPG, not electric-only driving. I'm sure we'll gain quite a bit of experience with this in the next few months. Hopefully, maybe, some of those silent owners who are quite pleased with their purchase will sound off too. We've seen a lot of venting over the years... where they've already made up their mind. So no matter what suggestions are offered, they're already done. When it comes to plugging in a hybrid, that is definitely new territory. We are bound to encounter a variety of misconceptions and unrealistic expectations. The best we can do is what we've done in the past, just keep sharing real-world experiences.

7-08-2012 **62 MPH Assumption.** What do you do when an assumption undermines your own actions? That's what some of the Volt supporters have been asking themselves recently. Turns out, there was a sincere belief that once speed exceeded 62 MPH the plug-in Prius would revert back to HV mode... despite information to the contrary provided countless times over the years. With all my talk about the boost effect, I thought they were just greenwashing. We've seen the intentional spreading of misconceptions in the past. Why would this be any different? To my surprise, that belief was real. No wonder some of the retaliation was so harsh. That assumption enabled the antagonists to shoot the messenger without consequence. It was just looked upon as rival automaker banter, acceptable regardless of what was said in defense of their own. To think something like that could persist for so long. Thank goodness some are now questioning what had previously been assumed to be correct. A power-split hybrid drawing enough electricity from the battery-pack to allow the engine to run at an extremely slow RPM, raising MPG significantly as a result, should be obvious. It clearly wasn't. The plug provides electricity, rather than the engine. With it, there's much more electricity available to draw from... which is exactly what happens when you exceed 62 MPH. That's quite different from HV mode, which is just ordinary hybrid driving without plug-supplied electricity. There's no MPG boost like you get when drawing heavily from the battery-pack.

- 7-10-2012 Superiority.** It was like watching an avalanche. There were cries of superiority coming from the few remaining Volt supporters who believed the discussion about middle-market sales was somehow a campaign to prove Prius was better. Then when someone provided some historical background pointing out that the most popular sellers are typically not the vehicles that earn the highest scores in every category, they were at a loss about what to do next. Nothing followed later either. Those attempts to distort facts about Prius PHV no longer had an audience. The reality that simply getting over 100 MPG on the highway will attract lots of buyers appears to finally be sinking in. It doesn't take much study of hybrid history to confirm how big of a deal being affordable has been. That's absolutely essential to achieve high-volume sales. No level of promotion with change that. It's the nature of the industry... and even more of a problem when you look beyond the market just within our borders. Global realities and demands of business, not to mention oil-dependency or environmental problems, are only now becoming a worry. They're noticing a big penalty for having only considered needs from an engineering-only perspective. Why did it have to come to this? Why couldn't they have listened sooner? Ugh!
- 7-10-2012 Statistics.** The sharing of real-world data is priceless. It's a major component in market acceptance. Without owner endorsements, it's quite a challenge to get consumers to try something new. PHV very much falls into that category... since there is no basis of comparison available. Allowing assumptions to persist is not a good idea. So, I jump at the opportunity to provide information about my experiences. Today, there was a rather constructive review published. It wasn't perfect, but the effort to deliver true journalism was clearly there. It wasn't just the weak observational reporting we've had in the past. The following is what I posted as a comment for that review... Here are stats on my advanced model 2012 Prius plug-in: 5,752 miles. (includes a 636-mile road trip, 34-mile round-trip commute) 115 days of ownership. (it's been a thoroughly enjoyable experience) 185 recharges total. (There's a charging-station available at work.) 68.9 gallons of gas. (10% ethanol blend, measured at the pump) 574.1 kWh electricity. (3.1 kWh per-charge estimate includes conversion loss) 83.5 MPG calculated average overall.
- 7-11-2012 Factual Errors.** How much damage is caused by articles publishing facts that are incorrect? Some websites circulate errors too. What does that do to those who are genuinely trying to do constructive research on a purchase. The majority likely don't understand the numbers or how they are derived anyway. Being misleading makes that information even worse. They probably don't do enough searches to verify facts either. That limited effort makes clarity absolutely vital. It contributes to online debates quickly turn into heated arguments. Some people have no idea as to the accuracy of what they found. To complicate the problem further, they are unaware some of that is intentional. Information that's vague or outdated transformed into facts without a source. Some people spread that, not realizing they are contributing to efforts to greenwash. It's a mess out there. Adding a plug provides a whole new dimension of misunderstandings. I wonder how we'll deal with so much content new for so many people. Buying a new car now is much more difficult than in ages past.

7-12-2012 **Failure.** I pretty much had to respond to this today: "*What is it about the Volt that makes people actively root for its failure?*" Saying anything about Prius translates to speaking out against Volt. That automatic association is quite maddening, for all involved. No matter what you say, they hear spin to give the sense of Volt failing. That's why I have such a difficult time avoiding the topic. It comes back without even trying. There's a sense of self-fulfilling-prophecy compelled by the urge to defend. It makes me wonder why there still hasn't been any real offense taken after all this time. Why always react? Being proactive is so much better. Oh well. I posted this: Looking at the plug-in market exclusively, it's very easy to get the impression. Stepping back to look at the entire auto industry, there are those pointing out struggled efforts of the past and recent successes... all which point out the challenges Volt still faces. What has been the response? It's shooting the messenger and telling people to be patient, rather than actually acknowledge the concerns. Watching opportunity slip away isn't a good plan. But the fierce avoidance of setting goals does exactly that. In other words, if you don't actually define success, just about anything could be interpreted as failure.

7-12-2012 **Why?** How this question could be asked at this point is a topic of fascination: "*Why would anyone buy a Leaf or Prius over this? I don't even get it.*" Do those participating on that discussion thread this afternoon really not know, after all this time and all those attempts to explain? I provided this: Understanding buyers has been a fundamental problem. Price is a major priority for middle-market, the consumers who a hybrid like Prius targets. Look at all the cost-analysis papers over the years. A gain in performance simply isn't taken into consideration if it increases price. These vehicles are expected to be sold in high-volume at small profit margins. Car enthusiasts have never embraced common vehicles which focus primarily on getting from point A to point B using medium-grade components. Their version of competition is comparing rare designs that strive to exceed top-of-the-line specifications. They have no interest in the middle. In other words, the appeal factors for Volt don't match that of mainstream expectations. Notice how no one challenges the performance claims? The power & handling exceed what's actually needed. There are highly desirable traits which simply cannot be justified when considering a purchase of the family car. That's why there have been separate categories for sports & luxury vehicles. The difference between want & need is far greater now than when it was back in the days when monster-sized SUVs guzzled their way to dominance. There a very real need to balance efficiency with affordability. Watch how Volt adapts over time to better target middle-market buyers.

7-12-2012 **Bickering.** We've been watching the situation progressively get worse. Using me as a scapegoat isn't working well anymore, causing some to finally speak out about the bickering outcome. Ignoring those attempts to provoke results in the fabrication of intent. They claim I said things to get me to react. Reluctant to be their conduit of blame, I sometimes respond anyway. This was the post today, shortly after hearing that the president of GM's European division will be stepping down: It always comes down to the realities of business. Volt can remain a great niche, enjoying a classification similar to that of Corvette & Camaro, or it can become a popular seller like Cruze. Lots of profitable sales are required. The catch is time... and that pressure has been growing quite intense lately. The recent drop of stock price to under \$20 per share makes that all too clear. GM will need to focus on the business-sustaining products. That means vehicles like Cruze, Malibu, Equinox, and Sonic will get a bulk of the resources... undermining some Volt advancement. Blaming the competition is the best way to feel better, rather than actually dealing with the situation at hand. Attempting to be constructive, my suggestion would be to aggressively work to drop Volt cost by no longer adhering to the EV mentality. That obviously makes it appear as though it's an endorsement for PIP. Well, too bad. Step up to the plate by supporting something actually capable of achieving high-volume sales relatively soon rather than waiting for a miracle drop in production & battery cost. Diversification by creating a Volt family is good business anyway. So what if one model offers far less EV capacity. Isn't the point to spread the technology?

7-13-2012 **Time Overlooked.** The availability of public charging-stations is an interesting new topic to address. How will they be perceived? How will they be used? How will they be paid for? That last one is the biggest issue. Will owners of businesses be interested in offering them with the hope of consumer patronage in return? With so few plug-in vehicles on the road currently, that's a big uncertainty. Cost is a major factor to. You don't want to tear up a parking lot for just one. Leaving room to expand is important. The location itself is a problem too. Where do you put them to entice without taking away prime parking spots from others? Then there's the problem of snow removal, a serious dilemma for those of us in the north. The charging-stations prevent the plow from pushing away the routine Winter mess. Needless to say, there are a variety of concerns to address... just to stir installation interest. In the effort to justify cost, the aspect of time was completely overlooked. Business owners will never recoup enough from usage fees to cover the labor & equipment cost, so they must focus on opportunity. When visiting a restaurant or coffeeshop, a stay of 1.5 hours is quite realistic. Longer is not. The same is true for shopping. For strip-mall availability, the quantity needed and the competition to consider, the factor of time makes it compelling. I find it intriguing. That just happens to be the exact size of the PHV battery-pack. It takes 1.5 hours to fully recharge. Coincidence?

- 7-14-2012** **New Chapter, the past.** Many years ago, we watched the anti-hybrid campaign transform into efforts of support. The messages were mixed though. How much of an investment they'd become remained a mystery. With automakers like Toyota, Ford, and Honda, it was a push to get a lot from a little... always keeping price as a major priority. From GM came a complete disregard for that; they sacrificed being affordable for speed & power. We wondered if that would eventually change. It didn't. The next big step forward with motor & battery technology again focused on speed & power. That was a disappointment for many, including enthusiasts. But those disenchanted are long gone, forgotten by just about everyone. Online discussions revolve around the survivors, those standing true to an ideal rather than becoming realistic about what the market actually needs. That brings us to last week. On the big GM forum, no matter what I said about the demands of business, the reply from the die-hards was that my efforts were to prove PHV superior and discredit GM. In other words, they made up what they wanted instead of acknowledging what was actually posted. That finally upset other forum members. Their disingenuous replies were too much. It was harming the forum's reputation. They began speaking out, making themselves the target rather than me always being a scapegoat. I was awestruck by the change.
- 7-14-2012** **New Chapter, the present.** Even though things have settled down both on the big Prius forum and the big GM forum, there's still trouble. Thankfully, it's not that daily blog for Volt anymore. That turned about to be a conduit for hype, a source of building hope based on unsupported expectations. Prior to rollout, they said what ever they wanted without needed to take challenges seriously. The uncertain nature of the information was basically just propaganda, making it easy to accept & dismiss. Now, we know. Those facts can no longer be denied. So, no more blog. It's just a general newsfeed now. There is a forum though. That's where those particular die-hard supporters went to. And they sure are trying to stir the pot now. A new thread was just started, a blatant effort to spread misconceptions about PHV. Reading the quotes left me in awe. I was amazed they would even attempt such nonsense. That is quite a change from being frustrated, as in the past. This present is very different. It appears to be a desperate effort to greenwash. So, I collected my favorite quotes from the thread to document here... wondering if anyone will later believe what they posted. But in these early days of PHV rollout, there is still opportunity to mislead. That won't change until more real-world data becomes available.
- 7-14-2012** **New Chapter, 62 MPH.** I always wondered whether or not those particular Volt enthusiasts understood how PHV actually worked. Unfortunately, time has revealed they really do... but simply don't care. I've seen it far too often. How would you respond to that? This quote was a good example of the situation: *"However, you would get crucified here for driving 62 mph or less in an HOV lane so it really doesn't even work here."* No matter how many times you point out EV-BOOST mode, it doesn't matter. They don't want you to discover that MPG is over 100 while traveling faster than 62 mph. They just want to spread the belief that there's no benefit of having a plug unless you are driving slower than 62 mph. It's a misconception they've been working hard to maintain. They have been exploiting the assumption. That's how greenwashing works.

- 7-14-2012** **New Chapter, the engine.** The other aspect of design they want to mislead you about is that the engine starts up whenever you accelerate. No matter how many reports of PHV drivers running errands through the suburbs, exclusively with electricity, without the engine ever running, they pretend that isn't true. Heck, I've even done an entire 17.2 miles on my morning commute entirely in EV mode. They don't care. Pointing out motor-power and battery-draw falls on deaf ears too. Facts don't matter when you're still holding on to that "*vastly superior*" hope. And they said Prius owners were smug. Geez! Anywho, I liked reading this quote: "*The max speed 62 mph is not the whole story any time you step on the gas you use gas in other words the electric motor assists the gas engine.*" That just plain is not true. And on those occasions when the engine does start, it shuts off quickly anyway. But looking at the resulting MPG doesn't matter. They still push the mentality of purity... even though Volt has and uses an engine too.
- 7-14-2012** **New Chapter, marginal.** On the big Prius forum, the Volt owners there have claimed there haven't been any posts which belittle PHV. That was rather shocking to read. I see it all the time. How can they be so selective about what other owners have been saying. This was the example from that newest thread: "*The PIP makes no sense, it's too expensive for the marginal improvement over the basic Prius.*" Apparently, an improvement of around 50-percent is just marginal. That makes you wonder how they evaluate the difference between mild hybrids and traditional vehicles. Watching my MPG jump from 50 to low 80's is quite an increase. How can claim it isn't? But coming from a thread starting with the word "*disappointing*", it was obvious they wouldn't actually be constructive. It was really just an chance from them to collect & distribute so-called facts... and me the opportunity to document what they're up to.
- 7-14-2012** **New Chapter, nothing more.** One of the biggest efforts to mislead came about from the discovery that the third-generation Prius was designed to support a larger battery & plug right from the start. The spin had been that PHV was really a retrofit, an after-thought which came about as a last-minute scramble to compete with Volt. Finding out that isn't actually the situation puts pressure on the enthusiasts. Unfortunately, it puts those who innocently purchased a Volt and didn't know that in a bad situation too. They feel somewhat threatened as a result, backed into a situation they had nothing to do with. That makes reading this a problem: "*PIP is nothing more than a regular hybrid with a somewhat larger battery that can also be wall charged in addition to by regen.*" All but the staunch recognize that's not actually true. The rest of us know that the larger battery allows greater draw, which results in more power from the electric motor. It's the very reason the idea of a smaller battery-pack for Volt is so fiercely resisted. Less power is a tradeoff they are unwilling to accept.

- 7-14-2012** **New Chapter, downplay.** The effort to mislead doesn't always work. When that happens, those hoping to undermine switch to downplay instead. Here's an example from that "disappointing" thread: *"It's a Prius with a larger battery that under some rare conditions (driving at a snail's pace on flat ground) can drive a few miles on electricity."* I'm driving along with traffic, climbing up hills, and accelerating from stoplights all using only electricity. PHV delivers much more than they want to admit. That denial is becoming more and more obvious. Remember how Prius was sold years ago? People liked the idea, but were uncertain of how it actually performed. The test-drive experience made them commit. It's very easy to convince someone on the fence to buy, once they try it. That's because Prius looks so good on paper. The financial decision is sound. How it responds to everyday driving can only be determined behind the wheel. That's why greenwashing efforts try to hard to prevent that from happening.
- 7-14-2012** **New Chapter, dead end.** The most passionate effort by Volt supporters who want to undermine is well stated in this quote: *"Realistically, going forward I think the Prius is dead. It's doing great right now but the drive train is simply too expensive for the relatively small advantages it delivers."* Notice how there's an attempt to distract from the expense of Volt by calling Prius that instead. Anyone who's actually looked at the design can see it's not, that the HSD system is an affordable alternative to the traditional automatic transmission. The next thing which jumps out is the marginal reference again. The size of the boost is significant overall and enormous for short-trips. Saying that MPG improvement is *"relatively small"* is insincere, at best. I call it greenwashing. As for being dead, who's going to believe that? Ordinary consumers have been posting comments saying how much more PHV could deliver with a larger battery-pack. How come they can see that, yet those Volt supporters not?
- 7-14-2012** **New Chapter, has begun.** Whatever happened in the past is just that, past. This new chapter has begun. Volt has been on the road for a year and a half and PHV is just now reaching the first customers who were unwilling to order, wait, and purchase a vehicle they heard almost nothing about from actual owners. Those real-world reports and being available on dealer's lots make a big difference. Voting with your purse or wallet is the key. That couldn't happen before. Unfortunately, PHV is still limited to select states, but this is a start. It will be quite revealing too. If Volt sales remain stable, despite all the television advertisements, and PHV grows to a similar level, it sets up quite a battle for next year when nationwide availability begins. The point continued growth. Expanding the market quickly is essential. Delay reduces the benefit of the tax-credit. Mainstream volume must be achieved prior to expiration; otherwise, momentum will be lost. An impact to sales after subsidies are no longer offered could harm progress that had been made. We don't want that to occur. Can some level of cooperation finally be attained?

- 7-14-2012** **New Chapter, group think.** A good way to conclude this particular topic would be to point out how "group think" works. People tend to unknowingly follow the herd. When the potential of a threat emerges, they automatically go into defensive mode. They typically aren't even aware it's happening. So it's easy for assumptions to take place. They simply have no reason to question the reactions. The outside force must be incorrect. After all, what purpose would they have to participate? I see that a lot, when I point out a fact and it is summarily dismissed. Claiming it isn't possible is quite different from saying it's rare or unlikely. Yet, that's exactly what we've seen occur again and again. Very few make an effort to consider the design at this point. What you say is mostly just ignored. That's how we know a new chapter has begun. Rather than aspects of design being argued as they had been in the past, there's a "this group must be correct" belief. That makes it much easier for someone from within to finally have a voice... since everyone else shares the same conviction. At last, they can be heard.... rather than someone like me drawing all the attention... more evidence revealing something has indeed changed. The long, on-going, seemingly endless saga of hybrid evolution takes another step forward.
- 7-15-2012** **IR Thermometer.** I bought one of those devices with a trigger and laser-sight for measuring temperature. (It can measure distance too.) It takes only a second to find out how hot a very specific area is. That's turning out to be remarkably informative for me. I've often wondered how effective parking with the front of the Prius facing the sun could be. How much of a difference does that make for keeping the battery-pack cool? Turns out, quite a bit. Upon my first measure, I discovered it gets up to 150°F between the windshield and the window shade I put up, with the outside at 100°F. In back, the area between the glass and the rollout shade for the cargo area, it was 137°F and the area immediately under that 107°F. Then pointing the laser into the battery vent, it said 96°F. That provided some thought-provoking real-world data. Baking in the sun while parked all day at work is very hard on the batteries and there's been claims that "active" cooling is better... yet that only works while the vehicle is drive... hence the curiosity. I have the ability to start up the A/C remotely too, no plug required either. The analog gauge on my smart-phone shows a significant reduction in cabin temperature as a result. I haven't had a chance to actually quantify that yet though. In fact, that's what got me to finally purchase the device. I wanted detail... especially after having so many experiences with the solar-roof on my 2010, knowing it was beneficial but never actually being able to articulate how much.

- 7-16-2012** **135 MPG.** I've switched to taking the fast route to work lately. Watching each of the MPG values shown on the consumption display with 1-minute increments is all the same while cruising along on the 70 mph highway is fascinating. Just like in the past, those not believing the results claim you are going much slower than the speed-limit and holding up traffic as a result. Then, it was 50 MPG. But now with the PHV, it's 100 MPG. Just flowing along with the other commuters, each consistently maxes out the plot area available on the graph. Having an aftermarket gauge, I can see that MPG is actually higher. It varies quite a bit. 80 is usually the lowest. But the need to rapidly accelerate can push it down even lower. Any declination at all makes the value shoot way up into the 100's. Actually going down a hill, it tops out at 300 MPG. The 9.5 mile journey today 135 MPG. I look forward to seeing that day after day. When the cold season arrives, that should be especially interesting. Since the engine is running anyway, the need for heat will be a non-issue. Traffic slows though. Winter conditions means slow enough to drop below 62 mph. In that case, I'll be cruising along using only electricity and wondering how long the coolant feeding the heater will last. With the 2010, it was about 8 minutes during really bad snow-impaired driving. This Prius has an HV/EV button, optimized temperature tolerances, and nicer heated-seats. I'm definitely curious what that will be like. In the meantime, I'm still very much enjoying Summer.
- 7-17-2012** **Attack Articles.** It has been fascinating lately. As the plug-in Prius settles into the mainstream, which consequently means drawing less attention to itself, the result is Volt again becoming a target from those who feel threatened by change. Some of the attack articles have been brutal lately too, especially the comments readers post. That's the reason the whole approach from Toyota differs from GM. And no matter how many times you point out the differences, those supporters just don't see it. In their mind, this is just the same situation as a decade ago only with the next big step forward with automotive advancement. Recognition of why & how isn't understood, for them. For me, it's rather obvious. I clearly remember market expectation & reaction back then. It doesn't match what's happening now. That's for sure. I tried again to point out a few key points: Prius was a product designed specifically for middle-market. That was blatant too. No wild promises. No hype. It was simply a traditional vehicle replacement. Volt clearly didn't follow the same path. Rather than being designed to accept motor & battery improvements as cost justified like Prius, it started at the end configuration with the hope of rapid cost reduction. That's a profound difference. Priorities are no longer the same as back then either. So, what's with the claim that people want to kill Volt when they have been actually demanding something more affordable instead?

7-18-2012 **Better.** The obsession with MPG is remarkable. Higher is better, period. That concept of diminishing returns doesn't exist for some. Regardless of cost, they always want more. I see beyond bragging rights. It's the same old story... blinded by a single number. This time though, it's coming from Volt supporters rather than those trying to undermine the progress of hybrids. Nothing else quantitative gets any attention, especially sale counts. Only MPG matters. They spin it in the form of "*gas saved*" too. I summed up the situation this way: The whole "better" topic indicates something isn't going as planned. Having wandered from goals is a dead giveaway. For PHV, it was always clear. The target capacity was stated as 20km (12.4 miles). The target price was stated as a \$3,000 to \$5,000 premium. The target efficiency following depletion was stated as 50 MPG. The target efficiency was stated as roughly a 25 MPG boost. The target emission-rating was PZEV. Having hit so close to the mark right out the gate makes it a prime target to vent frustration on... especially since the business of the automaker as a whole isn't meeting plans either. That leaves us in an awkward position. Enthusiasts loyal to a particular brand just plain don't trust others who support affordable solutions from all automakers. And of course, there are some who simply just thrive on bragging rights, making the push for middle-market seem untrustworthy. So, what happens now? Continuing with the spin & bickering only reinforces the observation of outcome not meeting expectations. Not addressing details of need is trouble as well. We cannot just pretend all is well and hope for the best.

7-18-2012 **Most Feared.** The one thing I really, really wanted to find out prior to leaving the big GM forum was what those handful of antagonists feared the most about PHV. With their excuses for Volt so well rehearsed, it seemed pretty much impossible to get an answer. But stepping back to what the other members take over the arguing actually was revealing. Turns out, it's the 62 mph belief. That makes sense, since it was the least understood. There was no basis upon which to confirm their assumptions. So, they ended up discovering it delivered far better results than expected. So naturally, I only had a single chance to post detail... knowing they won't like the bitter truth of the situation: I find the careful avoidance of what actually happens above 62 mph quite telling. The 70 mph highway is 3 blocks from my home. The ramp onto it is uphill. The distance of travel on that stretch of highway is 9 miles. At that point, depending on whether traffic is flowing at 70 the entire way or slows to 65 about halfway, my average is between 115 and 135 MPG. (The remainder of the trip is another 7 miles, which is entirely with electricity. So overall MPG is always in excess of 200.) For many years, getting +100 MPG is what people have been asking for. Who has been asking for EV purity at high speeds? At lower speeds, sure, since you can drive with the windows open and there is an abundance of variety. But on the open road when you're just cruising, who? Notice the topic of this thread? Better is a great thing if you are an enthusiast. They understand & appreciate every little detail, including EV driving in absolutely every situation. They wonder who would ever be interested in less than a pure EV experience. The consumers from middle-market are quite different. They ask questions relating to cost and diminishing returns. They require a balance of priorities. They are pleased when MPG stays above 100 even when traveling faster than 62 mph.

7-19-2012 **Welcome, Prius.** This fit into the new chapter perspective perfectly, coming from the big Prius forum. It was the observation of inventory being filled. Seeing PHV available on the lot is quite a change from "sold order" deliveries. The key is how long they stay available, that's turnover rate... which none of us can judge yet, quite unlike that other plug-in. Anywho, it stirs worry when change is observed. I provided a "rude awakening" type response, making sure people have realistic expectations: Did you think it was going to be easy, that the sales wouldn't require any effort on our part? If so, better read the forums & blogs from 2000 to 2002. Toyota remembers what happened back then. That's why the ramp up isn't until next year. Some of us participated in that history firsthand. We remember those times quite clearly. You never forget resistance to change like that. This year is the shake out. Those hoping to undermine exploit assumptions with the goal of creating & spreading misconceptions. It gets ugly, but we persist by sharing details real-world experiences and identify strengths. Our endorsements are a weapon they have little defense against. They panic and unknowingly reveal their fears. We point out how well thought out the design is, confirming it is an excellent solution for the masses. The key to literally "just drive it". The outcome speaks for itself. Rather than feeding hype, you convey realistic expectations based on lots of owner information. That's out of the hands of Toyota, something only we can do... and it worked amazingly well in the past. Toyota's role becomes that of the observer, collection every little suggestion we provide and taking it into consideration for the next generation. It's rewarding to look back upon later; however, quite an emotional rollercoaster along the way. Prepare for the onslaught from a wide variety of competitors... once they finally figure out how capable PHV actually is.

7-20-2012 **Welcome, Volt.** Being available nationwide since late last year, the situation for Volt is quite different. We've observed it's turnover rate already. Specific vehicles sit on the lot for weeks. Sales are well under expectations. Some of that is from the concept of plugging in. Some of it is from uncertain expectations. Some of that, obviously, is from price. That last reason irritates the Volt enthusiasts more than anything, as this quote today so expresses: *"I wish people would get off the price thing as it makes no sense."* I enjoyed responding to that: You wish the automotive market made sense! The certainly explains the bewilderment of so many Volt enthusiasts. Those of us supporting hybrids years ago attempted to convey the illogical decisions being made by business & consumers. They were always dismissed as an effort to covertly promote Prius. No matter what we said, the words of warning were always believed to somehow not apply to Volt. Now those enthusiasts are scratching their heads wondering why the "better" points aren't well accepted. Turns out, that even a vehicle which performs quite well may not result in many sales. In other words, the purchase criteria for ordinary mainstream buyers makes no sense. That's why there are billions of dollars spent on advertisements promoting features of vehicles you'll never actually ever use. Welcome to the real world.

7-21-2012 **Welcome, Energi.** It certainly has been a wild ride lately. With Volt enthusiasts having run out of excuses for a more affordable model being offered, the turn to attacking those who make any mention of cost or tax-credit dependency revealed how desperate the situation had become. Shot the messenger and avoid addressing actual need at all costs, that's an undeniable sign of trouble. Diverting the discussion to Prius hadn't worked, since there's enough real-world data now to question why a 16 kWh battery-pack was deemed absolutely necessary for Volt. I was always amazed they felt so threatened by a plug-in hybrid offering just 4.4 kWh. Perhaps they were paying attention after all, quietly accepting the reality that adding capacity is much easier than reducing it. We already know Prius PHV can utilize sub-packs, switching to another as the other became depleted. And of course, combining all the cells into a single pack allows for greater discharge rates, which provides more horsepower. That then exposes the shortcoming of Volt, the loss of power with less battery available. Anywho, Ford is totally taking advantage of the situation. It was stated in the press release this way: *"The new Ford C-MAX Energi is expected to achieve more than 20 miles of electric-only range – nearly double the Toyota Prius plug-in hybrid..."* Knowing that PHV delivers more than the 11-mile rating anyway, that really gives the Volt enthusiasts something to worry about. Obviously, the price is still a concern and naturally that wasn't provided yet. But the point is difficult to deny. This other statement from Ford was a thought-provoker too: *"With a maximum electric-only speed projected to top that of Prius plug-in, C-MAX Energi drivers might be able to reach wherever they're going a little faster, too."* It's 62 mph for PHV. What does that actually mean? In the end, it doesn't matter. The point is that choices are expanding. The new offering is another endorsement of what middle-market is more likely to purchase. That's an new offensive coming from another front... which they knew was coming, but hoped it wouldn't matter.

7-21-2012 **Seeing Red.** That caused panic back with the Iconic model. When the charge-level indicator for the battery dropped to 2 bars, the color within changed from blue to pink. That was nothing but a driver convenience, so you wouldn't actually have to count the bars. The color told you at a glance. But rather than seeing pink, some people interpreted that as a light red and fear set in. They jumped to the conclusion that something must be wrong... taking drastic measure upon first discovery, some as much as pulling off the road and calling for help. Thankfully, those extreme over-reactions were rare, but nonetheless an enlightening insight into how some people think. Something similar is happening with the red zone on the the Eco-Meter now. But rather than panic, they do their best to never make it happen. And unlike the Iconic owners in the past learning of their incorrect assumption, some owners now may never find. I would suspect they are associated that red with the redline on a tachometer, indicating stress on the engine. That most definitely is not the case for Prius. But how to you get pass the assumptions some people make. How would they ever even find out their response is incorrect. Fortunately, the resulting lower MPG and traffic impairment they clues them in. I provided this on a thread today about this particular problem: Keep in mind the purpose of the PWR zone is to inform you that the ideal has been exceeded, so keep it brief. It is not there to inform that you are requesting too much power or driving in an inefficient way. Far too many new owners misunderstand that intent and assume it should be avoided entirely.

7-22-2012 Looking For Clues. It takes a long time to figure out what some people's motives actually are. Sometimes, they aren't even honest with themselves, making it unwise to accept anything claimed without detail to support it. Patience is required. Other influences help a lot, as we are now seeing with the emergence of Energi. The variety of perspectives provide clues otherwise never revealed. Looking for then is a challenge, but rewarding when actually found. Since once found, you can actually communicate constructively rather than just posting facts and hoping for some type of acceptance. Today, it was this revelation: "*The Prius family has done nothing but convince the vast majority of consumers that conventional powertrains are the smart choice and why compromise?*" I had no idea he didn't believe in progressive upgrades. That's just an inherent part of the younger generations. They naturally expect each new product replacement to be better than the previous. Those of us buying MP3 players over the past decade have experienced that firsthand. That's the case for computers over the past 2 decades as well. Each new one offered an improved processor, a larger hard-drive, and more memory. Why is believing the same won't be true for vehicles too? He obviously doesn't. Of course, if you read posts from Volt enthusiasts, many don't believe the increased power & speed from PHV is even possible. Some absolutely insist the engine will start up with anything more than just the lightest touch on the pedal. And that's exactly what I mean about them not being honest with themselves. How many times can you be told that's not true before you finally question your own assumption? Long story short, I now understand why that particular person has always fought so intensely against all hybrids yet heavily endorsed Volt. His ideal didn't meet business or consumer need.

7-22-2012 Motor & Battery Acceptance & Advancement. Stepping back to consider the big picture, that "*has done nothing*" is a quite a remarkable statement to make. Prius advanced the market, fundamentally altering the way people looked up motor & battery usage in passenger vehicles. Prior to rollout, the majority believed anything electric was so slow it couldn't be driven along with the flow of traffic. Now we hear complaints of ordinary people driving them the same way they do with other vehicles, weaving in & out of traffic and speeding. The majority also believed the only way to recharge a battery was with a plug. They are well aware now that isn't actually the case. In addition to that, PHV is about to inform people how much more hybrids have to offer. It's really too bad that acceptance has not been seen by that particular individual. But it is educational for us to learn that are some who have no appreciation for the market advancements which have already taken place. What other vehicle has provided such a fundamental shift in acceptance? In the past, it was always a new technology that was spread to other vehicles without any real attention given to how it was introduced. Significant improvement to emissions & consumption has clearly identified Prius as the leader. Know why? It's because each generation was better than the previous... an aspect the market has come to expect, quite contrary to the "*has done nothing*" claim.

- 7-22-2012** **Different Now.** Reading comments about how much things have changed since PHV pre-orders began gave reason for reflection. This was my contribution to that growing thread: Trying to point out that history as it was unfolding didn't make much of an impression for some. Others got swept up in the moment, not realizing it was about to come to an abrupt end. Heck, even the quarreling with Volt owners was inevitably short lived. That's why those of us familiar with such experiences took full advantage of the rare opportunity. Now PHV is in the hands of owners. Answers to questions are only a post or two away. No more wonder. No more anticipation. We are participating in a different stage. Market progress is what we make of it. Hopefully, we do a good job of sharing our observations, enticing others to join in. It's a different sort of excitement at this point. Jitters from pre-order uncertainty and the intense anticipation of delivery has been replaced by discovery at the dealer. Just like in the past, the curious will crunch efficiency numbers and justify the well-balanced offering of features. But it isn't until they actually sit behind the wheel for a test-drive that the worth is confirmed. The rapid shut off of the engine and smoothness of the motor simply cannot be conveyed online. There's that eerie silence too. Interestingly, the lack of excitement from plugging in at home adds to the well thought out nature of the design. You don't need to do anything special. PHV is basically just another portable device to recharge. You plug-in each evening much like you do with your smart-phone already. I'm thrilled to be among the early owners, knowing it won't be long for others to join in. The addition of an affordable plug is a natural next step, something easy to understand the benefits of. In a market quite finicky when it comes to matters of acceptance, that's a very good thing.
- 7-24-2012** **EV Expectations.** The current PHV owners get lots of questions about what to expect for EV driving. With Prius being a plug-in hybrid, that's really the only way to find out. It's difficult enough figuring out how an full EV will respond. With the ability to utilize an engine, that definitely confuses matters. Hopefully, my contribution will be helpful: Acceleration from stoplights eats EV range. So suburb conditions are more efficient than "city" driving. A/C usage cuts it down too. Keep that in mind. Fortunately, once you've went through the warm-up cycle, rapid on & off of the engine really helps out. People get worked up about using gas until they realize how nice that works out for driving beyond EV capacity. The more scenic route for my commute takes me through the suburbs, with a variety of speeds from 45 to 55 and the occasional stoplight. It's 17.2 miles. The result varies between 400 and 550 MPG with a slight downhill bias. On the way back, without plugging in again, it drops to the low 100's. With a fresh recharge, it's in the 200's. For me taking the fast route, the 70 mph highway, it's 16.6 miles. The result to work is usually between 225 and 250 MPG. With a recharge there at work, the overall average is usually around 200 when I reach home. Also note that I'll take advantage of the HV/EV button on the way home, using the engine to preserve EV for use later in the evening. Doing that, I end the day somewhere in the 100's. Long story short, you'll see a substantial MPG boost regardless of your driving situation.

- 7-24-2012 Tire Rotation.** I didn't have an opportunity to bring the Prius into the dealer until today. For just a routine tire rotation, there wasn't much of a need. Nothing else is required during the 5,000-mile service. Of course, the backup beep was starting to become annoying. So, I had the rotation done along with getting the beep change from continuous to single. Both were done quickly and free of charge. That's always nice. At 6,687 miles, everything is running absolutely perfect. Not costing anything wasn't end result either. I actually got a coffee and a free car-wash out of the visit too. Certainly no complaints about coming out ahead like that. Imagine if all visits to the dealer were so positive. Fortunately, the system doesn't have any belts. That's great for reliability. Not having power-steering is a plus too. And the brakes last a remarkably long time, since most deceleration is achieved using regeneration rather than friction. In short, things are going well.
- 7-24-2012 Price = \$32,950.** That was unexpected. Of course, some of that is likely attributed to differences in features the base packages offer. But nonetheless, the plug-in hybrid from Ford will have a price fairly close to that from Toyota. Taking the larger tax-credit available due to the larger capacity, the price actually ends up lower. It will be introduced next year with a sales expectation of 10,000. That's a bit on the low side, but reasonable considering the circumstances. Like with Volt... which we were told countless times... it's the second year that matters... even though those same people are now being hypocrites by not following their own progress criteria. Whatever. The point is a plug-in with an affordable amount of capacity will be offered. That's a big difference from the very-large-or-nothing approach we've been dealing with from GM. That choice from Ford will be 7.5 kWh. The capacity tested in the Two-Mode plug-in prototype was 8 kWh. So, it's not like the size hasn't been considered. Again, whatever. Consumer purchases will tell the story of acceptance, not an automaker executive decision. With both Toyota & Ford targeting \$30,000 as the price for middle-market, we should see some interesting sales numbers starting next year.
- 7-26-2012 Plug-In Sightings.** My first Nissan Leaf was a week and a half ago. I was night biking and it passing just happened to catch my eye as I was turning. So, there simply wasn't enough time or light to confirm what I had actually seen. The distinct tail-lights were easy to confirm when I had my first proper sighting yesterday, just 3 blocks from my home. Then today, I saw another. This time, I was driving side-by-side rather than it just passing by. I tapped the horn & waved. Unfortunately, a SUV decided to push its way through immediately after that. So, the moment was all too brief. Oh well. Yesterday brought another surprise. At lunch, just after having I went out to plug in the Prius, another PHV drove by. I pursued on foot for a block, enough to confirm I had indeed witnessed what I thought. Was it the only other known PHV in Minnesota? The distinct blue makes it a possibility. I'll have to send an email to him to find out. Unfortunately, that owner has become very quiet lately. That's an unfortunate consequence of Prius ownership. It works so well, online participation is typically short-lived. They just drive it. I was quite shocked by that unexpected opportunity and quite surprised by the timing coincidence with Leaf. It sure will be nice next year when sales begin here. Being one of so few isn't fun. It much more fulfilling when you're driving something the masses can purchase. After all, my career in software development & support depends upon large numbers of users.

- 7-26-2012** **Partial Charges.** What the heck! Twice today I got to my destination with plug-supplied electricity still available. That feels like wasted recharges and lost efficiency opportunities. In reality though, MPG is still outstanding. That (and reduced emissions) is the point... which is especially redeeming with the knowledge that others will have different driving needs anyway. Then later when increased capacity becomes affordable, my own results will be different as well. So, I have partial recharges used from time to time. I suppose there will be instances when I won't have time to recharge the battery-pack entirely either. Today, it was a little over a mile on the way there and over two-and-a-half available on the way back. I bet that will really surprise some who assume the capacity is too small.
- 7-27-2012** **Why Bother?** I wonder how many posts like this will continue: *"If you're going to use gas all the time, why bother with a plug? If you're going build a car that can run off battery alone, why limit speed/accel, and use such a small battery the range is meaningless?"* Those individuals just plain don't understand. The affordable 75-100 MPG market is becoming increasingly more apparent. The typical consumer certainly doesn't respond to my 83 MPG average as meaningless. Their reaction is always one of excitement. They most definitely don't ask those questions. In fact, it's like the "complexity" arguments of the past. The only people who cared were those who understood the intricate details of how an engine & transmission actually worked. Most people in middle-market have no idea how an automatic transmission works. They don't care either, as long as it is affordable & reliable. That makes you wonder who the audience will be for the "why bother?" type questions. Hybrids of the past have taught us a lot about what to expect from hybrids of the future.
- 7-27-2012** **Missing The Point.** It still continues. Fortunately, the audience is quite small now. The hype & anticipation has been replaced by the practical & sensible aspects of the purchase decision. In other words, when it's finally time to vote with wallet or purse, actions don't often match original comments. This caught my attention on that old daily blog for Volt, which is now just another green newsfeed but with a clear comment bias for Volt: *"GM needs more time to establish it's green halo & it's technology halo more, and when it does finally start to settle in to the mindset of those on the coasts, that is when you will see the tide turn."* They aren't hostile to outside posts anymore, but they still miss the point... and oddly, accuse you of that very thing. Of course, what the heck does a "halo" have to do with selling a vehicle to middle-market consumers anyway? Profit doesn't come from a showcase vehicle. It comes from the ordinary vehicles we see parked in neighbors' driveways. Regardless of their misguided purpose, I felt compelled to post this: Think about what happens when Li-Ion density goes up and price goes down some more. Most people focus on the high-end, overlooking an affordable choice for the masses in the near future. Toyota already has a 4.4 kWh system that doesn't require liquid cooling. Transferring it into their smallest model Prius to offer that choice is fairly difficult to argue against. It seems a very sensible business move. Remember, the "killer app" is rarely the one which performs the absolute best. It's whatever is adopted in such high volume that it becomes almost ubiquitous. That means being affordable is essential.

- 7-28-2012** **Plugless Drives.** Late this evening, I got one of those "*please rescue me*" calls. In this case, it was a family member unexpectedly trapped at the airport. I had already finished for the day. The battery-pack was depleted, the display reset, and the plug-in timer set. Now, there was the need for a spontaneous drive. At a very comfortable 66°F degrees outside, I was looking forward to it and intrigued what that would bring in terms of efficiency. This was my first drive with the PHV as an ordinary hybrid, but with a Li-Ion battery-pack instead of NiMH. The 37.7 miles of driving was a delight. The result was 64 MPG. With an effort-free outcome like that, not using any plug-supplied electricity, I certainly am collecting some great real-world data to support this Prius with.
- 7-28-2012** **True Colors.** We saw this coming. There was a group of Volt enthusiasts who only cared about bragging rights. Their complete disregard for cost and battery-pack capacity made that obvious. But it wasn't until Ford's recent Energi press release that confirmation of what I had been saying all along made their responses hypocritical; yet, they still didn't care. It's intriguing to see their own concerns of the past are now being abandoned for the sake of putting Prius down. The insults are truly amazing... to the point where some Volt owner are seeking disassociation with that group. They want nothing to do with those enthusiasts. It's an embarrassment to know principles aren't being followed. In other words, a product for the masses isn't what they wanted from the very beginning. The trophy mentality persists. Sure glad that cannot be denied anymore. It means on to the good stuff, finally. Looking at what Ford has actually done, it sets an interesting stage. Their plug-in hybrid will offer a 7.5 kWh capacity. This was apparently accomplished by filling the entire false floor as well as raising it. That's similar to what the test-model Prius PHV had done, which used a lower density 5.2 kWh battery-pack. So based upon market acceptance, Toyota could do the same later. It really depends upon consumer response. Toyota has a nice system with the 4.4 kWh which could be utilized by Prius v or the Camry hybrid. We'll see what happens with Ford's Fusion plug-in hybrid in the meantime. Gotta start somewhere. And increasing capacity is easier than decreasing it... especially with those showing their true colors now out of the way.
- 7-28-2012** **Being Affordable.** The return back to the basics sure is nice. I didn't know how much more of the cost disdain I could tolerate. It was amazing how there was no regard for middle-market. Having ordinary consumers considering the purchase of a plug-in hybrids is what we were striving for. Now that is becoming realistic. It reminds me of the early days of Prius rollout. The price-gap was just small enough to entice. It was very close to being affordable. Some real-world data and a test-drive pretty much finalized the decision. We're at that point where you can see questions of consideration popping up from those who are not enthusiasts too. They see the plug-in model as the next natural step in efficiency improvement. You just recharge every night like you do with other rechargeable devices. Being affordable is the key. Sustaining profitable business isn't what an enthusiast cares about away. We need a high-volume solution, not something only a few will have to brag about.

- 7-29-2012** **Remembering Two-Mode.** Prior to the rollout of Volt, some enthusiasts were downright hostile when any mention of that past was brought up. Others simply dismissed it as being far too different to discuss. Now, no one wants address it... likely because that pattern is very easy to see at this point. It too was a heavily anticipated new technology, inspired by a remarkable amount of hype without market need to actually support it... in other words, an ideal driven by want. The key weakness was disregard for cost. A dramatic drop would supposedly follow in the coming years, justifying the design. That still hasn't happened. In the meantime, sales would be strong enough to establish that new approach. That didn't happen either. Long story short, it was an over-engineered business nightmare. Sure it worked, but there weren't many consumers interested. Volt also works, but how in the world will it achieve on-going sales in a market simply wanting MPG improvement. Mainstream consumers haven't been clamoring for a pure EV experience. At such a premium for that, it's a hard sell. The need is for a big boost in efficiency. Toyota, Ford, Honda, and Hyundai are all activity pursuing affordable solutions. Heck, even VW wants to join in. GM knows their recovery will continue to be a challenge, so why not set the stage to diversify? Why such a strong hold on specific capacities? The size & power obsession with Two-Mode basically killed it. Does that inflexibility make sense for Volt too? Remember how sales just limped along after the initial rollout finished?
- 7-30-2012** **Electric Assist.** Continued attempts to belittle PHV persist. The latest is portraying the plug-in system as an electric assist. I find that quite amusing. Clearly, it isn't. The traction motor is capable of delivering up to 80 horsepower. 51 of that comes directly from the battery-pack, drawing up to 38 kW. When more power is needed, the gas engine joins in. It delivers both thrust for the wheels directly as well as generating additional electricity for the traction motor to take advantage of. How is that in anyway an assist design? The engine is helping out. Primary motivation is coming from the electric side. The engine assists. The intentional misrepresentation is frustrating. But then again, it's easy to frustrate those making an effort to greenwash. All you have to do is post detail. They're always vague. Providing values to quantify the design puts them in an uncomfortable position. They were hoping people would just assume they were correct. You reveal they were not. And of course, you can then provide real-world data. The incredible MPG numbers do a great job of reminding people of purpose.

7-31-2012 **0.1 Miles.** I'm getting better and better at estimating how much EV to use and when. After all, the work-commute and running around town is quite repetitive. You get familiar with the driving conditions. That recognition of patterns makes the decision for HV/EV button use easier and easier. A few times, I've driven up my driveway with only 0.1 miles having shown on the display since before turning the corner onto my street. Is that considered hypermiling? I'm not actually doing anything to change the driving itself, like pulse & glide. It's just knowing when to use EV and when to use HV. Switching to the appropriate mode is no big deal, especially since you only would do it once or twice during the entire drive anyway. This is definitely a paradigm shift with the way with the way people drive. Remember how the automatic transmission was a profound change to from having to manually shift yourself? This is trivial in comparison. Think about how many times the clutch-pedal would have to be pushed during a typical drive. This is nothing... and the results are huge. But then again, driving in EV mode all the time delivers remarkable results too. But if you know you're going to do a bunch of suburb driving after having been on the highway, it's better to take advantage of the great HV efficiency while cruising at high-speed and saving the electricity for later.

8-01-2012 **Slow & Steady Growth.** You'd hope that's what the focus would be on. Nope. A few had things like this to say: "*Volt is crushing PIP*" and "*Also, this month the Volt outsold the Plug in Prius by nearly 3-1*". Knowing that model of Prius has only been available for a few months and is only available in 15 states doesn't matter. It's all about being "better" than the assumed competition, hence this comment: "*Plug Prius sales continue to drop month over month.*" The cumulative effect of the pre-orders is simply ignored. Reality is, there basically hasn't been anything from Toyota to promote PHV, on television or even online, doesn't matter either... quite unlike what GM has been doing. If I had a nickel for every Volt commercial. The heavy advertising makes you think too. Will it continue? Anywho, some simply don't care, especially with respect to coming up far short of the re-revised sales goal. Of course, they won't address fleet sales either. Fortunately, more are shifting expectations. It's still frustrating though. Now the story has been changed and the next few years are suppose to represent market establishment (proving the technology) rather than market penetration (becoming a mainstream vehicle). That's quite different from the expectation back in late 2010. It doesn't make good business sense for Volt, since it's a bet-the-farm approach. Both Ford & Toyota are quite different, also offering no-plug models. So, they'll be selling lots of hybrids in the meantime. It wouldn't be so bad if there was some type of guarantee. But the extreme between vehicles delivering MPG averages in the 30's and one with a 38-mile EV capacity represents a massive product gap. That's means slow & steady growth has become essential.

- 8-02-2012** **New Expectations.** I'm not sure what adjective best describes the situation now. Even the Volt enthusiasts turned antagonists are giving up. They're realizing the shift to electricity is going to be met with far more resistance than they ever imagined. The challenges Prius faced a decade were assumed to have paved the way, dispelled misconceptions to the point where acceptance of a plug would be as simple as pointing out the price of a gallon of gas. The thought of a 50 MPG hybrid with a battery-pack only a quarter of the size of would even be considered as competitive choice was laughed at then dismissed. The situation wasn't taken seriously, nor was acknowledgement of need. Want blinded judgment. The desire for a "leapfrog" jump in technology made seeing market realities very difficult. Now, they do. True, some will claim the drawn out advancement was actually the plan all along. But that's still the same outlook nonetheless. So, it's not even worth expressing the "too little, too slowly" concern anymore... since that is indeed what happened. The requirement was not fulfilled. New expectations are the result. It's going to be more expensive and take much longer... hence the well deserved motto rearing it's ugly head one more time... over promise, under deliver. This is very similar to what we saw in the past. Reaction to challenges far greater than anticipated resulted in a "reset" scenario. It's quite strange to witness the pattern repeat.
- 8-03-2012** **What Started It All.** It was the overwhelming amount of incorrect information being posted on the (back then) new daily blog for Volt. After already having went through the very same nonsense with Two-Mode development, I wasn't about to just watch that happen again. Two-Mode was a bit different though, it was portrayed as a direct competitor with the existing Toyota system. Volt was intended to leapfrog it, which is how the "*vastly superior*" motto came about. Anywho, the abundant posts with misleading statements about how Prius actually worked is what started it all. Now, some simply label my comments as hate, even though the original message of "*looking for an ally*" still remains true. It was always hybrids against the gigantic offering of traditional vehicles. That meant vehicles with a plug would be facing an enormous challenge. They simply didn't care. That hopelessly unconstructive trophy-mentality dominated. What I get a kick out of now is that it still does. The Volt enthusiasts refuse to acknowledge the reality that a new generation of Prius is expected just 2 years from now, including improvements to the PHV model. Some are even trying to spread the rumor that the plug-in doesn't have a TMS (Thermal Management System). I find that amazing. They're trying to spin the cooling-fan system as something which doesn't qualify. That's both misleading & disingenuous. In a way, I find it ironic that it reveals the over-engineering problem GM has frequently faced. That trophy-mentality means always striving to deliver more, even if it isn't necessary and adds substantial cost. Thankfully, the continued financial struggle is helping some change their attitude. Of course, part of the change is likely due to PHV real-world data. The plug-in system works better than the enthusiasts had anticipated... despite me repeatedly posting data to the contrary, based on my driving opportunities with one back in 2010.

- 8-04-2012 New Battery Cost.** It was quite normal for those considering the purchase of a hybrid to have considered cost to replace the battery-pack. That doesn't happen much anymore, since the longevity is well proven now. Most simply never encounter that situation. The majority see it lasting as long as the vehicle itself. Rollout of a plug-in model, though, has reintroduced that consideration. It's quite reasonable for the cost to drop significantly by the time replacement would ever be an actual concern. So, there's much to actually think about. Much if it likely won't matter, since the tolerances & cycles of these plug-in batteries were carefully researched, just like those for the hybrids a decade ago. The vehicle warranty alleviates most of the worry anyway. These were my thoughts on the topic today: This first plug-in Prius will become quite enticing for enhancement as the system, since the system was designed deliver EV anyway and already has a charger & port. Just think what people will do when battery cost is a fraction of what it is now. While driving, the battery-pack will draw up to 38 kW, then the engine will join in to provide some thrust and additional electricity. A larger battery could provide that additional electricity, as well as additional capacity. This could result in unusually high resale value, even with lots of miles. The gas-engine is babied, not ever having to work hard. And the brushless electric-motors can last a remarkably long time.
- 8-04-2012 It Continues.** The sales numbers are out and the news is wildly being spun. My favorite is the claim that GM will come close to their 40,000 goal for Volt/Ampera production this year. The 45,000 for the United States and 15,000 for Europe goal has mysteriously vanished. See what I mean about new expectations? Whatever. Some of that spin is actually rather amusing. Sales of PHV were 695 in June and 688 in July. Supposedly, that indicates a falling demand trend... even though July was 3 business days shorter than June. Geez! And that's only a difference of 7, which is well within the margin of error (paperwork reporting delay). It shows how desperate the situation has become. I see quite a few Prius every time I drive. They're all over the place, here in Minnesota. So, it will be fascinating to see how PHV are once availability here begins. Meanwhile, the other hybrids making slow headway. The regular model Prius lead the pack with 9,954. It was followed by Camry-Hybrid with 3,162. Prius c came next at 3,197, then Prius v at 2,839. The eAssist version of Malibu came in with 1,938. That's rather interesting. Sonata-Hybrid is another to ponder, at 1,888. Lexus was next with 1,499 for CT200h and 1,171 for RX450h. The final hybrid over 1,000 for the month was Fusion-Hybrid at 1,109. It's an interesting mix afterward. The trend basically continues. Growth would be great, but that's asking quite a bit in this economy. Volt's magic number was 1,849. That wasn't much of a surprise considering there was such a large television advertisement campaign... plus \$10,000 of tax-credits and HOV access for purchases in California obviously helped too. Makes you wonder what will happen with PHV after it's been available for that long. Toyota isn't doing any promotion yet. You bump into an online banner if you've been searching for Toyota vehicles or Prius. That's it. Nothing else. Like in the past, the word-of-mouth endorsement from owners is the primary method of stirring interest. This is why it's not worth arguing. The sales approach is so fundamentally different, the online debates would be endless if you didn't just eventually move on. Anywho, the other worthwhile numbers to mention are those for diesel. No surprise. Same old story. Jetta led the pack with 3,787 sold. That was followed by Passat with 2,171. We have no idea what the numbers for Japan are yet. Those are always way better than here... the land where 30 MPG is still considered "fuel efficient".

- 8-06-2012** **\$4 Gas Is Back.** Summer is travel season. Yesterday's outing for me was a bike trip with friends. That was 103 miles of driving with only a single charge. The result was 68 MPG. Certainly nothing to complain about from that... especially even with \$4 gas now making a repeat appearance. After all, I did spend more on food & drink as a result of pedaling 51 miles. Taking advantage of the warm (here in Minnesota) is rewarding. When a beautiful days comes along, you don't squander the opportunity. Anywho, I'm quite curious what the more expensive cost at the pump will do for sales. Prius has always done well then. What does that mean for others? The days of guzzler promotion are long gone. But the advertising for efficiency vehicles is really screwy. The commercials for Volt don't really tell you anything; expectations are quite vague. The one we see for traditional vehicles don't really have a specific MPG anymore. The magic 40 has been obscured by the generic "*hybrid*" labeling. That makes it really difficult to identify what people will flock to. Affordability is still a major priority. The price of gas influencing decisions about size & power make that clear. The monster-size SUVs are gone! Where did they go? Now that we're seeing \$4 again, what affect will that have? I suspect the kick off of the auto shows late this year will really stir interest in hybrids & plug-ins.
- 8-07-2012** **Called Out.** My lack of online participation is starting to make the GM enthusiasts crazy. They always felt vindicated having someone supporting a plug-in with a smaller battery-pack to taunt. I didn't mind, since they were a great source of feedback... especially when it came to business need and affordability. But now that Volt has proven not to fulfill those requirements, I've moved on. So, now they are calling me out by name... hoping for relive the days of hype. I read the posts on the big forum and the daily blog, seeing references to me by name. A quick look at the other post activity explains why. They've got nothing to discuss there anymore. You'd think that big forum would have on-going threads about Volt. That's not happening. Same with the daily blog. The participation has all migrated elsewhere and it's making them crazy. Websites catering to the niche have their fans, but getting ordinary consumers involved doesn't happen. Middle-Market always wins in the end. It's easy to see that on the big Prius forum, where I have been posting frequently. There, we get lots of ordinary consumers participating. The difference is astounding. That's my vindication.
- 8-08-2012** **Street Parking.** How do you argue with someone who has no idea what they're talking about? A friend of mine tried yesterday. The new parking system that's being installed downtown is quite different. The guy saw terminals being installed, one on each street. Not bothering to actually look at one up close, it would be reasonable to make a quick assumption that they could be plugs for plug-in vehicles. But it only takes a moment to question where the electricity would come from. Simply bolting down an object onto the sidewalk doesn't accomplish that. There's no cord for a car to plug with either. Yet, the guy absolutely insisted... even when my friend stated that was a replacement for the old coin-meters for parking. People jumping to conclusions without any thought is a very real problem we have to deal with. I suspect much of the misunderstandings about hybrids come about from instinctive reaction rather than taking a moment to consider the circumstances. The guy was clearly wrong, but he didn't give my friend any opportunity to explain why. That's really unfortunate.

- 8-09-2012 C-Max Attention.** Ford stirred the pot and the internet has reacted. Attention is fading away from a certain other vehicle that worked really hard to retain the spotlight. It wasn't the goal of Prius to be a "halo" vehicle and that never actually happened, despite the claims otherwise. The difference is sales. If the vehicle itself sells well, the goal of achieving high-volume production and resulting cost-reduction as well as money to invest into further development is fulfilled. Selling only a token few is totally different. Doing it through a dependency on tax-credits makes the situation even worse. Thank goodness Ford's upcoming offering doesn't resemble that at all. C-Max is striving to achieve the same as Prius. Being a dedicated hybrid (in this market anyway) and offering a model with a plug puts it on that same course to success, baring nothing is resemblance to the "halo" image. I'm quite curious how the introduction will go. Rollout can be complicated with so many factors at play, include efforts to undermine. We'll find out in a few months. The attention now seems promising.
- 8-10-2012 Remembering Insight.** I immediately dismissed that Honda as a mainstream contender, way back in 1999 with my first in-person encounter. It was very small, manual transmission, and used an all-aluminum frame & body. How could a 2-seater with such an expensive design compete? Turns out, it was confirmed quickly that it could not. Volt draws on similarities I hadn't noticed until just recently. Thankfully, it is an automatic. But compared to the seating both Prius PHV & Energi offer, there's no contest. The cost of the battery-pack is a major challenge that will always hold it back too. The Toyota & Ford systems allow for adding capacity. Lack of flexibility is the same limitation Insight had. More didn't do any good. With Volt, less would cause a power penalty. It's stuck with a one-size-fits-all dilemma. Not being able to leverage efficiency from the engine is the same situation. So even with disregard for business need, there are engineering barriers. Of course, none of that will stir consumer excitement anyway. Interest from middle-market will be stirred by the usual purchase factors... just like when Insight was first offered. Some things just don't change, even with a plug.
- 8-10-2012 Past & Future.** The vague & ambiguous statements were presented to stimulate excitement. GM allowed hype to flourish. Unfortunately, that left Volt wide open for the "*over promise, under deliver*" to play out. Notice how no other automaker does that? What I find intriguing is how different the opinions are from those who joined into discussion following rollout. They have a perspective quite unlike the people who participated online prior to operational details being available. Each reveal over time resulted in the disenchanted jumping ship. We remember names of those who argued intensely in favor of the design, then changing their tune dramatically after finding out that info wasn't actually correct. Now, those names are nothing but a memory from the past. Some assumptions still continue. There's strong belief battery cost will drop dramatically quickly and that people will consider EV a major purchase priority. What are they basing that upon? Owners of PHV will grow, each sharing stories of their experiences. That's not hype. That's real-world data from a design with affordability a high priority... the same success factor attributed with strong sales from previous generations. And think what will happen for Prius when battery-cost finally does drop. The PHV model will thrive. The simplicity of +75 MPG from just plugging in each evening is a easy sell with a sticker-price at the mainstream level. We could see the introduction of a high-capacity option as well. How will Volt attract interest, especially if we see Ford's plug-in competing directly with Toyota's?

- 8-11-2012** **47 MPG Rating.** That's the official word on C-Max. It was revealed today. The sticker will say: 47, 47, 47. All three values (city, highway, combined) got the same MPG estimate. That sure makes the situation easy to consider and no likelihood of confusion or misleading. Gotta like that. Of course, the plug-in model later will introduce a new dynamic. But so far with Prius PHV, that hasn't actually been a problem. Still being a hybrid after depletion keeps things simple. Ford's approach to efficiency, following a very similar FULL hybrid implementation as Toyota, helps the entire industry. Having a power-split device, the system is very flexible. Many different combinations of engine, motor, and battery result. To think that it took this long for genuine competition to emerge; it gives reason for pause. Supporters of hybrids expected something similar to Prius ages ago. True, the versions of Escape & Fusion were worthy advances. But neither was intended to directly compete. This is the first to take Prius on directly. A good old fashion rivalry is long overdue.
- 8-12-2012** **999 MPG Day.** Sometimes, you just don't wander far from home. Today, it was one of those days. There was only a single errand to be run, nothing else. So, I didn't use a drop of gas. The drive was entirely using electricity. I find it remarkably redeeming. The route was the same as that one 2 years ago... that one where the Volt enthusiasts absolutely insisted it was impossible to drive a plug-in Prius anywhere without the engine ever started, especially climbing a hill out of the valley at 45 mph. They absolutely refused to believe that I had indeed done exactly that. Today, I did again. They were wrong and very stubborn not to believe the firsthand report. Now, other owners are sounding off saying the very same thing. The hope was PHV would be underpowered and dependent upon the engine. That's not the case. It never was. But their efforts to greenwash were difficult to counter. Of course, they were also wrong about cold engine startup. Again, they refused to believe the design would deliver such performance. Yet, it does. I'm thrilled.
- 8-13-2012** **Growing Anticipation, thoughts.** Thoughts of the cold season are beginning to emerge. Posts asking about heater usage are gaining attention. I was excited to jump in with: Watch for our reports in a few months. As the snow begins to fall, the role of EV-BOOST mode become the center of attention. That's the mode which you get much more electricity from the battery-pack than in HV mode, but it's not EV since the engine is running. The plug-in model is designed to take advantage of that situation, since the engine must run to provide heat during the winter anyway. Currently, you can witness the +100 MPG that mode delivers while driving faster than 62 mph. That resulting efficiency is very important, since the engine will run at slower speeds in the winter for heat. So you won't get as many "EV" labeled miles, but you'll still get outstanding results.

- 8-14-2012** **Growing Anticipation, discussion.** Thoughts about the upcoming temperature drop is stirring new discussion threads. This snippet within a response caught my eye: "*this is where PiP shines*". How could I resist not responding to that? So, I did: The anticipation is growing. We welcome winter's arrival. There's a discovery process with each new Prius. Our online community here makes unexpected observations... about things Toyota never mentioned. The design speaks for itself through the firsthand experiences we share. It's how the "*under promise, over deliver*" reputation came about... quite the opposite of a certain other automaker. We discover things along the way. But in this case, we have aftermarket gauges and lots of cumulative knowledge already. Watching how the warm-up works with EV now provides hints of how it will work in the cold. Warm-up is faster than with the regular model. We can preheat the battery-pack simply by having the recharging conclude close to departure time. ECO mode still provides heat until the coolant drops to 114°F. The engine stays off for multi-minute intervals while driving in stop & slow winter traffic. Having more electricity and more motor power available will deliver a nice improvement to winter efficiency.
- 8-14-2012** **One Size Fits All.** This quote speaks for itself: "*I think that the winning strategy for automakers will be to offer different ranges as different models or levels within a model...*" In other words, pressure continues to push Volt supporters to acknowledge the need for more than a single configuration. They had been working really hard to offset the current disappointment to the next generation design. That didn't address offering more than just one choice though. It focused entirely on cost reduction. Diversity continues to be a serious problem. This is why enthusiasts absolutely refused to acknowledge the Camry or Highlander hybrids. That existence of multiple battery & motor options, especially with the plug having already added a new level of performance, was simply too much to deal with. Demands of real-world production & sales require it though. Automakers cannot expect to succeed with a one-size-fits-all approach. Look at the expansion of Prius taken by Toyota this year. Look at what Ford plans to do next year. The slow pace from GM is really starting to show, which isn't good considering the financial situation and increased consumer interest in high-efficiency vehicles. It's missed opportunity, handing over sales to the competition. That's a loss they cannot afford.
- 8-14-2012** **2 Kayaks.** Today was the first day of true Summer recreation. I loaded up both kayaks onto the roof, one 12 feet long and the other 14. That experience was repeated many times with the Iconic Prius, a few with the 2010 as well. This was an entirely different experience. The paradigm shift had me wondering. With 2 massive objects interfering with the aerodynamics of the vehicle, the loss of efficiency was looked upon as a worthwhile sacrifice. After all, no vehicle could carrying that same load without also experiencing a similar penalty. No vehicle without a plug, that is. In this case, the 16-mile trip resulted in 83 MPG. I easily can handle that drop.

- 8-15-2012** **390 MPG at 2,503 Miles.** Seeing that reported from a plug-in Prius owner sure is exciting. How far you drive makes a huge difference. Fortunately, this isn't like the Volt supporters always sticking to less than 12,000 miles per year for their expectation setting. Carefully avoiding any reference to the standard 15,000 annual measure was bad enough. Not taking heater usage made it even worse. Remember all that nonsense we had to deal with? It was always analysis write-ups treating the ideal as something all owners would normally experience. With Prius, we make an strong effort to prevent that type of misleading. This report very specifically highlighted the situation as low-miles. I go out of my way to contribute high-miles data. We're showing the spectrum of possibilities, making sure those curious about their own potential understand all the factors at play. It's really nice knowing you support a design capable of satisfying a wide variety of driving needs.
- 8-16-2012** **Fusion Energi.** We got a tiny bit of info from Ford today. Basically, it will be the new Fusion hybrid with a bigger battery-pack and a plug. That really doesn't tell us much, but it certainly stirs the market. Knowing the regular Fusion hybrid will deliver 47, 47, 47 just like C-Max, it's reasonable to see interest in hybrids growing next year at a faster pace than we are seeing now. More charging-stations showing up at popular public locations will add to the potential. There's a nice rivalry growing between Ford & Toyota now. We all like that. There's a mutual benefit. It's something I've been looking forward to for a very loooong time. The advantages of the FULL hybrid system will really become apparent to ordinary consumers with the choices growing like this.
- 8-17-2012** **Recognizing Potential.** Some of us saw it many years ago, having engineering backgrounds and technical detail posts online. Others noticed it along the way. Newbies are recognizing potential surprisingly fast. My guess is that the reason stems from so many misconceptions having been dispelled already. Rather than expending effort debating operation, thought has shifted over to the "upgrade mentality" instead. That's the norm for portable electronic devices. What will the next improve upon? Now with several generations of Prius on the road, the design has proven to be upgradable. So, it makes sense that we are now seeing posts asking what those upgrades could be. Here's what I posted to stimulate discussion: 60 kW is the max electric traction output available from the +2010 models. 27 kW is pulled from the regular model's NiMH battery-pack. 38 kW is pulled from the PHV model's Li-Ion battery-pack when plug-supplied electricity is available. Additional kW is supplied from the generator by the engine when more power is needed. So, there is unused potential which could be tapped into with a more powerful battery-pack. Of course, we've always known Toyota builds for the future. The EV button hinted at that. PHV provided proof. More can still be delivered.

- 8-17-2012** **Those Mode Buttons.** Living in Minnesota, squeezing out more heat from engine waste is a benefit I enjoy. The improvement that new ECO button on the 2010 offered was immediately clear to see for me. Getting stuck in heavy commute traffic caused by a fresh snow is really annoying. I cannot imagine just how frustrating that is when you're burning up \$4 gas going nowhere. In a Prius, the engine will remain off for as long as it can. The demands of the heater are usually what cause it to start up again when you're stuck in a seemingly endless line of traffic congestion. Watch what ECO mode does during Winter driving. ECO lowers the coolant threshold from 145°F down to 114°F. The result is the engine staying off longer, yielding higher MPG while still keeping you warm. My duration my 2004 could stay off was shorter. My expectations for the 2012 plug-in are anxiously waiting confirmation. My brief taste of snow last March wasn't that informative, especially since I was on vacation at the time. The system has been tweaked to deliver heat faster than any other Prius model. That's very exciting to know. Falling temperatures are on the way.
- 8-17-2012** **Poor EV.** Now that C-Max Energi is grabbing so much attention, those in favor of Volt are really at a loss. The arguments against Prius PHV fall apart when applied. It certainly is vindication for me. The design opportunities I've pointed out FULL hybrids can deliver are being taken full advantage of by Ford. There's a great balance the power-split device offers. There's also flexibility, which is difficult to explain without implemented examples... which we finally have them. The plug-in system I now drive everyday is a great candidate for high-volume sales. All the elements mainstream requires are there. However, the focus is just like you'd expect from any type of automotive repartee. The form in which it manifests itself most often is to say PHV offers "*poor EV*" abilities. Notice the same old pattern of the past? Yup, the vague is back. Rather than actually address details of the purchase decision, it's using adjectives to belittle. Thank goodness that shallow approach isn't how middle-market buyers choose a vehicle.
- 8-18-2012** **Biking.** I spent the day with friends, on a long biking trip. We drove to the trail, then rode for 48 miles. It was a great Summer experience; however, it was also a chance for try out a new bike-rack on a traditional vehicle. I was passenger in a vehicle that used triple the amount of gas as mine. Eek! So my PHV sat in the garage all day, never touched. What a waste! We had a good time though and it never hurts getting that alternate perspective. It isn't often an opportunity like that comes along. I'll get to use the PHV plenty of other times anyway. Of course, the fundamental problem of being stuck with a trunk without fold-down seats was obvious. With the Prius, having those 3 bikes on back would still leave a ton of cargo space readily available. With that sedan, everything was trapped inside. Turns out, we have a lot of cargo. Each person had a bag of stuff along with helmets. We had a cooler too. It's amazing how quickly you can fill a vehicle when it comes to recreation.

8-19-2012 **9 Seconds.** The obsession with EV purity borders on absurdity. Why is that so important? What makes that absolute worth the cost? The whole point of a hybrid is to seek out efficiency opportunities, based on the energy available. At no time has that ever meant using electricity as much as possible. It takes between a minute and a minute and a half for the engine in my PHV to warm-up. During that time, emissions & efficiency are still outstanding, even though the engine is running. The plug-supplied electricity allows the most graceful of warming... well above what the regular model (no plug) delivers. The engine shut off afterward is remarkable too. On the drive this morning, I watched the timer on my audio system. Accelerating hard (but not flooring it) from 0 to 45, the engine ran for 9 seconds. That's it. How can such a short time be a bad thing? The reduction of gas consumption is quite significant.

8-19-2012 **Bankruptcy, again.** Long story short, watching this unfold hasn't been much of a surprise. Who knows how it will actually play out from here. But the events & decisions made up to this point don't paint a good "recovery" picture for GM. This were my thoughts upon reading an article by a well known financial publication bringing up the topic: For continuing to point out the efficiency product-gap and slower than planned plug-in progress, there some here that choose to shoot me as a messenger, rather than actually address the financial situation. Fortunately, the dismissal of goals and blatant effort to shift focus won't change the message. The requirements of business are often claimed as pencil-pushing efforts that undermine the spirit of automotive enjoyment. But reality is, there's still a major business burden to deal with. Those outstanding 500 million shares of stock should make that obvious. The unclear plans for the future should confirm it. We're seeing some of the same problems from before the bankruptcy emerge again. The biggest was the heavy emphasis on monthly sales, rather than judging from an annual perspective. The next was the disconnect between need & want, basing success on hope without regard to the market itself. Remember the mess Two-Mode became? What a massive waste of resources. All that time, money, and talent devoted to something few would benefit from. Volt fell into that same trap. Had there also been a lower-capacity choice or a no-plug offering, things would be different. Instead, there's a major dependency on tax-credits for a limited audience. What happens when those expire? What happens if cost cannot be reduced enough to be competitive? What about the rest of product-line? For that matter, how will further research & development be funded? That's a lot of risk during a time when risk cannot be afforded.

- 8-20-2012** **Recognizing Change.** Most of the time when people see something new, it simply gets accepted without much thought. We've become use to products getting better over time. We even accept innovation as it that miracle of engineering was destined to naturally happen anyway. It's to the extend where some change goes without any notice. Differences sneak in without causing any type of resistance. They just become the norm. That's the approach Toyota has always strived for with Prius. Having a display screen a decade ago served as a mechanism for conveying efficiency information. That fact that it was there provided the means for offering other features... which consumers consumers simply accepted. They just did without any other thought. It made sense to have your phone, music, comfort settings, navigation system, and reverse-camera there too. The same goes for the hybrid system itself. People accept the engine & motor design. It has become the norm for a ballet of gas & electricity to provide power. That makes adding a plug no big deal. The system is setup with a battery. Greater capacity just expands upon abilities already available. Will people even recognize that change? Will they even care? Or will it simply be accepted.
- 8-20-2012** **Plug-In Routine.** The act of plugging in has become such an ordinary task for me, even my friends think nothing of it. After all, they all own several plug-in devices of their own. Making sure their phone & computer are charged is part of their routine anyway. What's another device requiring similar needs? You pull into the garage, unload stuff from the car, then plug in. It's no big deal. I was hoping that would be the case, but was uncertain how long that would actually take. Turns out, there's nothing even to adapt to. The act of plugging in is so basic, the process seems ordinary almost immediately. Think about all the other rechargeable devices we have. Many households have plug-in tools. Heck, most have had a battery-operated vacuum for decades. We even have toothbrushes that you place into a recharge-dock after using. Think about all the music players out there. Now the tablet is becoming a popular everyday piece of equipment you carry & plug too. We need very little to take the step toward plugging in a hybrid. There isn't even the problem of forgetting. If you do, the engine will run. You forget with your phone, you're out of luck.
- 8-21-2012** **Exposition.** I think I may be annoying some of my online colleagues. A few of my posts recently included lengthy explanations of the situation, plus some background that may or may not be pertinent to the discussion at hand. The extra information without request often prevents topics from straying. They tend to forget that and often don't have the desire to supply overhead detail proactively. But with so many newbies right now and not having resources readily available to refer to, it really is helpful. We've seen that in the past. I have to remind them of that. I do have to wonder myself about the effectiveness. You never really now how much prevention is actually necessary. Everyone's experience level is different. I keep an eye out for trends though. Seeing a pattern is the clue that we don't have clarity about a particular topic. Misunderstandings after the fact are more difficult to deal with than providing exposition up front. So, that's what I do.

- 8-22-2012** **First Rain.** Today was when I plugged in for the first time in the rain. It was no big deal. The system is designed to deal with moisture. But it's still an event worthy of noting. After all, you can only do it first once. Then all which follow are just part of the routine. Reading specifications for the equipment itself gives all someone like myself what they need to understand the care taken to account for real-world situations. The engineers took everything realistically possible into consideration. Rain is ordinary. There's still the thrill of actually using the produced equipment afterward. Years of waiting for the opportunity make it significant for you, even if there's not much to the process itself or that anyone else would care. In fact, it's exactly like you would normally do, only you get wet. I enjoyed it though. Next is snow.
- 8-24-2012** **Lot Sharing.** While busy in a store at the local strip-mall, a Nissan Leaf pulled into the same lot. That's the first time I've ever shared where there wasn't a charging-station. It's about time. Having an ordinary encounter is something I've long waited for. Unfortunately, I was too busy to sneak out to say "Hi" and none of the for in that EV likely had an clue to even look for a plug-in hybrid. It would have been exciting to have exchanged a few quick pleasantries, but that simply wasn't realistic. Oh well. There will be plenty of other opportunities over time. This was just the first. It's very much a mixed blessing not getting noticed. After all, the goal of becoming mainstream is to simply be part of the crowd.
- 8-25-2012** **309 Miles, less than 1 Charge.** I had an absolutely wonderful excuse to drive up to central Minnesota today. It was an errand that had to be done, so why not make a day of it, see the sights along the way? And that's exactly what we did. I started with a full charge and used EV only when traveling in city & suburb conditions. The highway travel was all HV. The entire trip was 309 miles. I used only 70 percent of the EV available, resulting in 4 miles still remaining once we got home. I was thrilled with the results. Without any effort, the efficiency was great. The final average after all that distance ended up 58 MPG. With all the undermine attempts over the years claiming the battery-pack being worthless for long-distance travel and the weight of it causing a penalty, results like this certainly stir some emotion. They were very, very wrong. Antagonists certainly don't have much to misled with anymore. The design is proving very, very effective.
- 8-26-2012** **0 Miles.** I didn't drive the Prius at all today. It was one of those rare circumstances where I didn't actually need to go anywhere at all... in a car, anyway. I biked about 20 miles, but that trip started & ended at home. It actually seemed a little odd passing through the garage without any reason to touch the Prius other than to take out my sunglasses. But that's what happened. It was a beautiful Summer day, one of the few remaining this year, so full advantage was taken of the opportunity. On my spreadsheet, for lack of any other way of logging a no-drive day, it was noted as 999 MPG with zeroes in the distance columns. That's quite a dramatic difference from yesterday's adventure.

- 8-27-2012** **4 Blocks.** It was late at night. I had 4 fairly short blocks to go and only 0.1 mile of electricity available for EV. What the heck! Why not? Watching the Eco-Meter, I kept the speed at the lowest possible draw to keep going at a reasonable pace on that lonely neighborhood road. That ended up being 18 mph. I made it just fine to the gas station. The cold engine wouldn't need to start up until after I had documented that current tank's statistics. It's a bit of a moot point after having driven so far without having plugged in much. But there's this element of curiosity of wanting to know that you simply cannot resist. The discovery process is quite compelling when you are already driving what is an excellent fit for being a common vehicle of the future. Then, no one will care. Exceeding 75 MPG will be no big deal. Unfortunately now, we have automakers proudly advertising MPG in the mid-30's.
- 8-28-2012** **First Competition.** To be a "killer" of "Prius" as the article title implies, more criteria would need to be exceeded. The published claims hover a little too close to cherry-picking, rather than being a slam dunk. C-Max is well thought out, a very good endorsement to the FULL hybrid design many of us have been endorsing for over a decade now. So, there's no problem at all acknowledging what Ford has delivered as companion worthy of helping to overcome the reign of traditional vehicles. What I find fascinating is how the publicity for C-Max focuses on Prius v exclusively with detail but generically refers to Prius. That will establish a heightened awareness for both the Ford & Toyota products. It's a subtle approach to build the market rather than just garnish bragging rights. That's a dramatic difference from what we've seen from a certain other Detroit automaker. I'm excited to see the field expanding, finally. The well-established reputation Prius has speaks for itself. So when offerings expand, consumers will have choices to consider. Their resulting education is priceless. In the meantime, I'm quite pleased with my 85 MPG average with the plug-in so far. More real-world data from owners will help us overcome the terrible rut the industry has been stuck in.
- 8-28-2012** **Surprise Safety Feature.** Normally when you encounter a vehicle stopped ahead, you either lift your foot off the accelerator-pedal or press the brake. Without anyone approaching, the road was basically just us, I knew that vehicle would be getting out of my path soon. So, I didn't bother. If for some bizarre reason it didn't actually move, switching to the other lane on my right was no big deal. Whoa! All of sudden the display screen changed to a warning (an exclamation-point with a vehicle image) and an alert sound shrieked. The radar system on the Prius detected the danger and was attempting to inform me. I had no idea that safety feature existed, especially without the dynamic cruise-control even on. Apparently, the radar is always scanning the area in front of the vehicle. What a surprise. Sweet!

- 8-29-2012** **Charger Available.** Every now and then, a PHV owner reports getting unplugged before charging is complete. It was easy to blame Nissan Leaf owners for not understanding the charge indicator-light, since their system illuminates when complete. That's the opposite of Prius. Of course, there is the possibility that they felt EV need paramount to a plug-in hybrid and didn't care. It's hard to tell. However, that misunderstanding shouldn't last too much longer. The excuse is weak. That indicator education is simple. The charger itself also tells you status of the vehicle plugged into it. For the public charging-station type I use, the screen clearly says "Available" when draw from the vehicle has ended. That's important, since usage isn't always free. If someone pays for service and the cord is removed prior to finish, do you think they will be ok with that happening?
- 8-29-2012** **First Sighting.** YES!!!!!! I saw a new Prius approaching. He was turning left. I was turning right. As I did, the green color stood out. Could it actually be? Sure enough, the emblem said "PLUG-IN HYBRID". My jaw dropped. With only 2 known PHV in all of Minnesota, what was the story with this third one? I had to find out. So, I just stopped along the drive. Sure enough, he pulled up along side me without concern for blocking traffic. His was only 2 weeks old, driven all the way from Portland to vacation out here. Encountering mine (and at that point the wildly excited driver) was quite a surprise for him. So, we pulled into spots and chatted for a bit. That was sweet. The potential for PHV next year when national rollout begins is remarkable. Just listening to the conversation two owners can stir up is powerful confirmation. All the rhetoric about the battery-pack being too small will fade away fairly quick. The simple operation and overall efficiency speaks for itself. Getting the word out about that is the key... something we as owners are happy to provide.
- 8-30-2012** **54 MPG.** That's the new requirement stated in the CAFE rules just revealed. Seeing a fleet average that high seems a bit of a stretch considering how much automakers other than Toyota still have to strive to increase MPG in their variety of vehicles. But then you realize those numbers are different from the measurement EPA provides. The criteria is less stringent. It's easier to fulfill these. Nonetheless, it is an improvement to the current situation. Our fuel efficiency standards are pretty disappointing. The industry lowered them. 40 had once been the goal. Now, we see the combined value down in the low to mid 30's. Considering how long Prius has been available, that's bad. You'd think an effort would have been made to match that. Decades from now, they'll look back at what happened with amazement. Instead, of trying to be competitive, the monster-size guzzlers became popular. Prius actually had to face Hummer as a mainstream choice. What the heck!?

- 8-31-2012** **More Stations.** What a pleasant and quite unexpected discovery today. Within next few months, the plans are to have 2 more charging-stations installed at the ramp where I park for work. That's exciting. When rollout of the plug-in Prius finally starts here in Minnesota, there will be more than just a few token spots available. That's a big plus considering how inconsiderate a few traditional vehicle owners have been in the past. When there is only a spot or two available, people have been known to park there with a vehicle that can't even be plugged in. That's referred to as an "*ICE'd*" spot, since it is used by an Internal Combustion Engine vehicle rather than a plug-in hybrid or EV. With more spots, that's less likely to happen... since the area set off to the side for plugs will be highly visible rather than something easy enough to claim ignorance to. The spot situation is difficult enough when you've got a variety of plug-ins all wanting to use them. After all, who should get priority when availability is limited? And what is the protocol when your charging has completed but you haven't left yet? Is it acceptable for the next person to begin using that charger without checking with you first? For those of us with smart-phones and the connection-service, we'll get notified immediately. How will we respond? Then of course, there's the issue of cost? I have already seen a change from a per-hour to a per-kilowatt approach at one location locally. How will that change over time based on demand? There are many questions. Getting answers starts with having more stations available.
- 8-31-2012** **Efficiency Cost.** That has always been the biggest topic of debate when it comes to hybrids. That's why the cost of Volt has been such a concern by so many. Anywho, on the opposite end of the spectrum is eAssist... or so we thought. The point of that particular technology was making it so inexpensive it would be feasible to make it standard. That seems to be reasonable too, if it actually delivered a decent MPG bump. Turns out, the efficiency difference is only modest and the price way more than anticipated. For Buick Regal, it will indeed be included on all models. However, the 2012 (with eAssist an option) was \$27,055 and the 2013 base (with eAssist standard) will be \$29,015. That's a nearly \$2,000 increase. For a large sedan delivering only 29 MPG combined, that doesn't exactly stir much attention. The hybrid Camry delivers 41 MPG combined and starts at \$25,990. The hybrid Fusion delivers 47 MPG combined and starts at \$27,200. How exactly is GM's hybrid even remotely competitive with Toyota or Ford? This is the concern many of us have been really worried about. Even if things look good at the moment, next year and the following don't appear that way.

- 8-31-2012** **Month End Trouble.** It's getting intense. The friction Volt continues to cause now is worse than last year. That's because there's more pressure to deliver now than there was then. Availability in all 50 states and wide recognition is what makes it different this year. That should translate to higher sales. Instead, the outlook look bleak... just bragging rights among other plug-in models rather than taking the market by storm as it had once been hyped. I tried to injection some realism into the situation, but you know how that usually turns out: GM's own second-year sales projections is what we should keep focused on. They were originally 60,000 annual here, which is the mainstream minimum that's been used for ages. So, it made sense. Volt's purpose is to become a common vehicle, right? As this year began, the number got revised to 45,000. Fine. The adjustment was reasonable, acknowledging a slow market startup but still pushing to get beyond the tax-credit dependency. 2,500 falls well short of the revision, bringing the rate to 30,000 annual. What does that mean? Reading this thread, that s a good question. Not remembering when things happened and the omission of information is one thing. But voting down of facts, how is that constructive? With Ford about to enter the plug-in hybrid market, the mixed messages about Volt will become a liability. Market need must be addressed. Want should not dictate approach.
- 8-31-2012** **Two-Mode Discontinued.** Announcements from GM tend to be ambiguous, so you can never really hold them to a particular decision later on. It's irritating that other automakers are clear about their intent, yet GM still remains as it was in the past. But with all the spin coming from supporters, it really doesn't matter much anyway. Sales end up speaking for themselves. Results of them have been so bad, we get new of Two-Mode being discontinued just before the month comes to a close. The choice to get ahead of the inevitable bad news seems to be a good one. We'll find out soon enough. I'm relieved the nonsense is over. Once hyped as the solution for their entire line-up, it quickly became something only for the large guzzlers. Seeing it not catch on after all these years (nearly 6 now), the time had come. Either we'd see that next generation promised or the program would come to an end. Looks like it's the latter. My summary of the situation was in the form of a comparison, since there's an obvious parallel enthusiasts continue to refuse to address: The Two-Mode aspects of meeting middle-market need closely resemble that of Volt. Even though both delivered significant efficiency improvement, the cost has made them well out of reach. Too much sacrifice was made for the sake of capacity & power. A better balance is required. Problem is, the vehicle won't stand out then... which is not the type GM has wanted to build & sell. In other words, a radical approach shift is required. This decision may be a sign of that actually happening.
- 9-02-2012** **i-MiEV Sightings.** I saw my first Mitsubishi EV, called the i-MiEV, a few days ago at the Minnesota State Fair. Today, we just happened to drive by a dealer. There were 4 available on the lot. It was an odd sight, but still not as out of place as a Smart or Fiat dealer. The radical looking small car isn't what you see on the road around here. Several other cars have mimicked Prius over the years, confirming the sensible nature of the size & shape even for non-hybrids. The lack of basically any hood at all is a step beyond that, not something a traditional vehicle could adopt either. No engine at all and limited range already make selling an EV a big challenge. Visual appeal adds to that. I'd be intrigued to find out what others think. After all, Nissan Leaf much more closely resembles a traditional vehicle. But even with that, sales have been under expectations. I obviously reducing the use of an engine rather than eliminating it entirely. People's needs differ though. It's good to offer a variety. Time will tell.

9-03-2012 **999 Again.** I thought the start of the holiday weekend two days ago presented a rare event, driving the entire day using nothing but electricity. Turns out, today was the same way... 9 miles before... 10 miles this time. That's fun to experience. It's a nice benefit of living in the suburbs. Most of what you need is only a few minutes away and you usually don't need to jump onto a highway. That was indeed the case both days for me. There's no effort to drive with pure EV. It just happens at times. Owning a plug-in hybrid means outstanding MPG. Having an engine that rapidly shuts off is part of that. But seeing the 999 MPG from time to time is still nice. Just think if I had a shorter daily commute. Then I'd see it far more often than an occasional weekend. My frequent road trips means dropping all the way down into the 50's. Can you believe I can tolerate such low efficiency? Imagine if other vehicles had that problem. Sadly, most don't even achieve 50 at their best.

9-03-2012 **Very Very Different.** It doesn't take a rocket-scientist to see what's happening. Sales pressure continues to build. Enthusiast of Volt are clearly on edge. On what's left of that daily blog, I posted: Facts getting voted down is not a good sign. That's a dead giveaway something isn't right. Originating from this statement, *"Toyota beat the advertising drum repeatedly for years to build up the image of the Prius and make it more acceptable and desirable."*, it's fairly easy to see what the actual story really was. Misconceptions were abundant then. "YOU HAVE TO PLUG IT IN" was by far the biggest. All of the early owners were constantly explaining to people how the system actually worked. "CAN YOU DRIVE ON THE HIGHWAY" was a close tie with "HOW OFTEN DO YOU HAVE TO REPLACE THE BATTERY" for the most common questions. Let's not forget how cheap gas was back then and how low of a priority using less was. What would the point be of heavily promoting the first generation knowing the second generation was already well into development anyway? Remember, that's when the switch from sedan to hatchback took place. That change alone would seriously complicate the purchase decision. The fact that Prius wasn't even available on dealer's lots until 6 months before the rollout of that next generation began was another. (Prior to that required direct order and delivery wait.) Why promote something in such limited supply? Long story short, the situation for Volt is very very different.

- 9-04-2012** **August Sales.** Here in the United States, it was a good month for Prius. Sales counts for other hybrids are mixed. The hybrid version of Camry was among those that did well, selling 3,840 in August. That outpaced Sonata with 1,766 and Fusion with 1,071 by quite a bit. The Lexus hybrids aren't doing too bad either... CT 200h at 1,472 and RX400/450h at 1,170 and the ES at 817. The eAssist story is rather odd, Malibu at 2,414 and LaCrosse at 1,024 sold, since that version of Malibu is the only 2013 model available and LaCrosse isn't offered without the hybrid system. So, neither really tells us much about actual demand yet. At with MPG so low, what's the point? The only other noteworthy number to point out is the Lincoln MKZ with 998. As for Prius, there were 13,311 for the regular model, then 3,428 for c, then 3,325 for v. PHV, still only available in 15 states, came through with 1,047 sales. I can't wait until nationwide rollout for the plug-in. At that point, there will be plenty of real-world data to entice sales too. Less than 6 months doesn't tell much of a story yet. Lastly, there were 70 for Silverado, 63 for Escalade, 36 for Yukon, 36 for Tahoe, and 26 for Sierra. Needless to say, this is why Two-Mode isn't something GM is interested in selling anymore. With numbers that low, what's the point? The story for Volt continues, the 2,831 sales in August falls well short of goal and is subsidized by a tax-credit triple that of PHV. Fortunate for Toyota, they have a large market in Japan too, allowing production to take advantage of higher volume... something that's really important when subsidies expire. Next year certainly is going to be interesting. The availability of plug-in vehicles should push hybrid sales highway. The question is, what MPG will consumers seek?
- 9-04-2012** **Plan B.** What is it? Knowing the sales of Volt will continue to be a struggle, what the heck will GM do? What are supporters expecting? What will consumers purchase? Something will be produced in high-volume for business-sustaining sales. What will those vehicles be? What about when the tax-credits expire? The situation is a confusing mess. This is why the media and online-comments go wild. We have no clue what to expect now that hope didn't match reality. Of course, there was no sense of realism in the first place, hence the fallout. It was mostly hype, since there wasn't data to support the claims. Putting all your eggs in one basket is never a good plan anyway. What other high-efficiency offering will there be? And will it actually be affordable? Remember GM's own goal of "*nicely under \$30,000*" when Volt design just began? What is the alternative plan?
- 9-05-2012** **Same Old.** First thing this morning, I was treated to an article comparing the plug-in Prius to the Vauxhall Ampera (that's the European model of Volt). Getting a non-American opinion seemed hopeful. But instead, nothing. There was neither mention of emission-rating or expected efficiency. All it did was focus on EV abilities and portray the design as a stop-gap. This is the modern version of the same old GM support we saw nearly a decade ago. It boggles the mind that such desperation would emerge again. They call the technology a compromise to distract from the reality that it delivers upon business need. In other words, the PHV model appeals to consumers with just the right balance of traits to achieve high-volume profitable sales... which infuriates the competition. But rather than attempt to greenwash, they instead to label it as inadequate. Think that same old nonsense will work this time? It failed miserably before.

- 9-05-2012** **Exaggeration.** To conceal the problem at hand, a common technique is to exaggerate. The thought is over-emphasizing will cause the reader to agree with you and simply dismiss the topic without giving it any further consideration. This example today was a classic: "*Many journalists started writing stories that GM shut down because lack of sales... that the sales had gone down to nothing.*" I never saw anything claiming an absolute like that. It was surprising a supporter would even attempt such deception, but that's common practice in politics. Heck, keeping people from wondering about detail is what we see in television commercials all the time. Sadly, it's easy to distract... especially when there's brand loyalty as a factor. Needless to say, I wasn't thrilled about reading that and fired off this in response: Nothing? No. It was said that supply was much greater than demand, that there was already enough inventory available to sustain sales for awhile. It made sense too. GM had anticipated a demand of 3,750 per month. Selling at a rate of roughly one thousand less and meant dealers didn't need to have any new ones delivered soon. Profit is lost when unsold vehicles sit on the lot. Avoiding that is good business.
- 9-05-2012** **Facing Reality.** Some just plain don't want to. Volt didn't meet expectations. I helped the process along today: The withholding of CS-mode efficiency data was the first sign of expectations not being realistic. The MPG following depletion fell well short of what had been hoped for. Then came the reality of heater demands in Winter. No matter how many times we pointed out the impact to EV range electric-heating would have, the enthusiast just plain did not want to acknowledge it. They even fought intensely against the benefit of having a HOLD button, despite the reality that it could help overcome that problem. The reason for resistance was obvious. They wanted to differentiate Volt from Prius... hence all the "*vastly superior*" chanting we had to endure prior to rollout. Now there's the reality of acceptance. PHV delivers great all-around efficiency and without the need to consider purchase of an aftermarket charging-station. PHV also comes close to middle-market pricing without dependency on tax-credits. Energi availability will change the dynamic too, creating more pressure to compete with an array of features rather than just heavy EV focus. The reason for the "*too little, too slowly*" concern will become more apparent in the next year. Time is not abundant. Reality will be faced. Change will be required.
- 9-05-2012** **Accord Plug-In.** Details revealed by Honda today about their upcoming hybrid with a plug were interesting. It will have a 2-liter gas-engine, a 124 kW electric-motor, and a continuously variable transmission. Since the system uses clutches, it's a confusing mess trying to figure out how the system actually operates. Supposedly, it will be totally electric up to 62 mph. What happens faster than that and once depleted is still unknown. The 6.7 kWh Li-Ion battery-pack will supply 10 to 15 miles of EV travel. It takes up a large chunk of the trunk, making it narrow & tall. Since the pack itself is located behind the rear seat, there is no fold-down or pass-thru available. How consumers will perceive it is anyone's guess. Price will obviously have a big influence. The EV purity is what I'm curious about. Utilization of electricity on-paper differs quite a bit from reality, since most people's expectations don't account for all the variables at play in real-world driving. Simple things like the need for heat are a big unknown until you actually sit in the driver's seat. I know this firsthand, having owned a plug-in Prius for almost 6 months already. Time will tell.

- 9-06-2012** **Japan Sales.** August was yet another strong month for Prius in its domestic market. 23,828 of the liftback model were purchased in Japan then. The count for the c model was great too, with 19,076 purchase there. Imagine if we saw that many here. Not only would Prius be mainstream, it would be near the top. There were times in the past when sales spiked here, but never were they sustained. The thought of not one but two models accomplishing it would be clear evidence of traditional vehicles losing their title of common. Someday, the standard choice will be hybrid. Sadly though, that won't happen here anytime soon. As the technology continues to be refined and batteries enhanced, the thought will become reality. After all, the business-sustaining aspect of is already. Long gone are the days of being dismissed as a niche. Yeah!
- 9-06-2012** **15.2 Miles.** My record continuous EV distance has been 17.5 miles. I made it all the way to work, taking the long route, ending with 0.3 remaining after having parked. The morning temperature was 88°F. That's well above the norm here in Minnesota, so I don't often refer to that particular experience. Here, the maximum EV distance I've seen on a regular basis on my morning commute has been 14.1 miles. So, today when it hit 15.2 miles, I was left scratching my head wondering how that happened. The drive was quite typical, a mix of hitting lights green & red with medium traffic... nothing I haven't seen routinely. The variables at play are plentiful. Even someone with a heightened awareness like myself can miss all the circumstances there are to observe. This complexity is why we tell owners to "Just Drive It". The response to random outcome can lead to a misinterpretation of how it was achieved. So like me, we just point out the observation for the sake of giving others an idea of what the system is capable of delivering, but carefully avoid setting that as an expectation.
- 9-07-2012** **Intersections.** It's rather surreal when you pull up to an intersection in a plug-in Prius when there are already 3 more Prius stopped there. The other vehicles were an old-school Pontiac and a Smart Car. Where have the monster-SUVs gone? To think that they, along with giant pickups, dominated the roads. I still remember, years back sitting in the Prius at an intersection with my father, pointing out that my vehicle was the only car there in that crowded maze of traffic. Things certainly have changed. The claims that \$4 gas wouldn't have the influence protagonists stated were indeed the case. Clearly, consumer preference is different now. A quick survey of any store parking lot confirms that. The lust for size & power has vanished. It's as if that ugly chapter in our history never happened. Seeing so many Prius now on the road does an especially good job of validating progress. Symbolically, the intersection well represents what's happening. The stop & go marks the end & begin. The guzzlers are fading away. Yeah!

- 9-07-2012** **Available In Canada.** Today, sales of PHV began in Canada. It's nice to see that market finally getting an opportunity to purchase. I'd go nuts not having any way at all to purchase one until sometime next year. Purchasing mine in California then having it transported to Minnesota is unusual, but knowing a great salesperson out there made all the difference. Now, I can collect & share real-world data to help others with their decision... here in the 45 states that PHV isn't available in yet. Canada is different. You cannot cross the country border as I did with the state. It gets very complicated. Things like warranty coverage and safety/feature configuration are the same here, so it's no big deal. Paying the appropriate sales tax and titling isn't too terribly difficult either. There, the option to purchase elsewhere simply wasn't available. Being that far north, there's the obvious desire to enjoy the new vehicle before Winter sets in too. I understand the situation, but can only provide so much vicarious experience. Now, they can firsthand. Sweet!
- 9-08-2012** **Vastly Superior.** The past week has been loaded with examples of flagrant bragging. There have even been cries of "*traitor*" to those who purchase an imported vehicle, even though that import significantly reduces the importing of oil and provides employment for many here. This is likely why the membership has increased significantly on the big Prius forum and participation on both the daily blog for Volt and the big GM forum has dropped significantly. We are at a turning point. In other words, this is the transition from enthusiast to mainstream. That's putting tremendous pressure on need, which is a big departure from all the attention previously place on want. The difference between this and the past is scale. The time has come for a solution for the masses. Needless to say, there isn't any reason to participate on the struggling blog & forum anymore... except one, trolling. They've been dropping quite a bit of bait lately, calling me out by name and surprised I don't respond to all their taunting. I finally did. This was my favorite quote: "*He is just loathe to admit that the PIP is inferior. Yet anyone with even a bit of honesty would immediately point out the fact the Volt is vastly superior as an EREV. It has no compromises in its drivetrain.*" I responded to it with: Except cost and engine efficiency and emission rating and... Of course, there is no solid definition of what "EREV" actually means. There's just vague references to speed & power, both of which are blurred by the plug-in hybrids Ford & Honda will be offering. Again, ordinary consumers have different priorities. That's why they purchase cars like Cruze & Malibu.

- 9-08-2012** **Battery Size.** It was inevitable. Seeing how great the MPG is from the plug-in Prius, argument tactics to favor Volt are changing. Attention is being diverted to battery-size. They are attempting to portray the PHV approach as too small. Since most people have no concept of scale, they are hoping the same appeal other bigger numbers had in the past will now apply to plug-in vehicles. Assuming bigger is better is the key, hence moving away from the detail MPG provides. This is the quote on this new topic got me going: *"You mean the 4.4KWh battery that ONLY powers the car in EV mode if you drives like grandma?"* It's sad to realize they think that will work. These are different times. Consumers are no longer compelled to purchase more size & power than they actually need. The financial consequences of that choice have been quite painful. Repeating that mistake is unlikely. Many have learned that lesson the hard way. Anywho, this was my response: Greenwash. You get 4.4 kWh of electricity benefit regardless of how you drive. My morning commute includes 9 miles of driving at 70 mph. Again, so what if the engine runs? I see +100 MPG for each of the 1-minute segments on the consumption-screen while cruising at that speed. The benefit comes from the engine running at extremely low RPM (varying between 992 and 1024). That rate consumes very little gas, hence the high efficiency. Having the engine run is a big deal in Canada and the northern states too; it allows the heater to take advantage of hot coolant.
- 9-08-2012** **Sonata Hybrids.** I sure have been seeing a lot of them around here lately. Minnesota has many Prius, which can be attributed to a number of supportive factors. So, it really isn't a surprise that is happening with this newcomer. It makes me more curious than ever what will happen with C-Max when it becomes available in a few months. Following that, both the Ford & Toyota plug-in hybrids will debut here. I can't wait... though, I'll have to. It would be rather strange rolling them out until Winter is well away. That's a long time from now. We're just seeing the first signs of Summer ending now. Anywho, I doubt many people notice those hybrids as I do. To them, it's most likely just another Sonata. Sadly, they probably aren't even aware a hybrid model is available.
- 9-08-2012** **Politics.** It doesn't matter what the topic is. The same old rhetoric can be found. I closely follow the claims about hybrids. So, I'm quite familiar with the circumstances of how those hoping to undermine progress function, like raising doubt. No matter how much information you provide, it's never enough. They mislead ordinary people to take a counter-productive stance themselves too. For hybrids, it was always the "save money" argument. Since when isn't just breaking even the goal? Why must you somehow come out ahead instead? And how will that raised standard actually be measured? The devil is always in the details. Don't allow vague sound-bites to dictate outcome. Without specifics, they can basically say anything they want and just later claim their statement meant something else or was misunderstood. Sadly, the examples of this with hybrids are plentiful. Setting of unrealistic expectations is another that comes to mind. It's all quite frustrating... which is why there are so many who simply avoid politics. They know how insincere the comments they hear can be. Oh well. Stand true and continue to provide lots of real-world. That speaks for itself, allowing consumers to make their own decision rather than be told what to think.

- 9-09-2012** **No Charging.** Today was my first ordinary day (not vacation) when I didn't recharge at all. There were 4 separate drives... one to the coffeeshop... one to the grocery store... one to the lake for a walk... and one to do family stuff at mom's. 25 miles was the total distance traveled. The result was 57 MPG. There isn't much else to say. The efficiency is outstanding even when you don't plug in. The hybrid system shines even without extra electricity. I don't plan on ever doing this particular test this often, it just worked out to be a nice opportunity to observe what happens. After all, there will be circumstances where it simply isn't realistic. In this case, I couldn't reach my garage since there was work to be done on the driveway.
- 9-09-2012** **Keeping it real.** That's very important. It's why I've refrained from filming my commutes until the weather cools down. In the depth of Summer, the battery-pack delivers above average capacity. Showing that would establish unrealistic expectations, especially on those days with really warm morning commutes. It's the same reason why each post includes an on-going average with values measured at the pump. The real-world data speaks for itself. No cherry picking, just an all-inclusive summary of my usual activities. Over the years we've seen others set themselves up for failure through misrepresentation, portraying a technology in a way that the everyday person will not experience. It's hard to believe they cannot see how poor of a choice that is. They get hung up in the excitement and cling to the group-think of enthusiasts. With my 6-month anniversary rapidly approaching, I'm really looking forward to creating a document that provides summaries & detail along with a story of what I've experienced so far with the plug-in. It's like the next level to blogging, where you look back and reflect upon those events.
- 9-10-2012** **\$3.89 Per Gallon.** The price of gas is climbing. That doesn't surprise anyone, especially with hurricane shutdowns influencing oil supply. We're boiling the frog though. That old cliché fits the situation well. As temperature rises, the frog doesn't notice. Eventually, that point of being too late is reached. The frog simply dies. We're seeing exactly the same thing with how much people are willing to pay for gas. They just tolerate it to the point where all of sudden the guzzler vanishes. \$4 seems to be the limit for many. I delight in seeing the shiny new replacement in their driveway, something much more efficient than previously. In fact, I cannot recall when I last saw a new guzzler. Some of the purchases are even Prius. More will be hybrids over time. After all, the misconceptions of the past are long since disproven. How could anyone argue them with so many on the road now? Well, Prius is plentiful. Slowly, the economy is recovering too. Not seeing people flock back to the old ways of disregarding MPG is satisfying too. Just look at the television commercials. What do they highlight now? Priorities have change. The price of gas is clearly having an influence.

9-10-2012 **Getting Worse.** Long story short, GM faces a serious dilemma. The explosive commentary online today about cost verses price draws attention to that. The situation we feared is now a reality. We were led to believe Volt would take the industry by storm in 2010, a design which would "*leap frog*" Prius in every respect... because it was a "*vastly superior*" technology. That obviously didn't happen. Now here comes a number of automakers offering plug-in hybrids, including Toyota, Ford, and Honda. It's exposing the difference between want & need. GM's heavy dependence upon financial incentives to sell the only high-efficiency vehicle they have to offer makes the bad situation even worse. What are we waiting for? Who will actually benefit from it? How will the next generation solve the long list of needs to fulfill? It's an ugly problem that's quickly growing worse.

9-10-2012 **6-Month Report.** Here's the real-world data I've collected so far with my 2012 Prius PHV:

9,316 = Total Miles

184 = Days (6 months)

85.1 = Lifetime MPG

109.4 = Total Gallons (measured at the pump)

909.2 = Total kWh (including charging losses)

3,596 = EV Miles (displayed amount)

5,713 = HV Miles (displayed amount)

794 = Total kWh (displayed amount)

293.3 = Recharges (based on capacity replenished)

assumption: one full recharge, including charging losses = 3.1 kWh

9-11-2012 **Pressure.** GM's campaign against hybrids a number of years ago was unbelievable. Now, the situation and circumstances are quite different, yet some keep trying to portray it as if it's still the same. That's not constructive. Toyota delivered a product designed for middle-market. GM clearly didn't... could have... but chose not to. The decision was to make an attention-getter instead. Remember the "*halo*" statements? The results of that choice are now making themselves apparent. The pressure to deliver a configuration suited for mainstream consumers is building. When will it become so blatant we'll get some type of actual plan? That doesn't seem likely yet, especially with enthusiast responses like this: "*It must kill them that the Volt is the number one selling plug-in vehicle in the world.*" That old trophy-mentality is undermining Volt's own success. Notice how there hasn't been any television or radio advertisements for the plug-in Prius? I'm continuously hearing & seeing them for Volt. Spending a lot on promotion along with dealer discounts is an acceptable way of introducing a new product, but that's not sustainable and it's been nearly 2 years. Pressure is building.

- 9-12-2012 Cannibalization.** That is indeed a big concern. Seeing how much Volt enthusiasts celebrate conquest sales, it's pretty obvious how "*alternative*" perspective is still a barrier. Yesterday, I was interviewed about my plug-in. The guy was somewhat surprised when I stated the choice to purchase a hybrid was "no brainer". After having driven them for over a decade, why wouldn't that be the norm at this point? The push of traditional vehicles instead was inevitable. Automakers have been resisting change. Thankfully, the introduction of plug-in hybrids will help to push regular hybrids (the full type anyway) even deeper into the mainstream. I'm thrilled by the quantity of 2012 Prius that I encounter on the road now around here. Hopefully, that hints at the potential PHV has when it finally becomes available. Nonetheless, we'll still see lots of promoting that portrays MPG in the 30's as "*highly efficient*". Unfortunately, I cannot sight any information source as to what motivates purchases now either. We see efficiency rising in priority, but the factors which compel consumers to purchase a traditional vehicle instead elude me. My guess is lack of real-world data. With all the greenwashing effort at play, it's easy to see how confused they could be about what to actually expect. In other words, I see 2013 shaping up to be a pivotal year and owners playing a major role to increase marketshare. We cannot just watch the flat trend continue. Growth is a must, especially with fallout from GM's efforts working against the hybrid market.
- 9-12-2012 Other Plug-Ins.** Discussions of a constructive nature simply don't exist anymore. The groups in direct support of Volt just plain don't want anything to do with the Toyota or Ford plug-in hybrids, and we certainly are getting antagonist posts on the big Prius forum now. It more confirmation of change. Another was the attention brought to the Honda today. That upcoming Accord will be the first with two electric-motors. So, some of the operation will mimic what we recognize with the FULL hybrids, but it will utilize clutching more like Volt. The design blurs the line for EREV even more, further emphasizing the importance of actual outcome rather than advantages assumed on paper. Anywho, this was my contribution to the madness: Efficiency increased significantly from a battery-pack small enough to conceal is key. It keeps cost in check while at the same time keeps the plug from interfering with interior layout. 85.1 MPG is my average from 6 months of Prius PHV driving 9,316 miles. I plug in each evening and usually at work. I've taken a few +100 mile trips as well. That's a significant improvement over my 2010 and dramatically higher than what any traditional vehicle can offer. The goal is to deliver something for mainstream consumers. That means a balance of priorities, like other mainstream vehicles, not pushing for maximums.

- 9-12-2012 New Commercial.** The first with the plug-in model is now being shown on television. It carry a catching tune and simple lyrics: *"This is a car that loves to have fun. Mile after mile, to and from. Now there are four for all to use. Tell the neighbors, your friends, everyone the news. Let's Hum Hum Hum Hum, Let's Hummm, A Prius for everyone. Now there's a bigger one if you want more space. A small one if the city's your place. And even one you can plug in. So hop on in and give one a spin. Let's Hum Hum Hum Hum, Let's Hummm, A Prius for everyone."* The liftback (regular model) drives by the v (wagon), then drives by the c (compact), then by the PHV (plug-in). You see an animated man plug it in too. This is followed by all 4 of them driving along a scenic road. It's one of those carefree advertisements with an obvious message. Toyota wants consumers to be aware that there are now 4 distinct models available. It's a basic introduction which should serve well. You're obviously not going to make a purchase decision with so little information. But then again, what in the world were promoters thinking in the past when showing you how their vehicle performed while sliding sideways on dirt? When would you ever actually do that? I enjoyed seeing that. I think it will effectively spread the word too.
- 9-13-2012 Refrigerator.** A large electronics retailer is closing a nearby location. That meant clearance hunting. Little did I know the compact refrigerator I've had my eyes on for awhile would jump out at me. But with such a huge discount, how could I resist? So, I pounced on the opportunity. It shocked the employee sent out to load that into my car though. She had assumed Prius was a small hatchback. The refrigerator, though technically having a "compact" label, offers dual doors and 4.5 cubic foot of interior space. That makes it mighty big in a box. I smiled, then lifted the 95-pound beast... slipping it effortlessly into the cargo area. When I shut the hatch and turned around, I was greeted with a dropped jaw and wide eyes. She had no idea a Prius could so easily swallow up such a large purchase. It was really sweet getting such a reaction. People fall into the trap of assuming. I definitely got her with that. Then I pointed out it was a plug-in and silently drove away. What a great experience!
- 9-13-2012 Promotion.** Have you noticed how Toyota's first television commercial with the Prius PHV didn't actually feature it? There was simply just a mention that a plug-in model was available. There really wasn't any fanfare at all. In fact, this is the first. It took 6 months to hear just a peep. That's a drastic difference from what GM has been doing with Volt. It was advertised heavily even before rollout and I hear & see commercials on radio & television everyday. This is one of the many reason I was constantly frustrated with the enthusiasts. They'd claim GM was following in the very same steps as Toyota, doing the same thing with Volt as had been done with Prius, but turn a blind eye when evidence like this was presented. They'd also claim GM was starting from scratch, pretending no knowledge or experience whatsoever was gained from EV1 or Two-Mode or BAS. It amazed me that they'd see only what they wanted to... and claim that's what you were doing. Thankfully, the promotion difference paves the way for other opportunity. The most effective means of "advertisement" for Prius has always been owner endorsement. That continues with the Prius family. All Toyota is doing is simply point out the availability of other Prius models. Owners themselves spread the detail. They allow us to influence demand. It's like allowing people to walk wherever they desire. Eventually, a path will form. That's the best place to pour the cement for a sidewalk. Don't tell people what they want. Provide the opportunity to choose. Long story short, one size does not fit all and a good product shouldn't need a lot of advertising.

- 9-14-2012** **Game-Changer.** It's quite remarkable when those passionately supporting Volt actually agree with what you've been saying for years. They won't admit it, but their actions speak for themselves. The forums & blogs plainly confirm the situation. The statements have been quite terse, though surprisingly long-winded despite the clarity. Volt is a platform for the future, not the game-changer in had been hyped to be. It's not going to draw interest from those considering the purchase of a Cruze or Malibu. Cost won't come down for a number of years still. Just like with Two-Mode, expectations for what would come next have been totally absent. They really get upset when you draw attention to the parallel circumstances too. Seeking acknowledgement of need has been the point, to push a shift away from the trophy-mentality for the embracing of feature middle-market demonstrates as priorities instead. With both Ford & Toyota poised to offer their plug-in hybrids as mainstream choices next year, the most recent exchange of online posts was quite predictable. It's what happens when pressure builds from \$4 gas.
- 9-15-2012** **Changing History.** Fallout reaction never ceases to amaze. Changing history is the latest attempt. That's pretty desperate. We all know how different things appear looking back a decade later than they do at the moment they are unfolding. Countless details are left out and the outcome back then was quite uncertain. But since things are proceeding so much slower for Volt than supporters ever imagined, they now have nothing else to try. Heck, even shooting the messenger didn't work. Yet, they persist, still trying to paint a rosy picture. Reality is, conditions are very different. Time isn't a luxury as it was all those years ago. Gas is \$4 and there won't be something cost-effective for many years still. It's an ugly situation. Effort is being wasted on defense rather than offense. That's very unfortunate. Reacting instead of being proactive is what we tried to prevent. Of course, they don't want to acknowledge that particular history. We're stuck with rhetoric, nothing actually constructive... just pointless arguing.
- 9-16-2012** **Potential.** GM's choice to place all it's eggs in one basket with Volt continues to be a problem. There is no hybrid equivalent to help it advance design quickly, bring production costs down, and assist with reliability reputation building. Remember, supporters of Prius were stressing the advantage of the power-split approach way back, since the very beginning. We pointed out how plug augmentation later would allow the same system to deliver much higher efficiency simply through the use of more battery power... which is precisely what ended up happening. From another perspective, Volt reverts back to tradition vehicle efficiency after depletion. Prius doesn't. Prius remains a high-efficiency vehicle even when depleted. That means a model without a plug is very realistic... which is quite obvious now, but was highly debated ages ago. The one-size-fits-all promotion is another problem. Look at Camry. That hybrid system offers much more power. Consider the size of Prius v. Think what would happen if those two vehicles got merged. Think what would happen with a plug were added. Think about the all-wheel drive that the Highlander & Estima hybrids already offer. The potential is very easy to see. With Volt, what's going to happen? This topic of production temporarily being halted should have stirred that type of discussion; instead, we get spinning about history & purpose. That's clearly not a good sign.

- 9-16-2012** **As Winter Approaches.** That rhetoric from others is almost entirely gone now. Focus has clearly shifted over to Prius, specifically how the plug-in operates as the temperature drops. The question which really stirred specifically addressed the heater. I was happy to jump in with: Heat from the engine does not defeat the purpose of having a plug. You still get an extremely efficient system even when the engine runs. Just look at what happens when you accelerate onto a highway when the system is cold. The result is MPG above 50 during warm-up. That's a fantastic worst case scenario. Heat comes from warmed coolant. Once warm, the engine will shut off. It will remain that way until the coolant temperature drops below a threshold (which is 114°F in ECO mode and 145°F in Normal & Power). The engine will then start up and run. It doesn't take long for that threshold to be reached at the engine shut off again. So while driving in EV, the engine will cycle on & off. That's actually the same as what happens with the regular model Prius, only you have much more power available when driving with the engine off. For me, with heavy commute congestion caused by snow, I remember being shut in hopelessly slow traffic watching the engine start up every 8 minutes. That seems like a surprisingly long time to have the heater running without the engine providing any warmth to the coolant... until you witness it firsthand and think about how Prius was designed specifically with heat creation & retention as a priority. Remember, heat is also needed for cleansing emissions. So generating it quickly is very important.
- 9-16-2012** **\$3.99 Per Gallon.** Last week closed with oil at \$99 per barrel. That pushed the price of gas here to \$3.99 per gallon. Normally, we're on the lower side. Now, we're somewhere in the middle. Living on either coast would be more expensive... hence many of those states targeted first for plug-in rollout. Of course, that may be one reason why we adopt rather quickly here. Out wait is longer. Anticipation can be an effective attracter. Anywho, seeing gas hit the \$4 more often is clearly having an effect. There's a push for small traditional vehicles. That puts pressure on the plug-in offerings, making it the priority of cost even more important. This is a critical time, when opportunity should not be disregarded. Unfortunately, that's exactly what's happening. The downplay continues.
- 9-17-2012** **Auto Start-Stop.** 12 years ago, Ford boasted about delivering this ability. It took until now for it to finally happen. Needless to say, hope differed significantly from reality. What will consumers think? If most of your driving is non-stop, benefit of having the engine shut off when not needed won't account for much. There's the problem of still needing to run the cooling-pump and A/C system too. Fusion will be the debut vehicle to offer the feature. It adds \$295 to the purchase price. How will MPG even be interpreted? The savings is likely less than the margin-of-error a computer estimate could provide. It's a strange option to sell on a 2013 vehicle, now that plug-in hybrids are available. It reminds me of FFV sales. Getting people to spend extra (in that case, the ability to use E85 fuel) on something that should really be standard didn't work well. Demand was so low, the promotion just fizzled away. It never became standard either. The idea just basically died. This probably will too. I certainly haven't heard any consumers or even consumer-groups wanting it.

- 9-18-2012** **Temperature Dropping.** The days of morning commutes with the temperature in the mid-70's are gone. That means EV capacity will be somewhat reduced and the engine will run for heat from time to time. Yesterday's temperature on the way to work was 54°F. First impression was that I could already see a change. But then again, I was driving a bit faster than usual. I don't expect to see results above 200 MPG anymore on the fast route. That was quite normal for the 70 mph route. In this case, I pulled into the parked spot seeing 168 MPG for the average on the display. Early this morning I had to run an errand, so I won't have full capacity available for the drive to work in a few minutes. The temperature was 45°F. It certainly isn't Summer anymore. Fall has arrived. Fortunately, EV power isn't diminished. My climb up that steep residential hill didn't require the engine. 40 mph uphill with electricity is no big deal with battery-pack delivering 38 kW (51 hp). That's why cruising at 62 mph without the engine is also routine. Anywho, it's getting colder. Discussions about Winter are growing.
- 9-18-2012** **Roadway Recognition.** It finally happened. Hooray! I was at an intersection. The woman starred over with a look of disbelief, then excitement. She rolled open her window, pointed to the "Plug-In Hybrid" emblem, then yelled: "*I even like the color!*" That was my first roadway recognition. I wasn't expecting it. So, the surprise was extra exciting. Next year, when you can actually purchase a Prius PHV in Minnesota, the story will be different. Having to buy one now and have it shipped over or flying out to drive it back is highly unlikely... hence her disbelief seeing mine. Not being alone is what I'm looking forward to. With so many Prius on the road, mine blends in. Other owners will notice the subtle differences though. In the meantime, I'm preparing for the big freeze. The approaching cold-season brings new opportunity... stuff I'll experience firsthand, but won't be able to share with anyone else in person. Oh well. There will be some from other northern states online posting their experiences. Mine will be about long exposure to very cold conditions. Other will be more about snowy driving. They'll have even less of a chance of getting recognized. Roadway encounters will be quite limited. I'll relish this first one. It's a good memory.
- 9-19-2012** **Overkill.** The chapter having closed is obvious. Even the offense effort on the big Prius forum has fizzled. We've moved on. What started as subtle downplay amplified as the time progressed, turned into some rather intense exchanges. At this point, it's very easy to see that Volt is overkill, the same over-engineering problem we've seen with other consumer products. A good analogy is trying to sell a SLR camera to someone who is simply looking for a point & shot. Arguments about value are valid, but they don't actually fit requirements and are more than the budget can afford. Toyota's priority focus differs significantly from GM, which Volt enthusiasts now see... hence so much of the old propaganda falling on deaf ears. The mainstream audience simply isn't looking what had been given so much attention. Reality has set in.

- 9-19-2012** **New Behavior?** It's difficult to answer questions about Prius operation, now that there's a smaller model that uses a different engine & motors. Assuming behavior isn't new seems reasonable. Why would tolerances like temperature differ? And if they did, it wouldn't be but a large amount. Though, there are modes to choose from. Fortunately, observations so far have matched postulations. So, now that daily temperatures are dropping, new questions have been relatively straight-forward to answer. Asking about the heater is what I can see as a very popular post topic. Winter performance is often what convinces those toying with the idea of a Prius purchase to take the plunge. It's nice knowing aspects like reliability and battery-life are no longer top concerns. In fact, we rarely hear about them anymore. Simple things like heat availability are the focus now. Cool. (pun intended) Anywho, my response to one of those questions today was this short & sweet reply: ECO mode reduces the temperature tolerance of the engine coolant in the regular Prius from 145°F to 114°F, meaning the engine will shut off sooner. I suspect Prius c has the same shut off point. It's one of the benefits of ECO not realized until the cold season arrives.
- 9-19-2012** **0.1 EV Miles.** Several times this week alone, I've ended up pulling into the driveway with just 0.1 miles of EV remaining. It's quite clear that you become familiar with your surroundings after awhile. I take advantage of that HV/EV button, toggling the engine on when electricity alone is not the most efficient choice. That is pretty much always when on the highway. But there are a few times when driving home I see that a long suburb stretch would be better driven in hybrid mode. It takes surprisingly little thought about when to do that too. It's to the point of almost being automatic. I figured that would happen eventually. This soon was a nice treat. With the screen right there in front of you, that really doesn't take much effort to contemplate need. It's like how you estimate arrival time getting home so you don't miss the start of a television show. No matter where you are, the guestimate is remarkably accurate despite all the factors of influence to consider.
- 9-20-2012** **Middle-Market.** I ultimately asked this in response to the endless spin about target & goals: "*What is Volt attempting to achieve now?*" It's an attempt to look ahead, moving beyond those still spinning the past and shooting the messenger. My question followed yet another attempt to redefine middle-market, which I replied to with this: No matter how many times I answer the question, it keeps getting asked. The reason why is simple. The answer wasn't liked and raising doubt is an effective way to prevent conclusions from being drawn. That report about plug-in electric vehicles just published highlights the painfully slow progress anticipated for them. Fortunately, Toyota took the priority of affordability very serious, designing a plug-in system that would significantly improve efficiency without requiring a large battery-pack. That targets it squarely at mainstream consumers, those who have considered the regular Prius but would like more from the system. The simplicity of a full recharge from an ordinary household outlet in just 2.5 hours and getting a big MPG boost regardless of driving is compelling. The fact that the system can be augmented even further simply by increasing battery-capacity makes it a competitive platform. Unfortunately, that's not what GM delivered. They're trapped with an inflexible design and the consequences are becoming apparent.

- 9-21-2012** **Done.** The sure sign that discussions are done is when there's nothing constructive posted anymore, when it degenerates to nothing by stirring old history and shooting the messenger. That's what happened with Volt. The enthusiasts cherry-pick data, then accuse you of being hypocritical & vague. It's the same pattern of spin we've seen for years, nothing new. The response to expectations not being met is textbook, quite familiar & predictable. It does get messy though, since some of the information they present is misleading due to it not having happened when they imply it did. That's what makes fact checking so difficult. Few people have detailed blogs as I do, allowing them to search for a very specific mention of something. It allows me to ensure the attacks, simply allowing them to fizzle out due to lack of substance. That made this particular quote an especially appropriate one nice to conclude with: *"You have become just as bad as the anti-hybrid anti-prius folks in the early 2000's. Blowing hard with nothing behind your statements."* And I did: For that to be the case, I'd have to be against plug-in vehicles entirely, just as those opposing hybrids were against any use of battery & motor. The proper comparison is being just like those who opposed Two-Mode, seeing it as an expensive approach without the ability to reach a wide audience quickly. And sure enough, that's exactly what became of it. I see the market for plug-in hybrids being embraced soon, not having to wait for a next generation design or being dependent on tax-credits. I also own one already, with lots of real-world data to back my statements.
- 9-21-2012** **Battery Questions.** Some do come up still, from time to time. Fortunately, most are easily answered... like this one: *"I have a few cordless tools that the batteries need to be replaced every few years. I guess it is a different technology."* That's quite difference from many years ago, when there were fierce undermining assaults launched by very determined antagonists. Nowadays, there are innocents queries from those hoping to become Prius owners. Thank goodness. The information I posted from seeing that particular comment was: The hybrid doesn't allow deep discharges, which is what shortens the life of rechargeable batteries. There isn't any protective mechanism to prevent that on your cordless tools. They cannot just fire up an engine to continue operating; instead, the battery gets stressed. After all, think about how often people ignore low indicators... using their phone until the very last moment of electricity is squeezed out. That just plain won't happen with a regular or plug-in hybrid, since the system automatically controls that for you.
- 9-21-2012** **On Paper.** When all else fails, that's how a vehicle is promoted. Calculations derive from assumptions & generalizations. The numbers shown are idealizations, not what you should actually expect. Real-World driving isn't like that. There are no patterns when it comes to the everyday needs of ordinary consumers. They don't adhere to any type of routine. Quite of a bit of variety occurs. Just between food & entertainment, it doesn't take much to imagine the lack of anything predictable. Add a child to the equation. What happens? You end up running all over the place. From day to day, results will vary dramatically. It's simply not realistic to read a review and hope the results are what you'll get. That's why the rhetoric is able to persist for so long. Those hoping to undermine just feed you fragments of information that's out of context and not in sequence. They confuse & mislead. It's the same old greenwashing we've seen over and over again. The only difference now is that effort is focused on plug-in vehicles rather than regular hybrids. It's really unfortunate, but quite predictable. Avoid on-paper calculations from others. Watch for detail from owners.

- 9-21-2012** **Explosive Reactions.** The topic of Volt sales sure is creating a lot of buzz online. Last week focused on cost. This week, the focus has shifted to leases. How does an automaker make money when it offers a lease at a price clearly undervalued? Last month, the deal was \$250 down and \$199 per month for 2 years. That doesn't make sense for a vehicle so expensive, especially considering it had been \$299 per month for 3 years. Again, to stimulate the market is one thing, but initial rollout is long since complete. In fact, the mid-cycle upgrade is now available. So, finding out that roughly two-thirds of the "sales" last month weren't actually sales is quite unexpected. Having a bunch of lease returns to sell on the eve of a next-generation debut sounds like a formula for large losses. How can that be a good thing? The resulting higher numbers we see now give the impression all is well though. Reading through the comments posted, you hope for the best. Sadly, there wasn't much. I did find a rebuttal article though. It took the downplay perspective, calling this Volt one for early adopters and telling us to be patient for the next generation. That brings us back to the source of the explosive reactions, hype. Having called Volt a "*game changer*" for so long and claiming it would "*leap frog*" the competition set expectations too high. Now, enthusiasts are in damage-control mode dealing with all the fallout resulting from the hope they themselves had contributed to.
- 9-22-2012** **Newbie Observations.** It's always fun confirming the observations of a new owner. Their posts are filled with excitement detailing their own personal discovery. My contribution to that today was: Yup, you nailed it. Slowing down can be rewarding. I discovered that years ago, even before getting a Prius. Back then, it was less about efficiency and more about simply keeping a steady pace. A fast speed-limit gives the impression of better, but that often doesn't work out that way. Turns out, going slower is much more appealing than the ever-changing variety you encounter from big highway congestion during commutes. Having a display in Prius clues you into the MPG benefit from exploring alternative routes, even when there's a few stoplights thrown into the mix. It's worthwhile to try other roads. Efficiency gain can sometimes be counter-intuitive. And yes, with a plug you notice the same type of efficiency bump. Of course, the advantage of an electric motor becomes more pronounced at higher speeds with that extra electricity available. But the gain from drives through the suburbs is obvious regardless of Prius model. Have fun continuing to discover the advantages the hybrid system has to offer.

9-23-2012 **10,000 Miles.** It only took 6.5 months to drive that distance. Almost all of it was "warm" weather. True, it spent a number of days near the freezing mark and even got snowed on overnight. But that was brief. Only now is the temperature dropping again. Two days ago, it 52°F on my morning commute. Yesterday, it had dropped to 46°F. This morning, there was frost on the windows. I didn't recharge either, giving myself a firsthand experience with cold engine warm-up again. It was basically like with my 2010 Prius, but could have been ever so slightly faster. It's hard to tell with just casual observation. Anywho, the next 6 months and 10,000 miles won't be the same as the first. My average was 85.0 MPG, measured at the pump. That's 117.637 gallons of E10. The calculated total (using 3.1 kWh per full recharge) for electricity was 973.1 kWh. I'm looking forward to the discovery process a new Prius always brings. I suspect recharging the pack just prior to departing will offer the advantage of warmth from the exchange of electricity. I have a feeling the EV will be more handy than anyone has anticipated, since most tend to forget how awful stop & slow traffic is from snow. Who wants to remember that? Having 3 years of real-world data collected from the 2010, it positions me well for PHV comparisons... especially living here in Minnesota.

9-23-2012 **10,000-Mile Report.** Here's the real-world data I've collected so far with my 2012 Prius PHV:

10,002 = Total Miles

197 = Days (6.5 months)

85.0 = Lifetime MPG

117.6 = Total Gallons (measured at the pump)

941.7 = Total kWh (including charging losses)

3,824 = EV Miles (displayed amount)

6,171 = HV Miles (displayed amount)

851 = Total kWh (displayed amount)

313.9 = Recharges (based on capacity replenished)

assumption: one full recharge, including charging losses = 3.0 kWh

- 9-24-2012 Diesel Returns.** I couldn't believe what was be posted today. It was a repeat of the same old stuff, literally nothing new. It was as if I was reading an old thread from the past. Only, I wasn't. This was about the upcoming diesel version of Cruze, which requires AdBlue to cleanse emissions. Remember than nonsense? You needed about 7 gallons of the stuff for every 15,000 miles of driving. It is sprayed on the exhaust to chemically treat it to be cleaner. Problem is, the result is barely clean enough to pass the minimum. Prius is on the opposite end of the emissions spectrum, without even needing an additive. I posted the following in response and still in disbelief: Reading the very same responses to the very same topic now as several years ago suggests the outcome will be the same too. How will this diesel & urea attempt be different? We now have a greater choice of hybrids, some offering significantly higher efficiency. The smooth & quiet from battery & motor is quite a contrast to the mild clatter of a turbo diesel. Many hybrids offer significantly cleaner emission ratings as well. And reliability has already been proven. Heck, even resale value remains high. So if anything, it will be an even greater challenge to attract diesel buyers. The added cost and higher fuel price doesn't seem to make it competitive either. What's the point, especially with eAssist being spread to other vehicles?
- 9-25-2012 Lease Comparison.** I stumbled across a deal for the advanced model plug-in Prius. It was for the New York City area. \$2,399 due at signing and \$269 per month for 3 years, plus an acquisition fee of \$650. There's also a \$350 disposition fee when the lease ends. That's far more realistic than what GM is currently offering for Volt, just \$250 down and \$199 per month for 2 years. Those offers represent quite a difference. Comparing them doesn't even require a calculator. One is realistic, something you'd expect to see anyway. The other is unusually low. Makes you wonder how long the offer from GM will last. I'd expect some type of change after month end. But then again, maybe not. There's so much emphasis on monthly sales, the hope is the low lease gamble will pay off later. You never really know how things are going to play out.
- 9-25-2012 Sales Reality.** This is what I was greeted with this morning: *"So let's stack the Volt against cars in its own category – plug-in electric – the Volt is the runaway winner. In August, at 2,800 sold the Volt was on its way to tripling the Toyota Prius PHV's 1,047 sales"*. Such blatant greenwashing is vindicating. It was frustrating in the past, but now I see it as competition desperation. Why would you mislead like that? Anywho, I responded with: Since Volt is available in triple the number of states, that statement is clearly not constructive. How about this? *"TMC expects global sales of its hybrid vehicles to well surpass 1 million units in 2012. With its plan to launch 21 new hybrid models between now and the end of 2015, TMC expects to maintain this level of sales, forecasting global sales of its hybrid vehicles to be at least 1 million units a year from 2013 to 2015."* What are the plans for Volt? The mixed messages we are getting from GM leaves us wondering what to expect. There's no competitive hybrid, just eAssist and diesel. Two-Mode appears to be discontinued. And the volume for Volt is far short of mainstream minimum. What will middle-market be purchasing in high-volume?

- 9-26-2012** **Chrysler Testing.** The small fleet of plug-in hybrids Chrysler had been testing (109 trucks and 23 minivans) have been showing signs of trouble. Some battery-packs have been overheating. That's a real problem when a vehicle depends exclusively upon electricity without an engine for propulsion. Unfortunately, detail about the design itself has been all but silent. Supposedly, these hybrids utilize the Two-Mode system, but simply have a larger battery-pack. Due to the clutches, it can easily disconnect from the engine for electric-only travel. That sounds nice, but puts more burden on the electric draw than an air-cooled battery could reasonably allow. This is why Toyota, Ford, Honda, and Hyundai have all decided the maximum speed for electric-only will be 100 km/h (62.1 mph) and set a maximum draw rate. Beyond that could result in too much heat... hence having engine join in when a tolerance is exceeded. This is why Toyota tested their plug-in Prius for 2 years using ordinary consumers. They needed real-world data to confirm the design was a sensible balance. Chrysler was smart enough to try the same thing. Fortunately, that revealed a problem which could be dealt with prior to rollout. This gives them the opportunity to alter the way the system behaves as well as try other battery types & configurations, then try again.
- 9-27-2012** **What's Left?** It's somewhat bizarre seeing Volt enthusiasts provoke and get virtually nothing in return. People simply aren't interested anymore. They've moved on. With 2 years of fading attention, there really isn't anything remaining. You really do have to ask what's left? The newest attempt to justify the slow pace is more downplay. Rather than actually acknowledge the original plan of 5,000 per month or even the revised expectation of 3,750 per month, the entire industry production is now being taken into consideration. Mainstream minimum is a dream long gone. They are counting all luxury, sports, and exotic vehicles. Including the rare is a bit desperate. But when you do that, it places Volt somewhere in the middle. How does that make any sense at all for a technology that intended to become the next standard in automotive design? The downplay has become such a routine, they abandon their own push for progress. When you begin undermining your own goals, something is clearly not working out. All they have to do for confirmation of that is read their own posts from 2 years ago.
- 9-29-2012** **BRAKE!** Quite unexpectedly, I discovered another Prius safety feature. The previous was having the system sound an alert and flash a warning (an image of a vehicle) on the screen when you do nothing to acknowledge the presence of a vehicle you are approaching. It knows when see it when you either lift your foot from the accelerator or press the brake. I hadn't considered what it would do when the radar (part of the dynamic cruise-control which is always active) detects a vehicle but you already have your foot off the accelerator. The system recognizes that as danger too. But rather than providing a generic do something alert, it's flashes "**BRAKE!**" on the screen. Seeing that was sweet! I was quite impressed; however, it left me scratching my head wondering how I'd ever be able to actually catch that event on photo or video. That's too much of a risk to trigger intentionally. Darn. Oh well. At least I know the safety feature exists. That most definitely isn't common. Too bad. Maybe some day.

- 9-29-2012 Road Trip.** We jumped in the Prius, stuffed with cargo and 2 bikes on back. 168 miles later, all of which were in HV mode, the result was 48 MPG. No complaints about that. In fact, that's rather remarkable. Compromising the aerodynamics of the car with so little sacrifice to the resulting efficiency is fantastic. That was a great endorsement to the technology. Unfortunately, that will reduce my lifetime average, since returning home likely won't be on a warm windless day like it was today. That point of simply having fun and getting to escape on a road trip won't be lost. I still have a big chunk of the EV range remaining too. Don't forget that regular hybrid driving depletes it, just not at the rate electric-only driving does. It's a Prius after all, seeking out efficiency opportunities for the best utilization of battery power. The consumption of EV capacity was 2.5 miles, dropping from the original 12.9 estimate to 10.4 miles. Stay tuned for the report of the drive back home.
- 10-01-2012 No Driving.** Today was one of those rare ones, when I didn't drive anywhere. That sure makes data collecting easy. Fall colors beckoned. It was beautiful weather. We went for a hike around a local lake, took lots of photos, and didn't use any gas or electricity. The Prius sat there parked in its spot, unmoved, unused. We had fun without it. There's always tomorrow!
- 10-02-2012 1,652 Sold.** What can be said about seeing that number? It's a clear gain from Prius PHV sales the month before. September showed an obvious improvement. I'd say that's good news, especially since the plug-in model is still only available in the initial 15 rollout states. Growth should continue... regardless of how those supporting other hybrids spin the situation. Next year will be different anyway. National availability will be a welcome change. And as with the precedent Volt established, we await the second-year results prior to making judgment. I doubt supporters will actually abide by their own request, since the hypocritical nature of the situation is difficult to deny. They'll likely try anyway. Thankfully, other choices from other automakers will become available. That diversity will help settle down the polarization we are currently still having to deal with.
- 10-02-2012 969 Sold.** That's an impressive number for the debut sales-month of C-Max hybrid. It's well short of Ford's direct competition though, the v model of Prius. There were 3,088 of them purchased here in September. But that's ok. Toyota has more of an ally than a competitor anyway. Many of us with Prius already see it as a friendly rivalry, helping to accelerate the acceptance of hybrids as the standard market choice. In short, it's a very good start. Hopefully, the situation won't get spun into some pointless flag-waving exchange. That's often the case when it comes to GM. Thankfully, that usually doesn't happen with Ford. So, the outlook is a positive one. This represents genuine progress. It's what the mainstream needs.

- 10-03-2012 Efficiency Chatting.** Talk of engine improvement coming from Toyota has stirred again. Direct-Injection will be introduced next year, first deployed in a hybrid. Specifically, the Crown hybrid will get it. In Japan, that's the equivalent of our Camry hybrid here. What a great way to start. New engines for the traditional vehicles will shortly follow, using direct-injection as well. This obviously translates to what we've been hoping for all along, the next generation Prius offering even greater efficiency. The hints given so far seem to indicate an overall increase of 10 percent. Talk of even higher MPG from other advances will add to that. Other automakers have already demonstrated the gains to be achieved. Toyota's focus on other priorities left them playing a bit of catch up. Though, the timing now nicely coincides with the usual upgrade cycle anyway. That certainly gives us something to look forward to.
- 10-03-2012 61 MPG.** We took a side-trip today, driving even further north. There were no bikes this time. Specifically, we went all the way to the very start of the Mississippi River, the headwaters where it is nothing but a tiny stream emerging from Lake Itasca. That was a unique experience. There just happened to be a forest fire in the distance then, which filled the state park with smoke. That resulted in photos quite unlike what countless others have taken at that same popular location... a strange twist of good fortune. It was a bit on the cold side. There was very little wind on the way up, hence the smoke settling. Later on, it turned into a substantial crosswind... which ended up clearing up the sky, providing a great view of Fall colors. We drove to and climbed up the (now rather ironic) fire tower. That consumed 7 miles of EV, which was a true delight. I thoroughly enjoyed the scenic vista using nothing but electricity. The drive back home was pleasant, despite the wind. With a maximum travel speed of 60 mph and use of some plug-supplied electricity, the resulting average from that 198-mile journey was 61 MPG. I'd say that was great efficiency.
- 10-04-2012 Fall.** It has arrived. There was much to learn about the plug-in during Summer. I would have liked to document it more with video. But I it took all the resources I had available just to get a good jump on discovering what PHV has to offer. Sadly, the warm-season is all too short here in Minnesota. Fall is nice, but accepting the transition can be a challenge. There's a bit of denial that certain outdoor activities just plain aren't realistic now. Anywho, the dropping temperatures will bring about additional discovery. The most obvious is the pressing question of blocking the front grille. Fortunately, the answer is simple. Yes, I will. The routine won't change because this Prius has a plug. The lower part of the grille will be blocked entirely. The upper part will be exposed entirely. That worked well in the 2010 model for the past 3 Winters. The engine still gets the air it needs to operate, but the cooling of the coolant is greatly reduced in favor of retaining that precious heat. I wait until the daily high no longer exceeds 55°F degrees. That's when first notice warm-up taking longer. It's also when you fire up the heater... since morning temperatures routinely are below freezing. Enjoying Fall colors has been the hope, but the leaves are falling remarkably fast this year. There aren't any vibrant reds or oranges either. It's not as exciting as other years. That's why focus is more on what having a plug is like instead.

- 10-04-2012** **Leader?** Taking some time to enjoy Fall colors, checking the stir from monthly sales have been a low priority. But now that the weather is blustery (cold, rainy, windy, and overcast), peaking into the online world is actually a nice change of pace. Kick back and be amused, eh? Yup. Volt supporters are up to the same old spin... avoiding mainstream comparisons and failing to mention the plug-in Prius is still only available in 15 states. Whatever. The rest of us see what's really happening. I especially looked forward to reading the comments from Detroit. With sales of Volt steady, the headline saying "*Volt expands its lead among rechargeable cars.*" had me wondering. Sales of Volt only increased by 20, from 2,831 to 2,851. Sales for PHV increased from 1,047 to 1,652. That's 605 more for Prius, reducing the gap not expanding it. Turns out, there was almost nothing said online. People have grown tired of the nonsense. Even this on the big GM forum didn't get much of a reaction: "*Volt is doing well in it's market but that doesn't make it a good car for GM.*" The progress is far slower than what's needed. It's obvious attention has moved elsewhere. I kept it simple: The competition for Volt has been and will continue to be GM's own product-line. Traditional vehicles hold a massive share of the production and clearly remain the business-sustaining revenue source.
- 10-04-2012** **Understanding Plug-In Hybrids.** The difference between Prius PHV and Volt became confusing when GM revealed thrust from the engine is used directly sometimes. The purity of electric-only was suppose to set Volt apart, but it ended up not delivering upon its own distinctiveness goal... making an understanding of approach & intent anything but clear. Soon, Ford will enter the mix. Their plug-in hybrid blurs the technology promotion further. That makes sense though. Each automaker must not impinge upon other patents and each has its own expertise. Honda makes that point a big one. The descriptions of their "*Hybrid*", "*Engine*", and "*EV*" drives are destined to be confused with the operational modes their plug-in hybrid will offer. Fortunately, that's actually a good thing. Rather than the looks-good-on-paper problem we've had to deal with so far, people will turn to actual real-world data instead. Yeah! The fact that Honda's plug-in hybrid doesn't rely on liquid cooling either will just be an important fact for those understanding production costs. Consumers won't care. Consumers will care about having a HOLD button though, which Honda offers. Of course, GM now offers that too. So, there is hope. I'm thrilled that those we had viciously fought against it now claim there was never any doubt of its benefit. PHV supporters remember though, since Toyota offered it from day one. Long story short, the industry making progress toward identifying standards & expectations for the masses. The rhetoric & propaganda is being replaced by feature & data. That sure is a nice change.
- 10-04-2012** **Jetta Hybrid.** It looks like it finally will actually happen. With so much being invested in diesel, it made everyone wonder how VW would ultimately compete. The hybrid will be available the end of this year. \$24,995, plus a \$795 destination charge, is the price for the base model. There will be a 27-horsepower electric motor combined with a 1.4 liter turbocharged gas engine. They will be connected to a 7-speed dual-clutch transmission. Maximum electric-only speed is expected to be 44 mph. The estimated efficiency is expected to be 45 MPG combined. Both the automatic & manual diesels only offer an estimate of 34 MPG combined... making the hybrid an obvious efficiency leader for their product-line. No one has any idea how VW customers will respond. The hybrid is quite a shift from their approach in the past. But with the price of both gas & diesel continuing to rise, something needed to happen.

- 10-04-2012 Wagon Sightings.** Spending a few days up north sure revealed a surprise. The wagon model of Prius (known as "v") certainly is popular. Away from the cities, that tends to make sense. I can easily see the need for more cargo room out in the country. There were plenty of regular models. But the lack of the smallest (known as "c") seemed to confirm that impression. Routinely sightings of that many of a new offering being chosen is great. Taping into another consumer demograph is exactly what was hoped for. Antagonists claimed the other models of Prius would take away sales from the regular liftback. Clearly, that didn't happen. Instead, sales have actually increased a little. Combine that with sales of the new, you've got confirmation of growing demand. 2012 is working out to be a really good year. That's quite a contrast to the multiple disasters in both 2011 and 2010. The competition should be pleased that the market itself is expanding. But in the short-run, I bet they're not feeling that way.
- 10-05-2012 Emergency Stop!** I had to hit the brakes really hard. It wasn't a case of slamming them and hoping for the best with the anti-locks. This was a stop as fast as possible while monitoring the obstacle in front and the vehicle following behind. A very large turkey had wandered onto the road, which I was traveling on at 60 mph. It took up about half the lane. That's a big bird. Hitting it with the Prius was obviously undesirable. Swerving into the opposing lane wasn't an option. I had no choice but hope a controlled stop would do the trick. It did. Phew! There was a strange sound though. Both me and my passenger got pulled tightly back into our seats. The sound coincided with that. It was the shoulder strap. I had no idea that in the event of an emergency, it would tighten up rather than just lock as with vehicles of the past. That's a new safety feature I was unaware of. Sweet! Discovering that made me really happy. The turkey was pretty happy too.
- 10-05-2012 Snow.** It snowed this evening. The heater was running on a low fan-setting & temperature the entire drive. Just like with the regular Prius, the plug-in kept the engine off until the coolant dropped below 114°F. Unfortunately, our journey was over 50 miles and the drive through town was really short. The rest was country highway cruising. So, I don't really have much else to report yet. Though, during the brief warm-up period, I did get an opportunity to try out the heated seats. The effect with the new synthetic leather felt nice. Anywho, it won't be long before I block the lower grille. Fall was way too short this year.

- 10-06-2012** **New Attack.** Hype about Volt is long gone. The silence about last month's sales is deafening. The big GM forum had virtually nothing to say. Several days later, on a new thread specifically about Volt sales and speculation about a Voltec product-line, a new attack emerged: *"Comparing the 2011 4cyl Buick Lacrosse to the 2012 version with eAssist yields an MPG improvement of 31.6% city and 20% highway based on EPA ratings. Not too shabby IHMO yet for whatever reason, the inexpensive and effective eAssist technology continues to get ridiculed and flogged by certain "hybrid snobs"... "* Among those listed as snobs, there was the big Prius forum, which was also called "anti-GM". There are obvious attempts to build up a new following, since the old has completely fallen apart. There are many names from the past gone now, enthusiasts disenchanted from the rollout not meeting expectations. So this outcome really isn't a surprise. It was inevitable something else would emerge to take the place of Volt's struggle. Anywho, I had to respond to such a blatant attempt: Whatever reason? 29 MPG combined is terrible! Taking about lowering our standards. Ford's hybrid Fusion delivers 47 MPG combined. Toyota's hybrid Camry delivers 41 MPG combined. In GM's own words, it is a "stop gap" technology. How can it compete? Unlike the Ford & Toyota designs, adding a higher capacity battery-pack and a plug isn't realistic either. What's the point? There's a massive product gap between eAssist & Voltec too. What more reason do you need?
- 10-06-2012** **Dang Good.** That was my assessment of the 168 miles of driving I did today. It started with an ice-scraper. With the outside temperature at just 34°F, snow from the night before wasn't melting quickly. There wasn't much, but it certainly was a taste of what's to come. You sometimes forget about the bliss the warmth of Summer brings. But then again, the cold-season can be fun too. It's quite different though. And with a plug-in hybrid now, it's bound to be exciting. Anywho, I was up in northern Minnesota without anywhere to plug in. So, I only had 1.2 miles of electricity available. With so little remaining, the entire trip would basically be just with the engine supplying the energy. I had a cargo area stuffed full, a passenger in front, and 2 bikes to carry on the back. It was a great scenario to see how the Li-Ion battery-pack would perform compared to the NiMH. Having done that same trip the same way in the past, I was expecting low 40's for the outcome. Instead, the result was 47 MPG. That's pretty dang good. Heck, some hybrids at their best cannot deliver that. This situation was far from ideal, yet the efficiency was still worthy of celebration. Yeah!
- 10-06-2012** **\$4.69 Per Gallon.** Why gas is currently that price in San Francisco is a bit of a mystery. Other cities in California have also seen a sharp rise in price. It is a bit odd. Reason isn't getting much attention though, timing is. There's a major political election rapidly approaching and hybrids are poised to benefit significantly from gas trouble. When consumer wallets & purses are squeezed, change happens. Embracing hybrids isn't a big deal anymore either... the affordable models, that is. But with the price so high, even the expensive ones may see a decent bump in sales. It's hard to predict how people will react. After all, the monster-size guzzlers used for commuting have pretty much vanished entirely. Now, we're seeing a steady growth in small cars and a drop in how much consumers are willing to spend. It's a thought-provoking new trend. What will happen? Some automakers will be well positioned. Some automakers will struggle to adapt.

- 10-07-2012** **Attack Escalation.** Sure enough, the effort to divert rapidly degenerated into a full blown attack. That was very easy to see coming. With so much being driven by emotion, you cannot expect a constructive response. Rather than just answer the "*What about the product gap?*" question asked, the focus shifted to Prius reliability, specifically the transaxle. That's quite desperate considering how well proven it is. Ford uses a similar approach too. But it's what happens when no other rebuttal is available. I found the remark quite telling, especially since product offering was the topic. There was a discussion about what GM's high-efficiency plans could be. Why not address the issue? That seems quite appropriate. Needless to say, I didn't fall for it. My response was to point out the situation and ask again: Red Herring responses to distract from the question being asked say a lot about the situation. There is nothing available or even planned between a 40 MPG traditional vehicle and a +100 MPG plug-in. We see the other automakers revealing their designs to address the need with both advanced hybrids and plug augmentation. From GM, there's eAssist and Voltec, nothing in between. The lack of choice is missed opportunity. Asking again, what will GM do about that product gap?
- 10-07-2012** **Backup Cameras.** It looks like NHTSA (National Highway Traffic Safety Administration) will be enforcing an improvement to passenger vehicles starting with 2014 model years. Comments about that have been mixed. I think it is a move long overdue. This is the comment I posted: Prius has had a dashboard screen since 2000. It seemed a no-brainer for other vehicles to also offer a visual interface, yet they didn't. There's a large variety of feature which could be offered. Why the heck has it taken so long? The fact that it took an act of Congress to finally issue a federal, mandate based on a safety benefit goes to show how painfully slow the automotive industry is to accept change... even something so obvious. Parking lots are filled with hazards a back-up camera could easily reveal. Why didn't this happen much sooner? Think about our younger generations. How many of them already carry a portable device with a screen, many with a camera too. It's absurd that vehicles don't have that standard. Heck, screens are ubiquitous with mp3-players and cell-phones. Look at how many aftermarket navigation systems were sold because there wasn't a screen available in the dashboard already to offer that option. But like other safety features of the past, it isn't much of a surprise that the automotive industry was finally pushed to deliver this. They resist right up to the bitter end rather than embracing improvement technology as it emerges.
- 10-07-2012** **Future Mandates.** I tossed this thought into the mix, quite curious what discussion it will invite: Pre-Collision will likely become a safety mandate someday too. Having a vehicle with short-range radar (a component of dynamic cruise-control) respond with an sound & visual alert when it detects danger in front of the vehicle is an obvious improvement. Mine has been triggered twice already over the past 6 months. In both cases, I saw the danger at that same moment. But the heads up was really nice to have. Another benefit is that it gives passengers, who are obviously less attentive, a notice... since the driver will be too preoccupied to do so. Envisioning delay in widespread offering of that feature is easy. Change for the better is usually met with lots of resistance. Fortunately, resistance is futile.

- 10-07-2012** **Repeating History.** We've heard this countless times before: "*When you are above 40mpg, you are using little enough gas that another 10mpg, or even 20mpg increase becomes insignificant.*" This part is new though, now that plug-ins are available: "*Above 40~50mpg, the next step is to just go gas free, ala the Volt.*" That's what the attack mutated into. It's hard to believe such an argument would even be attempted. But with so much pressure now, the willingness to try isn't a surprise. My feedback was: I went from 50 MPG to 85 MPG. That means my annual 20,000 miles of travel will use roughly 165 gallons less gas. At \$3.89 per gallons, that's \$642 each year. From 40 MPG, that would be around 265 gallons, about \$1,031. Who will be convinced that's insignificant? Consumers will see the difference, taking the cost of electricity and time to plug into account. They'll wonder why GM doesn't offer a "Volt lite" model, an affordable choice, then purchase one from another automaker. The next step is clearly not the current configuration of Volt.
- 10-08-2012** **Great Commute.** The morning drive to work today sure was exciting. I hadn't taken the route along the river for quite awhile... mostly due to road construction. That's over now. Yeah! I now had the opportunity to indulge, enjoying a maximum speed of 55 instead of 70 mph. The slower roads usually mean a more relaxing flow, rather than speed variance being all over the place. To my surprise, all but the final few lights were green too. It sure was nice. Too bad I wasn't filming that particular experience. Oh well. I did get photos. A stoplight caught me with just 0.8 miles of EV remaining. At that point, I had already traveled 15.5 miles using only electricity. The quality my new camera can deliver for screen captures is stunning too. A faster processor, extremely high resolution, and a very large sensor really make a difference. The engine didn't start until traveling 16.1 miles. When I finally parked, the total distance was 16.6 miles. The average displayed was 999 MPG. Is that a great commute or what?
- 10-08-2012** **Need verses Want, part 1.** The final page in the last chapter of a very long saga was presented today. The founder of that daily blog for Volt is selling his Volt. He'll be getting a C-Max Energi as a replacement. This upcoming plug-in hybrid from Ford shares many design aspects in common with Prius PHV. We saw many signs leading up to this, so there's no reason to dwell or even emphasize his particulars. It's frustrating to know antagonists will make the decision personal anyway. We all knew something would happen when his lease expired. But the assumption was that he'd simply upgrade to a newer model then, not get a different plug-in. Needless to say, I had thoughts to share on the big GM forum: I'm intrigued to see how the reaction to this plays out. Those once very passionate enthusiasts frustrated with the struggle of Volt are having their comments drown out by others now. They no longer have the voice they once enjoyed. Those others see what Toyota has delivered and what Ford is about to, wondering why Volt is supposedly "*vastly superior*" when evidence to the contrary is becoming easy to find. Each time new information about Volt came out that revealed another goal had not been achieved, they made up excuses. Who did they think would be convinced it was still a design with high-volume potential? Sales have confirmed their worse fears too. Acceptance is far slower than they even imagined. The demand isn't there to break out beyond a niche. Ordinary buyers simply aren't interested. And how does attacking Prius help? Geez! That's when you know things aren't going as planned.

- 10-08-2012** **Need verses Want, part 2.** This was my follow up, after reading some not-so-kind posts about the decision to sell: It's the classic want verses need situation. We've seen it before. We'll see it again. We'd all like more power & capacity. But in the real-world, there are other priorities. Volt enthusiasts were lured by the purity of EV and the belief it could be affordable. That didn't happen though. It turned out to be an ideal not realistic for the masses yet. The vehicle rolled out has disenchanted many. The technology will take time to adapt, straying from what had been hoped for to a more practical design. Mainstream consumers don't make purchases based on desire anymore. They did, but that world has faded away as lessons from the past are learned. The market is different now. This is the other shoe dropping. Gas is quickly getting very expensive and other automakers are beginning to offer their designs. Remember, traditional vehicles continue to be the true competitor. For a hybrid or plug-in hybrid to become a replacement for the masses, it must fulfill the requirements those traditional vehicles do as well as offer much improved emissions & efficiency.
- 10-09-2012** **Need verses Want, part 3.** When posts now contradict posts of the past, it's obvious something isn't going as planned. Consider what changed. Finding that Volt enthusiasts (those few remaining stubborn die-hards quoted many times here, not excited new owners) have become hypocritical leaves you in a difficult position. The ideal is to simply keep the discussion going in that direction. It sure is tempting though to point out how what you supported years ago is the same as what they are now saying. In fact, I even got a quote today to that effect: "*Why doesn't anyone at GM listen?*" It confirms the same thoughts are being shared. Of course, I wondered that 5 years ago when details of the Volt development didn't correspond with actual need. The executives & management were setting goals based on what they wanted to deliver, not what mainstream consumers had as purchase priorities. They weren't listening when we pointed the decision factors considered by middle-market. It was as if nothing at all had been learned from Two-Mode. Unfortunately, the enthusiasts liked what they were hearing and willingly accepted promises at face value, without merit or even bothering to ask for detail. It was terrible to watch. As it unfolded, more and more became disenchanted until there were only niche buyers remaining. They called themselves "*early adopters*" but didn't recognize how they differed from those who bought Prius in the early years. When rollout finally did happen, things were a mess and rapidly got worse. Within a month, the situation got really bad... so much so, that founder became curiously quiet. Then he sold the website and basically disappeared. This was a person held in high respect by many, including me. Then we got the news yesterday. That marked the end. Even those Volt enthusiasts are now seeing what's really needed, how different that is from what they wanted.

- 10-09-2012** **Steady Rain.** It was a uncommon event. Rain like that has been infrequent, especially on my daily morning commute. Conditions have been near the drought level, in fact. So today when rain fell steady onto the highway, we all slowed down and got trapped in our own congestion. It was a taste of what's to come this Winter, since even just a trace of snow will cause slow commutes. Needless to say, I was excited. That was an opportunity to observe a situation hypothesized countless times. How would the PHV handle it? There's much more battery-capacity available than the regular model Prius. Running out of electricity is quite typical when trapped in heavy traffic... especially when you have to run the defroster to keep condensation from building up on the windshield inside. Now, I had an ample supply available. The benefits of a plug were about to reveal themselves. Guess what? They did. I happily drove along in that stop & slow traffic without any worry of the engine starting from the demands of the morning mess. Heck, I could even be quite generous with the accelerator-pedal. There was still 4.2 miles of EV estimated. That was plenty to get be well beyond the chaos of those vehicles. In fact, that would likely be enough to get me all the way to my parking spot. Guess what? It did. The 16.7 mile journey ended with 0.3 EV miles remaining and an average of 166 MPG. With results like that in those conditions, you don't mind the traffic.
- 10-10-2012** **Misrepresentation.** Now that the situation & audiences changed, it was time to start a new thread on the big Prius forum. It could serve as a venue to share observations. The hope is to provide an opportunity to step back, no longer tying events of the past to anything or anyone specific... a stab at starting fresh. Titled "*Plug-In Prius misrepresentation*", I quite curious how members will respond. If nothing else, it is a constructive endeavor to raise awareness. This is what I posted to get things going: I started participating on other forums & blogs upon discovering incorrect information about the upcoming Prius PHV (plug-in model) was being posted. That activity still continues... even though owners are now providing real-world driving data to contradict their claims. Worse yet, attempts to clarify are perceived by some as an effort to undermine the competition. They use vague references to make your posts appear to portray PHV as superior... even though the detail provided was simply clarification to show misrepresentation. This thread was started to compile a list of common problems those particular enthusiasts of the competition refuse to be constructive about. Feel free to post your encounters.
- 10-10-2012** **Grille Blocking.** I started another new thread on the big Prius forum. That's something I normally don't do, since it's usually better to let the new owners take charge. Then owners with lots of experience & knowledge help by providing information for them. In this case, it wasn't realistic. There are too few plug-in Prius owners in the north to make that effective... and essentially, we're all basically new still. I'm aware of what to look for though. So, I got us going with this: The practice of grille-blocking for Prius dates back a number of years now. It is done to reduce warm-up time and to extend heat-retention time. Both result in the improvement of efficiency & emissions during the winter months. Lots of real-world data exists for the second & third generation liftback models of Prius, but there isn't anything yet for the first plug-in. This new thread was created to collect that information.

- 10-10-2012 Coolant Temperature.** This is the first of my observations, research prior to blocking the grille: My commute (fast route) to work is 3 blocks of suburb driving, 9 miles of 70 mph highway, then the remaining 6.5 miles at speeds below 60 mph. I trigger the engine at the second block by toggling the HV/EV button. Entry onto the highway and the entire distance in the fast section in EV-BOOST mode, which usually delivers an average of 115 MPG. At the slowdown point, I noted the coolant temperature had risen to 172°F with the outside temperature at 34°F and the grille not blocked yet. Unfortunately, I didn't note what the coolant high-temperature was back when it was still summer while driving that same route. Oh well. 34°F is quite warm for winter in Minnesota anyway. It will get much, much colder. Anywho, the next 5.5 miles of driving were all in EV mode, with the engine off. That meant the coolant would cool fairly quick without any of the grille blocked. To my delight, it didn't too much. When the engine did eventually start back up, the temperature was 118°F. While driving that final stretch, I watch the temperature rise to 132°F and the overall efficiency drop to 155 MPG.
- 10-10-2012 Sunset Photos.** I was running an errand after work, driving along the river valley. The sun was setting. With the ceiling of clouds opened up just enough on the horizon for the sun to peak out, I was starting to get excited... and a bit concerned. I had my new camera along with me. I had studied the settings and felt confident I could take sunset photos at a moment's notice. That time had arrived... but where? I needed an open area with nothing but trees in the background and enough length to allow the capture of a wide cloudscape. Could I find such a location within the next few minutes? There was a park down in the valley itself. I wondered... then took the chance. Yeah! It appeared to be a good choice. But dang, there was someone right behind me appearing to be concerned I had the same idea. Sure enough. Fortunately, she didn't want her vehicle in her photos and wanted close-ups instead. Stopping at the location I abruptly chose made us both quite happy. We both snapped up a bunch of photos. It just a few minutes, the dazzling array of rapidly changing colors was just a memory. Phew! I actually got a bunch of nice sunset photos, the first with my Prius PHV. And to my delight, the special LED lights on my advanced model look stunning in that particular situation. See... [photo album 178](#)
- 10-11-2012 Discredit Efforts.** They continue. That shouldn't be a surprise to anyone anymore. In fact, spin has become an expectation. At this point, we've basically heard it all too. You say something, they change it. They say something, they change it. Sticking to facts just plain doesn't happen; acknowledging goals doesn't either. Strangely, that's kind of a good thing. It confirms progress is being made. Rather than speculation as in the past, we now know. The denial of certain individuals makes it rather obvious: *"Every owner I know doesn't get the EPA in their Prius - or "massages" the data like John."* Statements like that will be amusing to read back again later, as a reminder once that person finally moves on. The antagonists do eventually give up. But they hold on until evidence contradicting them becomes overwhelming. Here's what I contributed: I set the cruise-control on my trip up north last week. In HV mode to preserve the EV for later and with 2 bikes on back, the 168-mile drive resulted in an average of 48 MPG. Despite that aerodynamic compromise and letting the car manage speed, I still came within 1 MPG of the EPA. The entire trip, driving up there without the bikes, then the return home came to a total of 701 miles. That distance had 2 recharges, using 6.2 kWh total, including charging losses. The displayed gas consumption was 10.24 gallons. That works out to an overall of 68.5 MPG. The real-world data speaks for itself. Attempts to spin & discredit won't undermine that.

- 10-11-2012** **6 Miles.** My most recent example of intention misrepresentation of the plug-in Prius was to spin the EPA sticker mention of "6 miles" as the only capacity available for EV. The troublemaker totally disregards detail of the measurement itself, pretending the reality of the engine shutting off after that high-demand moment at the 6-mile mark doesn't happen. They want you to believe the entire plug-in capacity is already depleted then and absolutely refuse to acknowledge you've actually got more than half remaining still. My personal highest is 17.5 miles. The other day, I got 16.1 miles. Neither was an effort to milk EV distance either. It just worked out that way. Most of the time it's close to 13 miles... which clearly higher than 6. In the past, I found those efforts to undermine frustrating. Now, the feeling has transformed to vindication. Such an obvious attempt to mislead confirms the real-world results Prius PHV delivers are better than they had hoped.
- 10-11-2012** **100 MPGe Combined.** That's the big news today. It's the official rating C-Max Energi just earned. (108 city and 92 highway are the other MPGe values.) This upcoming plug-in hybrid from Ford has a higher combined value than Volt, which gets 98 MPGe. So, you can imagine the stir online by tomorrow. Prius PHV delivers 95 MPGe. A smaller battery-pack (4.4 kWh compared to 7.5 kWh) made the outcome quite predictable. In fact, that's why Toyota & Ford are thought of more as allies rather than true competitors of each other. They share the goal of wanting to produce an affordable plug-in for the masses, soon. That's quite different from Volt, which has transformed into a long-term venture instead. Replacing traditional vehicles starts with delivering something realistic for high-volume sales right away. This is what we are seeing emerge now. The timing is great. The rating is great. The excitement is building.
- 10-11-2012** **C-Max Spin.** It only took a matter of hours. Rather than allow attention to focus on Volt, there's a clear effort to keep the spotlight on Prius instead... by demeaning it. That figures. Ironically, that's a great way to get people to abandon GM hope. A good old fashion rivalry between Ford & Toyota will be great. That will benefit both... leaving the Volt enthusiasts without an audience. Anywho, this was the first attempt that emerged: *"The c-max hybrid and plug-in versions are better versions of the Prius. I've heard that you can reasonably drive the c-max in all electric mode (unlike the Prius where if you sneeze the gas motor comes on)."* I found that rather amusing, since it's so easy to disprove. This is how I responded: How much longer can that misrepresentation of Prius continue? Currently, claiming the engine starts from anything but the lightest pedal touch is easy... since many people still assume behavior based on old reports. My guess is within 3 months of nationwide rollout that will end. The bigger battery-pack offers more electricity to draw. That translates directly to more propulsion power. A simple test-drive experience reveals a Prius that easily handles suburb driving without gas; however, that isn't the point of a plug-in hybrid. The point is to deliver a significant emission & consumption reduction. The message of *"all electric"* is promotional angle, not a goal. And when the engine does run, you still get over 100 MPG while electricity is available. What's wrong with that?

- 10-12-2012 More Data.** Here's yesterday's observations, without the grille blocked yet: It was 43°F outside. Traffic on the 70 mph stretch was pretty routine, except for the big trunk merging out at the 9-mile mark. That caused me to slow down a half-mile sooner, to 60 mph... which caused the engine to shut off. At that point, the coolant had warmed up to 175°F. I almost made it the 16-mile mark (specifically to 15.9) entirely in EV mode before running out of electricity. The coolant temperature had cooled down to 118°F by then. A few minutes later, arriving at my destination with coolant warmed back up to the point where the engine shut back off. The act of running brought the temperature up to 132°F and topped off the battery-pack enough to allow electric-only driving in HV mode. And I did, to the ramp and up to my usual parking spot without the engine. There, the display said I had traveled a total of 16.7 miles and had an overall average of 163 MPG.
- 10-12-2012 Still More Data.** Today's observations were intriguing. Starting out at 34°F outside, I thought it would closely resemble the first day's data collecting. Instead, the coolant temperature was a little cooler and the engine wasn't needed anymore once reaching the slowdown point. I drove along the 70 mph stretch with commute traffic, noting 163°F at the usual the 9.5-mile mark where it changes to 55 mph. Then the system automatically switched to EV from EV-BOOST, remaining like that all the way until I parked. There was enough electricity available to complete the journey without gas. That was unexpected. What a nice surprise. At that point (16.7 miles total), the coolant temperature had dropped to 107°F. That means if I would have desired warmth from the heater, the engine would have started specifically for that purpose, since the threshold is 114°F. Fortunately if it does run, some EV distance is replenished too. That's a nice side-benefit from the warming process. Anywho, the outcome was quite pleasing. The overall average was 192 MPG. Now, I'm more curious than ever about the effect grille-blocking will have.
- 10-12-2012 C & Classic.** As I was taking an afternoon stroll with my sweetheart to plug-in the Prius, I just happened to notice a very very exciting scene approaching. There in one lane was a c model Prius. Immediately next to it was a Classic model. What a remarkable sight! There was a decade difference between the two of them. Side by side, they got closer. We both watched as the two different yet rather similar Prius drove by. It was quite a rare event, one which I can foresee never happening again. After all, there weren't that many Classics in the first place. To see it in formation with its own successor several generations later made it a moment to remember... and cherish. You cannot get much better confirmation of success than something like that. It was very exciting to experience, especially with someone special.

- 10-12-2012** **No Gas.** What a bizarre experience. A good friend and I were making a run out to the recycler with a refrigerator. With his guzzler towing a trailer, seeing the price of gas at \$3.58 per gallon was quite a compelling sight. Why the heck was it so low? It's \$3.79 everywhere else. We decided to take advantage of the opportunity. As we were pulling up to a pump, I pointed out that particular one appeared to be out of service. There was a plastic bag on the handle to indicate that. Strangely, the next pump down had one as well. Looking over to the next row, those did too. What the heck? Others appeared to be at pumps, but something didn't seem right. We stopped. Grabbed the pump. Then there was an announcement over the loud-speaker... no gas. Huh? At that moment, a big tanker arrived. Things started to make sense. That must have been a clearing out of summer-formula gas. The low price was to empty the station. And it did! We didn't bother waiting. My gas was the winter-formula arrival would instantly bring a price increase. What an odd event to witness, especially since he and I both own Prius.
- 10-12-2012** **43 MPG.** Looking at the very first photo of the battery-pack in C-Max Energi, you quickly realize the unique circumstance Prius is in. Ford did what people envisioned a plug-in hybrid would be... a significant portion of the cargo area consumed by battery. It appears to be just under half the height of the space below the cover shade. So there's decent room still, but the loss of a flat floor-to-seat region for something like a bike is gone. That's something Toyota didn't want to sacrifice. Prius has everything squeezed underneath. The C-Max storage tradeoff is greater battery-capacity, which equates to further EV travel and more power. But it's not like Toyota won't offer that later anyway. Diversity is the key. And of course, the smaller pack in Prius means a lower price to pay and greater efficiency after depletion... which leads to the mention of 43 MPG. We just discovered today that the plug-in model of C-Max gets that rather than the 47 MPG the regular hybrid does. That's more of a difference than anyone expected. How will those considering the plug-in model see that? 43 is still pretty good.
- 10-13-2012** **Suburb Driving.** This is another one of those misrepresentations brought up countless times in the past that hopefully will finally just fizzle out. No matter how much I posted my observations (from the early model PHV back in 2010) that a light foot on the pedal wasn't needed in suburb driving to prevent the engine from starting back up, certain individuals absolutely refused to accept it. My hill climb out of the valley in EV was simply dismissed. Heck, quite a few times the response them saying it was impossible to start up the plug-in within the engine running. That was very frustrating, knowing they didn't care about actual facts. Saying whatever they wanted to undermine Prius was their intent... because there was so little data available to contest their statements. It's rapidly becoming easier to dispute. The feeling is a transformation to vindication. Phew! I really enjoy errand-running on weekends using nothing but electricity. The darting around town seemed like such a chore in the past. The smooth & silent is a refreshing experience. Of course, how fast the engine shuts off after having warmed up is nice too. It stops freaky fast after a hard acceleration.

- 10-13-2012 EV-BOOST.** The term itself was coined to identify the misrepresentation taking place... over and over again. So many times, I'd read the implication that once you exceed the 62.1 mph (100 km/h) speed threshold the benefit of having plug-supplied electricity was lost. Those with ill intent would vaguely state EV mode was no longer available at faster speeds, hoping readers would make the incorrect assumption that HV mode was the only alternative. EV-BOOST is an automatic extension of EV mode, resulting in much more electricity being drawn from the battery-pack than would happen in HV mode. This allows the engine to run at a much slower RPM, resulting in less gas being consumed. I really enjoy seeing 100 MPG displayed on the screen while cruising along at 70 mph. Who cares whether or not there is EV purity? How long would you be able to maintain that electric-only drive anyway? Why not take advantage of the gas engine sharing battery power? Isn't the goal to get the technology out to the masses soon?
- 10-13-2012 Answer To Volt.** That particular misrepresentation really got me going in the past. Of course, that was the purpose of antagonists. They knew that wasn't actually the case, but it gave the impression of Volt being "*vastly superior*" without any actually data to prove it. They'd claim Toyota was scrambling to deliver a plug-in to compete. In return, I'd asked "*Who is the market for Volt?*" We all knew one vehicle was intended for the masses and the other featured attributes appealing to a niche, but they'd refuse to acknowledge that. When would it ever make sense to compare a vehicle with an engine triple the capacity of another? Yet, that's exactly what they did. The plug-in Prius being real-world tested at the time had a 5.2 kWh battery-pack, the Volt had 16 kWh. (Now, it is just 4.4 kWh.) No one in middle-market was asking for that kind of range or power. Requests were for something offering much improved efficiency at an affordable price. Toyota delivered a system way back in 2003 that was capable of 100 km/h (62.1 mph) using only electricity. Problem was, the batteries of that time were very large, very heavy, low-capacity, and very expensive. A plug simply wasn't realistic. Lots of waiting was required for the battery technology to advance. Those antagonists didn't want you to know that history, so they'd spin it to make the upcoming plug-in appear to be an after-thought retrofit rather than the plan-ahead it actually was. Whether or not that effort to misrepresent will continue remains to be seen. Hopefully, simply raising awareness about it will help prevent that.

- 10-13-2012** **Clueless Conclusions.** How does one deal with such screwed up facts: "*The Prius Plug-In went on sale last fall and last spring was among the fastest-selling cars in the U.S. In some months, it even outpaced Volt. GM fought back with Volt leases...*" It didn't go on sale last fall. That's just when pre-orders were submitted. All you were doing was reserving one with your choice of options. The commitment to actually purchase didn't occur until after the car was delivered to the dealer in the spring. Some people chose not to. For those that did, that sale was counted then... having nothing to do with last fall. The concentration of pre-order deliveries gave a false impression of sudden demand. Did the writer have any clue about what really happened? You get the impression of strong growth, which wasn't the case. Of course, reading about GM fighting back is misleading anyway. With Volt approaching 2 years since rollout began and 1 year availability nationwide, how does that even compete with the plug-in Prius still being only available in 15 of the 48 states? We appear to be back to the filler reports again... stuff written without research about high-efficiency vehicles just to stimulate the publication. They draw whatever conclusion they want to keep readership active. Historical accuracy doesn't matter. Outcome doesn't either. Sadly, even goals are absent. It's a bit of a mess at the moment. Ugh.
- 10-13-2012** **Mile After Mile.** There's another commercial now promoting the Prius family. It's very similar to the other, the same animated world with the regular Prius driving by interesting & relevant scenery. Then, there's a clever camera angle change to reveal other models behind it. It's a great way to continue to raise awareness about more than just a single Prius being available now. You don't even need sound to understand what you're seeing. It's quite obvious. That does a great job of confirming Toyota's commitment to hybrids too. Even if you know nothing at all about Prius history, seeing there are 4 to choose from compels you to investigate... which works out fantastic for those of us sharing real-world experiences online. Also, the line "*a Prius for everyone*" hits competitors in a big way. Volt's lack of diversity is becoming much more apparent now. I was greeted with hostile responses prior to rollout, when I pointed out the one-size-fits-all approach would become a problem. Back then, they didn't expect a Prius family or for Ford to deliver choices so soon. We have automakers readying to deliver and Toyota already well positioned. Viable options for middle-market is very exciting.

- 10-14-2012** **Most Worrisome.** There are two topics which continually stir passionate response. When a discussion about Volt had been brought up in the past, the topic had been price. But since that is now overwhelmingly obvious, not much time is spent on it anymore. So, the question has become what makes a supporter worry the most now. It would appear to be the one-size-fits-all problem. Lack of diversity is a violation of basic business practice. You don't put all your eggs in one basket. Supporters were hoping there's enough time to delay that particular issue. Now, it has become difficult to conceal it as a shortcoming. The technology needs to be spread to offer choice. We get confirmation of that too. Threads often bring it up. A recent twist has changed that though. Ford's ability to deliver two hybrids offering 47 MPG makes the 37 from Volt stand out, especially when hearing reports of how often plug-in Prius owners get 50 MPG. Turns out, that stirs some intense reaction. Facts put the pressure on too, making them really worry. It's too bad they didn't want to acknowledge the concern 2.5 years ago, when that Freedom-Drive publicity stunt highlighted that as important to address. Some still don't. Instead, we got yet another one of those gross generalizations about driving patterns... which is very hard to believe at this point. Oh well. I was happy to contribute my real-world data: That statement of "The plug-in Prius delivers a solid 50 MPG after depletion." is very easy to confirm. This weekend provided the perfect example of deviation from any pattern. It's something quite normal which throws travel estimates into disarray. That's what real-world is all about. In this case, we had a family get together to celebrate a birthday. I didn't have an opportunity to recharge. All driving today was powered entirely with the gas engine, 85 miles total. The result was an average of 55 MPG.
- 10-15-2012** **Data Collecting.** I enjoy it. With the seasons changing, you really don't know for certain what will happen. My collecting of data is becoming a source of intrigue, since I know how cold it will get in 2 months. Then 3 months from now, it will be the dead of Winter here in Minnesota. That sure will be interesting with a plug-in Prius. The regular model certainly brings a new experience to those unfamiliar with the importance of keeping warm and still being efficient... especially when it comes to warm-up on short-trips. But since my morning commute is farther than battery-capacity and warmth for the heater comes from the engine, my interest is specifically on heat retention. Today, as usual, I fired up the engine prior to climbing up the ramp onto the 70 mph highway. It was 45°F outside. Traffic was flowing just under the speed limit. There was no need for the heater. At the 9-mark, traffic slowed and the engine shut off... automatically swapping the system to EV mode from EV-BOOST. The coolant temperature was 168°F. To my delight, it was another one of those commutes where the engine never restarted. In fact, I finished the 16.7-mile drive this time with 0.1 miles remaining. The result was a pleasing 192 MPG. Coolant had cooled to 100°F. Now, I'm more curious than ever what the results will be after blocking the lower-grille entirely.
- 10-15-2012** **Persona Special Edition.** Toyota announced a new package for the liftback Prius today. It's between 3 & 4 with some distinct changes to make it visually distinct. The most obvious uniqueness will be a color choice of Black Cherry Pearl. On the exterior, there will also be 17-inch alloy wheels. On the interior, there will be charcoal colored SofTex material with black accents and red stitching along with a few other differences to make it stand out. At \$27,130 for the MSRP, you can envision those wanting a Prius that has a little bit of character of its own seeking out this particular package. It's good to see the variety expanding.

- 10-15-2012** **Another Sunset.** This time, I was driving by a lake. I could see the sunset beginning to emerge, but was quite uncertain about where I'd actually be able to park. I wanted to someone see the lake through the line of trees, to show the reflection of pink on it rather than clouds only. This time, I only had about 2 minutes to decide what photos to take. It was quite fortunate I just happened to be in the area at the time. That opportunity could have easily been miss. Thankfully, I didn't. Settings for the new camera were now familiar too. I was well prepared this time. Hopefully, you can tell... [photo album 178](#)
- 10-16-2012** **5 Seconds.** Today was forecast to be the warmest day we'll see here in Minnesota for a long time. That equated to 57°F on the morning commute. I toggled the HV/EV button to start the engine. It shut off at the 9.5-mile mark. Coolant temperature got up to 168°F. The remainder of the trip wasn't the usual all EV though. Unlike my other days of data collection, switching from the 55 mph road to 50 mph included a hard acceleration. The engine ran for roughly 5 seconds. That caused coolant to rise from 136 to 139°F. The remainder of the 16.7-mile route was with just electricity. There was 0.5 miles of EV left upon parking. The average was 198 MPG. Coolant had dropped to 121°F. My curiosity about Winter is definitely rising.
- 10-16-2012** **Bailout & Gas.** The presidential debate brought up favorite topics of mine. Gas prices and the bailouts got a surprising amount of attention. I enjoyed seeing of how one particular candidate stated his goal was to have us become energy independent but then in the same breath mentioned approving an oil pipeline from Canada. Since when are those provinces to our north part of the United States? He also mislead about the price of gas, claiming it was only \$1.87 when the president first took office. Leaving out important details is how the "being vague" aspect of greenwashing works. Failing to mention that was when the economy collapsed and that gas was \$4 before that is one heck of a detail to omit. People fall for that type of misleading though. It's really unfortunate. The same is true with the bailout. They exclude to give a false impression. True, the initial loans were paid back, but our government still owns 500 million shares and their market value has already resulted in a loss of about \$9 each. There's spin about drilling permits too. It's all so frustrating to know reality doesn't match what's being claimed. Anywho, it's at least reassuring those topics are getting attention. In the past, we were actually encouraged to guzzle... because it was "*good for the economy*". Aren't politics fun?
- 10-17-2012** **HV Compare.** My data collection for grille-blocking had an unexpected opportunity. It was 55°F this morning, very close to yesterday's temperature at the same time along the same route. That meant a great chance to do a direct compare. I'd use regular HV mode instead of EV-BOOST. The result at the 9.5-mile mark was 188°F, warmer by 20 degrees. That was interesting. At that point, I switched over to EV mode, continuing the commute to my usual parking spot. There I observed 136°F as the final coolant temperature, 15 degrees warmer than yesterday. Losing more on the high end tends to make sense. Later with much colder conditions outside and the grille-blocked, the retention of heat will be of upmost intrigue. Of course, what got me on this particular drive was the end result. It was 108 MPG with a surprising 5.0 miles of EV still remaining. For having traveled 16.7 miles, that's pretty darn good. In other words, I could have easily went over 20 miles without any worry of dropping below 100 MPG. Gotta like that.

- 10-17-2012 Unplugged By Someone Else.** I needed to make an unexpected trip to the mall this evening, without any electricity available. There are plug-in stations there, something I wouldn't usually be able to take advantage of living so close. The price had been recently dropped, now \$0.49 per kWh. This happenstance was too good to pass up. There at the mall, I went about my business, checking charging status along the way. I suddenly got a text stating: "*Your vehicle has stopped charging at ... because the plug has been removed.*" With so few plug-in vehicles here, especially near closing. That wasn't a good message. Something was wrong. Sure enough, I spotted someone walking away from my Prius then getting into his to sit and observe. Laying down on the ground was the plug. He had absolutely no reason to be touching it. Were his actions just out curiosity or an ill-intent encounter? Needless to say, I silently drove away without doing anything other than returning the plug to its holster. Hopefully, that was a rare situation.
- 10-18-2012 Demand Spin.** It was interesting to read an article from Detroit with this title: "*Electric car market is badly in need of a charge.*" A graphic started out with this setting expectations: "*Problems for battery cars*". Seeing that in bold print above a chart with numbers and images of vehicles was a bad sign, especially before any wording. This is what followed: "*Sales of electric and plug-in hybrids cars have not lived up to expectations.*" The tone was pretty obvious. The expectations themselves were never explained either. For that matter, the count of Prius PHV didn't have a disclaimer pointing out that it was only available in 15 states. It was all quite vague... the same old spin we've come to expect. They paint a picture of demand by leaving out detail. This time though, GM had a featured vehicle. Volt was the dominant plug-in, which indeed has been struggling. Next came Nissan with Leaf, who's sale projections were much lower than Volt. But again, leaving out particulars leaves you to believe something else... especially when seeing the counts for Ford and Mitsubishi. Naturally, only the American sales were mentioned. Also, we know much will change by next year when C-Max Energi, Honda Accord plug-in, and Prius PHV all become available nationwide. But with politics so hot of a topic now and government bailouts & tax-credits along with gas prices getting so much attention, this view of demand is no surprise. 2013 seems so far away.

10-19-2012 **New Topic: Unplugged.** I has no idea how much attention my thread would draw. It's an entirely new topic no one has ever addressed, since the circumstances are so unique. Boldly going... Anywho, many are jumping in to contribute their thoughts. As for me, I'm glad my decision was to just quietly drive away. Who knows how a confrontation would have brought. This was my follow up: Basically, there's no reason to ever interrupt a charging session, regardless of who. Once a recharge is complete, then someone immediately plugging into their vehicle with that same plug is acceptable. That's why some chargers offer 2 parking spots. Nothing good comes from walking away after having laid the plug down on the ground... which is exactly what happened to me. We also face the reality of a plug-in spot being used by a traditional vehicle. The term we identify that situation by is saying the spot was ICED, since the vehicle parked there preventing you from using the charger has only an ICE (Internal Combustion Engine). Sometimes people just don't care. It's tempting to setup my GoPro camera to capture an unplug event on film. But hopefully, what I experienced will be quite rare. Then again, such occurrences would serve as a source for finally overcoming the belief that a cross-automaker alliance really is possible. Volt rhetoric of the past had strong roots in brand loyalty rather than the motive of high-volume sales. Moving beyond that by way of traditional-vehicle supporter backlash could happen. Reasons for bonding often come from unexpected sources.

10-19-2012 **Cold Start.** Those attempting to misrepresent PHV would claim the starting of a cold engine following plug-in capacity depletion would result in terrible emissions & consumption. That was a big antagonist topic prior to rollout, but not anymore. Proof quickly emerged from owners that the battery-pack had a reserve not included in the EV miles estimate, specifically set aside for the warm-up process. The system doesn't actually start a cold engine the way the rhetoric claimed it would. The RPM is kept under 1500, rather than revving high as people would assume. That provides the opportunity for warming without strain, preventing it from being dirty & inefficient. It's too bad they took advantage of the lack of real-world data rather than just considering system design and goals of the past. But with that other plug-in struggling to meet its own self-imposed sales goals, the misrepresentation was no surprise.

- 10-19-2012** **Change Happens.** The transition away from conflict of the past has been a welcome expectation. It's finally happening. And of all things, I just happened to contribute in a very unexpected way. The active thread resulted in more thoughts on the situation: Getting a heads up on my phone from both ChargePoint (the charger) & Entune (Toyota's service) about charging being interrupted is nice. ChargePoint's latest upgrade gives you notification when recharging is almost complete, detecting that rate is slowing. You automatically get the following text: "*Your vehicle plugged into ... is drawing very little power and my be fully charged.*" It also provides a phone number. If an unplug incident happens to me again, I won't hesitate to call. That way, ChargePoint will have it on record and will report to the owner that preventative measures may need to be taken. Heck, they might even have some handy suggestions available too. In the event of charger sharing (2 spots, 1 charger), knowing that your recharge is almost complete gives you the opportunity to offer the charger to the other vehicle as soon as it becomes available. It will be rather interesting as time proceeds. There was a lot of animosity about PHV from Volt enthusiasts in the past. Fortunately, that's faded away as those concerns sighted actually transpired. We are now looking at an upcoming year with plug-in hybrids from Toyota, Ford, and Honda. The diverse variety of choices repositions the approach to plug-in support.
- 10-19-2012** **EV Goal.** How many times does that come up in discussions? We continuously hear the misrepresentation of PHV stated in terms of an EV goal. In fact, that's by far the biggest argument used against it. Why? It's a plug-in hybrid. When has there ever been a statement made that its purpose to offer electric-only travel? For over a decade, the goal has been to significantly reduce emissions & consumption. Each generation has brought improvements to engine, motor, and battery. Who says that intent has now changed? What's wrong with getting 100 MPG on your daily commute? At what cost is the efficiency tradeoff too much? Remember, vehicles purchased in high volumes are those which offer a balance. So what if other vehicles favor more of a particular aspect. There are always going to be luxury, sport, and niche vehicles. Those aren't what middle-market buy though. Just like with computers, there's always something faster or with more capacity... but that doesn't make it the better choice... especially if it isn't necessary.
- 10-19-2012** **Maximum Capacity.** Did you know that hybrids don't drain their batteries entirely? Avoiding deep-discharges is how they achieve longevity to match the lifetime of the vehicle. People often allow their portable devices to exceed the safe tolerance. That reduces the battery's total capacity... eventually taking it to the point of basically being worthless... hence having to replace the battery. Hybrids prevent that by running their gas engine to power a generator for electricity when the battery gets low. The plug-in variety offers a plug to supplement that. Both types strive for the same goal, but not all automakers choose the same depletion point. They make assumptions about vehicle usage, environmental conditions, and battery chemistries. Toyota plays it safe, cutting off Prius PHV at 63%. That means the engine unconditionally fires up when reaching the point of only having 37% of the overall capacity remaining. You aren't allowed more. Stopping sooner means less electricity is available, but it helps to guarantee ample battery performance later in life. Is that too conservative? Ford seems to think so, stopping with their Energi system at 75% instead. Allowing a draw down to 25% may be fine or may turn out to be a damaging idea. We truly won't know for many years. The things people will do to their plug-in is still very much unknown. The market is quite diverse.

- 10-19-2012** **\$3.32 Per Gallon.** The price of oil is staying around \$90 per barrel now. Having settled there means the price of gas has dropped to where you'd expect, somewhere around \$3.29 per gallon. The recent spike sure caused some excitement. It's nice to see lower. A docile rollout of the plug-in hybrids is the preferred approach. I couldn't imagine how we'd handle a crazed demand crunch. That's when expectations get out of hand. People tend to panic rather easy. Of course, they fall for hype rather easy too. High ticket purchases aren't something you just want to jump into blindly. The real-world experiences early owners share really make a difference. We don't even have Winter data yet. It won't take long to get annual results though. Then we can begin to establish realistic expectations. I'm 7 months into ownership already. Gas prices staying relatively low in the meantime will help matters. After all, supply is quite limited and will remain that way for awhile.
- 10-20-2012** **New Fallout.** An article yesterday revealed the growing problem GM is facing, something few typical enthusiasts have considered... consequences supporters have been avoiding. So, I posted the following on the big GM forum, where Volt discussion has pretty much grow silent lately... likely due to the lack of good news and attention having shifted over to Ford's upcoming plug-in hybrid: Production goals are set for good reason. An automaker must match supply with demand. Underestimating means paying a premium for extra parts and overtime for the workers, which cuts into profit. Overestimating means having to slash prices to reduce inventory but continue to pay worker while production is idle, which cuts into profit. In other words, not meeting expectations has consequences. Decisions eventually must be made as a result. This thread celebrates Volt leading September sales among plug-in vehicles, but does not address supply/demand issues. In the past, we've heard every excuse imaginable. It didn't matter much though. There was time to resolve still. That time is running out now. An article published yesterday points out how the production of battery cells for Volt never transferred from South Korea to Michigan. What does that mean for Volt next year? In the case of plug-in hybrids like Prius PHV and C-Max Energi, the only real difference between them and the no-plug model is basically just the battery-pack. That design approach provides flexibility to sell more or less of the plug-in model, allowing it to adjust supply based on demand with less overhead than the one-size-fits-all Volt. Reducing exposure is very important for business-sustaining profit. Not having any alternative available, like a second model of Volt with a smaller battery-pack, leaves it very exposed. Every aspect of production relies entirely upon sales of a single configuration. What will GM do? We're seeing sales of Cruze (25,787), Sonic (7,525), and Spark (2,223) rise significantly. That puts the record high of 2,851 for Volt with heavy incentives (price discounts & tax-credits, plus lots of advertising) into perspective. So even without considering the plug-in choices from other automakers, the problem within GM itself should be clear. The monthly counts favor emphasis on traditional vehicles, not setting large production goals for Volt.

- 10-20-2012 **Rebuttal Material.**** That was requested today. It was nothing we haven't dealt with countless times already. I provided: Who is considered a hater? In the past, it was anyone who felt threaten that they'd somehow be forced out of their guzzler. Thankfully, it's not that bad anymore. Arguments focusing on the battery are dying fading too. Of course, the rebuttal to that is just pointing out what actually happens with the acquisition of oil. People really don't want to acknowledge that situation. My guess is those opposing hybrids stems from two sources. First, they really don't understand how the technology works. They make assumptions, which is easy to do considering how much incorrect, outdated, and misleading information there is still. Change is very difficult when there's uncertainty. Second, they have strong loyalty to an automaker or the domestic market. In that case, they'll say just about anything. Excuses are frequent & abundant. We've heard it all. Ultimately, the real-world data speaks for itself. Experiences shared by owners is what gets people to take another look, to overcome what they had previously thought or felt.
- 10-21-2012 **Standard Household Outlet.**** A plug-in sale was lost today. The cause was a salesperson misleading the person into thinking a charging-station was required to recharge the Prius PHV. We don't know whether or not that was unintentional or a misunderstanding. You could see how an informed salesperson would want to convey the steps required to have the high-speed recharge ability at home. But in that same process, it would be very easy to skip over the basics... failing to mention that the installation isn't necessary. Just an ordinary standard household outlet is all that's actually needed. The 120-volt connection already in your garage is what the included charger uses. Long story short, this person today ended purchasing a 2012 instead... not finding out he didn't have all the information he needed to properly make the decision until after it was too late. Needless to say, this will now be an important detail mentioned often when discussing the plug-in model. We don't want to hear of buyer's remorse caused by a salesperson's inattentiveness.
- 10-22-2012 **Software Updates.**** Remember when there was one for the 2004 Prius? There were cries of owner's lives being at risk. It was like the world was coming to an end. More recently, the word "*recall*" was given a stigma to represent something exclusively to deal with a serious problem and not include improvements & preventative measures. So now when there's a similar software update needed for Volt, what do you think happened? Nothing... a reaction like we should have had all along. It's too bad GM had invested in and depended upon guzzlers so heavily back then. The enthusiasts have transformed from favoring large SUVs to expensive plug-in hybrids. That's a definite change for the better.

- 10-23-2012 Ugh.** When they accuse you of being loyal, being paid, or just lying, you know all has been lost. There's no chance of constructive discussion at that point. Heck, you can't even get useful observations or opinions anymore. They stopped trying. We all knew the inability to grow sales would result in some type of fallout. Apparently, that's how the most hopeful of enthusiasts are expressing their assessment of the situation. Reaction manifesting in the form of unsupported & unrealistic claims is quite understandable, predictable even. Too bad it came to this. Needless to say, the topic is Volt. With the industry setting their sights on what the other automakers will be doing next year, lack of substance from GM just doesn't cut it. Change only comes from the market actually embracing something... not endless hope that someday something will be realistic. Think about what consumers currently shopping for a new vehicle will consider. They're not going to care either way about rhetoric online. What's important to them is what they'll be able to purchase.
- 10-24-2012 Outdated Surveys.** Sadly, the presumed latest & greatest information now being conveyed about the plug-in market is already outdated. The report I came across today didn't include the plug-in Prius, yet it gave the impression it was representative of all vehicles using plug-supplied electricity. How can they even attempt to provide credible data without providing a disclaimer about it not being representative of the current choices? There should be a concise statement about limited availability and the upcoming expansion of configurations. How are readers supposed to know about changes if they aren't explicitly stated? Leaving that out allows them to make assumptions. Surveys related to the vehicles can't possibly be accurate without a basic understanding. What kind of perspective comes from an unclear market.
- 10-24-2012 New Owners.** Avoiding full is for battery longevity. That's why the display typically hovers around 6 bars and the entire capacity isn't actually displayed. Assumptions about charge-level and EV driving are common... and growing, due to the number of older Prius becoming used purchases. You'll enjoy 100 MPG from time to time, but the point is to significantly improve emissions & efficiency... not electric only. In fact, that's true of even the plug-in model. The engine will run when it makes sense. The system seeks out opportunities for optimal conditions and takes advantage of them. New owners sometimes unknowingly fight the system, cancelling out the benefit. For example, as the system runs to warm the coolant, it is also recharging the battery-pack... a benefit very easy to overlook. Keep your eyes & ears attentive. You'll be impressed how well thought out the approach really is.
- 10-24-2012 Consumer Reaction.** Times are changing... by how much is the question now. Ford's plug-in choice is difficult to gauge. That 694-pound difference resembles what I see in my career as a software engineer. As time progresses, the application becomes more and more refined. Ford is well on its way, making a genuine effort to achieve a nice balance of priorities. Toyota has a lead of about 7 years and 2 large markets to work with though. It will be interesting to see how people react to the differences. Realistically, there is room for the diversity. Choice among shared goals helps all involved. Next year will be very interesting.

- 10-24-2012** **10,000-Mile Service.** It went well, though a bit late. My vacation, the lack of engine use, and me getting sick delayed the routine maintenance. I enjoyed getting to chat with the head mechanic there, as he was pleased to speak with one of the very few plug-in Prius owners in Minnesota. They basically just checked fluids & brakes, rotated tires, and changed the oil & filter. That's all quite routine. The not-so-routine part was connecting the car to their system for a complete status dump. Toyota benefits from collecting detail like that, as do owners. No software updates were needed. Of course, having an advanced model, I get them via bluetooth connection to my phone which downloads via Wi-Fi at home. It's totally automatic. What isn't automatic though is the darn oil-level check at the dealer. Arrgh! It's the same old problem countless thousands of owners have experienced around the country over the past decade. They overfill the oil by pumping it directly from bulk barrels. I should have complained then, despite the service itself being free. But I really wanted to know by how much. Turns out, I ended up draining 24 ounces out to get the level about 1/8 inch below the "full" mark. It had been 1/2 inch above. That's 2/3 quart too much! I'll end up sending a reply to their customer-satisfaction email about that. What a waste. Good thing oil is the only trouble I've ever experienced there. All else is great, especially the complimentary cookies & coffee.
- 10-24-2012** **\$4.29 Per Gallon.** That was the price for diesel today. The price of gas has dropped to \$3.37 per gallon. Needless to say, that positions VW well for the debut of their soon-to-be-rolled-out gas hybrid. It will deliver an undebatable efficiency benefit over the diesel, pretty much killing any argument we've had to deal with in the past. The fact that it will also cost more to fill the tank makes it a futile endeavor to do anything other than acknowledge the market acceptance of hybrids. For a diesel-favoring automaker to embrace change at a time when the choice seems so obvious, I cannot imagine constructive arguments against them.
- 10-25-2012** **Getting Colder.** It snowed over lunch today. By the time I left work this evening, the temperature had risen to a balmy 39°F but was windy as heck. I needed to use the heater at some point, since the windows would eventually fog up. With the weather front that had just passed through, the forecast for the next two weeks was for temperatures mostly in the 40's. Time to block the lower-grille. That meant this commute from work was my one opportunity to observe the system still exposed in action. As expected, it automatically bounced between the coolant levels we've become quite familiar with. The engine started, then ran until it hit 130°F. Driving proceeded as usual in EV, with the heater set to 76°F and the fan on low. I had the seat-warmer set to low too. When the coolant dropped below 114°F, the engine fired up again. That cycle happened 3 times along my 17.5 mile drive home. The end result was 127 MPG. That's quite good. I'm really curious about the heat-retention the lower-grille now blocked will provide, especially when the real cold arrives here in Minnesota.

- 10-25-2012** **Misrepresented Consequences.** They become obvious as time progresses. New owners posts threads about confusion you aren't certain how they could have such as impression. Regardless of source, you're stuck trying to figure out how to overcome that hurdle those wanting to undermine actually had some success in. Today, there was this attempt to clarify: Prius is a plug-in hybrid. The misdirection of purpose by focusing on EV rather than the resulting MPG is understandable. It's quite enjoyable driving through the suburbs using nothing but electricity... but all that is about to change. Last year's unusually mild Winter prevented the word from spreading about the realities of driving in the cold. This year could be quite different. Consumption of battery-capacity for the sake of cabin-warming is a rude awaking for EV drivers. Having a gas engine available means being able to save electricity for propulsion instead. It also means the act of running the engine for heat will recharge the battery a little too. In other words, beliefs & expectations of how the system operates were overly simplified... resulting in the discussions we are engaging in now, as aspects of it are revealed. It's complex. The interplay of HV and EV are difficult enough to understand even without buttons allowing you to toggle modes.
- 10-26-2012** **Grille Blocked.** It's the same routine for the plug-in I've been doing for the other Prius over the years. I block a majority of the radiator opening to reduce the amount of cold air being forced through the vehicle. It takes 20 minutes to do and costs \$2 to do it. The purpose is heat-retention. Though, there is a small aerodynamic benefit as well. When heat runs out sooner, the engine has to run more often. The temperature of the air used for combustion makes a difference too. Warmer results in more power. The actual difference made from the effort is difficult to quantify. But considering how little effort it takes for an entire season of efficiency gain, why not? After all, the new Ford hybrid actually includes motorized grille blocking. That's rather obvious automaker recognition. Anywho, I did it manually this evening. Taking half-inch foam pipe-insulation, I just squeezed strips of it between the openings in the lower grille, sealing it up completely until Spring. No maintenance of any kind is needed in the meantime. That simple step is all it takes. Now, I'm ready for the cold season.
- 10-27-2012** **Just Drive It.** Assumptions about efficiency and being mislead about how a hybrid should operate is nothing new. We've been dealing with incorrect beliefs for over a decade now. The advice for Prius is always the same. That is true for the plug-in model as well. Problem is, we'll have to repeat it over and over. But then again, first posts often come about as a result of that assuming. So, we end up with online participation which wouldn't of had come about otherwise. Some of those owners even become advocates due to their discovery from having learned about the clever design. This was today's example: There's a frustration pattern emerging. They all seem to disregard MPG. Why would you make the "worth it" comment without any reference to efficiency results? The point of a plug-in hybrid is to significantly improve efficiency. Even with the engine running, that's what you get. In other words, we're back the same old advice all new Prius owners are given: *Just Drive It*

- 10-28-2012** **Monthly Sales.** What happens in response to October's results is anyone's guess. Monthly sales don't tell the whole picture. It's just the outcome of a series of events with detail often forgotten or overlooked. Whatever the case, we know there will be much attention to the plug-in vehicles. Clearing out of 2012 inventory will be the first thing easy to neglect mentioning, though the discounts from that are likely to be sighted without including reason. Long story short, the objective has always been outcome for the year as a whole. Fluctuations from month to month is nothing new and usually don't represent a trend. Enthusiasts will spin numbers anyway. Watch for it. The obvious clue is the avoidance of goals. Not meeting expectations has consequences for the business and the market as a whole. In a few days, monthly sales counts will be available. Stay tuned.
- 10-30-2012** **Reliability.** It makes you wonder how a vehicle so new could be considered when it comes to reliability ranking. Somehow though, Prius *c* already earned the title of "*most*". That certainly was eye-catching to notice today. Most vehicles work flawlessly the first year or two. So, I am left scratching my head... despite knowing how well designed Prius *c* actually is. The system takes the Classic model to the next level. Just imagine if that refined of a smaller system would have been available a decade ago. The Classic has proven itself worthy of a very high reliability ranking itself. Years of improvement should make it even better. We'll certainly find out. They sell fairly well here and are extraordinarily popular in Japan. Toyota really did their homework. The test of time speaks for itself and reliability is something most listened for when it comes to new & used purchases.
- 10-30-2012** **EV Distance.** It's rapidly becoming the biggest understanding issue, an indication of a new misconception brewing. The purpose of a plug-in hybrid is to significantly reduce emissions & consumption. That's the same as a regular hybrid. It just raises the bar to a higher level. Adding a plug and increasing battery-pack capacity extends & enhances EV, an ability already available. People in general don't take the time to consider that though. They just assume "range" as the benefit of a plug, not MPG. Those asking about the plug-in and even new owners focus exclusively on distance. The efficiency outcome itself doesn't get any attention. The incorrect belief of intent could become a big problem... especially as the already complex effects of Winter become intertwined with PHV observations.

- 10-30-2012** **Panic.** The worry is growing. That EV value likely won't be understood for awhile. Some new owners watching it drop seem to panic. Here's another response to the situation: My estimated range dipped down into the 10's. At one point, it had returned to the 13's. Now it's back into the 12's. That EV value is based entirely upon your own particular driving conditions experienced. And now that it's getting cold out, the odds of seeing high numbers are more likely. In my case, the drop came from a trip up north. There was lots of inefficient driving (highway with bikes on the back) and no opportunity to recharge. The system adjusted accordingly to take that into account. New owners don't understand that, especially in this case when so few miles have been driven. They assume something is wrong. The advice we have to give to those new owners convinced that the system isn't working correctly is to have them focus on MPG results instead. After all, Prius PHV is a plug-in hybrid, not an EV. Even when the engine runs, you still get great efficiency. My lifetime after as of 11,500 miles is 81 MPG. What's wrong with that? So what if it isn't all electric? That isn't the goal.
- 10-30-2012** **Getting Colder.** 30°F for the morning commute. It was the usual 70 mph route, 3 blocks of suburb driving before hitting the highway. No heater yet, just cracked two passenger windows to the glass from fogging. 9.3 miles into the trip, the high-speed cruising in EV-BOOST mode came to an end and the engine shut off. At that point, the coolant had warmed to 166°F. Driving in EV all the way to the 16.5 mile mark, the battery-pack was depleted. The coolant temperature had dropped only to 105°F. That's not too bad considering the time & distance traveled without the engine. When it did start back at that moment, it only ran for 0.1 mile. As soon as the coolant hit 114°F, I was back to electric-only driving again... in STEALTH mode which doesn't offer as much power as EV mode. But that's ok, because all I had to do was climb up two floors to get to my parking spot in the ramp. Unexpectedly, I noticed the coolant temperature had continued to rise even though the engine was off. That actually makes sense now that I think about it too. The concentration of fresh heat from the pistons would take a little bit to circulate through the rest of the system. Anywho, the end result was a coolant temperature of 130°F and an overall average of 164 MPG.
- 11-01-2012** **Website Outage.** The horrific storm on the East Coast of the United States is somewhat surreal to contemplate from the perspective of the center of the country. The residents there now face an intense recovery period, many challenges & decisions. It was a combination of several bad things to make an even worse situation. Strangely, some businesses benefit from circumstances like this. There's the obvious hardware & contractor boom. There's also the less obvious burst of new vehicles into the market. Major discounts are offered for hail & wind damage. It also provides the opportunity, which we've seen taken advantage of in other forced times of change, to switch to a more efficient choice. I won't see any of that though, here in Minnesota. Instead for me, it's just a website outage due to infrastructure complications in 1,500 miles away. Good luck to those struggling to get their lives back to something normal.

- 11-01-2012** **YMMV.** No matter how many times that "Your Mileage May Vary" disclaimer is mentioned, the inevitable not-what-was-expected scenario plays out. This time, it's with Ford's new C-Max hybrid. The initial results reported are all over the place. MPG variances are quite wide, spanning from upper 30's to upper 40's. It sure would be nice if this results in a rapid spread of hybrid understanding. Ford's newest market entry being a hybrid-only model with an optional plug could be just the thing we need to stimulate the needed education. Unfortunately, some people are still unaware of efficiency influences... totally oblivious to things like winter-formula gas. Of course, if nothing else, it directs attention to MPG. The old obsession with size & power is thankfully turning into a bad nightmare of the past.
- 11-02-2012** **Climate Change.** For many years, we heard spin about Global Warming. It was quite clear those saying it didn't understand what climate change actually was. Who cares what the biggest contributor is. When there are lines at the gas station, you know there's a problem to be dealt with. When frequency & magnitude of storms increase, that's reason enough to take action... especially when solutions like FULL hybrids are already available. During the recent political debates and all the surrounding rhetoric, the topic wasn't actually addressed. Why is uncertain. My guess is there's been so much twisted of facts and misleading that it's pointless trying to have a constructive discussion about it... until a hurricane hits shore. Sandy could possibly be the worst ever recorded for our country. What a mess. Combine that with the recent drought, it's clear we shouldn't just accept our fate. We should use the intelligence we've been given. That makes so much more sense than just hoping to drill our way back to something normal. Geez!
- 11-03-2012** **Next Generation.** So much for taking the market by storm. We were told so many things about Volt. Most didn't turn out as hoped. This is what one of the enthusiasts said yesterday about the emerging status: *"I do think that next year, the PIP will be the leader and that the Volt early dominance is short lived... unfortunately."* Downplay until the next generation was the final stage, since that's exactly what happened with Two-Mode. There's not really much to say at this point. I simply posted: 60K annual domestic has been the standard to which new vehicle sustainability has been measured for over a decade. The point of the tax-credit is to help the automaker reach that level of sales quickly. So when it expires, sales will continue at that level. Each vehicles faces competition within its own automaker's offering. That's the reality of business & profit. We all see how that target continues to be moved, reducing former expectations. It's a bittersweet situation, knowing traditional vehicles still dominate. The goal of replacing them won't be accomplished by making excuses. How will sales be increased?

- 11-04-2012 Downplay & Double-Standards.** As the spin of October sales grew, I responded with: It's quite amazing to read the "*Nobody ever claimed...*" comment when my blogs are stuffed with quotes proving otherwise. Whatever. My purpose has always been: "*To significantly reduce emissions & consumption in a reliable & cost-effective manner.*" That means a technology with heavy dependency on tax-credits and no chance of achieving mainstream sales until a later generation doesn't fulfill the purpose. Just like we've seen with computer technology over the decades, the choice for the masses is a configuration realistically affordable. As costs are reduced, capabilities are increased. That's the way it works. The downplay we get from Volt supporters now is just a recite of what some of us were saying all along. Again, the blogs confirm that as well. As for claiming Toyota cannot continue to evolve but the technology GM uses can, that's a double-standard. We all know what's possible stepping up motor, battery, and power-carrier. It just isn't viable for high-volume sales yet.
- 11-05-2012 Natural Gas Vehicles.** It must certainly seem like I'm really hard on Volt. It doesn't take much digging for a reality-check though: "*The only electric vehicle brought to the mass market in America was General Motors' (GM) Chevy Volt. This car was a dud from the get-go simply based on its price of around \$40,000 before rebates.*" When the introduction starts with that and ends with this: "*Too big, too expensive, too many issues.*", you know trouble is brewing. With hybrids in the past, it was diesel vehicles. This time, it's natural gas vehicles. That's switching reliance to a different non-renewable fuel, compressed natural gas (CNG). What the heck? A plug-in hybrid can ultimately utilize electricity & ethanol for fuel, both of which are renewable from a variety of sources. Anywho, the article published this morning went about stating how NGV was the ultimate solution... yet never mentioned either the emission-rating or any efficiency estimate. Two vital pieces of information were missing entirely. There was no mention of the storage tank to hold the CNG either. In an odd twist, it did point out the opportunity of using CNG in hybrids rather than regular gas. But again, detail was absent. Long story short, there's always going to be pressure from some alternative, making downplay a poor choice if you want to build support for a technology.
- 11-06-2012 Forgot To Plug.** No, not the Prius. That was indeed plugged in, as usual. However, the routine was disrupted by the assembling of a new grill in my garage... the type you barbeque food with. I needed the 110-outlet to power both a heater and a light. So, as you could easily imagine, I forgot to plug the charger for the Prius back into the wall afterward. Darn it! Oh well. That first burger off the new grill was quite tasty. After all, being really cold outside is when grilling is especially enjoyable. It's more rewarding when you have to rush out into the cold to flip. Anywho, I looked at my phone when the alarm-clock sounded that next morning. That clued me into something not being right. Huh? There wasn't an email informing me that charging had begun. That's because it hadn't. Who knew that notify feature would come in so handy. Needless to say, I rushed out to start it then. At least some recharging could take place before I left for work.

- 11-06-2012 Hyundai & Kia.** Turns out, their values reported to the EPA and displayed on their window-stickers were inflated. Roughly 900,000 customers will now need to be reimbursed for having been misled about the efficiency estimate. With so much emphasis on delivering 40 MPG Highway, then finding out it wasn't actually true, you have to wonder how the market will react. For that matter, what will it do for resale values. It could be harmful to new sales as well. Hmm? It's an unusual & unfortunate situation. Those numbers not being accurate could become quite a problem. After all, even when they are some people take issue. Too bad this happened. But then again, it's better to find out before the number of owners affected became any larger.
- 11-06-2012 Cheap Gas.** When one of the biggest antagonists of Prius argues that gas is cheap, you know it's an attempt to stir trouble. With respect to inflation, that is true. But we now drive much further than we did decades ago. With annual distances higher, we're paying more. We also have other expenses now that we didn't back then. Think about how much you spend on cell & data usage per month, neither of which existed decades ago. We have gaming & videos systems too, neither of which were part of the household expenses either. What about cable or satellite services? What about portable electronic devices? What about the frequency in which we eat out? In other words, considering the big picture makes a huge difference. And even when you do take that into consideration, how is it suppose to portray Prius as a poor purchase choice? Long story short, his posts were intended to provoke. Fortunately, his trolling bait pretty much went unnoticed. Few want to engage in arguments like that anymore. With so many hybrids & plug-ins entering the market, the rhetoric of the past doesn't draw much attention anymore.
- 11-06-2012 691,281 Sold.** That's how many Prius were purchased worldwide from the start of 2012 through October. (1,028,900 is the total number for all hybrids from Toyota.) Seeing a quantity that high changes everything. There's simply no way to have a constructive argument against Prius at this point. That's a decent size chunk of annual production, even for a large automaker. The effort to make the technology viable as an everyday choice has clearly paid off. The technology has proven reliable & affordable. It represents a paradigm shift about to take place. Justifying the business decisions becomes a sensible one, rather than the risk it had been perceived of in the past. We need to reduce emissions & consumption. Hybrids deliver that... the FULL type, anyway. I'm especially excited to be driving the proof that the transition to using plug-supplied electricity is no big deal. All the nonsense of the past is rapidly fading away. Consumers have embraced change. Yeah!

- 11-06-2012 Coldest Yet.** I captured another drive last week, but didn't get time to type up my notes... there was this election distraction, you know. This data was my coldest collected so far, still quite warm by Minnesota standards though. It was 29°F outside. At the 9.3 mile mark from the 17.2 mile morning commute, the engine shut off slowing down from 70 mph. The coolant temperature had got up to 166°F from that drive with EV-BOOST. That's plenty to provide heat for cabin warmth, which I wasn't actually using then. Heck, I haven't even started wearing my winter coat yet. Anywho, what I'm most interested in is the retention of heat while driving in EV mode. From 60 to 45 mph, with a variety of traffic & stops while the speed limit drops in 5 mph increments along the way, I drove along in smooth & silent bliss. At the 16.0 mile mark, the battery-pack was depleted and the engine started back up. The coolant temperature had dropped to 109°F. The engine only ran briefly, settling at 130°F as I pulled up to the usual spot in the parking ramp using only electricity (EV in HV, also known as Stealth mode). The final result was 153 MPG. That's still pretty darn good. When the real cold arrives, then things will get interesting.
- 11-07-2012 With Heater.** Today's drive took on a different approach. Even though it's still to warm for the heater yet (40°F this morning), I wanted to see how much of an influence it would have on coolant temperature in the mild conditions. So, I turned it on with a setting of 75°F and the fan on low with blower settings for window & foot. At the usual 9.3 mile mark, upon switching from EV-BOOST to EV mode, the engine had heated up the coolant to 157°F. That's a little below the 166°F expected without the heater on. At the 13.4 mile mark, the coolant temperature was just about to drop to 114°F degrees. Since I was quite warm, didn't want the engine to start up, and there was still 3.1 miles of EV remaining, I shut off the heater. To my delight, I arrived at the usual parking spot with 0.1 EV still. That was sweet! At a total distance of 16.7 miles, the coolant had dropped to 100°F. The result was an average of 184 MPG. Now I'm well prepared for seeing what happens when the daily high is well under the freezing point. Of course, the basis of comparison will be difficult... since driving conditions can change dramatically. I've seen MPG climb when up due to heavily snow congested traffic with my 2010. Now having plugged-supplied electricity available, Winter results will be very exciting to witness and a fascinating comparison with the 2010 data I collected along that same commute, also with grille blocking.

- 11-09-2012** **Fast Commute, But Cold.** Having documented many aspects of plug-in Prius driving on paper, it's now time to get share some info in video format... complete with both dashboard & scenery. Colder temperatures bring lower efficiency, for all vehicles. Prius is no exception to that. Air & Tire resistance increase. Gas is switched to winter formula. Combustion itself produces less power. You've got a variety of easily overlooked influencing factors easily overlooked. And that's just Fall. When Winter arrives, traffic is slowed by snow & ice to make your MPG drop even more. This particular commute with my plug-in Prius nicely shows how my drive to work in Summer, which had resulted in the low 200's for MPG, now only gets around 150. It gives you an interesting dose of perspective. That's still quite remarkable. Watch the video closely. Notice how that even at 70 mph, most of the time MPG stays over 100 once the engine is warmed up. That's what owners have termed as EV-BOOST mode. Even though gas is consumed, the quantity is much less than from a hybrid without plug-supplied electricity. At the conclusion of the commute, you can see the average resulting from the 16.7 miles of driving on that 37°F morning was 143 MPG. You can watch the video here: [Prius PHV - Fast Commute To](#)
- 11-10-2012** **Questions Like This.** The introduction of a model with a plug has really stirred curiosity. Some researching Prius PHV have no idea what to expect. This particular question today got me: *"Do I need to drive below 62 to get the benefit of the PIP? Or can I set the cruise at 70 and still get some value out of it?"* I just happened to film a recent video providing the answer to exactly that. So, I was especially excited to respond. I provided a link along with: I sure am glad that only comes up as a random question, rather than becoming a chronic misconception. Phew! Watching that video I captured of a random commute last week, you can clearly see the benefit at 70 mph. That mode is what we've coined EV-BOOST, where there is an obvious benefit from the plug-supplied electricity even though you are traveling faster than the electric-only limit.
- 11-11-2012** **Growing Interest.** Colder weather sure is stirring discussions online. We're all quite curious how the plug-in model will respond to the conditions. Getting countless posts from new c and v owners experiencing low temperatures for the first time makes patient a challenge. We look forward to owners sharing their experiences. Anywho, this was my contribution to the growing interest today: The cold season is quickly becoming a fascinating topic for me. Today started with the Prius sitting outside all night, in temperatures below freezing and no plug. It warmed up a little, so the precipitation was rain rather than snow. Good thing too; otherwise, it would have been several inches. As the temperature dropped, it did indeed change to the white fluffy stuff. Fortunately, that was short lived. My morning drive was just ordinary HV mode. After lunch, I got a chance to recharge. With the temperature at 27°F, running around town was a mix of EV and HV. Being able to choose when, is nice. You have to remember to shut off the heater when you park though. Otherwise, you only have 7 seconds after starting to. If you don't, the engine fires up. But then again, it's cold enough to need the heater anyway. The total distance today was 45 miles. The resulting average was 59 MPG. To my delight, the EV distance was 12 miles. When the engine runs, excess power is directed to the generator. The result is more electricity available when driving. So, it looks like the loss of capacity due to the cold is made up for by the need to run the engine. I'm quite pleased with the results. Now I'm especially curious to find out what my commute brings in the winter. Being able to recharge at work will deliver remarkable efficiency, despite the cold.

11-12-2012 Real Winter Driving. I started a new thread on the big Prius forum. This was the past: For those of you where the daily high doesn't get above freezing (32°F, 0°C), this is the thread to share your plug-in experiences. That's real winter, especially since the chemistry of lithium batteries reacts different than it does when temperatures are above freezing. 22°F was what I was greeted with this morning, along with a fresh blanket of snow concealing a slippery layer of fresh ice. It was the first true taste of winter for me with the Prius PHV. Jumping onto the 70 mph highway was as expected. When I pushed the button to start up the blower on the windshield, the engine fired up. Naturally, it took longer to warm up. But the speed of which was very similar to my 2010, but with much higher MPG. At the 9-mile mark just before the speed limit drops to 55 mph, the traffic had come to a crawl. The Prius simply switched to EV mode as I approached. To my surprise, the engine fired back up when the coolant dropped to 145°F from the 159°F it has been at 70 mph. My guess is the battery-pack was still wasn't fully warmed up yet. Normally, it stays off until 114°F when ECO is engaged. I shut off the defroster, which caused the engine to immediately shut off. To my delight, the light warm blowing you get with the system "off" was plenty to prevent the need to use the heater itself. That was great, since I chose to get off the highway to take a back route the rest of the way. EV was available until I ran out of electricity, which I took full advantage of. The windshield stayed clear for about 15 minutes. When I got stuck in the next traffic back up, there was only 0.4 mile of EV remaining. So, I pressed the HV/EV button to warm the coolant and recharge the battery-pack a bit. That worked out well. My commute that would normally take about 25 minutes was looking to take over an hour. Blah. Upon reaching the ramp and avoiding the slip & slide activity others around me had engaged in, I was delighted to see an outcome of 104 MPG. It was a very good first winter driving experience with the plug-in.

11-12-2012 The Drive Home. It was intriguing. Most of the snow & ice had melted, but the temperature had dropped to 27°F. I left the ramp and drove about 2 miles in EV mode. That totally defied what antagonists had claimed was possible, which I found quite pleasing. At the base of a very steep and very long hill, it was a great opportunity to take advantage of the engine. So, I did. When the coolant hit 119°F, the EV/HV button I had pressed to start the engine was pressed again to indicate I wanted to go back to EV as soon as warm-up was complete. The engine shut off immediately. Huh? I had expected the engine to continue running until the coolant hit 130°F. I'm not sure why it stopped sooner. No complaints about that though. The remaining drive was about 1.5 miles, all in EV with the seat-heater on high. My shopping was lengthy, around 35 minutes. The coolant had dropped to 71°F. The next destination was about 1 mile from there, including a steep uphill climb. This time, the decision was to see what the EV would deliver. Sure enough, got there using only electricity. The next destination was also with EV, the coolant temperature now at 64°F. Next at 58°F, it too was all EV. Now at 55°F, the hope to remain in EV was effortless. It drives very well in the cold. That was impressive to experience. I finished shopping. It was a long drive to the highway, wanting to travel with only EV until the battery-pack was depleted. Sure enough, I ended up getting over 10 miles of all EV driving. That was sweet, especially since the outside temperature had dropped to 25°F and the coolant only 31°F. It was a very nice introduction to real winter driving. The total journey was 40.5 miles. It consisted of 2 full recharges. The overall average came to 85 MPG.

11-13-2012 Heater Dance. I filmed another of my drives. This one was especially interesting. With the temperature at 24°F, resistance was futile. I couldn't let the opportunity slip away. I had to capture a drive on video that documented what happens when you start with a cold engine and drive the entire time with the heater on the generous side. The filming setup was a challenge, of course. I had to avoid blocking the vents to keep the windshield clear. I also had a new mount for the dashboard camera and a new Wi-Fi transmitter for the scenery camera. Both had problems along the way too. But there's no stopping once you start. You only get one chance and just hope for the best. Next time, I'll be better prepared. This time was intended to be practice. Luckily, the video turned out well enough to share anyway. Watch the instant MPG readout next to the speedometer. Once the system (heater & emission) is fully warmed, the engine shuts off and EV mode automatically engages. With the heater temperature set to 75°F and the blower set to medium for both windshield & feet, the ice cold coolant would take several minutes to warm. Following that, I was able to drive along in EV mode. Later, the system automatically switched to HV mode to produce more heat while also assisting with propulsion and generating some electricity. Watch for that; the MPG will drop below 100 briefly. Those engine on/off cycle happens several times throughout the drive to the coffeeshop and back. This is the same route I filmed several times with the 2010 Prius. Now using the plug-in, even under these terribly inefficient driving conditions you can easily see how the extra electricity really boosts efficiency. The 17.9-mile drive resulted in an overall average of 92 MPG, with 0.9 mile of EV still remaining. Normally, I wouldn't have the heater running as much and I'd take advantage of the heated seat. That will allow for higher efficiency, since the engine would run less often. But for the sake of demonstrating ordinary circumstances without any question of comfort, I didn't. After all, passengers in back don't have seat heating available. This is a link to the video: [Prius PHV - Heater Dance](#)

11-13-2012 C-Max Energi. Today, an article named it: "*Ford's High-Tech Prius Killer*". Coming from a financial publication rather than automotive, a title like that does make you curious what they had to say. Turns out, it was very little. Price of the vehicles and battery-capacities was all that was mentioned. You were given the impression Ford was somehow able to squeeze more miles out of the same physically sized pack. Leaving out vital information is called misleading. From what was printed, it would be extremely easy to believe there wasn't an interior difference. In person, you'd immediately notice they aren't even close. The larger battery-capacity comes from sacrificing a flat cargo area, a feature Prius PHV did not. The other blatant omission was the efficiency following depletion. There's a clear difference between 43 MPG and 50 MPG. C-Max Energi's value being some much lower comes from its extra 734 pounds, which obviously wasn't mentioned either. The writer stated just the particular facts he wanted to convey. In fact, only the tax-credit for Ford was included, without a peep about one for Toyota. It was quite frustrating to read. Oh well. Greenwashing about actual green vehicles is certainly better than in the past.

- 11-14-2012 Warm-Up Reminder.** Engine warm-up completes at 130°F when in EV mode. That's helpful to know after a hard acceleration. It seems like forever when having done that with a cold engine. But with the gauge, you can see exactly when it will shut off. It's just a matter of observing the coolant temperature. With a hot engine, you take advantage of the fact that it will shut off immediately upon completing a hard acceleration. Without seeing that value, it's easy to imagine new owners being really mystified as to what the system is actually doing... especially when heater demands in the Winter add to the demand for heat. The elegantly simple complexity of the design seems like an oxymoron, until someone points out what is actually happening. But even then, sometimes you need a reminder of the detail. After all, following depletion, the heater threshold changes from 145°F to 114°F depending upon whether or not you use ECO mode. That button makes a difference in the cold season. Forgetting to use it means more engine warm-up.
- 11-15-2012 Repeating History.** As the third year of Two-Mode sales began, it was quite obvious the affordability goal had been forfeited by other aspects of the design which exceeded actual need. That's how the "*trophy mentality*" originated. We saw the same obsession with awards misguide the intentions with Volt... which is now about to begin its third year of sales. Needless to say, that isn't going as planned. So, we get a new set of priorities from GM. This includes a completely different attitude toward the EV and a very confusing message about the future of eAssist (the second generation of BAS). It doesn't tell us anything about Two-Mode either. In fact, it was the same old lack of detail as in the past... the very same approach that led to all the unfounded hope and following disenchantment with Volt. No clarity. What a mess. After 5 pages of observation on the big GM forum, I finally chimed in with this: Notice how references are quite vague, using labels that identify a specific characteristic but don't actually take real-world driving into account? That's been the trap for many years. We place attention on marketing an idea rather than address need. Even the title of the article itself does that: "*GM will focus on plug-ins and EVs, but not hybrids.*" With so many different varieties of hybrid, what does that really mean? In the most generic sense, you could just say that indicates the only high-efficient GM will offer will include a plug. That doesn't make sense when you consider what Ford & Toyota offer though. There's obviously more at play than just a plug, but no detail is provided. It's the same old lack of clarity as in the past. Reading that GM expects to sell 500,000 vehicles with a battery-pack annually by 2017 makes you wonder what the strategy really is. It seems in conflict with the focus statement. What should we be expecting?

11-16-2012 **Understanding EV.** When the engine runs for power or heat, it confuses those trying to understand how the EV works. I filmed again. The result was over 13 miles of EV. But that wasn't the point, hence providing detail on video... It was my morning commute taking the route along the river, starting with a cold engine and a battery-pack near full. The temperature was 25°F outside, but in true Minnesota style I saw no need for the heater. My winter jacket did the trick, even with the windows cracked to prevent fogging. There wasn't a need to turn on the heated seat either. I was comfortable, gloveless and driving an iced coffee. The engine stayed off until I wanted it to start. Toggling the HV/EV button when turning onto the 50 mph section works best. With a 17.3 mile drive that route, there isn't enough battery to travel entirely EV anyway. And of course, there's the nice benefit of EV replenish resulting from the engine running to produce thrust & heat. Anywho, you get familiar with you commute after awhile, so the what to do when becomes rather mindless. So, pushing the button again while on the ramp to merge onto the 55 mph is a rather routine thing to do too. And I did, saving electricity for when it could be better utilized. I ran out of EV as I entered the parking ramp. That was perfect, since power demand was low enough for Stealth mode to get me to my spot, still driving with only electricity. You can see it automatically switch in the video too. Despite the cold temperature, the resulting average was 204 MPG. Using the heater, efficiency still would have been in the 100's. No complaints about that. The plug is delivering a significant boost, exactly as it was designed to. Here's a link to see it: [Prius PHV - Along The River \(25F\)](#)

11-16-2012 **Failure.** With so much hype, propaganda, and spin online, there won't be anything new labeled as "*failure*" anymore. Instead, attention is simply focused on the next best thing. Two-Mode is the great recent example. When sales were so bad no one even wanted to talk about the situation anymore, Volt ended up getting the spotlight from GM supporters. From those just wanting to support domestic automakers, they stopped caring about Volt... hence all the attention C-Max Energi is now getting. It's an ugly reality watching goals be missed. We all know the goal is to replace traditional vehicle production. Sadly though, lots of bragging about capacity & speed still happens along with providing countless excuses. Addressing want rather than need is a fundamental problem contributing to the mess. In the day of Edsel, the industry and world market was very different. We can no longer afford massive investments to not provide a substantial return.

- 11-17-2012** **Same Old Nonsense, part 1.** Want verses need has been the problem for many, many years. When someone supporting a solution for the masses states a model is required to fulfill minimums, enthusiasts panic in fear that somehow the model they support which exceeds those minimums will be taken away. It's the same old response every time. They make vague references to goals and limit scope to draw conclusions. That's why history keeps repeating. The reality of the situation is that middle-market consumers don't always buy the high-end model. Given the choice, they tend to purchase the one offering a balance of priorities for an affordable price. Knowing that, the one-size-fits-all approach from GM limits sales. The only configuration of Two-Mode we got was one that focused on requirements in excess of the mainstream. Plans were made to offer choice, but nothing was ever delivered. So, focus has shifted over to Voltec instead. Same problem. Why aren't we given any choices, like battery-capacity or engine & motor sizes? Both Ford & Toyota offer that. Product diversity is a key component to business success. Why is there so much resistance to that from enthusiasts? They keep telling us the absolute of electric-only is essential. That doesn't make sense when the intent is to reduce gas consumption, not eliminate it. You offer the choice to consumers... which brings us back to asking what the topic of "*not hybrid*" actually means.
- 11-17-2012** **Same Old Nonsense, part 2.** It's quite eye-opening to confirm someone really doesn't know the difference between want and need, after all these years. That's greenwashing at its best, when they have no idea they've been mislead. Anywho, pushing for detail is how to find out. Supposedly, the 0 to 60 acceleration requirement is 8 seconds. According to who? All those vehicles taking longer certainly aren't causing accidents. If so, the slower acceleration wouldn't be fulfilling a necessity. Clearly, the rate is fine. The enthusiast wants more. It isn't a need. The same thing happened years ago when 10 seconds was supposedly required. Then when the new Prius delivered that, they changed the requirement... even though there was nothing to prove faster was essential. Fear often contributes to the nonsense. Popularity of a new vehicle that's slower threatens the loss of what they desire. They can still have what they want, as long as they are willing to pay. You can still buy a guzzler. The choice hasn't been eliminated, it was expanded. That's what we want from a vehicle like Volt. Where's the model that's actually affordable? One with a smaller battery-pack to lower cost while also offering more space in back makes sense. Yet, they deny it.
- 11-19-2012** **New Photos.** I'm finally starting to get caught up on publishing photos. With the temperature dropping, having a basis of comparison available to refer back to will be helpful. A few days ago, the temperature on my morning commute was down to 25°F. That's a sign of undeniable change. Efficiency dropped to 204 MPG. Eek! Fortunately, the stimulus for working on photos came today. With the temperature back up 48°F, results of that same drive were considerably better: 328 MPG. That's still way off from what I was getting excited about seeing routinely throughout Summer, but there's certainly nothing to complain about. Winter lowers efficiency of all vehicles. Prius PHV is no exception. You sure develop a heightened level of anticipation for Spring having a plug though, elevated more so than with a regular Prius. In the meantime, I'll be watching it get colder and colder. There's much to stir excitement about that too. Being among the first to witness how the system copes with temperatures well below freezing is rewarding. You get to participate in history rather than just reading about it later. In my case, I'll be contributing photos to document those observations. See... [photo album 179](#)
[photo album 180](#)

- 11-20-2012 Observing EV.** Having missed summer opportunities to film my commute to work and it already snowed the week before, I jumped on the unusually warm fall day (48°F) to capture it with the plug-in Prius. This is the same route as many other videos. With the 2010, it was exclusively HV mode. With the 2012 PHV, there is the choice to switch to HV in the middle when it potentially could yield higher results. Instead, the plan was to take advantage of EV mode until it was depleted entirely. Remember, when in HV mode you still have electric-only drive available. It just isn't as powerful or as fast as when in EV mode. That means the slow part of your drive near the ending can still be without gas. Also, don't forget that the system is configured with maximum emission reduction as primary priority, not the highest efficiency. I was especially happy with the camera setup this time. The quality of the dashboard image has been improved. The soft lighting during most of the drive and the sun emerging at the ending just happened to be well timed too. Anywho, the 17.2 mile drive was 14 miles of EV with the remaining in HV. The result was an overall average of 328 MPG. That's about 3.0 kWh of electricity (including charging losses) and about 0.01 gallon of gas. Watch it here: [Prius PHV - Along The River \(EV\)](#)
- 11-21-2012 Failing.** Back when Volt was first rolled out, saying anything not complimentary was looked upon as a "fail" assessment. Enthusiasts were paranoid. Supporters replied with excuses. Since then, the enthusiasts have vanished. All that's left are supporters... who are still making excuses rather than adhering to their very own comments made this time last year. That's obviously hypocritical to disregard their own comments. But they twist it to make your own stick-to-the-same-priorities sound like inability to be flexible. Isn't it great how they find a way to spin just about everything? Anywho, I ended up stating this: That "*over promise, under deliver*" strikes again. It shouldn't have declared to be a "*game changer*". Expectations were set for mainstream sales volume in the second year. That wasn't realistic considering the state of the market and the production cost. There's also the 500 million shares of GM the federal government would like to sell back without a large loss. Looked upon as a niche, Volt is doing fine. There isn't a minimum required to become business-sustaining and using tax incentives are fine. It's that jump to middle-market consumers which presents the challenge still being faced. The heavy emphasis on monthly sales continues to contribute to the problem too. Enthusiasts don't really like to address what it takes to be profitable or actual need. The focus continues to be on want.
- 11-21-2012 103 F Degrees.** The engine didn't restart until coolant temperature dropped to 103°F. That was a bit of a surprise. Why? Normally in ECO mode the threshold is 114°F. But then again, this Prius is configured to work different anyway, to take advantage of electric-only opportunities. So now that it's Winter, I'll be keeping close attention to spot differences. It won't be long before the morning commute is routinely well below freezing. That's when the retention of heat, assisted by blocking the grille, makes a difference. When that coolant heat runs out, the engine needs to run temporarily warm coolant back up to keep you warm.

- 11-22-2012** **Leaf Sightings.** There's one in the neighborhood now. I just barely missed an encounter at the local gas station today. Ironically, that's a rather unlikely location for a meeting... since he'll never purchase any gas there. Someday, perhaps. Of course, the odds aren't good my PHV will get noticed. The visual clues about it being a Prius with a plug are quite subtle. But at some point, people will become aware and start looking. Leaf owners will probably develop a heightened awareness... since it's so lonely right now. Hopefully, that will change quite a bit next year. Then, I'll have to deal with charging-stations actually being full and actually try the "*ok to plug when complete*" sharing.
- 11-23-2012** **Forget The Past.** The purpose of participating in discussions on the unfriendly forums was to get information no other source could provide. In other words, it was the pursuit of argument points. Knowing their perceived shortcomings are quite valuable, since lack of substance is the downfall. They inevitably reveal weakness. So, you put up with their nonsense. Simple things like refusing to provide detail or answer questions are a dead giveaway of trouble... which is nice, since online participation is so much harder to determine intent compared to the articles with bias that's quite blatant. They avoid the obvious by doing things like asking questions of their own, diverting focus. Problem is, that's self-defeating. They can conveniently forget the past, but others won't. Repetition only works a few times before you lose the audience... which is precisely what we're seeing now. The antagonists are the only ones left. No more enthusiasts participate. The true supporters are long gone. They know the history of the topic itself as well as the history of those discussions. Debates have ended. Hype is gone. The next chapter has begun.
- 11-23-2012** **Keeping Warm.** The topic of heat and Winter efficiency certainly is stirring a lot of discussion. There's so much to cover and each new plug-in Prius owner has a different perspective, due to location and duration of ownership. So, it's difficult to know what to contribute. These were my ramblings today: Colder temperatures are definitely affecting my engine warm-up (as expected), but the EV driving is still as it was, down into the 40's anyway. Of course, up in the 80's it actually exceeded what I had experienced during normal morning commutes. We know that lithium chemistry responds differently in conditions below freezing. Resistance is quite a bit higher. So, there is no expectation of consistency then. 20% (of an overall capacity loss) seems fairly realistic. Of course, running the engine for cabin & emission warm-up results in battery warming in addition to battery charging... making it quite a challenge to quantify. Then there's the reality of headlight & seat-heater electricity consumption that wouldn't normally happen in warmer temperatures.
- 11-23-2012** **Cold Shopping.** My adventures into the holiday chaos started with lunch with my Sister, waiting was preferred. I simply wasn't interested in "Black Friday" craziness first thing in the morning. Fortunately, some bargains could be found later in the day anyway, which I did in fact do some shopping for. Driving from store to store in the cold would normally be unheard of, when an engine starts. Why would you move for such short distances? Since I could take advantage of the opportunities EV offers, that was different. All of my running around to eat & shop was entirely with electricity, despite temperatures in the low 20's. Having a heated seat helps. I wouldn't actually want to do that without. It was pretty sweet. That changes your attitude toward errands. Short trips into town to get this & that complimented by 999 MPG even in Winter sure is nice.

- 11-24-2012** **Fabricating Fiction.** Reading comments about articles on general audience publications stirs up lots of disturbing statements. This one caught my attention today: "*I talked with a tow truck driver and he said a lot of his calls are for the Prius which has a lot of failure of the main battery, which is an expensive thing.*" Funny how I've never encountered that, eh? You have no idea who any of the people involved are. You just know they felt compelled to post a negative comment without any data to actually support it. Fabricated fiction from the desire to undermine is nothing new. It happens all the time. Sadly, some very well known advocates of Volt do the same thing: "*Toyota hates the fact that battery plug-ins are catching on and they have to diversify away from their big hybrid only investments.*" The particular individual who posted that felt in was necessary to mislead, not liking the plug-in Prius. The hope is people will believe the model offering a plug is profoundly different, that Toyota hadn't planned ahead and incorporated everything into the regular Prius already. Only needing a larger capacity battery-pack and a charger confirms the investment was well thought out. Claims like these are what makes me feel good about the FULL hybrid approach. It has proven a wise choice.
- 11-25-2012** **Summer EV.** The seasonal effect is something EV drivers have been aware of for ages. The thought to point that out to the new audience we now have here was forgotten. I observed it firsthand many times throughout Summer. Now with Winter approaching, it's easy to see the difference. The increased capacity during the warm season was something I intentionally delayed getting on video, wanting to avoid giving a misleading impression of expected performance. That's a big reason I waited until the cold season returned to begin filming. If people are pleased with what they observe under demanding circumstances, they'll be thrilled later to discover it gets even better later. That's also a great way to endorse the technology. Way back in 2000, my Prius experienced the second coldest & snowiest December in Minnesota recorded history. Documenting details of those driving experiences proved quite valuable when rollout expanded. The hope is that very same thing will happen with the plug-in model. Having studied the design for over a decade and now driving it, there are particular normal behaviors that those new to plug-in technology could easily assume incorrectly about. We need to make sure to be explicit and routinely provide exposition to have prevent that. This is a perfect example of where that effort will be helpful.
- 11-25-2012** **Greenwashing.** The madness will go on and on. That's inevitable when it comes to being in a competitive market with much to be lost. This is the latest: "*GM is moving beyond hybrid technology as they already have with the Voltec system in a bit of a that-was-then this-is-now maneuver.*" That comment came from a staunch supporter who is well aware of the inability for GM to compete directly with hybrids from Ford & Toyota. Their hybrid system is too expensive and neither as efficient nor as clean. So, the decision was made to focus primarily on plug-in offerings instead. That's an interesting business risk. What do you sell to the many consumers who simply don't have access to a plug? It's a very real problem the lack of diversity doesn't address. I see the comment as effort to not tell the whole story, in other words, greenwashing. Here's how I responded: Having both an engine and at least one electric motor makes it a hybrid, period. The reality of the situation is how much that electric motor is utilized in contrast to the engine, which is being used in an increasingly efficient matter. It's not an absolute as marketing attempts to convey.

- 11-26-2012** **Agonizing.** In the old days, if you said anything that didn't shed a positive light on a competitor, the "*fanboy*" label was used. That's ancient history now. Under the same conditions, at least when discussing GM, you are given a "*hater*" label. It's quite disturbing how often that label gets used in forums and on article comments. Then of course, if you favor an automaker like Toyota, they start waving the flag. That's looked upon as "*bashing America*", even though the result is lots of employment here. Sadly, a certain few have even begun accusations of communism. It's all quite disturbing. But with Volt about to begin its third year of sales and volume still under the profitable level, the situation is increasing pressure on supporters. We all know numbers not meeting expectations results in losses. We all know the clock is ticking on the tax-credit too. To make matters worse, there's a wave of plug-in hybrids about to steal the spotlight. Ford's rollout is well on its way. Toyota will soon expand to nationwide availability. Sometime in the first half of next year, Honda will make its debut. All hybrid sellers already, they really stir emotion when compared to what GM has to offer. That ends up being agonizing for everyone. You either get labeled or you have to deal with the pressure.
- 11-26-2012** **25 MPG.** One strategy for dealing with the continued success of Prius is to force it into another perspective. With the plug-in model, certain people (you know who they are) always compare it to an EV. Why? That doesn't even make sense, nor was that ever the intention. The approach we've seen all along is to expand upon efficiency opportunities with an electric motor. That ability to drive alone through the suburbs with the engine off has been available since the very beginning. Back then, the distance & speed was limited. Over the years, both have increased. That wasn't the exclusive means of achieving high MPG results though. Running the engine at a lower RPM by having the motor provide propulsion power too was always a fundamental aspect of the design. Now that the engine RPM can be 0 more often, somehow that makes it a poor EV. Since when was that ever a goal? Never has an absolute of no gas ever been proclaimed. Reduction has been the intention, not elimination. This is especially important when you consider the means to which some electricity is derived. That source can be rather dirty. Continuing to improve upon engine efficiency as well as using renewable carbon-neutral low emission fuel makes sense. Anywho, the goal for the first plug-in Prius was to significantly improve efficiency without clean compromises. Seeing that achieved with the anticipated average of roughly 25 MPG better is quite vindicating... hence so much antagonistic response from those supporting other solutions... you know who they are.
- 11-27-2012** **Discovery.** This morning's commute appears to have revealed a correlation between the heater setting and coolant threshold. They seem to be tied directly, the lower the temperature on the heater, the lower the temperature on the coolant. In other words, a setting of "*HI*" will trigger the engine to startup when it drops to about 145°F but "*72*" not until around 121°F. I tested theory this by adjusting it to "*65*" and observed the engine staying off until 114°F. The end result of my 16.7 mile commute (taking the 70 mph route) today was 137 MPG with 1.8 mile of EV remaining. I'm looking forward to seeing what the commute will reveal when the heater is set to "*65*" for the entire drive. Note that on the regular model of Prius (my 2010), I never observed this. The threshold for engine startup was always 114°F in ECO mode and 145°F in Normal. It tends to make sense with EV that there's a sliding scale to make the heating smoother, since the duration between engine running could significantly longer than with a Prius only offering HV.

- 11-28-2012** **No Hybrids.** The endless debates continue. This was the latest contribution to that: There's a large product-gap between eAssist and Volt. No amount of rhetoric will change that. This thread is about GM's choice to not fill it. As we've seen with the plug-in Prius, it's feasible to significantly boost MPG through the use of a modest-sized air-cooled battery-pack hybrid efficiency even after depletion. That makes it a configuration capable of high-volume sales and business-sustaining profit. Reading the article, there's nothing mentioned about how the 500,000 per year goal will be achieved or even any expectation of what the distribution will be. With other automakers pursuing that gap, it seems quite a risk for GM to dismiss it. As the cost of lithium batteries drops and the tax-credit expires, the choice of a small & simple system with a plug for the masses won't be argued anymore. In the meantime, we still have to deal with those claiming the superiority of a system which didn't take the priority of being affordable seriously. That's really unfortunate.
- 11-29-2012** **Colder Operation.** The temperature continues to drop around the country. (It's actually been on the warm side here though.) So, online discussions about Prius operation in the cold are quite popular. With both owners of c and v experiencing Winter for the first time, there are quite a number of questions to address. It's all the same stuff we've heard countless times over the years. But to them, this is their first experience with a hybrid in the cold. The engine off behavior changes. Some is rather predicable. Some needs information to understand. All results in much improved MPG compared to what their previous vehicle would have delivered.
- 11-29-2012** **Accord Plug-In Hybrid.** Details were released today. This is Honda's first hybrid offering a second motor, making it more flexible than their ASSIST system with only one. Of course, we still don't know if it is a FULL hybrid though. That requires a power-split device, which allows a wide variety of energy flows that overcomes the limitation just a single motor/generator system can offer. Price was obviously the biggest curiosity. It will be available starting at \$39,780. Rollout will begin mid-January for 2 states, California and New York. National availability will be sometime later in the Summer. The EPA rating is 115 MPGe officially, which is the highest for any plug-in hybrid so far. As for depleted operation, the MPG estimate values are 47 city, 46 highway, and 46 combined. The EV range for the plug-in is rated at 13 miles, from the 6.7 kWh lithium battery-pack. It will feature a 137 hp 2.0 liter gas-engine connected to a 124 kW electric-motor. This will be the very first vehicle rated under the new LEV III standards too, earning a rating of SULEV20. The numerical part of that emission label represents the NMOG+NOx level. In this case, 0.020 gram/mile. Needless to say, the world of Volt having the spotlight exclusively is rapidly fading away.

- 11-30-2012** **Now Available.** It was quite a delight today to discover a dozen plug-in Prius delivered to a local dealer here in Minnesota. They're all 2012 models available for immediate purchase. I wasn't expecting them so early with the inevitable on set of Winter... which likely won't be a mild one here like last year. This being an area where Prius is quite popular year-round, endorsements from cold season driving go a long way too. So, it makes sense offering some here sooner. After all, some people have been waiting a very long time, not will to do an out-of-state then transport delivery as I did. Being available in December means they'd be able to claim the tax-credit right away. It provides a nice opportunity for a few lucky people to take advantage of. When Spring finally arrives, much of the rest of the country will hopefully have local availability too.
- 12-01-2012** **Buy Again.** Aren't surveys fun? Blah! Limited scope can give misleading impressions. That's why when the claim is vague... like when a percent is used rather than stating that actual count... you should be cautious. Don't accept claims at face value. Always do some research yourself to confirm. The recent example comes from a "*buy again*" ranking. Seeing that raised many questions from those of us wondering about the data itself. That's why I provide spreadsheets with raw numbers. You can draw conclusions on your own, rather than just accept the summaries as is. Anywho, this is how I responded to it on the big GM forum. Greenwashing through the use of percentages is why supporters back away when detail is requested. Volt sure as heck better score high. With such an audience (smaller and quite specific), how could it not? With a vehicle like the small model of Prius, it targets totally different consumers... those who spend far less, yet still have some high priorities... like emissions, efficiency, and high reliability. There are far more of them too. Also, I get a kick out of how the "*buy again*" question limits choice. What if a number of small Prius owners choose to purchase a larger Prius instead? That would count as a "*no*" even though all they did was decide upon a different model.

12-01-2012 **Endless Bashing.** We've seen it all before. Only now, it's playing out in actual sales rather than rhetoric about what could be. Today, it was: "*You are now just bashing GM. The Volt is an excellent vehicle and if it had a Toyota badge you would probably be praising it.*" My jumping was with this summary: Keep in mind that there really is a production level that isn't profitable. Schedules are setup with suppliers & workers for specific volumes. Coming short of that results in a penalty. True, the "*I drove a Volt today*" experience can be a very positive one. After all, we know what EV delivers. An expensive vehicle with impressive abilities will always score high reviews, but cost tradeoffs come with consequences. GM campaigned fiercely against hybrids for years. The only choice now, expressed in their very own words is to "*leapfrog*" the competition. Unfortunately, that requires all the necessary ingredients all at the correct time... now! In other words, battery cost must be low and consumer demand high. That just plain is not the case. Volt could be considered ahead of its time. But as supporters wait, the competition advances, narrowing the gap. Disregarding hype of the past and having fallen short of goals, what is there? The approach GM took with Volt doesn't offer the flexibility Toyota took with Prius. We have clear examples of how engine, motor, and battery can be varied. That isn't feasible with Volt. Reduction of battery results in a power & efficiency loss, both of which put it at a disadvantage. In other words, GM top the top-down approach and Toyota took bottom-up. That fundamental difference is now playing out, proving the one is not as effective as the other with middle-market consumers. Ford will help to confirm this, since they also took bottom-up. Say all you want about GM bashing. In fact, the feedback can be quite informative. But in the end, it boils down to achieving business-sustaining profit.

12-01-2012 **76 MPH.** Concern about stress on the plug-in Prius battery-pack when accelerating onto a highway with a cold engine generated this from me: Drop the pedal to the floor some time. I was surprised to discover the "protect" mode had somewhat of an override. The engine still won't redline, which in itself is rather low at 5500 RPM. Instead, it shoots past the 1500 RPM ceiling and you end up getting around 2750 RPM. I hadn't expected that to cause jump to 76 mph with a cold engine. The speed limit is only 70 mph on that ramp just 3 blocks from my house. It goes to show you how well thought out the design really is... and how infrequently you actually need maximum acceleration. As for shortening your EV range, it won't happen if you're driving beyond a short distance. The system is designed to restore that used during warm-up by taking advantage of the efficiency the power-split-device offers. Remember, heat is required for maximum emission cleansing. That extra engine load while warming up ends up being a win-win situation.

- 12-02-2012 Trophy Mentality.** It's all that seems to be left now. Nothing else to draw interest to Volt, as it is currently configured, is a sign of the next stage approaching. Ultimately, a model that's actually competitive will need to be delivered. Bragging rights about MPG don't attract middle-market consumers. We know this well, as Prius owners. The antagonists claimed the standout look of Prius was why people bought it, not the improvement to emissions & efficiency. Their mindset is having something compelling to flaunt will generate lots of sales. That's the "*trophy mentality*". Rather than something offering a nice balance of priorities, as Prius does, it was a focus on desire. Reality is, the shape of Prius is remarkably practical. There was no other midsize hatchback available back when it debuted in 2003. That's what it got noticed. Combine that with the benefits of the hybrid system, you got yourself a winner... as long as it's affordable. That's the catch. High-Volume sales don't come from a trophy. The profit-makers have to be so common, they end up becoming part of the crowd... as Prius has.
- 12-03-2012 Excuses, Incentives, Expectations.** What do I think there could be for penalties of heavy discounting in the extreme short term? Since we heard every excuse imaginable by Volt supporters for year #1, the response could be the same... wait until year #2. Of course, now some of those same people are saying the next generation. I'd say there may not be any, since there really needs to be some extra effort to get the upfront people familiar with the differences between the regular and plug-in model. It's not like Volt, where there's nothing direct to compare to or mix up with. The differences are so easy to accept (the sign of a well planned out upgrade), it takes hands on experience from salespeople to understand & convey the benefit. It's surprising easy to miss vitals of design, since attention is often focused on other aspects of the purchase. After all, in the past people new to hybrids often didn't know what to ask. Now that's the case with plug-in hybrids... and the education of sales staff often gets overlooked by critics. Think about how easy it is for a salesperson to sell a regular model of Prius instead. Selling more of the plug-in to customers specifically wanting to jump on the opportunity to own one will help change that. Remember the initial success of Prius? Toyota was able to seek out those buyers back then. They targeted highly interested consumers, rather than doing a nationwide launch initially. GM hoped to follow in those same footsteps too. Trouble is, the market is profoundly different now. For Prius, there's countless online references already, making detail about the plug-in model very difficult to find. For Volt, the opportunity to educate was instead used to flaunt awards and brag about performance. Toyota isn't going to follow that path. They are now seeking out those with strong interest in the plug-in. Seeing a dozen 2012 models now quietly be delivered to one dealership in Minnesota seems to confirm that. Watch closely. As we get closer to Earth Day, the excitement will build. Year #2 for the plug-in Prius, which starts then, will be one to capitalize upon... no hype about an expensive approach like Volt. What Toyota offers is configured for the masses. The incentive to increase sales as year #1 comes to a close should help confirm it... just by the simple matter of seeing who actually takes advantage of the chance to buy. To be a penalty, purchases would be limited to enthusiasts. To be a true gain, purchases will be dominated by those from middle-market who would have otherwise just bought a regular model instead.

- 12-04-2012 Third Place.** GM has built up a huge inventory of pickups. Currently, there are 245,853 available. Many are supposedly the much-hyped new Silverado. This makes you question what priorities are. With Volt having slipped to third place for plug-in hybrids, supposedly due to inventory shortage, how can you not? 1,766 Prius PHV. 1,539 Leafs. 1,519 Volts. 1,259 C-Max Energi. Those totals for last month are stirring emotion on posts. Discussions don't stand a chance of being constructive anymore. Trouble is brewing. Toyota's approach of offering a balance of priorities gives the plug-in Prius a strong chance of becoming a self-sustaining choice, selling just like the other models. But since it's a package upgrade, sharing the same platform as the regular (no plug) model, there's less risk. That's good when you see how volatile traditional inventory management can be. Of course, the underlying cause of the pickup surplus may simply just be the shift away from guzzlers. But then again, enticing those downsizing from trucks to choose a hybrid car rather than a traditional car is a win-win situation. Why not capitalize on it? After all, GM has been missing lots of opportunity lately. Betting the farm on Volt wasn't a good plan.
- 12-05-2012 NiMH versus Li-Ion.** Some are beginning to question Toyota's decision not to simply move to lithium batteries for all their hybrids. The lack of diversity they've become accustomed to makes understanding the move to diversify a confusing one. It gives the impression of indecisiveness. In reality, it's just an ordinary advancement step we take for granted in other industries. It's quite normal to see that hardware stores for rechargeable devices. Why not with hybrids too? I replied to the thread discussing this topic with: It makes sense sticking with NiMH for maximum optimization. How else are they going to penetrate deep into the challenging sub-\$20k market? The benefit of storage space is nice, as is the minor bump in HV efficiency. But cost is paramount. We'll see availability of Li-Ion expand over time. Having it in two models of Prius already is undeniable proof that Toyota is real-world validating for next generation rollout potential. As for calling NiMH obsolete, that doesn't make sense considering how common Lead-Acid batteries are still. For that matter, there are still some rechargeable devices being sold with NiCad batteries. It boils down to production & sales. That's the ultimate perspective check. Expanding the product-line is what's getting the most resources now... in a market heavily dominated by non-hybrid vehicles.
- 12-06-2012 Cold Soak.** Did you know it's better for battery longevity to let it rest before recharging? Most people don't. Hopefully, some plug-in Prius owners just naturally contribute to it. Setting the timer to not start until later in the evening (to take advantage of lower electricity rates) will automatically accommodate that. EV owners don't have as much flexibility. For that matter, plug-in hybrids with large capacity batteries don't either. Only taking 2.5 hours from a 110-volt connection and 1.5 from a 220-volt, you've got it with PHV. For me at home, I've been having the recharge start via the time at 4:50 am. If I ever recharge there in the evening, I wait at least 2 hours first. That works really well. I typically have several hours of things to do anyway. While downtown at work, there's always a 5 to 6 hour delay. I walk over to the car on my afternoon break to plug in. That works out really well too, especially since I'm not taking up a charging-spot the entire day then. Be able to help stretch the longest possible life out of the pack doesn't take much more than being aware of what ages them. Providing rest time while depleted, called a "*cold soak*", contributes to longevity.

- 12-07-2012 New Expectations.** For over 3 years, we had to endure the purist hype. Then it slipped that there would indeed be a direct engine connection. The eruption of semantic arguing which followed made it clear nothing would be straight forward about the rollout. Sure enough, we got every excuse imaginable about not meeting goals... most notably sales. The revised Volt sales estimate for 2012 here provided at the start of this year was 45,000. Obviously, that's not going to happen. What should we be expecting for next year? Currently, the promotion of Volt is focusing solely on "*gas saved*" numbers. Compared to driving what? And why is there no mention whatsoever of either the quantity of electricity consumed or the resulting smog-related emissions? Leaving out vital detail is rather blatant greenwashing. With plug-in Prius rolling out to the rest of the country now and plug offerings from other automakers, the draw factors to Volt become even more of challenge. Appealing to middle-market isn't what the trophy-mentality supports. Mainstream consumers have a balance of purchase priorities. Again, what should we expect? Keep in mind there's a \$7,500 price gap which must be overcome before the tax-credit expires, just to maintain status quo. To become more than just a niche within GM's production, sales must increase significantly. Remember, the point is to offer a product which delivers business-sustaining profit.
- 12-07-2012 How We Got Here.** Remember all the nonsense we had to deal with in the past? Most people cannot, because they weren't watching the hybrid market in the first place. Those who do remember, don't realize it was over a decade ago. The years get mixed up quite easily. It started way back in 2000. The "*payback*" and "*nickel*" arguments we among the initial greenwashing campaigns. The antagonists pushed a "*treehugger*" point of view, casting Prius supporters as extremes. They fought hard to prevent mainstream acceptance. That transformed to an effort to inflate costs. Remember the "*Dust to Dust*" debacle? When finally debunked, there was a rather blatant attempt to invoke fear. It was unbelievable how determined some were to undermine the advancement of Prius. They were very upset about the progress being made. Downplay is the theme now. Holding back the entire market for the sake of making time for the competition to catch up likely won't work either. With the growth we've already seen from the new larger & smaller model and the upcoming nationwide rollout of the plug-in, that hope to convince people that Prius is just a passing niche is long gone. Not only is Prius mainstream, it is now being recognized as an example of the entire industry shifting away from traditional vehicles.

- 12-08-2012** **Addressing Inefficiencies.** This quote speaks for itself: *"I am growing concerned that EV advocates may choose to ignore vehicle inefficiencies simply because the power comes from a plug."* The problem goes back to our roots, using MPG to represent efficiency rather than stating the amount of gas actually consumed. Most of the rest of the world states their efficiency in terms of *"liters/100km"*. That informs you precisely how much fuel it took to travel that distance. MPG certainly doesn't. Anywho, I joined the discussion with: Listing the amount of kWh consumed hasn't been happening. The attitude that electricity is free & unlimited is working its way into the mindset of those praising EV. There is genuine reason to be concerned that we could simply be switching from one fuel to another rather than actually reducing emissions & consumption. Supporters of Volt cringe whenever the topic of Two-Mode is brought up... since even though it was indeed a hybrid, it still consumed large quantities of gas. The large *"HYBRID"* labels it flaunted was a great example of having put lipstick on a pig. Watching for references to *"gas saved"* reveals a lot where GM's priorities actually are. When other automakers promote their plug-in vehicles. Comparing gas consumption between Prius & Prius PHV or C-Max & C-Max Energi doesn't have as much of an impact as comparing Volt to the industry average. The real winners are those who address efficiency candidly and don't place speed & power among the highest priorities. We can pretend to be green or actually be it. There's a difference, details of which some attempt to withhold.
- 12-08-2012** **EPA Estimates.** How are fuel economy results actually validated? It's winter here now. With temperatures below freezing and slower travel due to snow & ice, the outcome will vary quite a bit. EPA is for the sake of comparison anyway, not an expectation. The wording on the window-sticker states a range, pointing out the large numbers are only an average. And how are measurements performed on rollers suppose to represent the real-world knowing roads that aren't absolutely flat or traffic free. For that matter, how is the weight of the vehicle itself taken into account. My driving yesterday, most on freshly fallen snow, came to a total of 65 miles. Using 6 kWh of electricity, combined with the regular Prius gas engine, the end result was 83 MPG. How is that information suppose to be considered? What kind of analysis should be used to confirm the automaker delivered what the consumer has chosen to purchase? How close must results be to be acceptable? With MPG becoming a high priority, the shortcomings in estimates of traditional vehicles are finally gaining attention... after years of careless disregard. Who needs to educate the market about the wide variety of efficiency-influencing factors and the differences in the types of hybrids being offered? So many questions. So few answers.

- 12-08-2012** **Price Importance.** I like how some people forget to look at the big picture: "At \$32,000, the Prius PHV isn't serving your middle-market either. That's nearly \$8000 more than the base Prius..." They get so focused on Prius itself, they forget to look at other vehicles being offered and the situation automakers will be facing. I tried to point out those missing aspects: \$30,000 has been and continues to be the middle-market target. When the tax-credit expires, that goal of delivering a plug-in hybrid with a nice balance of priorities isn't in danger. Being able to shave off \$2,000 for 2015 is within reason. We see Toyota striving to keep cost in check. They aren't making sacrifices for the sake of offering more capacity. So what if there are other models of Prius available with lower prices. The point is to increase choice. None of them offer a plug. Market expansion is realistic when MSRP is at a level comparable to what mainstream purchases already are. High-Volume sales don't come from complicated justifications of price. It's quite simple to see how swapping in a larger battery and adding a plug offers a MPG boost.
- 12-09-2012** **Plug Pricing.** Sometimes, there is consideration of the rest of the market with disregard to the different models of Prius. It's the reverse of the other problem, where they are now only looking at the big picture. Needless to say, discussions get confusing. The problem comes down to price of the option itself. Focus solely on the vehicle as a whole overlooks the actual components involved. The smaller NiMH battery-pack is exchanged with a much larger Li-Ion battery-pack. A plug, charger, and adapter are added to. I responded to the on-going discussion based upon vehicle sticker-price: None of that addresses cost of the option itself. You want leather and a moonroof, that upgrade isn't free. You want HUD and a nicer stereo, that upgrade isn't free. You want larger wheels and LED lights, that upgrade isn't free. Toyota's goal was always looked upon as a premium, the price you would be willing to pay for the upgrade. You want a larger battery and a plug, you have to pay for it. The cost of that has a target of \$3,000 to \$5,000. How is that not realistic? I cannot envision someone making a purchase decision between a near-luxury guzzler and a plug-in mainstream hybrid. They are far too different.
- 12-09-2012** **Prius Sales.** For last month in the United States, they were: 8,925 for the regular model; 3,124 for the c model; 2,690 for the v model, and 1,766 for the plug-in model. The story in Japan is quite different. Last month there, the c model (known as "Aqua") has sales of 26,346. That nearly ten times more... so much, it was the top-selling vehicle there in November. The regular model wasn't as good, but still quite impressive with 22,039 purchased. The tally for v weren't available. There was a number cited for Corolla though, at 6,121. Stepping to look at the overall counts for the year so far, there were 246,170 for c and 301,102 for the regular model (along with 75,701 for Corolla) in Japan. That paints another impression of market demand. But the fact that Prius is popular in general is quite obvious. Here, it's 134,967 for the regular model, 37,677 for v, 32,582 for c, and 11,389 for the plug-in. Knowing that c and the plug-in weren't available until later in the year is good to know, but not essential. Seeing the total here for Camry hybrid at 41,213 provides an idea of the progress that's been made.

- 12-09-2012** **More Photos.** Although I only have one to share today, there's more photos on the way. It was extremely snowy. What a mess! The top highway speed on that drive was 42 mph. Most of the time, I was only going about 30. Sometimes, it was in the low 20's. We got several inches of the wet nasty stuff. I was driving through what remained after initial clean-up. There were quite a few accidents. Most come from people driving much too fast for the conditions. Slowing down is not rewarding for them like it is in a Prius. Today provided a fantastic example. I wasn't able to recharge before setting out on that adventure. It was 23.9 miles of very Wintery driving in a plug-in with a depleted battery-pack. That meant nothing but ordinary hybrid driving the entire way. The result was amazing, especially when you take into account the heater was running the entire time. 52 MPG is definitely worthy of a photo. I did indeed get one to document that event too. Here it is... [photo album 179](#)
- 12-10-2012** **Winter Arrived.** It is definitely here. We got about 8 inches of snow. Other parts of the cities saw as much as 14 inches. This morning's commute was a terribly slow one, with a temperature of 16°F outside. Traffic on the 70 mph highway was moving at around 35 mph. In the section where it slows down to 55 mph for the river crossing, vehicles were crawling along at just 9 mph. I was loving every minute of it. Upon encountering that stop & slow, there was 6.0 miles of EV remaining. I cracked the windows, reduced the fan speed, and opened the vent. With the interior already warmed up, the thought of turning on the heated-seat had even crossed my mind until 15 minutes into the electric-only bliss. To my delight, I made it all the way to the parking ramp without the engine starting up. I did have the seat on high for warmth though. I also wondered if the primary ingredient for keeping the windshield clear is a matter of air circulation, much more so than the humidity itself. A simple small fan should reveal that answer. Anywho, the result of that 16.8 mile snowy commute was 143 MPG with 0.1 mile of EV remaining.
- 12-10-2012** **Recharging In Snow.** Today was the first opportunity with more than just a dusting of snow. Since I had already recharged in the rain, this plugging in was no big deal. But like other events, documenting when is worth the effort. Those flurries turned into measurable accumulation too. The awning that was hoped to be installed at the ramp last month didn't happen yet. The 2 additional charging-stations weren't either. But now the plan is for 4 more. Cool! In the meantime, there's brushing involved. I have to sweep off the snow when I'm ready to leave work for home. This particular commute from work was going to be one quite worthy of documenting too. The uncertainty of how nasty the drive would actually be had everyone concerned. I was too. But not having the burden of wasting gas sitting there in hopelessly slow traffic is nice. It stops and you have no idea when it will begin again or how long it will actually take to travel even just a short span of road. For that matter, you don't know how easy it will be to drive along the road itself. There's usually not the fear of getting stuck, though sometimes that does happen at challenging junctions. The worry comes when the need arises for a sudden stop. Anywho, it all starts with a recharge. This time, it was while lots of new snow feel.

- 12-10-2012 Winter Extremes.** The commute home was a slow one. The temperature had dropped. The road to the highway was covered with an inch thick of ice. The city has a machine to cut notches in it to accelerate melting. That short-term result is a nasty washboard to drive over, riddled with large indentures. Everyone was going slow as a result. Of course, the slick spots on the highway were good reason to avoid speed as well. With the outside only at 5°F, use of the heater was constant the entire drive home. To my surprise, the climb out of the valley from the river was almost entirely with electricity. The coolant had warmed up enough for EV, but I had no idea how long it would last or if the battery was fully warmed up yet. Very close to the top, the engine started back up. It shut off fairly quick and traffic was only moving along at about 50 mph. So, I just let it stay that way until depletion. 90 MPG was the overall result of my 34 mile round-trip commute, with a recharge at work. That's truly remarkable for the those extreme conditions. Heck, that's considerably better any vehicle without a plug could deliver. Winter has taken on a whole new outlook. I'm quite happy, as you can see... [photo album 180](#)
- 12-11-2012 Different Perspectives.** Those new to hybrids are often oblivious to what happened a decade ago, to the point where they get frustrated. It often results in a reply which claims you are altering or distorting history... when in reality, they simply don't have all the facts. That's why I find the blogs so helpful. All you have to do is search for what was being thought & said back then, documented as it actually happened. Anywho, you get seemingly constructive comments like this without that knowledge of the past: *"Unfortunately cars like the Volt highlight that hybrids simply require a rethink, and a change in driving patterns if one is to truly expect notable fuel economy."* I replied with: The actual problem was that automakers failed to inform owners. They were kept in the dark. All you'd get was a crude analog speedometer. Then came Prius, with multi-information screen standard. It was a rude awakening. Factors like speed, acceleration, fuel-formula, air-temperature, tire-pressure, and oil-level all quickly surfaced as efficiency influences affecting all vehicles, but assumed to be Prius only. The rethink was long overdue. It stirred a movement which ultimately got the EPA to revise the way MPG estimates were measured. The fact that attention has now become so widespread is simply proof that concerns have penetrated into the mainstream. Plug-In hybrids introduce an additional variance. But since the complaints are engine efficiency (primarily MPG following depletion), the EV capacity really doesn't play a role in solving the problem at hand. It just helps to raise awareness about the complexity of estimates.

- 12-11-2012** **Air Circulation.** Blah. Driving was even worse today. The snow transformed into heavy dry masses mixed with stretches of chunky ice. It was an awful recipe for commuting. Traffic was nasty. Needless to say, I was able to test out my theory right away. On my morning commute, the slowdown area was after getting the interior nicely warmed up. I shut off the heater and fired up my tiny USB-powered fan. Sure enough, it kept the windshield clear, allowing me to drive from there on in EV without getting cold. On the way home, I simply turned on the heater and let it warm up the interior. Traffic was nasty from the start. Turns out though, there was plenty of EV anyway, even when the need to turn back on the heater came. Thankfully, we don't get storms that often and most aren't anywhere near that bad. This just happened to be an ideal opportunity to observe and interact with the extremes firsthand. The final results for those 35.6 miles of driving was 6 kWh of electricity (2 full recharges), 0.367 gallons of gas (97 MPG average), 17 miles of EV displayed, and 17 miles of HV displayed. I documented the results with my camera... [photo album 180](#)
- 12-12-2012** **Still Avoiding PHV.** You know progress isn't being made when the discussions don't change. If it's the same old rhetoric of the past, then there's no realistic way to claim advancement. How else can that be put? You read a new discussion thread about Volt, the comparisons continue to be about the regular model Prius. It's quite clear. After all this time, the supporters are still avoiding PHV. I find that so redeeming. To think that they finally recognize market Prius worked so hard to draw. The answer to my "who" question is mainstream consumers... those who couldn't care less about the reasons they state for purchasing a Volt instead. They are beginning to see that now. I wonder why. Is it sales? Is it real-world data? Is it a better understanding of the market? How come they don't mention the plug-in model when comparing Volt to Prius? Why hasn't that change?
- 12-12-2012** **Plug-In Spotted.** It's very exciting when you get greeted in the parking lot by someone happily yelling out to you: "*We have 9 Prius in our family.*" Then without a moment to determine intent, she's starts asking about the plug-in model. That was my first true PHV recognition, a random encounter totally unexpected but very welcome. That level of excitement is quite enthralling. I can't wait to do that when there isn't a snowy mess to deal with. Anywho, her determination to glean as much information from me as quickly as possible is something you have to witness to believe... which my sister did. We were out shopping, minding our own business. She got a kick out of the experience. Not having the plug-in available on most dealer's lots around here until Spring lowers expectations. That's also the case with the lack of charging-stations. I'm just collecting real-world data in the meantime. But it sure is nice responding to inquiries before that.

- 12-12-2012 Volt Discussions.** Stepping back to look at activity on the big GM forum, it's easy to see there isn't any Volt discussion anymore. Unless Prius is mentioned, the thread dies almost immediately. The content of posts themselves are nothing but comparison information. You can't actually find anything stand-alone anymore. That's drastically different from the big Prius forum. Discussions are abundant. Thread activity is dramatically more frequent. Mention of Volt is actually quite rare. 2013 is going to be rough for GM. With Ford ramping up for a good showing from C-Max & Fusion plug-in hybrids and Honda preparing to do the same with Accord, the road for Toyota is quite the opposite. It all comes down to audience. Who are those plug-in hybrids attempting to appeal to? At some point, something from GM will be announced. I can't imagine rollout of the Cadillac version of Volt being the only activity the entire third year of production. But then again, the past is loaded with unfulfilled goals. Remaining silent would be the lesser of two evils.
- 12-12-2012 Heater Variance.** I've observed that heater temperature is tied directly to coolant temperature. That's a new parameter for us driving Prius. No longer is there a specific temperature at which the engine starts back up for cabin warming. With the regular model, it was always 114°F when in ECO mode and 145°F when the other modes. With the plug-in, it varies. In other words, while driving EV with ECO, then engine will start up for the heater when the coolant is 125°F if set to "HI" but not if set to "65". While driving HV with ECO, that wouldn't happen. The engine would stay off. It sounds somewhat complicated, until you consider outside conditions and why you requested it to be warmer. More heat means running the engine longer. Taking extra time while sitting in the cold would be uncomfortable. So, it starts sooner and runs for a shorter duration instead. There's always a tradeoff when it comes to situations like that. With the regular Prius, electric-only driving doesn't last anywhere near as long as with the plug-in. Why sacrifice comfort when you can get great efficiency anyway? After all, even when the engine runs for heat, you still get a MPG boost.
- 12-12-2012 Winter Roads.** Commute traffic this evening... Ugh. I avoided the side roads, since they were still a mess despite the temperature climbing above freezing. That meant some pretty heavy congestion on the main highway. That also meant my first ever opportunity to drive EV entirely to depletion on the 70 mph route. 29 minutes of electric-only bliss. I was quite pleased how far I got, even climbing out of the river valley without the engine starting. The downfalls of Winter are turning out to be quite enjoyable having a plug. The screen that's display when you shut off the Prius is quite informative. Seeing 150 MPG for the drive was quite satisfying, certainly not what anyone else on that road was getting. It makes the cold season less stressful.

- 12-13-2012 Energi Report.** When the founder of that daily blog for Volt returned to share his report on the new C-Max plug-in (called "*Energi*") he traded it for, the response was a civil as you could expect... the topic was quickly diverted to a tangent and attention was lost. Those still there simply didn't want to address Ford's plug-in offering. For that matter, they still only make references to the regular Prius and avoid the plug-in model. Fortunately, it was quite unlike that on the big GM forum. There, they are hostile and don't even try to be honest. Oddly though, that still remains the better source for argument points. You actually get some type of feedback. Anywho, we have witnessed the hopes of mainstream fade away to niche for Volt and are now seeing plug-in hybrids capable of high-volume sales from middle-market. They never wanted to be realistic about the situation. The reaction continues to be the "*head in the sand*" attitude. All they care about is not getting a "*fail*" stigma. Oh well. It's not like we didn't see that coming. Meanwhile, the reports on C-Max Energi are beginning to emerge.
- 12-14-2012 \$2.99 Per Gallon.** A major argument point for Volt was the expectation of higher gas prices, much higher. Supporters hoped routinely paying over \$4 per gallon would contribute heavily to sales. They didn't want to acknowledge that the fuel industry has resources & incentive to prevent that. The assumption was prices would remain \$3 something. Seeing it now at \$2.99 was quite unexpected. That's a very big problem for an expensive hybrid like Volt. For an affordable one like Prius, the story is quite different. Even without the tax-credit, it is still within reach of ordinary consumers. We know that simply by observing models purchased in the past. There was a steady stream of 4 & 5 packages, whose price was relatively close. They sold well even when gas was at \$3. There was no dependency. Looking 2 years from now, no change in gas-price and the tax-credit expiration offset by the next generation improvements will be just fine for Prius. What happens with Volt, especially taking into consideration the pressure competition from Ford will create from both plug-in and regular hybrids. Other automakers will be joining the party too. Maybe 2013 will bring the long overdue acknowledgement of need. Thankfully, the blind hope of the past was finally abandoned.

12-14-2012 **Estimate Value Concern.** This was my response to a concern new PHV owner: We saw this coming... the same questions getting asked over and over and over again. It becomes annoying quick, when there's nothing actually wrong and it stems from not being well versed in how the system works. But that's what happens when a new technology is so well designed and so unintimidating middle-market consumers embrace it. To best explain the situation, you have to first recognize that the value presented isn't an EV range expectation. Prius is a plug-in hybrid. Its purpose is to significantly reduce emissions consumption, not to offer a pure electric-only driving experience. The larger battery-pack and plug simply expand upon efficiency seeking opportunities the system has been taking advantage for 15 years now. True, you will have plenty of EV driving, but that value is only an estimate based upon your own personal driving data. Reset the computer, the original value you saw will immediately return. Mine progressively got lower due to more blend driving rather than electric-only. The resulting MPG should be outstanding, since the plug-supplied electricity is still being used. Seeing a value much lower now than when you first bought the car is an understandable sign of concern though. But then again, some of the best advocates for the technology over the years have come from owners with a first-post convinced something is wrong. They learn how the system actually works, then becomes very excited upon learning how well it copes with such a seemingly simple situation that is really quite complex. Long story short, it's working fine and welcome to the forum. There are quite a number of threads on this topic already. Do some searches. Then if you'd like to learn a lot more, consider purchasing an aftermarket gauge to allow you to observe aspects of operation not revealed via the dashboard displays.

12-15-2012 **Blend Mode.** I've been playing with it, wondering if there's a simple way of conveying intent & benefit. The plug-in Prius will run the engine from time to time for heating the interior. Heat is also needed for cleansing emissions. Winter can be cruel to efficiency for all vehicle. But taking advantage of the engine running isn't a big deal with the PHV. When accelerating from a stop, why not push the pedal hard or press the HV/EV button to startup the engine? If it has to run anyway, why not use it for providing power to the wheels at the same time? Turns out, that's a rather efficient approach when the temperature outside is well below freezing. It keeps coolant (the source of warmth for the heater) above the threshold, allowing more opportunity for driving in EV. That may seem somewhat counter-intuitive, running the engine for the sake of using it less, but the outcome speaks for itself. I've found that approach worthwhile. Accelerating briskly does the trick. That's the very same advice we give new owners of the regular Prius anyway. Giving it to those with a plug too makes matters of education easy. After all, not giving any advice tends to allow assumptions to take over. People end up fighting the system, thinking they are achieving higher efficiency, when really they are not. In other words, don't be afraid of letting the engine run. Of course, I still don't know what to call it. Blend mode is rather generic, but it does make it clear that engine use is expected.

- 12-16-2012 Blatant Greenwashing.** How do you respond to an article that starts with this: *"Ford introduced its two C-MAX hybrid models last December, and just one year later the U.S. car maker is already nudging out Toyota for sales of electric hybrid and plug-in hybrid electric vehicles."* That's an outright lie. C-Max was introduced to this market in October, just 2 months ago. There's no possible way the writer could have made a mistake. The claim is blatant greenwashing. Sadly, the sentence that followed clarified motive: *"Ford introduced its two C-MAX hybrid models last December, and just one year later the U.S. car maker is already nudging out Toyota for sales of electric hybrid and plug-in hybrid electric vehicles."* People typically believe what they read. So, this was especially disturbing. The article later goes on to describe the two models as *"EV hybrid"* and *"plug-in EV hybrid"*, both of which are obviously misleading since the industry been using *"hybrid"* and *"plug-in hybrid"* as identifiers for years. Then to make matters even worse: *"...combined sales in November for the C-MAX Hybrid and C-MAX Energi plug-in hybrid totaled 4,848 in November, compared to a total of 4,456 for Toyota's Prius plug-in and Prius V hybrids."* How is drawing that conclusion by excluding the 8,925 sales of the regular model even the slightest bit honest? What about omitting 3,124 sales of the smaller model? Needless to say, some people aren't even trying to be constructive.
- 12-16-2012 Same Old Story.** Toyota & GM took fundamentally different approaches, yet claims are made that they didn't. So no matter what is stated afterward, it makes no difference. It's the stereotypical gearhead verses accountant type exchanges that go nowhere. We all know what sustains the business. Some just plain are not interested though. TOYOTA = deliver a vehicle configured to be profitable & affordable, then later introduce enhancements as cost warrants. GM = deliver a vehicle a highly appealing configuration, then focus on cost-reduction for future generation rollouts. The latter contributes heavily to threads just like this, where the prize is bragging rights and competitiveness with traditional vehicle purchases is of no concern. Fortunately, the new player to join in is stirring the topic, preventing the old rhetoric from getting much traction anymore. FORD = straddle the approaches TOYOTA and GM took, hoping to capture the best of both words.
- 12-16-2012 Balance.** When I posted the content of that previous entry on the big GM forum, I actually got a few regulars to express agreement with those observations. Sadly, there were still some rather hostile responses as well. They came from the die-hard enthusiasts who still believe a 40-mile EV capacity and \$40,000 cost is a well balanced approach for middle-market. That baffles me. It's not worth stating what should be obvious though: Toyota set a much lower cost goal and requested their engineers to deliver the best they could with it right away. GM didn't set a specific cost limitation for the engineers to stay under. True, there was the goal of *"nicely under \$30,000"*, but not achieving that by 2010 was obvious to everyone except enthusiasts. The plug-in hybrids from Toyota & Ford strive to deliver a clear benefit from plug-supplied electricity without requiring a large premium to be paid. You get a larger seating interior too. In other words, there was a pronounced effort to make it competitive with this generation. GM didn't do that. We suspect GM will with the next generation though... sacrificing some aspects of the design to make it capable of being purchased profitably without tax-credit assistance with high-volume production & sales. Enthusiasts won't be happy... which is typical of mainstream vehicles anyway, since most are well-balanced rather than standing out for lots of attention.

- 12-16-2012 Lower Threshold.** The coolant temperature threshold with the plug-in model is lower. 114°F is well proven for regular model. I was finally able to confirm that discovery late at night driving my PHV. It went all the way down to 94°F before the engine fired up again. Think about that for a moment. If it were 94°F outside, would you feel warm? We know that Toyota found a way to physically heat up the emission system faster with this model anyway. So, why not change the software too? I went out to run an errand. I pushed the defrost button with the temp already set at "LO". The engine fired up anyway. Fortunately, I had just come to a lonely stop. So, I shut the defrost off, then powered down the Prius and back up again. Using the head & foot option instead, no engine. That continued for about 1.5 mile until finally needed heat. So, I bumped the temperature to "HI" and allowed the warm-up cycle to run its course. When the engine shut off, I set the temperature to "65" and lowered the blower to 2 bars. The interior stayed comfortable and the windshield clear the rest of the drive. The engine did the usual cycling, starting up at 114°F and shutting off at 130°F. After a few cycles, I noticed a drop below 114°F. That peaked my interest. Without any interruption to heat, it went all the way down to 94°F before the engine started up. My theory is some other component was warm at that point, no longer immediately dependent upon coolant to sustain anymore. Long story short, setting the heater to "65" and the blower to 2 bars following warm-up appears to be a simple & efficient choice when you're driving in sub-freezing temperatures.
- 12-17-2012 Rose-Colored Glasses.** It boggles the mind. Supposedly, there's a shortfall of Volt due to the retooling that was done for Malibu. Now we find out that GM grossly over-produced Malibu. There's an inventory of 78,200 waiting to be sold. Clearly, the focus has not been on keeping sales of Volt steady. All those arguments I had about traditional vehicles being the true concern fell on deaf ears. They only cared about bragging rights. That fear about consequences of the trophy-mentality are now playing out. 2 years after rollout, Volt is still very much a niche. All that hype about it becoming part of the mainstream quickly has turned into "*wait for the next generation*" rhetoric. They are still wearing rose-colored glasses. Prius is constantly being called out as the enemy, not traditional vehicles. Yet the evidence obviously points out that's not the case. The business effort continues to be production & sales of traditional vehicles. Let's not forget that there are also 245,853 unsold GM pickups. Selling around 2,000 Volt per month so long after debut in a market with the choices of plug-in expanding, the outlook isn't good. Yet, the supporters still don't want to see it... which means there's not going to be any pressure from them on GM to alter priorities. Not saying anything is a sign of acceptance. Making excuses for the painfully slow progress is an endorsement for more of the same. When will they learn?

- 12-18-2012** **\$4 Gas.** We are seeing more and more small traditional cars on the road. They replace those nasty guzzling SUVs of the past. That's overwhelming clear evidence that \$4 gas really did make an impression on consumer priorities. Hearing about inventory of pickups and some midsize cars piling up makes you wonder what will happen. Production can only be halted for so long. While it is, workers still get paid. That's money lost. Nothing to profit from sets up a really bad situation. What decisions will be made as a result? Needless to say, at some point the rose-colored glasses must be taken off. The expiration of tax-credits is an obvious deadline. That's the case for CAFE requirements too. A trophy only takes you so far. Selling vehicles to mainstream consumers is major challenge not being taken seriously by some. Simply downsizing to tiny vehicles isn't a solution. Seeing gas now down to \$2.95 means opportunity to penetrate the market without pressure. Solutions can be introduced to the masses as the next natural step on automotive evolution. That's why the plug-in Prius is so well positioned. It doesn't look like a desperate attempt to solve a crisis already in progress. When people panic about gas prices, we've seen that they flock to small traditional cars. Having an assortment of Prius to choose from already common on the road when \$4 does return is a good plan.
- 12-19-2012** **Lack of Concern.** Remember the motto back when Two-Mode was being developed? It was "*Better than Prius*". When the technology didn't deliver, focus was simply diverted elsewhere. Now that there won't be any Two-Mode pickups produced anymore, we can see pressure building again. It doesn't take long reading comments from Volt enthusiasts to confirm that. There are plenty of comparisons to Prius that use words like "*superior*", "*idiotic*", "*inferior*", and "*pathetic*". As for the shift now, there's a huge effort to downplay expectations. Rather than acknowledging GM's extensive experience with motors & batteries, it's pushing the mindset of first generation and early adopter. It's lack of concern for the big picture that worries the most. Surging sales of small traditional vehicles don't matter to supporters. GM can sell all the Malibu, Cruze, and Sonic they way. As long as more Volt are purchased than plug-in Prius, they just plain don't care about anything else.
- 12-19-2012** **200 Million Shares.** That's how many of the 500 million government owned shares GM said it would buy back. The original purchase price was \$33 each. They will now be sold at \$27.50 each. That's a loss of \$1.1 billion and much later than had been hoped. The other 300 million will remain outstanding up to 15 more months. The plan was to make a modest profit to cover expenses, like a loan to the automaker with an unspecified interest-rate or duration. It didn't work out that way. And that's just in the United States. The government in Canada is still holding quite a number of shares too. The intent of buying so much public stock was to flood GM with capital to help the automaker with bankruptcy recovery efforts, to quickly establish long-term viability. That's why those pushing Volt to become more realistic for the mainstream quickly were so concerned. The "*too little, too slowly*" was indeed becoming the status of the situation. Today's announcement to buy back those shares is a step toward achieving that. It forces important financial decisions to be made sooner, rather than later.

- 12-19-2012** **Speed of Recovery.** That's been a major problem with GM on several fronts. We all know the hopes for Volt to reach mainstream volume (5,000 per month) in the second year didn't work out. That in itself puts GM in a position without a clear next step. Ending uncertainty with Two-Mode pickups helps. As for Two-Mode SUVs, selling less than 2,000 per year is far from what had been expected at this point. It's not returning enough to justify major investment anymore. eAssist doesn't seem to be making much progress either. Then there's the 500 million shares of government owned stock. Was it a good idea to provide the assistance? Most likely. But not recovering fast enough could allow the some problems to return though... which is exactly what we're seeing signs of now. How long should we continue to wait and for what?
- 12-20-2012** **Halo Vehicle.** It was a term coined by GM to insult Prius. It meant the vehicle was really just used to draw in customers from other automakers to get them to purchase their traditional vehicles... a kind of technology bait & switch. In other words, there was no intent to actually sell a lot of the hybrid itself. It was basically just a technology showcase to improve automaker reputation. Strangely, all the downplay of Volt by its own enthusiasts to deal with sales falling way short of expectations was to redefine it as a "*halo*" vehicle. Huh? Their thought behind that was that if Prius ended up thriving afterward, Volt could too. The catch is, Prius never was a "*halo*" vehicle. When it was given that label, sales were already above the mainstream minimum (5,000 per month). Prius wasn't a niche in any respect at that point. In fact, it was being purchased more than many other Toyota cars... often the third best seller here. The label was an attempt to greenwash. Needless to say, no Volt enthusiast would ever admit that. The only way to get any type of acknowledge was to trick them into unintentionally revealing the true situation... which was exactly what I did. Taking about a great way to end the second year. After endlessly asking the "*Who is the market for Volt?*" question, I asked this instead: "*What is the purpose of Volt?*" Following the anticipated wave of insults, I posted: "*The purpose of this generation of Volt is to be a halo vehicle. In fact, that is why there is this very [discussion] topic. Someday there will be a variant of Volt that sells in high-volume replacing traditional vehicles like Malibu & Cruze.*" They went nuts, rejoicing that I finally understood what they had been saying all along. In reality, I had just been presented with confessions that goals were not being met and those expectations have been shifted to several years from now. Admitting that, though indirect, was long overdue. Some of us clearly remember what expectations were 2.5 years ago. The hype was so unrealistic. The actual outcome was quite different. The advice given about challenges to be faced were dismissed and now the consequences are obvious. There are far more aspects at play beyond just battery-capacity and motor-horsepower. Volt didn't turn out to be vastly superior. The need was not fulfilled.

12-20-2012 **Early Adopter.** Remember how all the hype about GM being able to produce up to 120,000 for the second year of sales? Enthusiasts were so excited about Volt talking the market by storm, they had concerns about supply being able to keep up with demand. About 9 months before rollout began, things started to change. Information was learned out about aspects of the design that soured appeal. They began to panic, fearing anyone pointing out the detail was trying to kill Volt. They didn't believe a constructive effort to make it more likely to be embraced by middle-market consumers was possible. Instead, there was an effort to reframe attitude. Rather than being a product for mainstream now, it would be an advanced technology for the future. We saw it as an admission of the sales struggle to come. And sure enough, that's exactly what happened. Here's how I described an early observation of the situation: "*The ongoing downplay of Volt from a "Prius killer" and a "game changer" to a vehicle which needs a chance for early adopters to discover got ugly.*" It was obvious way back then that the goals would not be met. Who knew it would take this long for that reality to finally sink in? Now we can finally get to business. With nationwide availability by Summer, we should see its perception quite a bit different from Volt. The approach for Prius is to simply offer the larger battery and plug as an upgrade, looked upon as a premium package rather than an entirely new technology to adopt. The cliché of "*biting off more than you can chew*" comes to mind for Volt. Far too much was expected in such a short amount of time. Enthusiasts found out the hard way it will take as long as the Prius supporters said. They weren't trying to kill Volt after all. They were only trying to share experience about setting realistic expectations.

12-20-2012 **Moisture Inside.** Winter has stirred up lots of new discussion related to cold temperature operation of the plug-in model. With all the feedback about moisture on the inside of the windshield due to some owners not wanting to run the engine for warm defrosting, today's opportunity was a real treat. I would drive to work with the heater running the entire time. The blower direction was set to window & foot, the fan on 2 bars, and the temperature set to "65". We got about 1.5 inches of new snow and the temperature was 25°F. That made for a messy morning commute on the along-the-river route. In other words, plenty of moisture. After driving the usual 3 blocks in EV to get out into traffic, I fired up the heater. Consequently, the engine started. It ran to warm-up completion (a coolant temp of 130°F) then shut off. EV automatically engaged and I drove that way for a few miles. When the coolant dropped to 96°F, the engine fired up again and then shut back off shortly afterward. Back in EV, the system was now entirely warmed. To my surprise, the coolant temperature dropped all the way to 87°F before the engine started again. That was great! My drive continued, moisture free the entire time. Upon arriving at the parking ramp, with the electricity all used up, the final distance tally was 17.3 miles and the average 120 MPG. Set it, then forget it. No need to mess with the heater. Just drive it.

- 12-22-2012 Cold Shopping.** Running around doing Christmas shopping in the cold is much less of an annoyance when there's no gas involved. I always felt bad starting the engine to drive just to the other side of the strip mall or a few blocks to the next store. Yet, that's what had to be done... until now. I stopped at a half-dozen different places, then got just 1.5 miles shy of reaching home before running out of electricity. That was pretty sweet. Almost my entire outing powered by the plug. I was actually quite pleased it lasted that long. In Summer, it's easier to go further. Winter cold increases electrical resistance within the battery-pack, which lowers efficiency. You normally need to run the defroster too. But with all that in and out, the interior stayed dry. It all worked out quite nice. The gifts I ended up purchasing were nice too. Perhaps I was in a better shopping mood due to the Prius. You think?
- 12-23-2012 Heater Drain.** Living in Minnesota, what it does to battery-capacity is among my favorite plug-in topics. A year before Volt was rolled out, the winter data was always extremely vague. I pointed out how Leaf's range estimator took climate-control into account, even including a photo in some posts. Those enthusiasts got angry, claiming my actual intent was to undermine to make the plug-in Prius appear better. They knew even back then taking advantage of the engine for heat would be an overall benefit. Sure enough, today's running around (starting with a stop at the coffee-shop) provided the proof they didn't want to acknowledge. 14°F outside. 9.0 miles. 55 mph maximum. I certainly wasn't going to be cold. The heater was turned on the moment I left the driveway. It took 9 minutes for the coolant to reach the initial shutoff point for the 75°F setting. With all the up & down from hills and stoplights to contend with, seeing 53 MPG for the average at that point was quite redeeming. I was at precisely the halfway point. From there on would be mostly EV. The engine only briefly came on then. I accelerated briskly to trigger it, since the result in replenishing of both heat & electricity. Upon reaching the coffee-shop, there was still 5.9 estimated miles of EV range remaining. The overall average displayed was 86 MPG. Long story short, they apparently were right. That does indeed cast a better light on Prius. But then again, the intent was always full disclosure. Leaving out detail is not constructive. They were providing annual consumption estimates not taking effects of the heater into account. Prius PHV is a plug-in hybrid. The purpose is to boost MPG, not to be an EV. With my efficiency averaging in the 70's here in Minnesota, that most definitely is a MPG boost from the 40's I saw with the 2010. So what if the engine runs from time to time for heat. Purpose fulfilled.
- 12-24-2012 Darn Good.** Today's driving was more of a "normal" circumstance than the chaos recently with weather issues and running around to shop. I drove to mom's, back home, to work, then home again. The total distance was 45 miles. The resulting average was 63 MPG. Considering that included 3 cold starts (18°F from mom's, 10°F from work) and just a single charge, I'd say it was darn good. The outcome of that same situation with my 2010 would have been about 20 MPG less. The plug is definitely providing an unmistakable boost. Having real-world data available makes greenwashing considerably harder. It's difficult to mislead when examples become easier to find. That's darn good too.

- 12-24-2012 Warm-Up MPG-Boost.** There are a few PHV owners who really get worked up when the engine runs. They want the most EV possible, rather than focusing on the overall efficiency results. That's understandable. But when they don't mention the MPG boost during warm-up, you have to wonder if they are seeing that big picture. When the engine starts up for the primary purpose of generating heat, electricity is used to minimize the impact. Gasoline consumption is kept to a minimum by using the motor to allow the engine run at a much lower RPM. That's more efficiency. Waste comes from high demand. The hybrid system makes sure it stays low. A resulting benefit of that is the engine is able to run at an optimum speed. That results in electricity being generated. Some is used to feed the motor, rather than drawing from the battery-pack. Excess is used to replenish the battery-pack, of which was drawn from originally to help with the initial warm-up process. It's a wild dance. You can witness it too. The multi-display offers a screen showing energy flow. Arrows branch and change direction every few seconds. Managing electricity and the speed at which the carriers in the power-split-device spin is what Toyota refined many years ago. Now they take advantage of the mini opportunities that emerge while encountering real-world conditions. You can see that too. The dynamic nature of the system delivers MPG surprisingly high, an accomplishment other automakers have struggled to also achieve. Long story short, the boost is really nice but often overlooked.
- 12-26-2012 Coiled Recharger Cord.** What a pain. I'm sure the person thought they were doing the right thing. Clearly, they hadn't considered the consequences though. With small cords, like adapters for portable rechargeable devices, it was never wise to tightly coil them after use. Eventually, the braided wires within twist, resulting in a permanently tangled cord. Sadly, people continue to do. Apparently, some don't figure out they are the cause of the problem. They must just assume that's a normal part of cord aging. It's not. That can easily be prevented by loosely draping the cord instead. I wonder if the same thing will happen with charging-stations. The cords there are in near perfect condition still. What happens in a few years? Will they routinely be replaced, like hoses & nozzles at gas stations? Anywho, there's an added complication. Maybe that will help. The cords get very stiff in the extreme cold. When temperatures are well below zero, a tightly coiled cord poses a difficult challenge. The one I had to deal with today required rather serious pulling to straighten out. Fortunately, the reach needed is short for Prius, since the port is located in the back corner of the vehicle. For those with the port near the driver's door, good luck. That may pose to be a problem at times during Winter. The cold season can be cruel. Thank goodness we still see a substantial benefit from the electricity even in those conditions.

12-27-2012 Disaster Recognized. This was the start of the new thread on the big GM forum that marked the beginning of the end: *"GM got bailed out in 2009, they reorganized, got rid of toxic assets, they were afforded bankruptcy procedures no other business in over 200 years of bankruptcy precedent was afforded, all in the name of saving the General. At the time we were told the money being "given" to GM was not a gift but a loan and would be paid back and most likely Treasury would come out ahead getting more from GM than they were given. 2013, where are we at? Sure GM is buying back stock, but by the time it is all done and GM is a private company again Treasury will have lost between \$12-20 billion dollars. Far from that profit we were practically assured. What has GM learned from all this, apparently not much..."* To prevent a repeat of the recent outcry that happened when the stock buyback was announced, those who had spoken out with discontent then were prevented from doing it again, banned from posting (including me). I found that very telling of the situation, especially since many of the posts had nothing to do with Prius or even hybrids. In other words, the loyalists saw the unsold inventory piling up and saw some major objectives not being achieved. That same post also included this: *"On top of that, where is the profit from the Volt, you know the car that was going to save GM? A product so good they were going to sell 40,000 a year..."* It's pretty obvious at this point, the upcoming disaster is being recognized. There's going to be an onslaught of fallout when the year comes to a close. Goals were not met. Recovery was indeed *"too little, too slowly"*. Expectations for 2013 certainly won't be filled with hype, which was the purpose of the posts in the first place... being realistic, what a concept.

12-27-2012 Last December. Remember all the nonsense back then? When the excuses were exhausted, it turned to personal attacks. They'd just make stuff up too, attempting to invite & provoke. Then when things didn't go their way, the thread would simply be closed. That year didn't end well. This year appears to be much worse. Instead of just Volt struggling, all of GM is. But rather than just being able to use Toyota & Prius as a scapegoat, there's the advancement made by Ford with both C-Max & Fusion. The hope had been that the needed steps to recover had already been taken and it was only a matter of patience. With the growing economy, it would be business as usual resuming. Trouble was, that trimming of excess & overhead alone wouldn't be enough... but they didn't want to hear that. They didn't want to acknowledge how much the market itself was changing. They didn't want to recognize history in other industries. Now they know. Now they cannot deny. That's why the rhetoric is much more intense. This December doesn't offer a hopeful outlook. 2013 will bring some serious decisions. Supporters don't want to discuss expectations. There's a clear effort to ignore matters related to sales. Hype allowed them to be unrealistic. This is why we worried.

- 12-28-2012 They Could Win.** That was the thought. It's why debates were allowed to get so intense, why forum members were allowed to so blatantly drop bait. With the belief of victory just beyond the horizon, added attention was welcomed. That all just changed. The attitude of hope abruptly transmuted to hopelessness. GM's own words are coming back to haunt. There are so many goals still not achieved... and time has run out. Volt was one of many coming up short. By the time the third year began, the "*little system that could*" was supposed to have been squashed. Winning has become a matter of survival instead. The lesson about Two-Mode is only now being taken seriously. They finally recognize the pattern those labeled as "*Prius trolls*" had pointed out ages ago. It didn't win. The owners of Prius really were trying to help. Admitting that isn't an option though... not after what they said. Their own words are already making them look hypocritical. They wanted to be "*vastly superior*" rather than being part of the effort to replace traditional vehicles. Instead, the very "*failure*" they feared is unfolding right before their eyes.
- 12-28-2012 Realistic Expectations.** Vehicles for middle-market are rarely thought of as exciting. Choices for the masses rarely are. That's why there are car enthusiasts. They are the ones seeking something that stands out. It's also why Prius constantly gets mocked by them. They want no association with a hybrid configured specifically for mainstream consumers. It's the very reason "*Volt*" was doomed from the start... since it targeted those enthusiasts, not everyday drivers. But rather than consider realistic expectations, what the market actually needs, they focused on want instead. Prius constantly reminded them of the difference. That's why it became such an irritant. Hearing owners find it rewarding is the last thing they wanted to hear. To make matters worse, it was just awarded the "*best value*" title by Consumer Reports. Winter driving with the plug-in is proving worthwhile too... not amazing, just a decent MPG boost... none of the "*purity*" nonsense. We had realistic expectations. GM will obviously have to scramble to redefine "*Volt*" now, giving the next generation design a configuration that's actually capable of high-volume profitable sales.
- 12-28-2012 Now That It's Over.** Uncertainty isn't helpful to anyone. GM's belief that simply getting rid of legacy financial obligations and consolidating resources would be enough was a lesson in blind hope. Not dealing with all the issues, thinking enough money will somehow solve the rest, was futile. But what else could be done with such an unreceptive set of executives? Old habits die hard. Recent news that Toyota is again the world leader really hurts. In fact, you cannot even report it as a Prius owner without sounding smug. Of course, no matter how much praise I gave Ford, the Volt enthusiasts didn't hear that anyway. It was always looked upon as an endorsement for Prius. But the ultimate was being unwilling to address the buildup of traditional vehicle inventory. Pretending the rest of GM was doing fine was a red flag, a clear warning that further development of Volt would be a difficult investment to fund. Fortunately, those questions will soon be asked... now that it's over. No more excuses. The end of the year brings the opportunity to set more proper goals for the next.

- 12-29-2012** **Hold Button.** One of the earliest efforts to educate labeled as "*propaganda*" was the benefit of having a hold button, a feature allowing a plug-in hybrid driver to specify when to heavily draw electricity from the battery-pack. Since Prius offered it and Volt didn't, all comments were perceived as an attempt to undermine... instead of the overall purpose of persuading GM to offer it too. For some bizarre reason, Volt enthusiasts didn't follow the example Toyota provided: enhancements to Prius based on owner feedback. Needless to say, the arguments against a hold button seriously backfired. Those enthusiasts proclaimed there was no benefit, it was just a ploy to make Prius appear better. Then came the 2013 model, which included a hold button... and owners started to praise it. You could imagine how that made those of the past feel now. They became extremely frustrated. Some denied ever arguing against it. Some worked hard to discredit the Prius owners who originally suggested GM offer it too. Some new Volt owners kept making it worse by pointing out the benefits. It turned into a messy situation with no chance of resolution. Apologies rarely happen online.
- 12-29-2012** **Predictions.** We know how unrealistic those for Volt were. It was as if there was no consideration of the rest of the market at all. Those supporting it figured the engineering alone would stimulate sales. Now, we know even with the tax-credit that didn't happen. There are many other aspects of appeal. Ford, Honda, and Toyota are all choosing to rollout plug-in hybrids with smaller battery- capacities. You still get a substantial MPG boost, but don't have to sacrifice interior-space, production-cost, or HV-efficiency to such an extent. Toyota strived hard with Prius to offer a plug-in that offered the same cargo area and great MPG after depletion. The similarity to the regular hybrid is quite obvious. Ford's approach was to make a tradeoff with C-Max, hoping it would be minor enough to easily justify. As for Ford's Fusion and Honda's Accord, we simply don't know yet. Both setups appear to be well thought out, with the exception of the small trunks. Time will tell. 2013 is the year for that. I predict a slow & steady growth for Prius PHV and C-Max Energi as rollout continues (once Spring arrives). For the sedan plug-in hybrids, we have no idea what market potential there is. For Volt, the struggle for sales will become even more difficult.
- 12-29-2012** **Heater Struggle.** Just like with the regular Prius, the plug-in has a similar new owner struggle... they want maximum EV but don't acknowledge/understand/support the tradeoff. We'd constantly be hearing reports of people attempting to keep the engine off as long as possible, then complaining about the results. They'd fight the system, rather than "*Just Drive It*". Addressing the same questions & comments over and over and over again is a test of patience. We're trying though. In this case, there's a phobia about heater use. Triggering the engine to start is bad, period. That absolute is frustrating. Prius is a plug-in hybrid, not an EV. There isn't battery-capacity to support an electric-heater anyway. We hear requests to allow just the defroster to use that heat for keeping the window clear, but it's difficult to claim there won't be complaints about that not being used to warm the cabin too. You still get outstanding overall efficiency. Winter doesn't last that long anyway. What other vehicle provides over 50 MPG during its warm-up cycle?

12-29-2012 **Fire Spin.** One of the most annoying things about Volt in 2012 was the about reputation. The supporters were continuously spinning the fire report from 2011 into a conspiracy to cause harm. A great example was from an article published yesterday, with this opening paragraph: "Try typing "Chevy Volt" into Google, and chances are that the word "fire" will *appear near the top of the suggestion list*." I did exactly that. In the news section, only the word "sales" appeared. That's it. Nothing else. So, I tried the general web section instead. It came back with the following choices: "Review, MPG, Lease, Sales, Range, Specs, Gas-Mileage, Tax-Credit, Forum". There was no mention about "fire" or anything even related. It's a good example of greenwashing easily accepted. People just believe what they read, without actually checking. I did. The hope was that I wouldn't. What the writer claimed was quickly proven false. How many reader will do the same thing? My guess is very few, if any. The article itself was how Volt became a target for "*political discourse*". Ironically, it was the enthusiasts themselves who fed that particular fire. (Yes, pun intended.) Rather than focusing on real-world data, they chose to fight those battles instead. What would winning the arguments even accomplish? Wasn't the point to draw attention to "*saved gas*"? Why didn't they keep that goal in the spotlight? Why did they allow pundit bait to be bitten? For that matter, why are they still doing it? What a massive waste of time staying focused on something everyone else moved beyond an entire year ago.

12-29-2012 **Test-Drives.** A new thread was recently started on the big Prius forum. The person wanted information to make a purchase decision with, having a very open mind to a variety of different cars and understanding potential bias a source like the forum could provide. We went through the usual definitions of what people find fun & rewarding. If you've owned the same vehicle for a decade, you tend to overlook new pleasures technology improvements offer. Think about the driving experience without a multi-display or digital readout. That's all most people know. So, they have no idea what having them offers. It's even more difficult describing the experience of having the engine shut off while driving. That's why we encourage taking a test-drive. I put it this way: "*The test-drive experience was what captured interest of those sitting on the fence in the past.*" Many concur. They are intrigued by the idea of a hybrid, but really have no idea what to actually expect. Most of what they've heard focuses on old-school measure, like 0-60 times... of which we exceeded the ceiling on ages ago. Notice how computer buyers are no longer placing heavy priority on processor-speed anymore? That diversification of preferences in the computer industry was a painful transition. We're seeing something similar playing out in the automotive industry now. The test-drive proves it. Comments following one from the prospective person are often that of surprise & excitement.

12-30-2012 **Fusion Energi.** That's the plug-in model of Ford's hybrid Fusion. Reading comments on the big GM forum about the 100 MPGe rated it earned certainly is interesting. That particular group is becoming quite vocal about the need for Volt to diversify. Better late than never? Some of us have been saying that for years. In fact, my references in the past to GM's current *"one size fits all"* approach really upset some Volt enthusiasts... who now think a variety of models is a good idea. All they heard in the past was *"Prius"*. Now that Ford is becoming competitive too, their attitude is more receptive. However, some of it is still just a matter of pride: *"In case you haven't noticed, C-max is starting to kick Prius in the butt big time, and it's only been two months."* That's a good example of cherry-picking, giving a impression of all Prius when in reality it is only the larger v model. The actual counts are 6,627 for C-Max, 5,459 for Prius v, and 6,452 for Prius c. Notice how misleading that is knowing the detail? Then when you consider the 17,713 also purchased during those same 2 months, it's easy to declare that a greenwashing statement. Anywho, the particular comment I liked was: *"MPGe means nothing to the average person. People buying plug-ins are more concerned with pure electric range, than anything else. If they wanted a repeatable mpg average, the get a regular hybrid."* Some are still attempting to conceal the MPG boost benefit the plug offers. I'm not concerned with pure electric range. I'm getting a repeatable mpg average. That's why they got extremely frustrated with my posts there. They knew I had lots of evidence available to disprove their claims. Of course, what I found most amusing was the re-emergence of the plug-in Cruze, especially since 2014 models of GM vehicles are being announced without eAssist as many had expected. With Cruze offering a smaller motor & battery configuration, it will preserve the name of Volt. They like that idea... especially now that Ford is racing past GM by offering 2 different hybrids with plugs, both targeting middle-market and both delivering a higher MPGe rating.

12-30-2012 **Leaving GM Behind.** Countless warnings about this coming fell on deaf ears. The supporters of GM just plain did not want anything to do with the thought that Ford & Toyota could be establishing an intense rivalry. This is the good type, the kind of battles both sides enjoy engaging in. There's nothing hostile or anything with ill intent, just good old-fashion one-upping each other. We've been looking forward to this for many, many years. Now it has begun. GM will be left behind, simply due to not having a product available for middle-market. This comment from a Ford executive summarized the situation: *"The Fusion Energi plug-in hybrid is the exclamation point for Ford's transformed lineup of fuel-efficiency leaders that now beats Toyota across the board."* They are proud of having achieved higher MPGe ratings for both C-Max Energi (100) & Fusion Energi (100) than Prius PHV (95) in addition to directly comparing Camry-hybrid and Prius v. It's the first compelling evidence that GM simply isn't going to get attention anymore. Lack of a spotlight is a serious problem. Consumers had so little interest in Two-Mode, there wasn't really anything GM could do to draw sales. So many mixed messages left the mainstream wondering when GM would finally settle down and seriously invest in a particular technology. In other words, all the *"early adopter"* labeling backfired... which is exactly what we are seeing with Volt now too. The enthusiasts kept saying *"wait for the next generation"*. They contributed to their own demise. They didn't listen to the advice. They didn't learn from the past. Now, they are being left behind. Oh well. Their loss.

- 12-30-2012** **First Impressions.** With the interest in Ford's plug-in offerings rapidly stealing away the last bits of attention for Volt, we also get some of the rhetoric. It started with downvoting of real-world data. Volt enthusiasts use to do that with fact posting. That was easier to get away with back then, since there was nothing else to provide. That's not the case now though. Results from actual owners are difficult to ignore. In fact, that's what contributed to the recent panic by GM supporters. The numbers speak for themselves, rather loudly too. There's not even any need for any explanation anymore. The idea of adding a plug to a hybrid is proving quite easy to convey. People readily embrace the idea. So, I suspect the fears of "*shilling and bashing*", as the reply so eloquently labeled it, won't last long. When has attacking the messenger ever actually worked? You stop posting data, someone else just does it instead. That kind of information is too compelling to resist. Nothing stirs interest quite like first impressions either. It sure is nice witnessing this change. There's lots to look forward to in 2013. We can see it beginning to nicely unfold already.
- 12-30-2012** **Garage Sweep.** My garage is attached to the house. It's not heated, but the insulated door does help prevent things from getting too cold. That's enough to retain ground-heat enough to prevent the ground-freeze which happens directly outside those doors. The result is lots of standing water from the snow & ice carried in on the Prius. Radiant melting from the sun allows water to pool at the base of the black door and dribble in too. Sweeping that out was always a pain. I really didn't want to pull the Prius out onto the driveway and let it run without benefit while I pushed that water out. What would you do for a procedure that took 30 to 45 seconds on a regular basis? It was a routine I tried to avoid or delayed until coming home, since the Prius could sit in the driveway with the engine off due to being all warmed up. That isn't necessary anymore. First thing in the morning, I can just back the Prius out and let it sit there... still on, but not consuming any gas. It's a benefit of having the plug I didn't anticipate... especially with the morning sun shining in, a pleasant experience compared to doing that in the dark late in the evening. That allows it to dry during the day too. It would pretty always remain wet otherwise. The choice of using electricity when you want sure is nice.
- 12-31-2012** **Financial Obligations.** The federal government "*fiscal cliff*" is the big news now. The tax-cuts that were suppose to have been temporary were instead extended. Tomorrow, those extensions will expire. Allowing them to continue is a terrible idea. We'll never get out of debt if we don't find ways to pay for our financial obligations. After several attempts, it comes to outright ending. Some argue this is a bad time. When is it ever good? In the automotive industry, we watched GM go through a modern bankruptcy... a lesson not learned from errors of the past. Do we allow it to happen again? Hoping for the best and just implementing modest change hasn't been successful. We continue to see executive choices being made that are not competitive. The final day of sales for the year is today. The end of this week, we should have annual sales counts. Volt became a lightning-rod political choices and a textbook example of over-engineering. It was promoted as an upcoming solution, but then rolled out as a long-term product. What will profit come from in the meantime? How will GM payback debt and continue daily business? When will a competitive (affordable & high-volume) hybrid be available? At some point, a significant decision must be made. As with the tax related cliff, there's one with GM too... which year-end results will provoke. Something new needs to happen.

- 12-31-2012** **Looking Forward.** The usual technique for avoiding discussion of a current situation is to focus on the future instead. That daily blog for Volt doesn't have much activity related to Volt anymore. There is much less participation and most of the topics are just about the industry in general. Even so, the topic today reflects an effort to prevent a major eruption due to annual sales coming up way short of the estimate from the beginning of the year. Needless to say, it closely resembled hype of the past. I sounded off with: The target mentioned often by GM initially, now frequently by other automakers, is delivering a profitable plug-in for \$30,000. The tax-credit difference must be offset before it expires. That will only be enough to maintain status-quo... which is far from business-sustaining profit, a necessity to continue the investment. To complicate matters, the competition will not be standing still. They too will benefit from battery advancements and technology refinements. I see the growing variety of plug-in choices as a mixed blessing. Some will be helped. Some will be harmed. The winner will be decided by middle-market consumers, of which Volt currently does not target. What aspects of Volt will be modified to appeal more to buyers whose priorities for speed/power & efficiency aren't at the top of the list? Replacing high-volume traditional sellers is the ultimate goal. The next generation of plug-in vehicles must directly address that. They will be competing on the same dealer lots for the same group of people. No longer will there be just competition from outside. It will come from inside and with increasing pressure. GM will be competing with itself. Long story short, painting a rosy picture for 2015 without ways of supporting it brings about haunting memories of 2010 with added complications. Intent must be very clear. The opportunity for delay will be gone. Remember the previous goals?
- 1-01-2013** **Hypermiling.** I was amused how one of the final attacks from a Volt antagonist came in the form of trying to discredit my real-world data. He said I was "*hypermiling*" to get those results, careful to not state what that actually meant. It was the usual greenwashing technique, being vague with the hope people will assume an extreme. He knew I didn't do any of the nonsense associated with the stereotype. He knew I was a strong supporter of "*Just Drive It*". From watching my videos, he knew my approach was simply following the flow of traffic. In fact, that's the very reason I can so heavily endorse. I'm not doing anything special. But how would a casual reader know that? The term itself becomes quite confusing when you look into it too. With the plug-in Prius, you have the option of specifying when not to draw heavily from the battery-pack. The act of pushing that button could be considered hypermiling, since it is an effort to increase efficiency. But now that Volt also offers that feature, he cannot point it out anymore. It is yet another example of being vague. Watch for that. Those desperate to retain relevance will avoid providing detail.

1-02-2013 **No Audience.** It's fascinating to watch efforts to continue battles of the past in 2013. The most intense exchanges have been continued attempts to downplay. Turns out, there simply is no audience anymore. That old rhetoric isn't stirring interest. This is a new year. We all know what happened and what didn't happen. It's time to move on. Remember greenwashing long ago? There was a tremendous amount of resources expended just for the sake of preventing conclusions from being drawn. The hope has been to repeat that now. It isn't working. I asked: "*What are expectations for 2013?*" An answer was provided. The antagonists must have been quite frustrated. No one is showing interest in his bait, despite those very same arguments having result in quite a bit of nonsense previously. It's not worth wasting time on that now. When sales for the year are announcement, that chapter of the book comes to a close. The new year reigns in a very different market, one quite unlike before. It's very exciting to think about. Change is happening right before our eyes.

1-03-2013 **Downplay Backlash.** The enthusiasts of Volt continue to label the current sales as the "*early adopter*" phase. It seems to be a realistic reason for the lagging tallies, falling well short of what had been expected. They sight the rollout of Prius as an appropriate comparison, even though back then Toyota had no experience with motors or batteries and there was no particular rush since gas was so cheap back then. With GM, that most definitely is the situation. They already have extensive experience. And with gas hitting \$4 from time to time, fuel efficiency has become a purchase priority. Remember back when Prius had to compete directly with Hummer? We no longer have consumers in favor of guzzling. The SUV craze provided substantial barriers for hybrids. The situation is profoundly different now. Each automaker is trying to deliver worthwhile hybrids & plug-in vehicles. There's also a very serious awareness of climate-change growing. The drought & storms of 2012 make that painfully clear. So claims that Volt is experiencing the same circumstances as the rollout Prius did is just plain not true. That's rather blatant greenwashing, in fact. There's no reason to even bother pointing that out though. The conflict from within is growing. All those warnings about GM competing with itself fell on deaf ears. They didn't want to hear it. Now, evidence is becoming difficult to ignore. There appears to be an unintended consequence of all their downplay. GM is requiring dealers to purchase a special tool (cost is \$5,000) to discharge battery-pack sections before sending them away for repair. First, that's a little odd that they'd have to send anything away at all. Repairs should be so rare, they just replace instead. Isn't that what you'd expect in an "*early adopter*" phase? Second, some dealers are just choosing not to sell Volt as a result. If this is just an "*early adopter*" phase, what difference would that make anyway? They'll just start selling them later when Volt becomes mainstream. It's been problem after problem with pressure from traditional sales continuing to grow. Think about inventory on the dealer's lot. What is the consumer more likely to purchase? What is the salesperson more likely to make a decent commission from? The enthusiasts thought the third year of sales would be no big deal. They're finding out the hard way that most definitely isn't the case.

- 1-03-2013** **The Discovery.** This is pleasant to read: "*Oh wow. I was wondering if the cold could be killing my MPG.*" It's nice when a new owner figures out on their own why their efficiency has dropped. I replied to his discovery: Remember the days before having a display on your dashboard, when you were blissfully oblivious to the affects of Winter? Engine warm-up, winter-formula fuel, reduced combustion, increased rolling-resistance, heavier traffic... factors of efficiency influence for all vehicles that new owners of Prius become painfully aware of as the temperature plummets. With a hybrid, you also get the influence from heater use and a decrease of available battery capacity. Every year, it's the same discoveries made by newbies. They eventually figure out, then give thanks when the warmth of spring arrives. The emotion they experience is actually a building-block for the passion often associated with Prius ownership. You feel empowered after learning so much about what had always been affecting vehicle efficiency. Those who have firsthand experience with multiple Winters behind the wheel of a Prius appreciate when you experiment and share your finding. Eventually, you will become the teachers of new owners with the very same concerns about suddenly MPG dropping, informing them of the circumstances. It would be nice to set expectations sooner. But often, new owners join forum discussions as a result of Winter discoveries... then continue to participate later. So, it works out nice anyway.
- 1-04-2013** **Closure, part 1.** It's all over. The end of 2012 brought the end of Volt spin. I only had a single rebut to post, and that was only because this particular owner is still quite defensive about the results... doing everything he can to prevent conclusions from being drawn. I find it redeeming, especially with others wondering why he's still arguing and not moving on like everyone else. Anywho, his recent offensive maneuver was a great one to fortify closure with started with: "*Wrong... Where do you off saying that is the goal?*" Implying meaning rather than just answering the question is one of many greenwashing techniques... most of which are very easy to detect now. My post to that was as follows: I asked this question "*The goal of Volt technology is to replace their traditional propulsion system, right?*" and got that as a response. Then you went on about me somehow wanting overnight success, despite the fact that I've stated "*by the time the tax-credit expires*" countless times. Whatever. I'm not wasting effort on pointless discussions. We all know traditional propulsion systems must be replaced. 2,082,504 was the grand total for Toyota sales in the United States for 2012. Of those, there were 327,413 hybrid purchases. That's 15.7% now being hybrid, undeniable evidence that Toyota is striving to replace. We see Ford aiming in the same direction, introducing C-Max, C-Max Energi, and Fusion Energi. By the time the tax-credit expires, the market for Volt must be well established and cost reduced significantly. Otherwise, it will lose sales to GM's own inventory of traditional vehicles or lose customers entirely. That's market reality. There's nothing to question. The clock is ticking.

- 1-04-2013** **Closure, part 2.** Everyone except him acknowledges the 2015 tax-credit expiration, the upcoming CARB & EPA standards increase, the upcoming CAFE efficiency mandate, and the need to sell more hybrids and less traditional vehicles, not to mention competition from other automakers. Each ending in long fought series of battles always has a final few who continue to fight even when everyone else has already conceded and begun discussing what comes next. I find that particular stage very reassuring. You can see the desperation, yet know the next chapter will begin without fallout. It's simply that some accept change less willingly than others. Those few need to convince themselves this outcome was really what had been intended all along... despite overwhelming evidence to the contrary. The internet really makes that difficult, since all it takes is a quick search of blogs & forums to reveal thoughts people had back then. They try to dismiss, wondering how certain things could have ever been claimed. To them, the result should have been obvious, that it would have happened without any reason to question. For me, I feel vindicated. Reading my own comments confirmed concerns. Much of it boils down to not understanding the market, focusing entirely on the engineering alone. Those of us who helped with the rollout of Prius a decade ago are well aware. We know the pressures which come from aspects of technology that have nothing to do with the technology itself... so many players involved... so little recognition of the part they actually play. Needless to say, the die-hard enthusiasts now see the big picture... and are slowly learning to accept it.
- 1-04-2013** **Electric Passing.** For some unknown reason, the car I was following on the 3-lane highway at 55 mph slowed down to 50 mph when the lanes reduced to 2. Traffic started to build up behind me. I could see there was a truck about to merge in on the right from the ramp. There was no one in the left lane. I pushed the pedal and drove around. It seemed like no big deal. Then it hit me. That was a scenario I hadn't ever encountered with the Prius PHV. I effortlessly passed using only electricity. Sweet! That wasn't something I had ever considered before. What would happen if you were cruising along in EV at a top suburb speed and required a medium increase in power? The assumption would be that the engine would simply start to assist. The fact that it didn't without any effort to prevent it was nice. It was a genuine performance substantiation check. Cool.
- 1-05-2013** **Short Trips.** With the temperature only 16°F outside, the battery-pack doesn't stand a chance of delivering full potential on its own. Lithium batteries are restrained when used below freezing. It's a better tradeoff to start the engine rather than putting high demand on them. The perfect example was this evening, after having left the Prius sit in my unheated garage for over day. The drive was only 6 minutes long. The distance was just 2.6 miles. That's a MPG killer for the regular Prius. The warm-up for short trips isn't normally efficient. In fact, it's only a small amount better than a traditional vehicle for those first few minutes in the dead of Winter. That's not the case for the plug-in model though. PHV takes advantage of the battery-pack... not with pure EV travel, but the use of the engine is much more efficient. On that one-way drive, the outcome was 81 MPG. That's pretty darn good no matter how you look at it. On the return trip, the engine never started. Warmth within the battery-pack from the drive there 1 hour 40 minutes earlier was apparently enough to prevent the need. As a result, it brought the overall average up to 162 MPG. That's amazing! I do still miss Summer though.

- 1-06-2013** **\$2.89 Per Gallon.** With the price of a barrel of oil staying in the low 90's, seeing that for the price of gas makes you wonder. Is that where it will settle? You'd expect it to be higher. Some wonder there may have been an oversupply during the holidays, resulting in the low we see now. Some wonder if the price should have been that way all along but was higher due to fiscal uncertainty. Some see the price of diesel at entire dollar higher as a clue that the current situation is only temporary. Whatever the case, it means a challenge for hybrid sales. As people grow accustomed to paying more, the incentive to keep efficiency as a high priority falls. That does equate to a short opportunity for the new & affordable plug-in models to establish themselves though. They would then be able to capitalize on rising gas prices, even if they were only modest. For the more expensive plug-in hybrids and the electric-only vehicles, that's much harder sell. Once a model has been around for awhile, it raises the question of interest. How will it grow? Traditionally, there would be a large advertising campaign to introduce a next generation. That requires a massive budget and lots of inventory at dealers, which isn't realistic for vehicle like Volt. What does that mean then? It become a big issue. Fortunately, there's the Prius family from Toyota. That variety of choices and market penetration should really help with growth, even when the price of gas is low.
- 1-07-2013** **EV Observations.** I took advantage of the warm spell today. The temperature got a bit above freezing. So after recharging at work, I moved the Prius into an enclosed ramp and let it sit there for 6 hours. In there, it was 40°F. The outside temperature dropped to 30°F. That made me quite curious, since I wouldn't need the heater. Could I drive the entire capacity without the engine starting? I hadn't ever actually tried that, since climbing out of the river valley at 56 mph isn't the best use of it on a 17-mile drive. But I was wanted to push the limits in cool conditions. Sure enough, it was an effortless drive... all EV until depleted, including the climb. That should provide an interesting basis of comparison for when the temperature drops again. With it considerably colder last week, I wasn't able to identify a pattern. Smaller increments may be revealing. I'll keep watching. We know is the engine starts even without the heater on when the temperature outside is below freezing. The circumstances which trigger it are still elusive though.
- 1-08-2013** **Effective Analogies, part 1.** We still get echoes of the past, people comparing the efficiency of a traditional car to that of a SUV and being proud of the progress it represents. That embarrassing. Thankfully, my feeling is shared. This quote from an thread doing exactly that summed up the situation: *"That's exactly the kind of half-logic that causes the rest of the world to laugh at Volt buyers. You'd be saving money, compared to an SUV, with any of a whole host of cars."* Needless to say, it was on that daily blog discussing 2012 sales of plug-in vehicles. Discussions there are getting better, now that the rhetoric is gone and we have begun a new year. I was still a bit flustered though. We still didn't have an approach for those absurd comparisons. Then it hit me, an analogy everyone could easily understand & accept. That's what you need, something so simple there's no debate. Here's what I came up with: It's really unfortunate GM chose to market Volt that way. Comparisons to a 50 MPG hybrid, something that actually strives to deliver high efficiency, would be far more constructive. Then they would be able to point out the benefits of having a plug. Comparing to our domestic average of less than 30 MPG says a lot about how low our priority actually is toward reducing consumption. When would it ever make any sense to do something like that in the technology industry? It's like comparing Blu-Ray to VHS rather than DVD.

- 1-08-2013** **Effective Analogies, part 2.** Turns out, that was really effective. The analogy wasn't challenged at all. The discussion instead moved on to this: "*Yes, it took time for the Prius sales to jump so why not grant the Volt the same courtesy?*" Seeing an abrupt shift to something different is a good sign, especially when it's on topic. And in this particular case, it also set the stage for me using the analogy. Who knew the same one would apply again so quickly? I was delighted to use it too. Referring back to the past with total disregard for what happened in between is bad enough. Pretending the past simply didn't happen as all is even worse. I replied with: That's because that same courtesy was already given. TWO-MODE and BAS were the recipients. Volt built upon that experience gained from those previous battery & motor technologies. Again, this is like comparing Blu-Ray to VHS. It makes no sense disregarding DVD, referring back further as if no advancements were made in the meantime.
- 1-08-2013** **Proof of Change.** Today we had a new thread started by a new member on the big Prius forum. It featured a cost & comparison report for Volt from an owner's perspective. It had some obvious holes, incomplete information which could easily lead to incorrect assumptions. I jumped on it right away, but only addressed the poster as the author who could make updates accordingly. No big deal, leaving plenty of opportunity to fill in the blanks. Good thing too. The thread had quickly got a post describing Prius as an "*eco box*" and added the adjective "*sucks*" for good measure, then there was a "*blows*" included in a follow up. Those were from a well known troublemaker, a Volt owner who didn't care about being smug. His attitude had been pretty bad for months and I didn't want the new member to begin reflecting it. Too late, he did. So, I decided to push my luck. The author had replied with a comment about when a Prius owner gets a real electric-gas that doesn't use gas when on the highway, climbing hills, or accelerating... which we all know quite well at this point isn't true. That only happens if you push the pedal down hard. Ordinary driving is in EV with the plug-in Prius. Sure enough, he retracted that statement just minutes after I gave him a LIKE and a THANKS for making an effort to be constructive. The result of me stirring the pot, perhaps a bit too much, resulted in someone willing to reassess. That's pretty sweet! It's proof of change.
- 1-09-2013** **Lack of Data.** That had been the underlying problem with all the hype surrounding Volt. Now that real-world data is beginning to accumulate, there are owner reports. It's a big improvement, but missing detail and vague references contribute to assumptions & misconceptions. Stopping them in this increasingly complex market is a good idea. Getting help with that is questionable though. There's no way to request it without being explicit. Unfortunately, doing that makes you confrontational. Instead of just accepting what was posted as is, your effort to clarify get perceived as an attack. To make matters worse, certain members provoke to make you appear to be an antagonist rather than someone attempting to prevent. Fortunately, there is just barely enough data now to get us beyond that. You can leverage off of owner experiences to stir a constructive discussion. It's what happened yesterday. The thread topic and the intent itself clashed. In the end, that didn't matter. We could focus on the bits of detail that were provided. In other words, the hype addressed an unrealistic market expectation and the outcome of unachieved goals is no longer addressed... we just deal with other issues instead, simple things like recharging.

- 1-09-2013** **More Data.** Today's was especially interesting. I had to run several errands before leaving for work. That rarely ever happens. My running around is almost always in the evening instead. It was 34°F outside, warmer than usual too. I still had the heater on, of course. But it was only minimally needed. Anywho, after 29.1 miles of driving, I arrived at work. The end result was 80 MPG. That's well above what the 2010 Prius would have delivered under the same circumstances. Who cares if the engine runs from time to time. The goal of significantly reducing emissions & consumption was clearly achieved, even in cold season. True, I yearn for the return of the warm season, when MPG is higher. But the data collected this morning certainly is worthy of writing to home about.
- 1-09-2013** **Heater Threshold.** I had noticed enough of a difference with coolant temperatures and heater threshold to want to research further. I hoped to detect a pattern. Could I uncover & confirm reactions to specific settings and reliably repeat those results? The answer is, yes! The catch to performing all that testing was to not allow the engine to heat up the coolant too much. That's what has been preventing us from noticing detail in the past. Everything really needed to be measured within a small window of time, not spread out over weeks like we've been doing. We already knew with the heater set at 65°F, the coolant temperature would drop well below 100°F before starting the engine to warm it back up again. What I wanted to know what happened when it was set higher. Check this out: 68 = 118; 72 = 118; 74 = 118; 76 = 123; 78 = 127. The heater setting on the left corresponded to the coolant temperature on the right, several times at each level. I was even able to confirm results while driving and while stopped. In other words, if you set the heater at 74°F, the engine will remain off until the coolant temperature drops to 118°F. At 76°F, it's 123°F. At 78°F, it's 127°F. No longer is there a single cutoff point like the regular Prius. The plug-in model takes a tapered approach.
- 1-10-2013** **Missing Data.** The newsfeeds about hybrids sometimes pop up unexpected content. That was certainly the case today. There was a link to a blog and guess what I found... It was the same Volt owner getting remarkably similar comments. The snippet that caught my eye also had a confrontational type stance, though less caring and lacking any examples: "*you give me nothing of substance*". The follow-up is what really got me. It was the same link for more info, which got a similar response too: "*doesn't give us enough data*". The point was made. You can't just make a comparison, then draw a conclusion without also providing detail. Summaries only aren't acceptable. Greenwashing attempts of the past give reason to ask for missing data. Knowing how numbers were collected & calculated is very important. Long story short, if you don't, expect people to question your intent. Sincere efforts will be self-undermined otherwise. People are learning not to accept what they read without confirming it.

1-11-2013 **One Million Goal.** That's what Toyota set out to achieve a few years ago for 2012. Taking sales of the v model in Japan, hybrid sales in Europe & Canada, sales of Lexus hybrids, and sales of Camry/Highlander all into account, combined with the counts we have solid numbers for, it's easy to see Toyota is well on their way. Here in the United States, all models of Prius purchasing came to a total of 236,659 Prius. In Japan, the regular (liftback) model accounted for 317,675 Prius. There, Aqua (known as the c model here) had sales of 266,567. The numbers look good. It's a promise of sustainability, which is the point. Automakers must sell a bulk of their production as hybrids. There's no argument about that anymore. Greenwashing efforts of the past, attempting to label cars like Prius a niche, have failed miserably. That's why the rhetoric now is so intense. Those fighting change had no option left anymore but to accept it. Some will still attempt to spin numbers to conceal the reality of the situation. That does nothing for the business though. In fact, not facing the need to be competition has dire consequences. That's why watching Ford embrace this change has put so much pressure on GM. Seeing C-Max & Fusion plunge into the mainstream leaves Volt behind. That vehicle was promoted as a car for the everyday commuter, something we'd see as a popular purchase choice. Instead, it's been downplayed to a hopeful next generation, leaving Toyota in a position to begin reducing production of their popular traditional cars (Camry & Corolla) in favor of Prius here... in Japan, that has already taken place. We'll see more and more hybrids, so with plugs too. Eventually, the next goal will be stated. When should we expect 1.5 million sales annually?

1-12-2013 **Lowered Standards.** In a thread on the big GM forum about Equinox not getting eAssist, this was posted: "*Our AWD 2.4 gets excellent mileage (about 26 MPG) in suburban/rural driving in Maine.*" That's so bad, I don't even know where to begin. Remember years ago when 40 was the goal? It has since been lowered to 30. That's embarrassing. Once upon a time, we were leaders, we delivered great feats of engineering. Now, we downplay expectations. What happened to the 21st Century? We're going backwards! We've lowered standards to such a degree, some people are sincerely fooled into believing MPG in the 30's is helping us reduce our dependency on oil. How could that even make sense? Population growth alone should be enough of a problem to recognize that more needs to be done. Have they forgotten what traditional vehicles delivered in the past? Don't they know what some hybrids actually deliver? Are they greenwashed to such a degree that they assume what they here isn't actually true or that somehow traditional vehicles will suddenly be replaced entirely. More and more, I'm thinking it's the latter... that they've convinced themselves what they drive now is fine and sometime in the future hybrids will improve to such a degree they'll never actually have to make a conscious decision about which to purchase next.

- 1-13-2013 The Ultimate Quote.** Reading this, I was amazed: "*It may be a quality product, but if it doesn't meet the needs of the consumer as well as the competition then it deserves its lackluster sales.*" That came from the ultimate antagonist, a person so intensely in favor of Volt and against Prius he argues any criticism... totally unwilling to be constructive, just unfounded hope. It quite remarkable to encounter anyone so stanch. But then to read a quote exactly as I would post, how would you respond? He was making comment about Malibu. Why wouldn't the same apply to Volt? I didn't respond. Why bother? It's so hypocritical anyway. At best, you could label that as a double-standard. If Volt wasn't intended to fill the same role as Malibu, what the heck is its purpose? Anywho, I find it the refreshing seeing him post what I had been saying all along. Apparently, he heard & understood the words but couldn't see how they applied to the vehicle he most praised. Is that progress?
- 1-14-2013 What Can You Say?** Too little, too slowly was the concern stated throughout the development of Volt. It highlights the very situation being faced now. Yet, enthusiasts insisted that wouldn't be the case, this couldn't possibly happen. We're starting the third year of availability and attention is refocused on the next generation, hoping cost & volume will be what was expected back in 2010. Discussions don't even have Volt as a topic anymore. It would be nice hearing realistic talk about Volt in 2013 instead. Will we really just step back and hope for the best? What should the expectations be? Just writing off this generation and settling for slow acceptance doesn't give GM any direction or incentive. We still need a vehicle configured & priced for the masses. In all seriousness, the lack of diversity is what will end up holding Volt back. What's so wrong with a second model, something scaled back to resemble a high-volume top-selling middle-market car rather than only offering one that strives to exceed on many levels? After all, that's the type of vehicle which provide business-sustaining profit, not one that impresses at autoshows. Wasn't anything learned from Two-Mode's emphasis on want rather than need?
- 1-14-2013 Outside Temperature.** It clearly is a parameter taken into account for the heater, beside the coolant threshold... which explains why observations have varied so much. My recent evidence of this was watching the engine shut off when the coolant temperature warmed up to 112°F with the heater set at 70. What the heck? That didn't fit in the pattern I had measured a few days earlier. The obvious difference was it now being a little above freezing outside, rather than well below. The next observation of not-fitting-the-pattern was when it got even colder outside. Not using the heater at all, the engine shut off and 105°F and I was able to drive for 4 miles in EV. In the past, initial warm-up was always to 130°F anytime the engine started. That didn't seem to matter. Maybe time is a parameter too. Yesterday, my cold morning errand running with heater had an engine shut-off at 123°F instead. That was yet another temperature. Hmm? Today, with it 12°F outside and the need to get to work shortly before noon, I set the heater at 70 and jumped on the 70 mph highway with a full battery and a cold engine. Upon reaching the 55 mph section, there was plenty of reserve heat built up for EV driving... or so I thought. When the coolant dropped to 136°F, the engine started back up. Huh? Of course, in the end, does it really matter? The point is to deliver a significant MPG boost from plugging in. That is indeed what I've been getting. The same advice we gave in the past applies now too: *Just Drive It.*

- 1-14-2013 Mid-Research.** There are many observations to make & document still when it comes to when the engine runs. It feels like I'm confusing matters by interjecting seemingly random values. We may uncover a pattern as some point, ultimately identifying all the parameters used to determine when the engine is used. But the criteria is so much more complicated than in the past. Toyota really did their homework... delivering a system able to respond in such a dynamic way, we cannot beat respond in a way to achieve better. That makes sense. A computer should be able to take more into account more than a human, especially when it comes to delivering longevity in addition to great emissions & efficiency all at the same time. It's redeeming to see the flexibility in action. There are so many fine adjustments continuously at play. Yet even in the extreme temperatures we're experiencing now, the results are still great. I do yearn for warmer weather though. Having already witnessed the increase in capacity from higher temperatures, it certainly is something to look forward to again. Engine warm-up is so much faster too.
- 1-14-2013 Really Cold Driving, part 1.** Last night, the Prius had been sitting outside for about 2.5 hours, it was only 9°F. Even if the battery hadn't been totally depleted, I would have started the engine immediately anyway. That's simply too cold to endure... which is why I don't actually start the heater until the coolant reaches about 100°F degrees. Fortunately, warm-up began with it at 40°F. It's nice still having a tiny bit of warmth left from the previous drive. 2 minutes into this drive, the benefit of having a heated seat became evident. It was then that I looked over to see how the coolant was doing. What the heck? RPM stated zero! The coolant was only 101°F, yet the engine was off. I was in Stealth mode (low power & speed EV) already. How come the usual engine warm-up to 130°F didn't happen? Needless to say, there are so many variables at play, it would be too much of a chore conveying our findings to those without aftermarket gauges and keen observations skills. Because even with, it's a challenge.
- 1-14-2013 Really Cold Driving, part 2.** It's not worth it anyway. The other day I finally encountered what another owner had complained out, saying window fogging could be dangerous... but never elaborated about the circumstances. I wondered why anyone would push it... but then again, was well aware of how some owners disregard the refill warning. So, I kept experimenting. I refrained from turning on any ventilation, allowing the steam to build up really heavy on the windows. Then I hit them hard with outside air from the blowers. The condensation flash-froze to ice. That was indeed a dangerous situation. But with the temperature only in the teens, I can't imagine someone not just turning on the heater long before that would ever happen anyway. Then again, it's a common sight to see people driving around with only minimum snow & ice removed from the outside of the vehicle. Some take chances more than others.

- 1-15-2013** **Initial Impressions.** Those about the latest from GM are rolling in. All the enthusiasts were expecting the Cadillac ELR to introduce an upgrade to the plug-in system. Instead, they get a heavier vehicle with more power. It uses the same engine & battery and sacrifices range. Even the look is style over substance. The situation is so bad, there's nothing we can really post without sounding condescending. That's taking Volt in the wrong direction. What a mess! This should be a clue about setting realistic expectations. They keep hoping for a miracle and end up getting way less than hoped. I can't imagine sales for such an expensive plug-in without any efficiency improvements being any more than a trickle. This is yet another example of GM building what they want to sell... not what they need to.
- 1-15-2013** **After Thoughts.** Instead of Voltec 1.5 being revealed, we we're shown a vehicle that's 289 pounds heavier and consequently gets less EV range and lower MPG. What happened to the anticipated improvements? No upgrade to the system? As other automakers rollout their plug-in vehicles, GM decides to offer something even more expensive. Where is the choice of something affordable? Why a vehicle for the luxury market? This makes you wonder what's next. How long will it take to finally get a vehicle able to take the place of traditional high-volume sellers? What will ordinary consumers buy? We are not going to see middle-market buying large quantities of any vehicle that's not competitive; in other words, the vehicle much be share similarities to what people purchase now. GM clearly does not want to focus on that audience yet.
- 1-16-2013** **Posted Response.** Also having an upscale vehicle is fine, but we really do need a genuine competing car... something that gets hybrid MPG after depletion, is large enough to be practical for a family, and is reasonably priced. Remember the "*too little, too slowly*" concern? It's the same problem as in the past. How have things changed? Money from bailouts & tax-credits is suppose to accelerate progress. Upscale alone doesn't provide any sense of that. Rather than getting something for the masses, or even an upgrade to the system itself, we get another trophy vehicle. What's the point of offering a nice vehicle very few people will actually buy? It's not even a midsize. If we also got something that was competitive with offerings coming from other automakers, that would be a different story. But the deafening silence about plans with Volt is reason for concern. More is expected. Faster is expected.
- 1-16-2013** **Heater On, Engine On.** To add to the complex array of parameters we already have, I made yet another discovery. It was 12°F degrees on the commute to work yesterday. I set the heater at 65, then watched what happened when I turned it on (pressed the fan button) and off (pressed the off button) while driving. The hypothesis was the engine would remain off while the coolant temperature was still above the usual 114°F threshold. After all, it doesn't start when the heater is running. Why would the engine start up upon starting the heater? Turns out, it does. Huh? I performed the test three times was in motion, at 118°F, at 123°F, and at 128°F. Each time, the engine fired up and ran until reaching the usual warm-up shutoff temperature of 130°F. I also tried it once while stopped, at 127°F. Same response. Needless to say, we are dealing with a very dynamic system, one that takes a wide variety of conditions into account. The "*set it, then forget it*" advice is proving to be an excellent recommendation. The Prius will figure out how to achieve the best results for you. It is no longer the early days of hybrid driving, when the suggestions to improve efficiency were so simple you could easily to the same yourself.

- 1-16-2013** **Electric Only.** On the simple side, I stopped at the coffeeshop this evening with a toasty warm Prius. It sat there outside in the 23°F parking lot for 1.5 hours while I relaxed. The estimated EV distance remaining was 7.7 miles. My drive home would be with only the heated seat on high. The heater itself would stay off. Since the interior was still warm, there wasn't any need for window clearing. The glass had retained enough energy to resist condensation. Maximum speed would be 50 mph. It was a remarkably efficient trip, despite the cold. The entire drive home was with electricity only. I arrived home 7.5 miles later. I even had 0.9 of EV left.
- 1-17-2013** **Greenest.** The pressure sure is building. Seeing that certain groups are making their hate for Prius is overwhelmingly clear confirms it. The c model was named the greenest car by the American Council for an Energy-Efficient Economy. The regular model Prius took third place. The plug-in model got fourth. The v model came in at eleventh. It's bad enough hearing from people like me (an owner) repeatedly pointing out the importance of offering a choice for mainstream consumers. But then to hear that some of those popular choices from a competitor are also extremely clean & efficient really burns. That's why there was always so much rhetoric from Volt enthusiasts. Now there's a backlash with trucks too. Ford's F-350 was label the "meanest", which means the dirtiest. GM has a large inventory of pickups. SUVs are losing customers, who are now choosing the big wagons instead. We saw this coming. They hoped it would somehow not be as intense. The rest of us see the emotion as validation. How could we continue to dismiss oil-dependency and climate-change? At some point, the problems would become obvious. That time appears to be now.
- 1-17-2013** **Not Dead.** The switch to damage-control for GM has been rather abrupt. The reveal of their new plug-in hybrid, the Cadillac ELR, didn't get the reception they were hoping for. Even many enthusiasts were disappointed. The expectations was a technology upgrade; instead, it just ended up being cosmetic upgrades with nice creature-comforts and more horsepower. As a result, focus shifted back to Volt... and people are asking the same question I had been for quite some time. What should we expect for this third year of sales? The fact that last year's was just half that of what had been projected has people wondering. After all, attention to detail of the tax-credit has exposed the reality that there isn't actually an expiration-date for it, that the only criteria is sales. That gives little incentive for high-volume production until cost has been significantly reduced. For Volt, that's a major challenge to overcome still. The quote given yesterday from GM's top executive was: "*The electric car is not dead.*" A comment like that is confirmation of having missed an opportunity. We kept saying now. They kept saying later. We were right. Ford is preparing to rollout their second plug-in hybrid, the Fusion. Toyota will be expanding to rest of the country soon. And Honda will be rolling out their first. Now is the time, not in a few years. Waiting for a second generation is too late. They clearly didn't learn from lessons of the past. The situation is quite a mess now.

1-18-2013 **Just Wait For It.** Reading through the forum post, blogs, and comments, that message is being echoed from the head of GM all over the internet. There isn't an effort anymore to reach out to the mainstream with Volt. We're being told middle-market will get a choice from the next generation. There's no sales prediction this year, we only get a message conveyed of slow increase. It's not even worth posting there anymore. Heck, they are now reciting what I had been saying all along. They've even opened up to the idea of a model being quite a bit different, something to appeal directly to the masses. The thought was that would happen shortly after the second year, since fallout with Two-Mode followed the same timing. The long debates about priorities are over. The enthusiasts claimed all I ever did was post about Prius. But when you look back, there's lot of mention of consumers needs in general... the very thing being addressed now. It was frustrating for me that they'd totally ignore anything I posted about Ford, denying there was ever anything said other than Toyota. But now they know that wasn't ever the case. It felt good for them to have someone to blame, a scapegoat to deal with their own frustration of struggling sales. Focus has shifted away from this generation entirely. They're saying "*just wait for it*" instead. What a change.

1-18-2013 **It Was Inevitable.** I remember closure of the past. When the enthusiast came to terms with their expectations not being met, they'd lash out at those who had predicted the outcome. You could see it coming too. Bait would be dropped on a fresh thread, provoking individuals that were correct all along to challenge them. There's a basic desire to have one last fight, a glorious final battle. Denying them that is counter-productive. Even though you end up getting labeled as the troll, despite their dropping of bait being so obvious, you accept the invitation anyway. It's the classic "*can't see the forest*" situation. They focus on one particular tree. That disregard for the big picture is a painful lesson to learn. Hope clouds judgment though. Pride makes it worse. It played out like a textbook response. I tried to point out the past to them, to prevent the repeat of the history. I got scorned for my trouble. Oh well. The message about the need verses want got through. No one said the process would be smooth. Transition can be extremely difficult for some people. Our past obsession with size & power has made that change a painful one. They were determined to earn a trophy, rather than focus on the crowd instead. It was doomed from the start. It was inevitable.

- 1-18-2013** **Minnesota Morning.** Looking at my scribbles from the commute yesterday morning, I like what I see. It was 10°F outside. I drove the usual fast route, starting the engine a block shy of the highway by turning the heater on. My garage is insulated but not heated. It's plenty comfortable to drive those first few blocks in EV. That way, I don't get stuck at a light with the engine running. The heater was set at 74. I didn't use the heated seat today. I wasn't wearing gloves either. At the conclusion of the 70 mph section, at the 9.5 mile mark, the coolant temperature climbed to 159°F. Upon slowing down to 55 mph, which shut off the engine, I turned the heater down to 65 to keep it off as long as possible. At 10.8 miles, the engine started back up again. The coolant was at 136°F, clearly higher than the usual 114°F threshold. My theory is the outside temperature influences when too. After 2 miles, the engine shut off again. The coolant had reached 146°F. With the heater still at 65, the newly generated heat only lasted 0.9 mile. That was no surprise, being that cold outside. It was getting pretty warm inside though. So when the heater shut off 0.8 mile later, I shut the heater off too. Why let it start again. I was already 14.5 miles into the trip and only had 2.2 remaining. So, the rest of the drive was without any blower running and using only electricity. I arrived at my parking spot in the ramp with 0.5 mile of EV left. The overall average was 114 MPG. That's amazing considering how cold it was outside and how little was done to achieve that outcome.
- 1-19-2013** **Acceptance.** It's a painful process. Yesterday's concluding lash out confirmed even the enthusiasts are done with the long series of discussions, arguments, and debates about Volt shortcomings. Looking back, the first was the direct-drive uproar. They lost their purity hope. Then came the non-disclosure of depleted efficiency. GM absolutely refused to share MPG data, despite their heavy promotion CS-Mode. We knew something was seriously wrong. They didn't want to admit it though. When the price was finally revealed, everyone knew trouble was to come. And sure enough, shortly before rollout itself the MPG was finally revealed and was considerably lower than anticipated. Sales results the first year made it worse. Then came the second year, with sales at a growth rate far below expectations and the new Prius family doing remarkably well at the same time. That's why this comment yesterday came as no surprise: *"But rippin' his crapbox to shreds was always a bit of fun."* The hate for Prius ran deep, but the target to troll was gone and it wasn't rewarding anymore. They give up. Proof was reading this from one of the most extreme of those who despised Prius... *"GM needs cost savings to offset the inevitable elimination of the credit."* ...since that was what I had been saying all along. Hearing it from someone who focused on business results rather than engineering pride doesn't work though. That's why the resentment for me grew so strong. But the moment they got confirmation I was gone, the message immediately changed. That's so hypocritical, there's nothing which needs to be said. The point was to get them to accept that. It looks like they have.

1-19-2013 **Downplay.** To sum up the mess, allowing us to all move on, it's just a matter of looking at the downplay. Prius was configured to appeal to the masses right from the very beginning. It didn't offer power, speed, and handling in excess of what ordinary mainstream vehicles offered. In fact, it was quite plain... but with an usually smooth & quiet ride. Toyota went to great lengths to keep cost within check, delivering a design which could achieve profit without even requiring a generation upgrade. They rolled out that model and did indeed accomplish that goal... despite gas being dirt cheap then and their being basically no interest in reducing dependency on oil or worry about either type of emissions (carbon & smog). The intent & persistence was obvious. That most definitely is not what happened with Volt, which had even higher expectations. But none of the goals that were actually set are remembered anymore. Those who had backed them deny there were any. They'll even lie to protect their pride, making it pointless to argue. Instead, they'd downplay. New goals would be focused on instead, pretending that's what was intended all along. 2 years later, that's all the newbies know about. They have no clue any of that previous history took place. They simply assume (without any detail) it was a bit rough at the beginning and all is well now. That's how history is allowed to repeat. We've seen this pattern several times now, each ending in very unfortunate circumstances. The only real hope is that goals are downplayed to such a degree that they actually become realistic. Pride is very difficult emotion to overcome. It's so powerful, it makes believers see what they want. That's why no matter how often I mentioned examples from Ford, Honda, or even GM, all they would hear was "*Prius*". Heck, when I pointed out the differences between the hybrid Camry and Prius, all they heard was "*Prius*". It was truly amazing blinded they were and the resulting hurt from it. The disenchantment caused them to seek blame. I was an easy target. I won't hold it against them either... as long as they learned the lesson from their own disenchantment.

1-19-2013 **Defeat.** The only message I can find that still remains is this: "*The PIP was a hack job of an effort to respond to GM.*" That's the point Volt enthusiasts want to convey about Toyota. It makes them feel better believing the design didn't exist way back in 2003, that Prius wasn't planned to deliver up to 100 km/h (62.1 mph) all those years ago and only had to wait until a realistic battery became available. The owners from back then knew about the testing taking place with parallel NiMH packs. That worked, but it was expensive and the capacity was way too small. Delivering a system without compromise to price or interior room have always been major priorities. A top priority was to deliver high MPG using only engine-supplied power at high speeds. All of that is what we now find in PIP (the plug-in Prius). Reasonably affordable batteries using Li-Ion is what changed the situation. They want to portray that accomplishment as defeat. They hope that one bit of history won't be uncovered. Remember how much of an influence image (the trophy mentality) has on them, how big of a deal stigma is? They're hoping people who read that claim feel the same way, that they'll believe Toyota was desperate instead. That doesn't make any sense when you think about it, since there's no mention of Ford. Declaring victory by professing defeat is what makes them feel better about the situation. That's how certain individuals can move on without feeling disappointment. Thankfully, the rest already have.

- 1-19-2013** **Compromise.** Anytime there was mention of a smaller battery-pack for Volt, it was always contrived to be an attempt to endorse Prius. Every approach possible met with the same results. The enthusiasts found Prius a threat and would not accept anything resembling its design under any circumstance. (Watch for absolutes.) That large capacity was the key to survival. It's what defined Volt as different from the other other plug-in hybrids... even though it was just an arbitrary measure. That's why aftermarket upgrades were quickly dismissed. They exposed shortcomings... like MPG no better than a traditional vehicle after depletion. With Prius, it remains just as efficient as a regular Prius after all the plug-supplied electricity is gone. That the key to success. Prius PHV can reach a massive market as a result. With Volt, the primary selling feature has been the battery size... since reducing capacity also reduces the horsepower & torque available. But with Toyota, Ford, and Honda all seeking out middle-market, something needed to be done for Volt. It's why I over and over and over and over and over again suggested a second model. That way, the original would require compromise. The other could be consider a "lite" version. Guess what. That's precisely what those same enthusiasts who attacked me for that very suggestion are now endorsing. I was told by a pastor many years ago to note how often the word "*hypocrite*" was mentioned in the Bible. Those written words tell us much about life now. To think, the Volt enthusiasts are now in favor of what they fought so hard against before. Oh well, accepting this outcome despite all the grief which could have easily been avoided is form of compromise. It's what we need.
- 1-20-2013** **Remembering.** What should we remember? I obviously don't care about the personal attacks, where antagonists (having no interest in being constructive, wanting only to stir trouble) would focus exclusively on you to avoid having to acknowledge the big picture. I don't care about enthusiast lies either, since having real-world data available now easily prevents that greenwashing from re-emerging. They were just defending what remained of a poorly conceived plan. Having witnessed both Two-Mode and Volt fall well short of their own goals, you really don't want that to ever happen again. Will it? Could they really blindly hope for a miracle a third time? I'd prefer to start fresh. It looks as though we can too. But there is an inherent fear of repeating mistakes by not addressing what had already been tried in the past. It was truly amazing how bad the hype & rhetoric got. What comes to mind the most is how much stigma dominated discussions. The label of "*failure*" heavily influenced responses. Perhaps that's an important lesson to be learned, to remember how much emotion clouds logic.
- 1-21-2013** **New Video.** I was able to film this morning's commute. I sure hope the footage looks good. 62 MPG for the trip, with 1.7 miles of EV left. That's quite remarkable considering the outside temperature was -6°F. It's always a complicated setup anyway. The cold makes it worse. Things like a smudge on the glass are difficult to notice when you are trying to be brief and avoid causing condensation from your breath. The vents near the base of the windshield cannot be blocked either. That shift of the dashmat alters the lighting for both cameras, forcing you to guess what's needed. There's no opportunity to calibrate either, since a cold engine and the fullest battery possible are required. Needless to say, it becomes quite an effort to coordinate it all. Failures happen too. I know I'll end up having to abandon a video due to an equipment issue. That's reality. But I persist. Most of the footage turns out. Then you end up spending a ton of time with the rendering effort. It's a labor of love though. That level of detail is extremely informative. It's squashes misconceptions and puts and end to greenwashing, as well as entices the curious to want to learn more.

- 1-21-2013** **Another Video.** -6°F this morning, nearly identical to yesterday's commute. So, I took the other route, filming that too. Having a slower speed limited, so I was intrigued what the outcome would be. Unfortunately, the dashmat got in the way, interfering with the window clearing. Condensation became a problem. The extreme cold caused a camera's suction-cup to repeatedly fail too. That made for a fun driving experience. The end result was rather predictable, despite the unexpected. The Prius handled the conditions well. It's odd hearing the high-rev for heat though. The engine would run at about 1964 RPM. In the end, that got that longer & slower route down along the river was more efficient, as usual. The MPG was 63 today rather than the 62 yesterday. There was a 1/3 more battery-capacity remaining too. Hopefully, today's video captures actually worked. Stay tuned.
- 1-22-2013** **More Video.** Yesterday's effort failed. One camera locked up, preventing the final segment's file from being saved. That loss of footage meant frustration, but only a bit of patience. Being so darn cold here, waiting until the next day is no big deal. This morning's temperature was -2°F. Filming setup went better, so well I decided to try something different rather than try to refilm. I wondered how much EV travel was possible when no heater was required. No owner has ever tried that particular experiment before in conditions so cold. I'd put the heater on high and crack the windows open for ventilation. I'd drive with gloves off too, a good indication of how tolerable the interior could remain in temperatures that low. Wearing only my usual work clothes and my regular coat, my voyage starting from my non-heated but insulated garage had an unknown outcome. I couldn't even guess what would happen. The hope was electric-only travel until depletion. Lithium batteries work much better in Summer. I was curious. Turns out, the effort was worth it. Taking the back way (max speed of 55 mph), I pressed the pedal down really hard to start up the engine with only 0.1 miles of EV remaining. Traveling at 55 mph and quickly approaching a hill, I wanted to have extra electricity to buffer the very cold engine warm-up. I had already traveled 8.9 miles using only EV. That was totally worth it. Though, it did make me curious how much electricity the heated seat actually consumed. When I arrived at work, total distance was 17.2 miles. The final overall efficiency was 117 MPG. That's amazing.
- 1-23-2013** **Imaginary Interest.** What happens when a halo vehicle no longer gets attention? We are watching that play out now. My participation on the big GM forum was perceived as stoking the fire, the enthusiast proof of naysayers. In reality, it appears they now recognize I was only stirring the ashes looking for embers. Volt simply isn't discussed anymore. Even ELR only gets barely a peep, just days after the reveal. It's astounding to observe. There's nothing. Silence. They looked forward to the participation, having no idea the interest was really only imaginary. But with everyone else already gone, that should have been easy to see. After all, it's not rocket science. We all recognize who posts. If no one else ever joins each new attempt at discussion, something is wrong. And with the thread content itself not constructive, confirmation of trouble is abundant. Sales results next week certainly will be interesting. The rush for 2012 tax-credit eligibility has passed. Details about Ford's plug-ins are available. And the initial rollout of Honda's plug-in has begun.

- 1-23-2013** **Worth It?** An antagonist of the past reappeared. He was one who pushed the perspective that Volt's engine was there only for emergency backup, claiming virtually all but vacation travel would be done exclusively with electricity. Claiming such an extreme view, which has since proven to be false, caused him to stop posting. His return is now with a different perspective. Turns out, using fuel with a combustion engine is ok. The catch is the fuel should be clean & renewable. Naturally, that's what I had been saying all along. But why bother stirring up that? It's not worth it. Pointing out the agreement wouldn't accomplish anything. So, I'll just document his new attitude instead: *"Why are so many people pre-determined to get rid of the combustion engine? Is there some religious belief I'm unaware of? An EREV combustion engine range extender running on bio-fuel would give us a 100% sustainable, carbon neutral solution, all using our existing infrastructure of home electricity and liquid fuel filling stations. What's not to like?"* That type of turn-around never ceases to amaze me. When someone finds out their stance didn't payoff, what do you think they'd do... after a prolonged battle to save some pride, of course? I like the outcome, even without interjecting any type of *"I told you so"* comment despite all the frustration he caused in the past. You just quietly note that they finally heard what was being said. Phew! What a relief... and quite worth it, from the end-state vantage point.
- 1-24-2013** **No Heater.** I grew quite curious, then finally asked myself the ultimate question. What if I didn't turn on the heater at all? What if I just cracked the windows for defrosting instead? Between the heated seat and the proper winter attire, I'd be reasonably comfortable anyway. After all, a traditional vehicle wouldn't be able to provide heat from its engine in only a few minutes. With it too, you'd be relying on the same methods of keeping warm. Anywho, it was -2°F outside, providing a great opportunity to observe that extreme. Prius shined. I got 9 miles of EV out of the battery-pack, which included electricity from the camera setup prior to the 17.2 mile drive and providing electricity for my seat. The end result was an amazing 117 MPG. Let's hope the video footage actually came out. It's challenging enough when the temperature outside is warm and I did have a recent failure. With it significantly colder than freezing, problems happen. Regardless, I did get photos.
- 1-26-2013** **Vaporware Repeat.** It's hard to believe 6 years have passed. We went from a collection of unrealistic hopes to an idea struggling to survive. Using the label of *"vaporware"* early on was very offensive, the enthusiasts did not take kindly to it. Yet, they continued on with the something-to-prove stance rather than constructively adjusting expectations as market & design realities were uncovered. Unfortunately, that seems to be happening again. I'm seeing ideals emerge, claimed as necessary rather than being identified as reasonable high-end choices. That's a warning sign. Focus should be on what's most realistic for the masses, especially since the design expecting to deliver them is second generation. Why do they do that? It's one thing to strive for a goal. This setting of expectations beyond the reach of business & consumers is troubling... especially when it repeats!

- 1-26-2013** **Smog.** Photos of the rapidly growing problem of smog in China are capturing headlines today. It was so bad, some industry & service had to be shutdown. The air was like a thick fog, making traffic extremely dangerous. Seeing that is truly frightening. Rather than learning from mistakes we made decades ago and have been struggling ever since, they focused on economic growth instead. Now the consequences of that choice are becoming overwhelmingly obvious. Could you imagine air so toxic it's difficult to see? What a nightmare. Too bad some people here just plain don't care. In fact, some think the same thing believing emissions should be sacrificed for the sake of not having to invest in new cleaner technologies. It's that "*good enough*" attitude that's really presents challenges. What do you do what someone just plain doesn't care. Nothing you say will convince them, but you certainly don't want to wait until the situation gets so bad it becomes extremely expensive to repair. The best choice has always been to lead by example... which is precisely what Prius owners have been doing. Nice.
- 1-27-2013** **Efficiency Pressure.** As the cost of hybrids drops and the need to use less oil increases, the pressure for delivering higher efficiency results in comments like this: "*As if by magic a Jetta Hybrid appears!*" That begged a response. It's the kind of situation which contributes to greenwashing, starting as an uninformed mention then growing into a belief. Responses are sometimes misinterpreted as being confrontational. So, it's best to know the person prior to jumping in with background information. In this case, it was fine. We exchange constructive posts routinely. I replied with: That's like congratulating someone who worked hard for a decade to become an overnight success. Diesel (engine only) was doomed from the day hybrids rolled out. It was far too dirty and simply could not compete with ever-improving battery technology. It was destined to become a filler option as the transition away from traditional gas vehicles progressed, then be replaced by a hybrid of some sort. With automakers like Toyota, Ford, and Honda all striving to deliver a plug-in hybrid with an affordably-sized battery along with a no-plug counterpart, there wasn't any magic. It was inevitable that VW joined in, starting with a gas hybrid. Diesel (engine only) quite simply cannot compete with the +75 MPG some of us are now experiencing, especially with a PZEV emission rating.
- 1-27-2013** **Not Size.** I liked reading this comment: "*Hybrids are less still than 3% of the market and compete in segments with near 60% of the market. There's a reason for that small size and it's not the price.*" As the price of gas continues to put pressure on our society and people simply grow familiar with the plug-in hybrids (remember the "*don't by the first year*" mindset), the acceptance will become easier & easier. It's a bell-curve too. Momentum picks up after the slow initial progress. The catch is reminding yourself that 3% is actually around 1/3 of a million vehicles. In other words, this is yet another example of misleading by using a percent rather than stating the actual number. I rebutted with: How effective of an argument against hybrids do you think that will be going forward? It's rapidly becoming weak as the Prius family grows. Seeing so many on the road is far more of an endorsement to accept than a statistical percent. Ownership sends a powerful message. We've witnessed a clear change in priorities recently... the importance of efficiency. The emergence of plug-in hybrids pushes regular hybrids deeper into the mainstream than any monetary incentive could. It sends a very clear message that hybrids are indeed the next step in automotive evolution, not a niche as the greenwashing had persistently claimed. The perception of the market expanding strong, making it very difficult now to argue against.

- 1-28-2013** **Fiesta.** Oh my gosh. Believe it or not, the small cars with the 3-cylinder engines are about to make a comeback. Their return may not be with open arms though. Decades ago, there wasn't a technology solution called hybrids available. Now there is. That makes the reveal of a 1-liter Fiesta by Ford a head-scratcher. What will it cost and who will be interested? Supposedly, the direct-inject gas engine with turbo-charging will offer 40 MPG city and 50 MPG highway. Of course, nothing was mentioned about emission rating. It will offer 126 horsepower and 148 lb-ft torque, so it will be competitive in one regard. But special measures will need to be taken to deal with the extra noise & vibration caused by a 3-cylinder engine. This is definitely an unusual situation in a market now trying to introduce plug-in vehicles to the masses.
- 1-28-2013** **Halo Delay.** Since we are now in the double-standard/hypocritical/contradiction stage of rollout with Volt, the previous reasoning approach is basically pointless. Enthusiasts arguments of the past now work against them. That means taking another approach instead... though we can still introduce it by pointing out the irony of the situation. It was done by reciting concerns "*dead weight*" issues. I thought that was a great way of moving beyond old rhetoric. You recognize, then try something different: Prius supporters continuously heard "*dead weight*" arguments. It went on for years and years, despite the fact that there wasn't actually any long duration when either the battery or engine remained unused. Now when that is actually true for Volt, nada, zip, nothing. It's wrong on so many levels, how can we expect to get constructive feedback? The next step is going to be a challenge. What will the current owners think of a scaled back design, one that uses a blend of battery & engine? Approach will have to change to draw in mainstream sales. There is the possibility of GM choosing to support both a "*dead weight*" approach and one that strives for a balance. But without a non-plug model to supplement production volume, it's an expensive business risk. Maybe their reports will help with that transition. After all, details of the past are often forgotten or not even known anyway. Even though it takes much longer, the halo delay really could be the key. Arguing design shortcomings doesn't accomplish anything and they know quite well that cost-reduction won't be solved by technology breakthroughs alone.
- 1-28-2013** **PHV Surprises.** I especially liked reading this: "*I think one unexpected surprise for me was to learn that even in HV, mileage is improved by the larger battery capacity.*" It's exciting when a new owner discovers more than they had anticipated. He had several other enlightening things to comment about as well. I saw it as a great opportunity to ask about ways to identify that behavior, since most people assume PHV either drives in EV or HV mode. They don't realize there's a mode in between, despite the fact that the term "*blending*" is used so frequently. It simply never crosses their mind that they'd see MPG in excess of 100 while the engine is running. The fact that the motor has so much electricity available to assist the engine isn't something ever mentioned. So, I've been helping to promote a term for that, asking about it with: Sadly, there have been certain individuals trying to portray operation of the plug-in Prius as having no advantage once that engine begins to run. If you had encountered that greenwashing, it didn't seem to deter your purchase. Sweet! You clearly have discovered that's that what actually happens too. That proclamation of it being amazing, even in subzero temperatures, speaks volumes. Anywho, we've been trying to spread the word about there being a plug-in benefit even with the engine running by using the term: "*EV-BOOST*". Do you think that is an informative way of describing it?

- 1-28-2013** **EV-BOOST when in HV.** Most people have no idea there's still quite a bit of electricity left even upon reaching the depletion point when the engine starts. They just assume there's nothing left but ordinary HV mode driving. The fact that a minute worth of EV-BOOST still remaining to provide a smooth, low strain warm-up of the engine is often not known. Heck, even some owners don't notice it. That's one of those things you really only observe when using an aftermarket gauge. Anywho, I joined a discussion pointing out today's observation of that with this: Something is needed to identify the behavior. I was quite delighted witnessing it firsthand today too. It's warm now here (just above freezing). I drove 13 minutes in EV prior to depleting the battery, including a climb out of the river valley at 57 mph. Just as I reached the 70 mph section of highway, the engine fired up. I watched the SOC drop all the way down to 2 bars (specifically 18.4%). The result was the first minute of warm-up yielding 70 MPG, something clearly not possible without taking advantage of electric more than HV would offer. Just think if there was something in the car to document that behavior, an illustration showing owners detail about exactly what happened during that warm-up. It's a design feature some may ever even notice otherwise. Heck, I remember certain individuals claiming that wouldn't even be possible, that the engine would start cold and have to fend for itself. Fortunately, the boost during ordinary cruising on the highway is already easy to see. The instant & summary bars show MPG well above what you'd get in HV mode. Of course, that data is lost right away. Being able to download/send/share it afterward sure would be nice.
- 1-29-2013** **Labels & Purpose.** Marketing is intentionally bias. That's the point. It's purpose is to convince you their product is the best choice. Why can't those handful of Volt enthusiasts still convinced purity is the best approach see that? Needless to say, I didn't say much after reading this from one such person: "*...people that don't understand what EREVs are really all about.*" The reason was simple, that phrase followed a series of insults for those in favor of a different plug-in hybrid. He's been quite smug. I find that a relief. Thank goodness many owners aren't like that. Being among the few still holding on to hope of the past, I wonder if there will be a change in attitude following results this month's sales. In the meantime, I had thoughts of my own to document: The design is intended to deliver EV by avoiding use of the engine, only starting combustion when absolutely necessary, even if efficiency opportunities are lost. But since that wasn't even the point of the post, why bother? GM needs to produce a high-efficiency vehicles that is purchase in high-volume. No argument about semantics will change that. They must deliver something for mainstream buyers. Period. Volt itself can continue being appreciated by owners. That's great! There's nothing wrong with enthusiasts. They provide ambition & excitement. But enthusiasts are not middle-market, who don't share the same passion. They couldn't care less about whether a vehicle is called an EREV or a PHEV. In fact, most won't have any clue how the system actually works. They just need a practical & reliable vehicle that's affordable.

1-29-2013 **Misled Purchases.** They happen. In fact, that's how some owners discover the big Prius forum. They come there to voice their frustration, then vanish without any further comment. It's a common occurrence without any certainty of outcome. Once in a blue moon though, that misled purchase ends up creating an strong advocate rather than the assumed frustrated customer. This time, it was: *"Toyota needs to come clean and make it clear to buyers that the EV plug-in is not truly or exclusively electric... I was assured it was when I bought it."* I did my best to console & advise with: Sorry to hear you were misled, but please don't blame Toyota corporate. They delivered model of Prius you purchased to clearly display the "PLUG-IN HYBRID" emblem. Finding fault with salespeople & dealerships is an entirely different matter. And by all means, sound off when that happens. We, as owners & supporters, will help convey the detail needed to make a well-informed purchase decision. Hybrid means blending of two power sources. The EV you experience can indeed be with the engine off, but there is no promise of that or even that it will be the first miles driven. The addition of the plug enhances what Prius already offers, hence being a package option. The test-drive experience will reveal that, especially when you exceed 62 mph. The purpose is to provide very high efficiency and very low emissions... which happens regardless of how the electricity from the battery is actually consumed. Give it time. Your purchase in the dead of winter means there is much to look forward to. EV range increases as the temperature warms. The engine runs less often and at shorter intervals once the cold is gone too. Local errand running becomes a pleasure, rather than a chore, as a result. Being one of the few who owner a PHV back when there was still snow last year, I can point out how much of a difference it makes.

1-29-2013 **Expensive Gas.** It makes you wonder how a comment like this actually derives: *"When I bought my first Prius (Oct 2000) everyone was talking about how in ~10 years we'd be paying \$10/gal for gas...hasn't happened."* Was that a distorted memory of the past, consensus from a very small group, or some other misrepresentation. My personal logs certainly don't have any references like that and the forums of the time weren't discussing gas anywhere near that high. Perhaps it was some totally different venue, something not directly related to vehicles... perhaps related to energy instead. Whatever the case, I tried my best to prevent that comment from getting any more off track with: I'd suggest searching for some old comparison analysis reports. You'll find it was quite a challenge even arguing \$4 would happen. It was actually quite frustrating. The belief was gas would continue to be cheap. What's much more interesting is the change that happened when \$4 gas really did arrive. The guzzlers started to disappear, despite the arguments then having shifted to \$5 being the tipping point. Clearly, it wasn't. Now, we are still looking at \$4 being the norm for the next few years. That's somewhat of an influence, but people are slowing growing use to paying more. Becoming tolerant of higher prices poses a very real challenge for plug-in growth.

- 1-30-2013** **Late 2013.** That was what Toyota's major website revamp stated in the section for the plug-in Prius. The wording on the webpage says: "*Availability will open up to all other states in late 2013.*" That basically just tells us the expansion will be here & there throughout the year, but don't expect availability everywhere until later. We pretty much already knew that would happen anyway. Even within the new states could be spotty. I was told not all dealers around here would get inventory at the same time. We have also been told that the domestic market (Japan) would get priority as well. Since the EV market here has been so wishy-washy and loaded with political rhetoric, that isn't much of a surprise. The market is no longer choiceless like it was when Volt first rolled out. The this-or-nothing situation no longer exists. Ford offers a choice of two different plug-in hybrids. Honda offers one too. None of them resemble GM or Toyota in operational characteristics. Confused feedback from consumers already is reason to focus on existing markets more than expanding to new ones.
- 1-30-2013** **Inspired.** A thread on the big Prius forum discussing extreme-cold driving results inspired me to try more. Why not do it again? Although the temperature is considerably warmer now, a blustery 18°F rather than -2°F as before, it would still be a good example of Winter driving. I'd run errands all in EV. With a maximum speed limit of 50 mph and using only the heated-seat, it shouldn't be a big deal. I'd simply crack passenger-front and driver-back windows for air-circulation to prevent condensation instead of using defrost. The engine should stay off. I began with a fully recharged battery-pack. Charging ended 8 hours earlier. The Prius hadn't been used for 18 hours. It sat there in the garage overnight. Leaving mid-afternoon, conditions inside were about 30°F. That's far from ideal, nothing like the maximum battery performance we experience when no jacket is required. Anywho, I drove 3 miles to the bank. From there, it was 2.5 miles to the cable-company. From there, the drive to mom's was just under 1 mile. No engine up to that point. Next stop, the coffeeshop. I traveled a distance of 9.1 miles before running out of EV. The engine fired up and continued to draw electricity. The battery-pack was depleted down to 3 bars before the warm-up process began generating electricity instead. When I arrived at my destination to enjoy a coffee and type this post, the total travel came to 11.9 miles. The final drive through the parking lot to the spot was in EV, since warm-up had already completed. The resulting average for that entire drive was 198 MPG. It was an excellent example of what you could experience given the right conditions, a demonstration of potential... but not necessarily an expectation. YMMV.
- 1-30-2013** **Entirely Different.** 2013 is a fresh year, a clean page in history. Consumers now know of Ford's two plug-in hybrids (C-Max & Fusion), Honda's new plug-in hybrid (Accord), and obviously Toyota's (Prius). So perspective of the past doesn't apply anymore. In other words, previous excuses aren't valid. We start with an entirely new market. The situation emerging poses new questions, now that real-world data is becoming easier to find. Focus will be on results, not approach. Only enthusiasts care about system details. It's very similar to what we saw in the past with the difference between ASSIST and FULL hybrids. The typical consumer couldn't care less how it operated. They were interested in how well the vehicle would fit their needs & budget. I'm thrilled that technical debates are over. At this point, all comes down to sales. To specifically address Volt & Ampera, how sales growth will be achieved remains a huge mystery. Somehow, GM must keep interest from being lost to the other automakers. What will that do to achieve that, knowing the tax-credit will eventually expire? It's one thing to deliver the vehicle itself. It's something entirely different to make it a high-volume profitable seller.

- 1-31-2013 Deliberate Greenwashing.** You have to wonder what happened to journalism upon reading published statements like this: *"How green is it? In the compact car arena, without the EV mode, the 2013 Chevrolet Volt can get 40 mpg. That's pretty green in any book."* First, 40 MPG is nothing to be proud of from a compact hybrid when traditional vehicles are able to deliver the same thing. Second, being green doesn't just mean high efficiency. That only represents a reduction of carbon emissions. It says nothing whatsoever about the other kind, smog. In fact, some high-efficiency vehicles are actually dirtier. In the case of Volt, the book gives it a ULEV rating. That's just like most other traditional vehicles on the road, very common. EPA wrote that book. They are the Environmental Protection Agency, an official authority when it comes to being green. Yet, the author omitted any reference to them and deliberately painted a green picture for Volt. It in fact is not. A truly clean emission rating is PZEV. And you guessed it, that's what Prius delivers. Want to ponder the topic even more, think about how clean electricity from an old coal factory is. Think about the emissions it creates. The writer certainly didn't convey any information to that effect... a proper journalist would have. The article ended up just being a promotion for Volt, despite initially leading you to believe it was an overview of what automakers had to offer.
- 1-31-2013 Heater Greenwashing.** A handful of Volt supporters are attempting to exploit a behavior trait, trying to spin it as disqualification: *"PIP doesn't even get any EV only miles if heat is used."* Some still obsess with the absolute. So any engine run, even if brief, means it doesn't offer EV. You start by asking them for some detail. The response to that is usually a fairly solid clue to actual intent. It's just like when the EPA estimate was released. They ignore the battery-capacity itself and focus entirely on when the engine is first triggers. Shutting off shortly afterward doesn't count, despite the fact that Prius is a hybrid and that's the way it is suppose to operate. Getting a mix of EV & HV is a shortcoming as far as they're concerned, regardless of the resulting MPG. Whatever. I responded with: Who told you that? It certainly wasn't an owner. -6°F on this morning's commute was a great example. Despite using the heater in my PIP this morning, I drove in EV... 4 miles with the engine off, to be precise. The engine stops once coolant temperature reaches 130°F, then stays off until hitting the low threshold... typically 114°F, but sometimes lower if speed is really slow. Also, let's not overlook the reality that the plug-supplied electricity is used even when the engine runs. That is referred to as EV-BOOST. It pushes MPG above 100, which you routinely see while traveling faster than 62 mph.

- 2-01-2013** **No More.** Sales results for January were published today. The hybrids are holding ground. Thank goodness. Focus is shifting to plug-in models. We knew January is always a bad month and that the rush to collect 2012 tax-credits would cause counts to be lower. We also don't want to draw any conclusions on debut offerings, since they typically have a skewed impression of demand at first. That limits commentary to Toyota & GM still. 874 for Prius was within expectations, since availability was still limited to just the 15 initial rollout states. Now in its third year, Volt is clearly facing a struggle. 1,140 for sales is so low, there are no more discussions about it. I was actually shocked to find nothing beyond a brief mention. Even the spin has evaporated. Attention has been lost. No one wants to say anything about Volt sales now. After the expectation revision last year being way off, what could be said? Remember how 45,000 was stated? That meant 3,750 per month. Without growth, how will it survive? There is no hybrid counterpart. It somehow has to find a way to stand on its own, especially with competition growing and incentives later expiring. That doesn't look promising without some type of major change. Status quo isn't enough... which is why we aren't hearing anything anymore.
- 2-02-2013** **Challenges.** This summarized the general view pretty well: "*In my opinion, the PiP has two major problems, range and cost.*" Without history, judging market response is like throwing darts. For me with extensive experience, I see thoughts about the technology changing rapidly. By the end of the year, people will be familiar with the basics. That's a big step. But the way we spread real-world information now, it's fairly realistic. I posted this: The perception of "range" being low isn't a daunting challenge to overcome. After all, the audience is focused on "performance" numbers related to efficiency, not the old school more-is-better with speed & horsepower. Fortunately, the test-drive experience can be quite compelling. When it comes to "cost", there's a big question to ask. Is the point to entice someone who would otherwise purchase a regular Prius or it is to offer an affordable plug-in hybrid? There's a big difference. A larger battery-pack would offer more, but the tradeoff is higher cost. You also have to sacrifice both internal space and efficiency after depletion. At least with the plug-in Prius, things the system will be refined over time. Like with the computer industry, there will be battery & cost improvements. It's not like the automotive industry a few years ago, where the definition of "improvement" was to just make the vehicle bigger with no concern about efficiency.

2-02-2013 **Decision Making.** We're seeing lots of questions about the plug now. The increase is a good gauge of growing interest. I suspect we'll see steady growth as the temperature warms. In the meantime, it's random queries like this: *"I am thinking of purchasing a Prius plug-in and I will be using it to drive within 8 miles of my home. Since the speed limits in my area range from 20 to 35 mph will I benefit from using the EV mode? Or am I better off buying a the standard non- plug- in version of the Prius?"* After awhile, a pattern will emerge. That comes about from the basics becoming easier for the curious to find answers too. I responded with: Short trips are MPG killers with the regular Prius. If you had to deal with them and speed limits up to 45 mph, efficiency is heavily in favor of the plug. That makes the decision easier. The engine likely wouldn't be needed at all. 8 miles from home (16 round trip) is longer though, but the capacity would actually balance out nice. You'd still get great MPG overall. In the summer, you'd experience the rapid engine warm-up and not mind much when it runs. In the winter, you may get annoyed by the engine warm-up taking longer and running for heat, not just providing power after depletion. The EV experience is complimented nicely by the HV driving. It's what a plug-in hybrid is all about. Toyota designed a system for the masses, delivering a vehicle that takes advantage of electricity without sacrificing it just for the sake of keeping the engine off even when it's inefficient to do so. It's a balance some people like and others don't. Good luck with your decision.

2-02-2013 **Financial Burden.** In the past, greenwashing included some rather blatant number misleading... like expecting the price of gas to remain under \$2 per gallon throughout the entire lifetime of the vehicle. That was absurd, yet many articles did it anyway. Fortunately, the arrival of \$4 gas put an end to that. Another common thing to do was to force the perspective that the hybrid system must have a break-even price before it could be considered for purchase. Those attempting to undermine Prius used that "financial burden" argument to dismiss it from being a realistic choice by making any additional cost seem a penalty. The mindset is carrying over to the plug-in model, making some accept arguments at face-value rather than looking at the big picture. The who & what is uncertain, but the consequence is obvious. Greenwashing through the use of omitting information is wrong, period. We're trying to prevent that. This is what I responded with when the topic emerged today: The magic question is asking yourself how much you'd like to contribute to the environment and making a better future for the children. Some people disregard that benefit entirely, expecting the financial decision to *"pay for itself"* rather than helping out a little bit. Considering a small chunk of the price difference for that is realistic.

2-03-2013 **Common Sense.** The discontinuity between expectations & reality should be obvious. The matter should be so easy to see, you think of it as common sense. But no such luck. You read something like this and wonder if it's even worth the bother: *"Volt's engine can not drive the car alone without its electric motor. In fact, its electric motor is the main drive, thus the EV. Prius's engine can drive the car directly without any of the electric motor input at all. That is why it is a hybrid."* People just make up their own definitions to fit their own needs. A hybrid is a vehicle with two power sources. The way those power sources are used identifies the type of hybrid, it doesn't make it something else... like an EV. Yet, they'll just argue with you to no end. Prius cannot move by engine alone. The power-split-device doesn't accommodate that, since it is configured to do the opposite... allowing electric-motor propulsion instead. But they don't care about things like facts. Ugh. Definitions are the same way. The entire industry can follow a rule-of-thumb, a best-practice with well-proven results. That doesn't matter to them. If that isn't formally defined by some official authority, it doesn't exist... like the volume considered mainstream. Even though it has been acknowledged in countless writings as 5,000 per month, that popular consensus isn't enough. Accounting realities somehow don't count. Things like speed & power don't either. When an antagonist sets a boundary, they stick with it like glue until the hybrid exceeds it. Then they pretend it was criteria all along. Fortunately, we've been through this enough times now that it is no longer worth bothering. Common sense is beginning to prevail. Yeah!

2-04-2013 **Demand vs. Supply.** GM being it's own worst enemy is nothing new. Assurances about supply matching demand have been abundant. Production shared with existing high-volume traditional vehicles was suppose to provide an advantage. That's proving to not be the case. Volt doesn't share much with other vehicles. That adds to cost in every regard. Starting fresh by building an upgradable platform wasn't the approach taken; instead, it was to deliver a vehicle with end-state performance hoping prices could be dropped quickly. Unfortunately, opportunity is being lost in the meantime. Ironically, a weakness about the plug-in Prius frequently sighted by pundits could very well end up being top rollout benefit and is pretty much an extreme from Volt... it's too similar to the regular model. Volt has no hybrid counterpart. Prius does and it high-volume. Volt doesn't even have anything remotely close in comparison. It's stands alone. That means it isn't realistic to expect anything resembling mainstream sales for awhile still... ironically, what some of us were saying for years prior to rollout. But it doesn't matter anyway. History can so easily be spun and everyone seems to be on the same page finally. Demand doesn't matter if there isn't supply.

2-05-2013 **Losing Marketshare.** Someone stirred this pot, claiming plug-in Prius sales won't grow at all in 2013. This was one of the comments posted in that discussion: *"Trying to not sound like a PiP basher (but it will sound that way anyway) I think the PiP is only appealing to Prius owners that want a HOV sticker."* I chimed in with: It's easy to avoid that by including data with the comment. Heck, I could make the very same statement about Volt, since we did indeed see a surge in sales in CA when the HOV model was introduced there. Knowing how much Prius owners want more electric-only driving opportunities, more electric-only power, and a plug from countless discussions in the past, without any reference to HOV, that *"only appeal"* comment doesn't hold much water. Do some searches on the EV button. You'll find an abundance of examples. We even had a number of threads & surveys discussing how much that battery & plug augmentation should cost. The merits of keeping cost in check verses offering lots of capacity generated lots of participation. It was a very popular topic prior to PHV rollout. Now that there are PHV owners sharing detail of their ownership experiences, commenting on a wide variety of observations, interest is growing. Look at the volume of activity in the plug-in section of the forum. HOV rarely gets mentioned. It's obviously helps justify the purchase, but how many of the 15 initial rollout states even offer that? Lastly, think about how many Prius fence-sitters there have been, those who found Prius appealing but wanted a little bit more from the electric side. That increase in battery-capacity with the addition of a plug as a reasonably priced package option, could prove just enough to push them over the edge.

2-05-2013 **The "Real" Effect.** I was pleased to end my evening reading & responding to this: *"The second factor is ANY vehicle needs to be on the market three or four years before the vast majority of folks can even consider it "real" or even a possibility."* If you didn't guess, the first factor was the price of gas. Here's what I had to say about the second: That sensible logic really ruffles the feathers of both enthusiasts & greenwashers. The enthusiast yearns for rapid success, signs of strong high demand shortly after rollout. Heavy emphasis on bragging-rights how you to indentify them. Words over substance, a recipe for trouble they just plain cannot see. It's really unfortunate; yet, we've seen it play out several times now. The greenwasher is one who doesn't want to acknowledge all the aspects at play or take into account real-world data beyond a vague sampling. It's your own assumptions they take advantage of, painting a picture of failure rather than providing information rather than allowing you to decide. For me, I'm enjoying the first year of plug-in hybrid ownership during the wait. Just like with the previous generations, I knew it wouldn't even be until the summer of the second year that people would begin to take notice. Patience totally paid off then. At that point, you've collected enough data and summarized your finding to such a degree they are compelled to learn more. The *"real"* effect is something I've been looking forward to.

- 2-06-2013** **First 3 Years.** This shows a level of desperation I hadn't expected to encounter, taking me quite by surprise: "*The Volt is actually outselling the Prius.*" The statement itself wasn't so unreasonable, it was the data used to support it: "*Prius worldwide sales: 1997 sales = 300; 1998 sales = 17,700; 1999 sales = 15,200; First 3 years = 33,200.*" I was blown away by such blatant greenwashing. Ironically, it was on a daily thread in support of Volt rebutting an article published yesterday asking the question: "*Is the EV already facing extinction?*" To answer with such misleading of a response is amazing. We all know times are very different now. Last year, there was much anticipation of the upcoming rollouts of plug-in hybrids from Toyota & Ford along with the availability of several different EVs from several different automakers. That makes it a very different situation, without even addressing some of the other differences... which I was more than happy to post: Leaving out details like sales in 1997 not starting until December tells a very different story. Availability outside of Japan did not begin until the second half of 2000. Misconceptions were abundant and gas was dirt cheap back.
- 2-06-2013** **False Memories.** A featured story on the radio today was about how people remember things that never actually occurred. It's a surprisingly common problem too. Even more frequent is they don't remember correctly. I've got tons of firsthand examples of that. Someone will say something about Volt and I'll make reference back to it years later, an easy thing to do when you've got the quote documented in searchable blogs. They'll deny the statement was ever made. I also have proof that claims were made by someone else, even though they absolutely insist it was me. Facts being forgotten & confused is the reason for the pullback now. Why bother when 2013 should be the focus anyway? Sadly though, some either don't understand or refuse to be realistic. Reading this on the big GM forum fortified that: "*Drop the price \$10K. Fist fights will break out on Chevrolet dealer doorsteps the morning that happens. And that's just the grey-haired bingo-playing crowd. Put the Volt in the price range of a well-equipped mid-size sedan and it's game over. Volt wins.*" How could that possibly be achieved? Cost reduction is an extremely difficult challenge. The purpose of the game is to achieve profit. You can't just slash prices. Don't they remember financial disasters of the past. Oh! Apparently, some people don't. Of course, it could just be selective memory. After all, refusing to acknowledge mistakes of the past is a component of the pride problem we've been dealing with... bragging rights.
- 2-06-2013** **\$5 Gas.** The hot spot in the United States is downtown Los Angeles. Gas is now \$5 per gallon there, again. That's getting people to take notice. We know that Toyota & Ford are well positioned to take advantage of the opportunity, the desire for better efficiency by consumers. Hyundai will likely do well from this too. That could also work out to be very good timing for VW, with their new Jetta hybrid. Honda with its the upcoming Accord is anything by certain. Nissan is in a strange situation, choosing heavy emphasis on EV sales. That's risky. As for GM, Volt should see a climb in sales, but it will be impaired by competition from within. eAssist and the diesel version of Cruze about to debut confuses matters. Combine that with compacts like Sonic & Spark, there's a variety of choices with a huge price gap. The premium for purchasing a hybrid was always a big deal. \$5 gas makes it an easy decision, when the resulting price is similar to that of other middle-market vehicles. Too expensive makes it difficult to sell. This is why being able to deliver a profitable vehicle with an unsubsidized price of around \$30,000 has been so frequently sighted as a goal. It's especially challenging for plug-in vehicles. Time has already run out... reinforcing the configuration decision to keep the battery-pack in Prius modest sized. Waiting a few years still is too late.

- 2-07-2013** **Cruze Diesel.** The price was revealed today. It will be \$25,695, plus \$810 destination. That \$2,115 more than Cruze LTZ, but supposed well equipped. It's also \$2,640 more than Jetta TDI, so it's not exactly competitive. 42 MPG is the highway. That reveal has caused quite a stir. People were expecting a better rating. MPG for city is still unknown. It's obviously lower, a good reason to avoid stating it... knowing highway came up short. With diesel so much more than gas (50 cents per gallon here), the selling point for choosing it over the gas model will be a difficult argument... and that's before you discover what's in the trunk. There, you'll find a 17-liter (4.5 gallon) tank for hold urea. That's a liquid required to cleanse the emissions. And even with it, emissions much dirtier than Prius... only enough to allow the diesel to be sold here, not even close to the PZEV rating... the opposite end of the spectrum, in fact. All that effort for a loss of cargo space, extra weight, and extra expense for what? Remember that it was suppose to deliver MPG close to Prius? It isn't even a midsize car. It's a compact. How is this competitive? After all this waiting, the outcome certainly isn't what had been hoped for. Needless to say, even the GM supporters are expressing disappointment. There's no need for me to even bother saying anything.
- 2-08-2013** **Under-Rated.** Quite a number of diesel supporters came to the defense of Cruze diesel yesterday. There was a common theme to many of the responses... diesel MPG values are under-rated. Reading that over and over again without a single explanation why is reason for concern. We don't see that same claim from hybrid supporters. Sure there are plenty of hybrid owners posting stories of them achieving higher MPG than the EPA rating, but none claim that as an expectation. In other words, with a hybrid you could do better and with a diesel you will. Based on what? It's reasonable to see that will long highway cruises using a manual transmission, but that's a specific driving condition and Cruze diesel will only be available as an automatic. Making blanket statements without justification seemed perfectly legit for them, even though if a hybrid supporter tries that they get beat up. It's amazing how hypocritical the situation is. It doesn't matter though. 42 MPG highway with a city MPG lower and the fuel itself both more expensive & dirtier, why bother? This is just another example of not offering something actually competitive, yet touting it as a wonderful new choice for consumers.
- 2-08-2013** **First Year Wait.** One thing I have been hearing more of is the "*first year wait*" advice. It's a mainstream consumer mindset. They wait until the second year of availability before even considering a purchase. This is an old-school mentality that hasn't actually matched reality since the 20th Century, but some people still feel more comfortable with the delay. They figure if there are any problems, they'll surface and be resolved within that first year. There's nothing wrong with waiting either. Patience is a virtue and it has always been worthwhile with Prius anyway. So, the supporters who made their purchase immediately wait too. It's rewarding for everyone. We see the excitement building from those consumers who chose to live vicariously for a year. And now that the annual cycle is almost complete, online curiosity is clearly growing. It's easy to see that from the questions being posted too. They want detail to help them finalize their purchase decision. This is supposedly what would happen with Volt last year. That's why I recently had to deal with so much backlash... because it didn't. Will it with the plug-in Prius this year? Limiting availability to the already established rollout states fits well with the wait advice. We'll see.

- 2-09-2013** **Getting Along.** New members on the big Prius forum are sometimes baffled by the head-butting that comes from a small number of older members. It was even asked: "*Can we all just get along?*" That innocent & naive statement is important to take seriously. It's an excellent question. But just like political dead-lock, the situation is nowhere near as simple as it seems. Heck, just getting to address fundamentals is a monumental effort... which sadly, often ends with useless talking points. Nonetheless, it's worth a fresh attempt: Who is we? Who should we be? It would have been wonderful for all the plug-in hybrids to team up in the fight against traditional vehicles. Things didn't work out that way though. The "*over promise, under deliver*" situation and "*leapfrog*" attitude made things very uncomfortable and we've been struggling to find common ground ever since. In other words, there has to be agreement on goals. What are they? For when? For who?
- 2-09-2013** **Insults & Injury.** Advancing beyond the fallout of 2012 is going fairly well. The only people still stirring the pot are those who were injured then, meaning their expectations had a major disconnect with what ending up happening. As a result, they feel injured... so they lash out with insults. After all, attacking someone who represents the triumph you didn't have is a way of getting closure. It's not a good one. In fact, it's quite terrible. Fortunately, they are few... and quickly losing credibility through their own lack of politeness. It's odd to watch self-deprecation play out. The temptation to respond to the bait they drop is intense. Resisting pays off too. You can even point out the fact that you are ignoring their taunts. Long story short, 2013 is shaping up to be pretty nice. Newbies are looking forward. Everyone else is happy to see progress. Yeah!
- 2-09-2013** **Fundamentals.** Hybrids with plugs. Electrics with engines. How are consumers really going to distinguish them? Volt enthusiasts continue to praise "EREV" as the only solution for the masses, yet cannot actually explain how it differs from the other plug-in vehicles that sometimes use gas. The label is really just a marketing strategy, since there isn't any criteria defining what it is. This is just like the lack of goals. Nothing specific ever stated was an obvious clue that whatever happened next would invite conflict & confusion, as well as impede progress. You can't be that vague and expect to succeed. The problems of risk & profit aren't resolved by gimmick. Yet, attempts continue. Notice how most comparisons are based solely on specifications, absent of real-world data? Notice how the specifications don't address need, simply expressing a "*more is better*" perspective? Notice how much emphasis is placed on price after tax-credit, rather than production cost? Fundamentals are lost in a wash of marketing push. Are readers taking the time to consider what the differences actually are? What about levels of importance? How many? When?

- 2-10-2013** **Toyota Hybrid Sales.** I lost track of the file where counts from Japan were saved on. Oh well. We know that the C model (known there as "Aqua") and the regular model (often referred to as "liftback") have been holding the first and third spots there for monthly sales. Here, the regular model is frequently in the top-10. Stepping back to look at the entire year, an interesting total emerges. Remember that goal set a few years ago? Toyota wanted to produce & sale 1,000,000 hybrids starting in 2012. They did it! Again, I don't have all the numbers, but the ones available tell the story anyway. 892,519 was the final count for Prius worldwide. 90,569 was the final count for the other Toyota hybrids and all the models from Lexus, here in just the United States. Only 16,912 would have had to been sold in Japan, Europe, Canada, or anywhere else to bring the total up to 1,000,000. It's quite clear, the goal was achieved. Yeah! The technology is undeniably mainstream now. That level of annual volume makes that fact undebateable now.
- 2-10-2013** **Annual Report.** I have lots of data now, 11-months of daily & tank real-world data collected so far. That was enough to reveal the variety of graphs & summaries I plan to present in the form of an annual report in March. Having a single document highlighting everything we commonly refer to, with actual owner information rather than just generalizations & assumption will be quite handy. There are things some people haven't ever considered before. For that matter, I had to make sure my representation wasn't misleading or incorrect. A good example is the depiction of MPGe. Since that's a brand new concept, even the formula itself must be very clear. Anywho, I shared what I had on the big Prius forum hoping for comment, suggestions, and whatever feedback possible to help make the final version realistic to publish shortly after the anniversary itself. The fact that the plug-in Prius has only been rolled out to 15 states so far makes a resource like this quite timely. We'll have something available to refer to when interest stirs later in the other states. I'm excited about the document. None of the other generations of Prius had anything so comprehensive. Of course, they didn't have a plug either. The use of plug-supplied electricity adds a whole new dimension to the purchase decision.
- 2-11-2013** **Inadvertent EV.** All I can say is "*ugh*". Several times recently, I've looked at the display on the dashboard and discovered EV range was almost all gone. Without even realizing, I had driven off without firing up the engine. EV mode is the default. So if you're a bit distracted, that can happen. But when you were planning to use that electricity later, finding it almost all gone is a bit of a mixed-emotion experience. There's quite a thrill to realize EV works so well, the lack of an engine isn't noticed. But there's also a bit of a let down that an efficient HV opportunity was missed. When you inadvertently drive along in EV mode, the endorsement for that design certainly is difficult to argue against. That's proof of how well thought out the approach actually is. The needs of real-world driving were clearly taken into consideration, in great depth. It's a nice balance of priorities.

- 2-12-2013** **EV Commute.** Today was an unexpected treat. I drove using all of the available battery capacity (that's 62%, from 85 to 23 of the entire pack) on my drive home prior to the engine starting. Usually, it's cold enough to require the engine to start for heat. Winter is slowly starting to fade away though. Just below freezing temperatures are far more frequent than the nasty near-zero from recent memory. That's exciting, since the commute route includes a climb out of the river valley at 55 mph. Being able to show that someday on video would be nice. This evening, it was just me alone observing. It pleases me every time I do that. Way back before I got my own plug-in Prius, I got to drive an early model for a few days. Climbing up the steep residential hill in my neighborhood without using the engine was the highlight. Those trying to undermine continue to claim that isn't possible. I know it is. Going up & down is part of the routine. My commute includes frequent EV use. This time, it was all in one big chunk.
- 2-13-2013** **Stereotyping.** There is a new initiative. It's an effort to stereotype Prius drivers. With so many in traffic now, forcing them into an odious category isn't much of a surprise. That may seem a little harsh, but we all remember what happened with SUVs. There's is an undeniable feeling of dislike still. There's also the faint memory of what happened decades ago with minivans... those who wouldn't be caught dead in one ended up having that as their everyday mode of transportation. The realities of need always win out over want in the end. Some have more difficulty accepting that than others. This effort to label is nothing new. It's unfortunate, predictable, and unavoidable. With the internet so prevalent, seeing op-ed attempts to undermine circulate from website to website is no longer a concern. They all refer back to a source with little to no credibility. In the past, that didn't matter. Now, it's easy for readers to figure out what's going on. Those sources with data to support claims draw attention away from those simply stirring the pot. Things like stereotyping don't work. We've all been through that too many times online already.

- 2-14-2013** **Tesla Love.** Today may be Valentine's Day, but love certainly isn't the theme online in the automotive world. Last week, there was a report published by a journalist who took a long highway trip with the Tesla Model S. There was 200 miles of road to travel. With a 265-mile estimated driving range, the trip in that electric-only vehicle should not have been a big deal. But when it comes to EV understanding, there is reason for concern. Knowing how some reporters don't take the time and just jump in behind the wheel... as we've seen countless times with hybrids... this experience wasn't likely going to be an accurate portrayal of what owners would actually do. Sure enough, the actions taken became a bit unusual. He slowed down to 54 mph in a 65 mph zone, supposedly to conserve power. There was no mention of the speed he had been traveling at prior to then or if slowing down had any effect though. Running low on electricity, he stopped to recharge. That went fine, until a confusing narrative of what happened the next morning. The trip had started with the temperature just a little below freezing, quite comfortable for us northern folk. It was now just 10°F outside. That cold gives the impression of lost EV range, since the distance is represented as if the battery were to never warm up. It will as you drive, lowering internal resistance, which results in longer range. But he didn't know that; instead, he ran the heater on low for 30 minutes without driving anywhere or even being plugged in. That was a huge waste. He then needed to find an electrical source before using up most of the power remaining. He did too. But he only waited for the minimum recharge. You can guess the outcome too. He didn't have enough electricity. It was a strange account with advice not followed and wonder about intent. Long story short, there has been quite a stir online for the past week. You'd expect all the resulting controversy to be a big endorsement for Volt, since it eliminates the "*range anxiety*" fear. Interestingly, it hasn't. In fact, quite the opposite as occurred. Volt isn't getting any attention at all. More missed opportunity. I bet the Tesla supporters won't remain silent like that.
- 2-14-2013** **We Love Oil.** There was a video circulated online that did an excellent job of using sarcasm to tell the story of oil love. There were my favorite quotes from it: "*I love how when the oil companies are making more profits than any other industry in history, ever, they still get billions in subsidies every year. I mean, that's awesome!*" and "*I love how oil companies talk about making gas cheaper with more domestic drilling, when gas prices aren't going anywhere, no matter how much we drill. Oh yeah!*" and "*I love how pollution from oil is causing climate change, which is letting oil companies drill in the arctic so we can have, you know, more climate change. I love that!*" and "*I love how you grown ups are so oil crazy. You're going to leave us with nothing but scary weather, no clean energy, and now oil left. Good thinking! I love it!*" and "*I love how having our entire economy dependent on oil leaves us dependent on régimes from all over the world, who don't even like us.*" Doesn't knowing that make you feel the love?

- 2-15-2013 Problem With Prius, part 1.** Reading this on the forum dedicated to Volt caught my attention: *"My contention is that, though the Prius is one of the most efficient cars on the road, it still suffers from the same fatal flaw that most vehicles today suffer from: It runs on gas."* Since I have never posted there and am not even a member (despite easy to prove false claims that I am and have), it's a good source for getting perspective from. What do they have to say? After all, this is the good that thrives on bragging rights. Getting constructive posts in response to that new thread would be a sign of change. After all, they avoided acknowledge that their founder replaced his Volt with a C-Max Energi. Remember, the original hope was that Volt's engine would only be used as a backup, when unexpected circumstances caught them in depleted state. Having the engine run routinely for heat certainly was a topic of greenwashing, an attempt to undermine and so favor for Prius. So naturally, they would portray the plug-in model of Prius as only being able to run exclusively with electricity as a rare situation. Needless to say, they were wrong on both counts. That's why I was quite curious to find out what their mindset is now. Has it actually changed?
- 2-15-2013 Problem With Prius, part 2.** Nope, no change. There were the expected comments, the usual "apples to oranges" dismissal comments... which made sense. Why in the world would the hybrid model of Prius be compared to Volt? It was quite obvious they avoiding discussion of the plug-in model like a plague. Not wanting to even bring up the existence was a dead giveaway they fear it. After all, I got characterized as a threat last week by a Volt owner on the big Prius forum. Those sharing real-world data thorough enough to cast doubt on GM's one-size-fits-all approach get cast as wanting Volt to fail. The idea of a plug-in for the masses is unacceptable. Appealing to the middle is in direct conflict of having a standout vehicle. It's always the same old nonsense. They wave the flag and paint a rosy picture for the future, ignoring what's actually happening. I had really hoped 2013 would be the wake-up call, such a shock to enthusiasts that the greenwashing would vanish like we've seen in the past for particular misconceptions. Signs of that not happening are emerging. They still see a problem with Prius... which means hope of a compromise are unrealistic. A more affordable model that depends upon blending for high efficiency isn't what enthusiasts are willing to support. The *"no gas"* chant continues.

- 2-16-2013** **Idle Workers.** Missing the overall sales goal of 60,000 for Volt last year continues to reveal consequences. That really angers some of the supporters, one of whom just plain could not resist: *"It's just a shame it doesn't have a larger battery so that overall efficiency is as good as the Volt."* He obviously isn't pleased that Prius PHV hasn't shared the same suffering. I responded with: It truly boggles the mind that such a basic economic reality is so easily traded for bragging rights. That quote is a classic example. Misplaced priorities continue to be a problem. The point of idle-worker report was to bring attention to the consequences of not meeting sales expectations. Profit comes from meeting production goals. Workers get paid whether they build anything or not. Sitting there playing games and watching movies instead of increasing inventory results in financial losses. Remember, the automaker chooses what to produce. Not meeting their own goals results in a profit penalty. Having a trophy for highest MPG does not pay the bills. The smaller size of the plug-in Prius battery keeps cost in check, making it a premium package option rather than a substantial price differential. The 4.4 kWh of capacity is clearly more market-competitive than the 16.5 in Volt. Reality is, waiting for the next generation of Volt is turning into a costly risk. Reports like this will continue to point that out.
- 2-17-2013** **Warmed Battery.** Cold temperatures reduce efficiency. People know that. Most don't actually know why though. Like many things, it's just accepted without questions. After all, most people are not engineers or chemists or physicists. The science is just taken for granted. Those are usually safe assumptions... unless you're trying something new, like driving a plug-in vehicle. In the case with Li-Ion batteries currently, the electrical resistance increases as the outside temperature decreases. That means it requires more electricity to deliver the same power as it does when it's warmer. Knowing this, you can actually improve EV performance simply by delaying when you electric-only drive. That works out great when you have a drive further than the capacity available and need to run the engine for heat anyway. A clue that the battery-pack is happily warmed, through the use of HV mode and the cabin heater, is when the windshield no longer fogs up even when you shut the blower off entirely. At that point, EV driving is at its most efficient. Of course, you can drive in EV sooner, but that's consumes more kWh than waiting. This is why some plug-in vehicles offer a battery pre-warming feature that operates when still plugged in. Think about MPG. Results vary with the engine. Why not results from a battery-pack too?
- 2-17-2013** **Boosted Acceleration.** I just got back from a driving trip, an expected funeral to attend. It's nice being able to provide support like that, just jump in the car and go. Of course, that meant not being able to plug in. Turns out, it was a good thing. I noticed something I had overlooked before. Saving EV-BOOST for hard-accelerations was something I hadn't ever considered before. That just automatically happens when both commuting to work and back home, since the engine is fired as I accelerate to get onto the highway. But when you're on a trip, you are usually in HV-mode and have little or no EV power available. So, the engine revs high (up to 5500 RPM, which is actually rather low compared to some traditional vehicles) when you drop the pedal. Taking advantage of EV, the RPM is kept below 2000. It's basically the same fuel-saving approach the regular Prius takes when accelerating in the suburbs... using electricity to allow the engine to run more efficiently. Now with the plug-in, the same thing can be done at higher speeds. Saving some EV for that when on long trips, especially when I'll mostly be cruising on the highway, appears to be worth further observation. It could be a handy MPG tip.

- 2-17-2013** **Stable Gas Prices.** We're seeing gas prices settle around \$4 per gallon, with the price of a barrel of oil just under \$100. That appears to be fairly stable, making all players involved somewhat content. There will be a little bit of up & down with the upcoming seasonal formula change. This time of year, there isn't much supply interruption. Vehicle sales tend to pick up as the weather warms. Demand predictably matches the increase in driving. It's typically good for all. With respect to hybrids, this is the time of year supporters look forward to. The build up naturally resulting from Spring combined with Earth Day promotion stirs lots of attention. Consumers now realize \$4 gas is more than just a spike. It's the new reality. Fortunately, there is no expectation of a climb. This is where it is anticipated to stay for the next year or two. Slow economic growth combined with ever-increasing awareness of climate change is good reason to think we aren't going to see any rash decisions in the near future. Price stability brings sensible choices.
- 2-18-2013** **First Generation.** It's always fun to point out history that some are totally unaware of. It was this today which called for that: "*The PIP is still in its first-generation and will quickly become a dinosaur as plug-in technology improves.*" Needless to say, I couldn't resist. I waited for a response before putting my own here. And as you could have guess, that person didn't answer my question. Most of the time, wild comments like that without any substance are easy to squash. That was definitely the case here. This is what did the trick: Actually, the current version is third generation. The first used 2 NiMH packs in tandem with the Gen-II Prius ...never offered for sale but had real-world testing. The second used a 5.2 kWh sub-pack Li-Ion configuration with the Gen-III Prius ...never offered for sale but lots & lots of real-world testing by ordinary consumers. The third is what we have now, the first offered for sale and featuring a number of software & interface upgrades based upon the real-world data & feedback collected from the previous. The battery-pack was reduced to 4.4 kWh without loss of range. As for becoming a dinosaur & quickly, that's quite vague. Care to quantify?
- 2-18-2013** **Need For Profit.** It all boils down to that. True, low-emissions & high-efficiency are selling points. But unless profit is made, volume will remain small. To seriously consider production replacement, the technology investment must return on expectations. That reality made the Volt enthusiasts absolutely crazy and the supporters nervous. That's why both were always out to prove something. Now it's 2013. Consumers are well aware of the plug-in. There's nothing left about the engineering to reveal. It's understood. It's also quickly dismissed. Just like with Prius, the top decision-making factor was price. Lost opportunity is the result. With such heavy dependence on a large battery-pack, the approach is really struggling. That need for profit is increasingly more of a problem. Not achieving mainstream minimum is a big issue for vehicles intended to be daily drivers. When it's ultimately needed as seller to help sustain the business, gambling that the next generation will be a homerun (being a popular middle-market choice) isn't exactly a good plan. Heck, even Toyota didn't want to do that with Prius. There are multiple models available as well as bigger systems for larger cars (both front & rear drive) as well as an all-wheel-drive system for minivans and SUVs. Just think how long it will take to get GM to diversify like that, especially if their approach is plug-in only. That's why the pressure continues to build, despite so little attention from the media anymore. Supporters are well aware of what the "*too little, too slow*" concern was all about at this point.

- 2-18-2013** **Unrealistic Criteria.** I agreed wholeheartedly with this statement: *"To tell you the truth - it really sounds pathetic to keep on hearing how: "I'm not going to get an EV until it goes 500 miles and charges in 5 minutes." "* Exaggeration is a common greenwashing technique. Those attempting to undermine blow numbers out of proportion with the hope that you'll quickly dismiss the topic, rather than taking a moment to realize how weak the argument actually is. Thankfully, Prius PHV is well positioned to deal with that. Since the plug-in feature is just an upgrade option rather than an entirely separate vehicle, the opportunity for further consideration is quite realistic... even when the online nonsense persists. The rhetoric won't do much to prevent closer looks at the dealership. In fact, negative attention typically stirs curiosity. Despite not being able to meet the extreme criteria some claim is required, being a reasonably affordable package choice and not requiring anything other than an ordinary household outlet for recharging will give people reason for consideration. The test-drive experience melts away doubt. People will just forget that greenwashing in the end. Realistic criteria wins. We've seen problems of the past fade away as those making the absurd claims mysteriously discover they're outnumbered by practical-minded consumers. Remember how some claimed gas would have to get considerably higher than \$4 per gallon for people to consider downsizing. They certainly were wrong about that.
- 2-18-2013** **Not Alone.** There was reason for a little bit of hope today. I may not be alone at work anymore. To my surprise, there was a brand new iMiEV using the other charging-station. Having someone else there could finally set into motion the plans to expand. Management there has been saying several more charging-stations will be installed soon. That kept getting postponed though, which is totally understandable considering the expense and it being the dead of winter. Seeing the only 2 spots filled everyday would change that. They'd like to avoid sharing too, since there's an entire section set aside for plug-in parking. More usage is a win-win situation... especially considering the ramp features an 82 kWh solar-array. I'm looking forward to the change. Owning a plug-in for almost an entire year without anyone else mingle with has been a test of patience.
- 2-19-2013** **Tesla Support.** Owners certainly didn't remain still or silent. They quickly organized a trip, recreating the drive in that controversial report. It was their version of a rebuttal to prove what the writer had done didn't make sense, to refute his negative experience. They did too. There were four that drove the entire route. All made it just fine. The catch was planning ahead and fully recharging. Note that they used the same super-fast recharging stations he did, so we're talking extra minutes not hours. He got impatient and stopped early. Two of them also left the battery plugged in overnight to keep warm. Two didn't for good measure. He did not. It was an effort to set the record straight, done by those who support it... not the automaker. This is the very thing Volt supporters were told to do. Over and over again, you inform them of the power that owner endorsements have as an educational tool and a preventative. Makes you wonder if they'll do anything now. Excitement is building for Prius PHV, anticipating rollout expansion. Future owners are yearning for the opportunity to purchase & document. Tesla owners are getting a taste of what positive reinforcement can do. Being proactive rather than reacting after the fact is far more effective. Makes you wonder what will happen next.

2-20-2013 **Good Judgment.** It was the New York Times who published that misleading article about the Model S. They had backed up their writer too, until yesterday. Harsh words from the Tesla's CEO and the outcry of owners got them to change. True journalism cannot have controversy like that. The facts should speak for themselves. They finally did. This is very much like online eruptions of the past. Just look at Volt, there were so many it's hard to believe. However, with Volt they weren't all from reporters who, in the words of the NYT, didn't use "*good judgment*". There were quite a few enthusiasts who simply relayed a message of hope without giving it any actual thought. The most abundant example of that was the frequency to which effects of Winter on the battery-pack were summarily dismissed as rhetoric from Prius supporters. They didn't give it serious consideration. They just outright rejected the claims. Had they taken the time to think through the situation, as what was just done with Tesla, the outcome would have been very different. Fortunately, the conflict having arisen with this was short-lived... quite different from the years of poor judgment with Volt... which has been point all along... learn, then move on.

2-20-2013 **Pipeline Protests.** It doesn't take a rocket scientist to determine that our addiction to oil and recent climate-change events are preventing old-school thinking from gaining any traction. Just a mere thought of building a pipeline across the country stirs intense emotion. Why in the world would we devote so many resources to legacy technology? It makes no sense. Even if the act of extracting oil was a clean & undamaging process, it's still a limited resource. The infrastructure we put in place won't be able to be used by our children. Establishing wind & solar locally in communities spread throughout the country is an entirely different matter. It is with the use of waste bio-material for local ethanol production as well. How much oil do they expect to transport via the pipeline anyway? Shouldn't jobs be created in something that's actually sustainable? How will money for the construction and money from the refined product afterward be handled? Which country will control what? Who will be overseeing the well-being of the pipeline long-term? In what way is supplying more oil actually helpful? The list of questions is quite extensive. Those few are just the tip of the iceberg. What is the goal anyway? Looking at the big picture, using less oil is the key. Pumping more into the system doesn't seem a sensible solution.

- 2-21-2013** **EV Experiences.** At this point, we've seen countless posts stating observations of EV miles dropping due to the cold and lots of HV driving. Unfortunately, we still see numerous online claims about the plug-in Prius not being able to climb hills or drive through the suburbs without the engine starting. After 11 months of ownership, that's really annoying. It's about time we have a thread dedicated to the sharing of EV experiences. For me, this evening offered a great experience to share. I needed to run an errand, to pick up a number of provisions before the upcoming winter storm arrives. Outside, it was 21°F and dead calm. Inside, my Prius had been parked for 4 hours, plugged in immediately upon arrival home from work. The garage stays just warm enough to melt snow the Prius carries in. The battery-pack was obviously still warm from recharging having finished 1.5 hours earlier. Since the car had been toasty warm from the previous drive, just the heated seat would be all I'd need for internal comfort, no need for window defogging either. The EV distance estimate was 10.1 miles. The distance I was planning to travel was 10.6 miles, was very very hilly, and had a top speed-limit of 45 mph. The drive was great... electric-only the entire trip, both directions... despite the temperature below freezing and all the hill climbing. 0.7 miles of EV remained too. Errand running was always a pain prior to the plug. Once you're home after work and have eaten dinner, you normally don't want to take time late in the evening to pick up provisions. Doing it without using gas, with smooth & silent driving changes the experience. It's really nice.
- 2-22-2013** **You Still Get.** It's interesting what the new PHV owners have to say about the EV experiences. There are comments like, "*But only 10 miles?*", mixed within their positive praise. That makes sense from the perspective of electric-only vehicles being applied to a Prius. Even they want that plug to represent more than the supplement it was intended to be. But then again, for those new to hybrids purchasing a plug-in Prius as their first, it contradicts the belief that owners are only those who are upgrading from an earlier model. The greenwashers want people to believe it is just a "*novelty*" and have been successful to the point of even new owners referring to it that way. Fortunately, seeing the potential for more is easy. You still get quite a bit now anyway. The tradeoffs aren't big as from competing automakers. Toyota worked hard to deliver a balance. I put it this way: The addition of a plug comes without any big compromise. You still get 50 MPG even when the plug-supplied electricity is used up. You still get the full cargo area with seat down for transporting large objects. You still get a vehicle that's priced for middle-market consumers. That's something the other plug-in choices don't offer. The fact that we also get more EV power and the target distance of 20 km (12.4 miles) to do things like running errands without any gas is a side benefit. The actual goal was to deliver an improved hybrid, not make it an electric-only vehicle. We got exactly that. As for calling the generation we have now as a "*novelty*", that doesn't actually mean anything. For that matter, no label would. The plug-in model will have modest beginnings simply due to the market perception created by the other plug-in choices. Those who own one will enjoy the EV experiences.

- 2-23-2013** **One Size Fits All.** That assessment of GM's approach made some Volt enthusiasts absolutely crazy. They were very, very resistant to the idea of diversity... since it wrecked the "EREV" concept. Offering a model with a smaller battery, which consequently would depend upon blending operation more often, was a topic replied to with fierce retaliation. It was amazing how hostile some of those exchanges got. Now, they just outright dismiss it... since addressing the merits of balance never ended well. It made Volt too much like what Toyota, Ford, Hyundai, and Honda were all working to deliver. It wouldn't stand out then. Ironically, that mindset is anti-mainstream... but they refused to acknowledge the needs of middle-market too. Anywho, as anticipated, GM will pursue pure electric-only vehicles but will restrict availability... due to having heavily promoted the idea of a plug-in with an engine instead. Offering choice isn't going to happen. No 45-50 MPG regular hybrid. Spark EV will be limited to California & Oregon only. If you want high-efficiency, the choice will be Volt only with a 16.5 kWh battery. One size fits all. That means either the major expense to buy a Volt or getting an eAssist or Diesel instead. That lack of choice, a huge void in between, could turn out to be a risky business plan.
- 2-24-2013** **Spring.** We're getting a taste of it now. The daytime high temperature has climbed to just above freezing. That feels good. It's so much warmer than it had been just a few weeks ago, I cannot begin to explain the differences. Thank goodness I scrambled to document as much as I could. Experiencing stuff for yourself for the first time is a lot in itself to absorb. Doing it with a notepad & camera adds to the moment, but it also quite draining. Fortunately, it does make the arrival of Spring even more of a welcome change. The feeling of that was quite obvious today too. I felt it. The Prius did too. You end up forgetting just how nice EV is when dealing with snow, ice, and the heater. When those elements disappear, you are left with the smooth & silence. MPG shots up as well. A month from now, most of Winter will just be a memory. In the meantime, there's lots of potential for heavy accumulations of the white stuff still. Thankfully, it melts off the road rather quickly. Keeping the car clean becomes a challenge then. The true arrival of Spring is when you discover what color your Prius actually is. Seeing the shiny clearcoat finish is quite a change from the sand & salt crusted layer of the cold season. Fortunately, you still benefit from the plug year-round... even when the temperature is way, way below freezing... just not as much when it finally gets warm.

- 2-25-2013** **Single-Camera Video.** I got really lucky the other day, leaving work at exactly the right time. The sun was just setting on that overcast day, which had delivered about 6 inches of fluffy new snow. It made for a great opportunity to film my commute home without any special video setup. Lighting was perfect. Scenery was compelling. Traffic would allow driving EV the entire capacity. I'd be able to deplete completely without needing a hard acceleration or having to turn on the heater. That particular drive requires a climb out of the river valley at 55 mph, something I've been yearning to show others. The video turned out well. Now I have something to share with others. Maybe it will inspire a few owners to try that themselves. Watching it, you'll see me leave the ramp from work. I pull out of my usual spot where I plug in to recharge. It's a few miles of driving at suburb speeds, with the occasional stoplight. From there, I jump onto the highway starting at 55, then speeding up to 70 mph. Watch the exterior lighting. You can see it getting darker as I go. The snow begins to fall again too. On the vehicle gauges, what I normally see is what's on the video. I didn't reset. That way you can see the results of the entire commute, instead of just that drive. The 34.5 mile round-trip with two full recharges resulted in a 94 MPG average. Even though the temperature was just under freezing on the way to work and only 21°F on the way home, that's still quite good. The cold isn't so bad when you have a plug... [Winter Commute \(dashcam\)](#)
- 2-26-2013** **Understanding EV.** I had much to say after reading a post with: "*Not only are ice drivers not interested in mpg, many don't know how to figure it out.*" and "*These drivers can only look at the bottom line when buying a car.*" Those particular comments say a lot... and are quite familiar. It reminds me of when Prius first rolled out. Since new owners had no idea what their previous vehicle was actually getting for MPG, their complaints about Prius efficiency didn't have any merit. They were comparing to an expectation, not real-world data. It was eye-opening when they finally discovered all those years of thinking MPG was higher really weren't. Then of course, there were the discussions of maintenance. We liked to point out that the EV experience offered more than just smooth & silent driving. Since they had no idea how an automatic transmission worked in the first place, detail about the simplicity and the lack of gears in the PSD fell on deaf ears. For that matter, they didn't even know how much they had spent on repairs in the past. In other words, not being interested is an important reality for us to be aware of. I hear that frequently. The person simply wants a vehicle that's reliable and cheap to operate. That's it. Enthusiasts go on endlessly, praising aspects of operation & performance that the mainstream couldn't care less about. They get really angry too, when you point out how middle-market buyers don't share their priorities. Stealth, that mode in Prius when the engine shuts while still driving in HV, has proven to be a rare trait that actually does appeal to the masses. That's why EV, the mode in Prius that automatically supersedes Stealth, is so important. It's simply an extension of an already well proven approach... something an ordinary person still won't be able to figure out, but they will understand how it affects their bottom line.

- 2-27-2013** **Strangely Quiet.** Not hearing anything about Volt anymore is really strange. On the big GM forum, not a peep. Without anything new to discuss, sales well below what's needed for continued interest, previous attention focused so heavily on the next generation, the reality of this one remaining a niche isn't up for debate. The hope for growth to mainstream minimum is postponed. This is exactly what happened with Two-Mode. The enthusiasts got quite angry when I requested they study its history, to help avoid falling into the very same trap... They know monthly sales announcements are rapidly approaching. They know gas prices are stabilizing at a level not conducive to market expansion. They know that recent negative press about Tesla did more harm than good for Volt. They know that GM's financial situation and product gap means little hope of change this year. They know that the other automakers are in a much better position to respond to the growing pressure to offer a variety of affordable high-efficiency choices. They know there is nothing else to be said. This new year is presenting a very different situation than they had anticipated. The next step isn't clear. What should they hope for now?
- 2-27-2013** **Pondering Rollout.** We'll never know all the criteria taken into consideration with respect to PHV rollout. After all, this is the foreign market and the home market is given a higher priority. Anywho, there is some pondering taking place now. For example: *"I am not sure why it takes so long to go nationwide, but training and car supply are two factors."* Other thoughts are being bounced around too. It really doesn't matter though. With so many variables at play, all you can do is make sure the approach is flexible. I jumped into the discussion with: Reaction to rollout of other plug-in vehicles has become a decision factor. The most likely, the focus now is to penetrate deeper into the initial states instead of rolling out to the others. It's part of that "wait until the second year" mindset... especially seeing how slow and how much negative press the others have received. Knowing that Prius is well established and that the plug-in model is really just a package upgrade will help it reach mainstream buyers. So, taking advantage of that opportunity to do exactly that rather than spreading thin to other states does make sense.
- 2-27-2013** **Not Knowing.** New owners being unaware of a feature or how it works is something we've seen on the big Prius forum countless times now. Today, it was: *"Now that I've gone thru Dec, Jan and Feb with the PIP - I'd rate its cabin heat as poor."* How do you point out that they've overlooked something? Pointing out a feature can sometimes be misunderstood or taken as condescending. You don't want to embarrass the person either, especially since they were so willing to speak out. I tried to delicately respond to that with: That's what the HV/EV button is for. Using EV-BOOST mode (in EV, but the engine running for heat) will limit the amount of heat available. It's easy to confirm too. Push the button and watch what happens to the engine RPM. It switches from low to high, resulting in coolant temperature rise. Unfortunately, spreading the word about difference that makes has been a challenge... since it took us awhile to make the observations in the first place. We also discovered that the temperature setting for the heater itself directly affects when the engine runs. The higher the setting, the higher the coolant threshold. That's different from the way the regular Prius operates, which uses a non-changing threshold instead.

2-27-2013 **2013 Goal.** GM is quite ambiguous when it comes to goals. They are rarely ever official. More often than not, a statement will come in the form of hearsay instead. That's all the internet needs to thrive on. After all, much promotion of the past was based on unsupported hype. Remember early last year? Denial about those goals from then, despite the fact that they were portrayed as solid & reliable, became abundant... which led to a fury of backlash problems the end of 2012. Needless to say, all involved have been squeamish about saying anything related to 2013 expectations. Today though, that changed. An article was published, stating this: *"General Motors Co. is planning this year to build as many as 36,000 Chevrolet Volt and other plug-in hybrids, 20 percent more than it sold in 2012, two people familiar with the effort said. GM is planning to build 1,500 to 3,000 of the plug-in vehicles a month, said the people, who didn't want to be identified because the target isn't public."* Notice how accountability is carefully avoided? That's typical. What's also typical is the response. In a thread about that article on the big GM forum, a Volt owner jumped on and immediately attempted to change the topic. When a thread emerges stating something they don't like, the reaction is to undermine by diverting focus. We've seen it countless times in the past. That's how we know they aren't pleased. That number is well shy of the mainstream minimum of 60,000 and far from what had been hoped. The other GM vehicles will easily eclipse Volt sales, holding it firmly in the niche category... especially since the difference may actually be nothing but the new Cadillac model. That's not what had been intended for the technology. That's not what is needed either. It's a bad situation getting worse.

2-28-2013 **Serious Question?** I've been complaining about GM's product gap for years. No one on the big GM forum took me seriously though. I was attacked relentlessly, accused of trying to promote the competition. Some were downright hostile. Others simply made up lies. It got very ugly. Thankfully, not posting there anymore was all it took to get them to finally hear the words. Now, the very same questions are being asked by those who had previously been the barrier. For example: *"Why has GM not released a direct competitor to the C-Max and the Prius V to truly take it to Ford and Toyota in this segment?"* The answer should be obvious. The way Volt was promoted, GM self-deprecated their own sales opportunities. There was a very clear message of purity, endlessly conveying the idea of blending being bad. Now, they cannot sell anything that blends. This is why the thought of offering a Volt with smaller battery-capacity to make an affordable model is such a problem. Supporters don't want it and consumers have been greenwashed to believe blending is a shortcoming. Meanwhile, the C-Max and Prius hybrids are taking advantage of that ability with both plug & no-plug models. It never ceases to amaze me how some paint themselves into a corner, simply unwilling to consider the big picture and instead of hopelessly clinging onto an ideal... then suddenly discovering they're in trouble... or it may just be sarcasm.

3-01-2013 **Smug.** A new owner asked about that label. Most encounter a friend or family member who states the attitude of Prius drivers that way... generalizing, without ever having given the matter any actual thought. I jumped onto that new thread he started and contributed: We've been dealing with that false stance for over a decade. The greenwashers attempt to create a stereotype to prevent the idea of doing something better for our children & environment from becoming the norm. Realistically, it's as effective as labeling someone who used PDA years ago... since devices now are far more geeky and far more common. How many smart-phone users have you seen today? The idea has been embraced by the masses and is in no way whatsoever identified as a "*geek*" tool like it was in the past. It's a complete non-issue. Ironically, the new smug emerging is helping to remove the prior stigma from the greenwashing. There is a very small number of Volt supporters who are still flaunting "*vastly superior*" claims. It's hard to believe they can still have such an attitude. Thankfully, they represent only a tiny fraction of actual owners... much like the circumstance with Prius in the past. In other words, remember what we were taught in kindergarten? Name calling isn't a good thing.

3-01-2013 **Consequences.** There are some. That's the lesson being learned now. We're watching history unfold. It's not playing out as planned. Sales results for February were released today. As the rest of us figured, Volt fell well short of what had been hoped for. 1,626 were sold here. Assuming the upcoming Cadillac ELR purchases account for 6,000... which would be amazing having its rollout begin close to the end of this year... the rest would have Volt at a minimum rate of 2,500 per month. Less in the Spring means more per month must be sold later. That kind of growth rate, with so much competition ramping up, likely makes this the biggest gamble yet. It's progressively getting harder, not easier. That should have been expected. As enthusiast purchases are all fulfilled and choices increase, sales become a greater challenge. They've always assumed acceptance would come naturally, so little was done to reach out to middle-market when the opportunity was still ideal. Now, it's a scramble. Appealing to mainstream consumers is turning out to be a heck of a lot more difficult than they imagined... even though that reality had been pointed out so many times, it began to make some of them crazy. They laughed & jeered. That's typical. The accounting aspect of business often gets accused of bean-counting and stifling innovation, even though that is what actually funds next generation design. Will they see that irony now? Who knows. Whether or not the consequences are acknowledged doesn't matter. The spooky silence online means something happened. That's a dramatic change from what we saw late last year. It indicates this year is already different.

3-02-2013 **Big Picture.** It may seem harsh being so critical of Volt, but that's because 2013 is decision time. The third year is when choices about the current generation become critical. Sales somehow must be increased. To be able to sustain at least a mainstream minimum (that's 5,000 per month) when the tax-credit is no longer available, the purchases we see leading to that should be much stronger than they are now. How will that growth be achieved? It's bad enough having plug-in competition from other automakers. But when you step back to look at the big picture, you'll see the same old still exists. GM is competing with itself. February counts make that overwhelmingly clear. Looking at the middle-market cars offered, it's ugly: Cruze 17,947; Impala 15,424; Malibu 14,817; Sonic 6,025; Spark 2,836; Volt 1,626. Even Camaro's volume is higher, mainstream level in fact: 6,171. That's not what was suppose to happen. It didn't take the market by storm. How is the next generation model going to compete? For that matter, how it further research & development being funded? How much capital are those other cars taking? After all, heavy focus on them is what's generating profit. Those references to "*too little, too slowly*" appear to have been in vain. That mistake was made despite the warning.

3-03-2013 **Heater Dance.** 9°F outside this morning meant an opportunity to try out single-camera filming again. The sun was rising quickly; that meant I'd be pushing exposure limits with the contrast between dashboard scenery. I really wanted another example showing what happens while you "*Just Drive It*". The battery had finished recharging 6 hours earlier. The engine hadn't been used for about 10 hours. The garage temperature was around freezing. I pulled out, adjusted the camera, hit record, then drove away. After traveling about a block, I turned on the heater. It was set to 70°F with the blower on 2 bars. The request for heat caused the engine to start. Still being in EV mode (the default), I was looked forward to it shutting back off as soon as the warm-up cycle completed. That happens when the coolant reaches at least 145°F and there isn't demand for high power. The engine will then remain off until the coolant drops to 136°F. Note that lower the heater temperature also lowers the coolant threshold. As I drove, the engine starts up, runs shortly, then automatically shuts back off. That's why I call that a "*heater dance*". That same cycle repeats over and over again, until the battery is finally deplete of EV capacity. Following that, the same things happens in HV mode but with less electric-only power. The purpose of the plug is to boost MPG. So even when the engine runs, the system is still taking advantage of plug-supplied electricity. EV driving is not necessary for great efficiency. This video clearly demonstrates that. 17.9 miles was the total distance traveled. 85 MPG was the result, with 1.3 miles of EV capacity still remaining. See... [Heater Dance \(dashcam\)](#)

3-04-2013 **Something Else.** You know times are changing when this is asked by a Volt enthusiast: "*So what is GM supposed to do about the big hole in their product line?*" Well aware that mentions of Two-Mode, "too little, too slowly" and "one size fits all" really irritate certain individuals, I posted this in response: The "product gap" question has been asked ever since Volt was first announced. In fact, that's how those with both a business & engineering background knew it faced far more of a challenge than the engineering alone revealed. GM simply cannot compete with nothing but a large-capacity plug-in. Something else is needed. The obvious choice was offering a system without a plug that uses a much smaller battery. Toyota abandoned their design like that many years ago. Honda did just recently. Ford never bothered. Nissan didn't either. Newer hybrids like that from Hyundai and VW both strive hard to be a careful balance of price & performance, well aware of the history of others. GM decided to upgrade their BAS system, which had a variety of issues to address. That next generation was rolled out as eAssist. It also has a variety of issues... most notably, not delivering enough of an efficiency improvement to generate many sales. Mention of Prius causes quite a stir with some supporters. Their reaction and the obvious effort to avoid addressing it confirms that "hole" is a lot bigger than they care to admit. Something else is needed. Volt all by itself is not enough.

3-04-2013 **Oh Well.** Not much I can do about it, but I still regret having missed a great filming opportunity. I had my video-camera with me, but didn't realize what I was about to face. The lighting was actually too bright and there were times when the windshield got messy. But the experience was well worth telling. We just got a few inches of snow and the traffic was really back up, some of the worst I've ever seen on the 70 mph highway. So, I took the back way instead. It was 25°F, which meant no need for warmth from the engine. The heated seat works well and I'm from Minnesota, after all. That slower route allowed me to drive 11.6 miles in EV before running out of electricity. With some travel at 55 mph and several stoplights, that's pretty good for the winter. In fact, the estimate when I started was only 10.7 miles. When the engine started, I was quite curious how long it would take to warm up. Though, it really didn't matter. Once warm, it shuts off almost immediately after a hard acceleration. And indeed, it did just that when leaving the suburb route to get onto the highway then immediately getting off on the other side of the river. That on & off of the engine is a usual part of hybrid driving. That works out especially nice when dealing with heavy traffic like today, even without plug-supplied electricity. Anywho, when I finally made it to my usual parking spot, the end result was 160 MPG. It was a sight for sore eyes. The cold temperatures usually prevent the super-high efficiency. Today was an exception. It's the norm come Spring, but we're a way off from that still. Of course, then, it's not as impressive to see since all the snow is gone.

3-05-2013 **Rollout.** Talk of availability has taken center stage lately. I joined in with: The market is quite finicky right now. We all hear comments that price should be lower and capacity higher, but that isn't realistic. It makes promoting plug-in vehicles a challenge, especially now that consumers have already been led down the greenwashing path... lots of hype that wasn't delivered. We now find ourselves in the want verses need situation. It's a good place to be, though uncomfortable at first. Following the traditional path of advertising based on desire doesn't cut it as we change focus to emissions & efficiency being more important, though there is definitely a niche opportunity for some. As for the masses, which is the point of the shift over to electricity, won't share those priorities. Their purchases are far more practical. We would all like to basically eliminate the importing of oil. That's not going to happen though. It's another unrealistic wish. The large capacity batteries we want are simply too expensive. What we actually need are those big enough to significantly reduce consumption but still small enough to remain competitive. After all, the market for traditional vehicles is well established. Replacing them is a monumental effort. Toyota worked hard to strike a balance, directly addressing need while well aware of the consumer wanting more for less. You get a plug upgrade without any loss of the upper cargo area or lower HV efficiency following depletion. Over time, price & capacity will improve. But currently, we're still dealing with a market that doesn't understand plugging and place little priority on super high-efficiency vehicles. That can change rather rapidly though and Toyota is already well positioned to respond. Long story short, there are many consumers who simply dismiss the plug-in Prius without actually knowing how it works. They just make a basic assumption, then judge without actually having facts available. That means sales will fluctuate from month to month initially. Entrenching deeper into those markets with some presence established already rather than rolling out to new ones makes sense in that case. Let's also remember how many consumers simply never buy a car that hasn't even been available for a whole year.

3-05-2013 **Greenwashing Attempts.** We've seen many of the years. As hybrids became more common, they died down. It's difficult to argue with false information as disproving becomes easier. And with so many on the road now, that's very easy. Misleading about history is different though. It isn't as simple as looking up real-world data. When it comes to perspective & belief, the matter is that of opinion instead. You can come up with a consensus too, assembling a collection of sources who all considered the same hearsay as credible. That's the type of greenwashing attempts we are seeing now. For example: *"Well, Toyota never really wanted to build this car anyway. They were dragged kicking and screaming into this world of plug ins."* Few people are actually going to research the engineering itself. For that matter, even finding the needed information would be a challenge. Those of us who followed Toyota's design from the beginning saw the potential. It was quite clear the setback was battery cost. The system was already setup to deliver. It was a matter of waiting for the technology to become affordable. They want to portray PHV as a last-minute after-thought. They fear the idea of it being a solution for the masses already well established.

- 3-05-2013** **Reduced Range.** Volt has fallen so far out of favor, even the talk of reduced range from the CEO of GM doesn't stir much attention. Enthusiasts are so dead-set on the "40 mile" range being best choice, offering another simply doesn't make sense and they stanchly defend the one-size-fits-all approach. That lack of diversity should raise red flags. Owners themselves are remaining indifferent... since they aren't concerned about future sales. Those of who are concerned see a niche without a path to mainstream. I posted: Same question as always: WHO? Who are the consumers they want to sell to? We are all well aware of how price has been a major purchase factor for middle-market. Not pursuing an affordable option means being stuck with a niche. The price has to be considerably lower to appeal to the masses. The hope of a cost plummeting quickly isn't realistic. Batteries will continue to advance, but the "miracle" people are hoping for will take a few generations. After all, the computer & hardware industries have been continuously advancing rechargeable batteries for decades.
- 3-06-2013** **Power EV.** I gave it a try. ECO mode is pretty much always what I use. This changes the behavior of the throttle, allowing for more play. POWER mode changes the throttle to touchy, making your press on the pedal an amplified effect. It doesn't really change the amount of actual power, though it does feel that way and there has been questions raised online if there is a momentary burst of higher amps. Whatever the case, it raises the coolant threshold, causing the engine to run more often in the Winter. So, I tend to avoid using it... except when driving through heavy snow. I wanted to know what it was like while in both POWER mode and EV at the same time. Turns out, it's pretty much like I expected. The behavior is just like in HV. That thought had crossed my mind as to whether or not it would be harder to keep the engine from starting, since that is something I spend very little effort doing. My guess was that ECO mode made it easier. Turns out, that doesn't actually matter. Ordinary driving even with POWER worked just fine. In other words, drive in whatever mode you like.

3-07-2013 **Coffee Run Video.** I managed to capture one more drive with snow still on the ground. Just like the other suburb drives I've filmed, this one takes me to that distant coffeeshop. The run back & forth is a good basis for demonstrating what happens as the EV capacity is utilized, then what happens after it's gone... which is why I filmed that same route prior to getting the plug-in model. You can clearly see the benefit. This footage featuring that rare lighting circumstance when a single camera can be used. Too early or too late, there will be over & under exposure. The refresh of the screen will become an annoying flicker as well. In this case, I took advantage of the sun setting with the horizon obscured by clouds. It provided a nice balance between dashboard and scenery, as well as show a nice pink in the final moments before the sun disappeared. As for the drive itself, shown at 5X normal speed, you can see me pull out into traffic driving in just EV. But with a route longer the total capacity available, I fired up the engine right away. That resulted in a boosted MPG until warm-up is complete, then the engine shuts off. Watch the estimated EV distance value. I suddenly drops from 9.6 to 8.5 when I turn on the heater to blow air on the windshield to keep it clear for the filming. Capacity itself is unchanged. That's simply how you are informed of the potential EV loss the heater could cause. Driving was uneventful, the usual stoplights & stop-signs you'd encounter driving through the suburbs. When accelerating hard, the engine will come on to help provide power. Watching the MPG, you can see that doesn't actually lower MPG much and it shuts off relatively quick afterward. In the summer, it shuts off even faster. But at 28°F outside, it runs longer. Halfway through my drive back, you can see me approach a long hill. Climbing that with only 1.8 miles of EV remaining wouldn't be the best use for that electricity. So, I switched over to HV mode by pushing the button for that on the dashboard. When at the top, I pushed it again to switch back to EV mode. That feature comes in handy when you want to preserve electricity for use later. At the conclusion of the drive, the overall result was 135 MPG for the 15.7 mile round-trip. The entire EV capacity was consumed; that's roughly 3 kWh of electricity including charging losses. That was a great drive for winter, but I sure miss summer. In warmer temperatures, resistance with the battery itself is lower. That more efficient transfer of electricity allows you to drive further EV from each recharge. So whether you use gas or electricity, cold weather reduces efficiency. Here it is... [Coffee Run \(dashcam\)](#)

3-08-2013 **Speaks For Itself.** We've been watching the demise of Volt. It's certainly not a failure from the technical perspective. Enthusiasts always feared that judgment. Their focus was exclusively on engineering though. Downfall on the business side was something few ever wanted to acknowledge. You got the impression none of them ever took an economics or accounting or management class. And now that the very situation concerned & warned about has emerged as an undeniable reality, silence. They simply don't want to talk about lost sales. Fortunately, I don't have to point out the real competition anymore. This post in its entirety from just a random member on the big GM forum speaks for itself: *"The Volt as it sits today meets my commuting range needs, and that's true for most people. I hope they aren't developing a high-cost vehicle for a small slice of the population. They ought to be figuring out how to make a pure electric or Voltec at a lower price point and with PROFIT. That would drive the company forward - volume and profit. The Volt is a halo car, and I love it, but it's just beyond what I would pay for a commuter car (3rd family car) and thus we bought a Cruze a week ago."*

3-09-2013 **Dizzying Array.** Notice the struggle Microsoft is currently having with its newest operating system? If so, you've fallen for the same trap countless others have. They blame the most obvious player, since that's what the media tends to focus on. In reality, Microsoft became flexible and offered a platform that could accommodate the new world of touch-interface as well as support the legacy needs. The software is fine. The actual problem is the dizzying array of hardware choices. Consumers assume without trying, drawing conclusions based on impression rather than firsthand experience. Can you really make a purchase decision from a quick test at the store? How could you possibly about ultra-portable ownership from a model chained to a display table? Think about plug-in ownership. Same problem? There's no possible way you could learn about what it has to offer with just a brief encounter at a dealer. That's why analysis & survey papers being published now about plug-in vehicle future expectations don't reflect what could happen. Heck, just ask a person what the operating system in a computer does. They likely won't have anything beyond just the most basic understanding. It's even worse for a plug-in hybrid. Most people don't even know what an automatic-transmission does in a traditional vehicle. So comparing it to a hybrid is pointless. Adding a plug only confuses matters. Then when you consider that each automaker will take their own unique approach, the situation leaves you wondering how the heck we are going to take the next step. In other words, the hype of the past claiming an obvious winner was just a dream. Reality is quite complex. There will be many choices. Don't look at only what articles point out, also consider the other factors.

3-10-2013 **Quizzed.** I filled up with gas this evening. It was the final tank of the year. Tomorrow starts year number two. To think that the second is about to begin already. I so clearly remember taking delivery. That vivid memory was an entire year ago already. Anywho, evidence of so much time having passed was quite evident when paying for the gas. I mentioned it being my anniversary to the cashier. He began quizzing me with questions. One after another, he kept shooting them off. I was impressed. For anyone to fire so many sensible inquiries at me, I couldn't help but to be impressed. That was sweet! He had clearly been paying attention. To who though? There are only a handful of Prius PHV in Minnesota still. Perhaps working at a gas station raises your awareness. There's a lot to notice if you are attentive to the media. After all, with the price of gas having stabilized just below \$4 per gallon, the cost to fill up is a common discussion topic nowadays. Needless to say, I look forward to the upcoming days when seeing plug-in hybrids on the road isn't so rare. Soon. Pressure from tax-credits expiring and CAFE requirements rising will help, even if gas prices don't change at all. Battery costs should slowly drop, which will obviously help too.

- 3-10-2013** **\$3.49 Gas.** How do you sell a plug-in hybrid when that price for a gallon of gas is considered acceptable? Demand for fuel efficiency has for the most part just caused people to downsize to appropriate-size vehicles. For those who have a more pressing need, the solution is typically a sub-compact car. That makes selling regular hybrids a challenge. Increasing the size of the battery-pack and adding a plug makes it a real struggle to stir interest. That's why there is currently tax-credit incentives. They are intended to help stimulate the market and provide a price-buffer while the automaker scrambles to reduce-cost to make up the difference prior to the credit expiring. You cannot depend upon the price of gas increasing demand to justify a higher price. That's a big problem for Volt, with its \$7,500 credit. How could its cost be reduced by that much it just a few years? Prius only faces a \$2,500 credit to offset and it has the advantage of high-volume production. Achieving that is much more realistic in comparison. It's likely the price of gas won't change much in the next two years either. Oil supply seems to have stabilized and the economy is recovering. That's good news, since the market seems to indicate lower prices than even what the incentives offer are needed for plug-in hybrids to really take hold. People have become tolerant of higher gas prices.
- 3-11-2013** **No Heater Video.** -2°F in EV speaks for itself. I wanted to know if the battery-pack could deliver the power needed for my daily commute in such extreme cold conditions. It did... and I'm quite thrilled how well the video turned out. The ride itself wasn't exactly warm, but I did it without wearing gloves for the first 24 minutes of driving. The heated seat on high does a remarkable job. The point was to find out how well the EV would perform, so I kept the heater off. 9 miles of electric-only driving was what ended up being available. I fired up the engine shortly before the battery was fully depleted of EV, not wanting the upcoming hill climb at 55 mph consume lots of HV capacity (electricity is used to allow the engine to gracefully speed up). Watching the video to the end, you can see close-up display photos of the outcome. The total distance traveled was 17.2 miles. The result was 117 MPG. That took approximately 3.0 kWh of electricity (including charging losses) along with 0.15 gallon of gas. That would be impressive even if wasn't -2°F. I still miss summer though, since EV works better then. Here it is... [No Heater \(-2°F\)](#)

3-11-2013 **Annual Report.** My first full year of 2012 Prius PHV ownership is complete. I meticulously documented details of that experience. Here's the summary:

18,477 = Total Miles

6,328 = EV Miles (displayed amount)

12,123 = HV Miles (displayed amount)

365 = Days (12 months)

574 = Recharges (based on capacity replenished)

239.9 = Total Gallons (measured at the pump)

1,721 = Total kWh (including charging losses)

1,505 = Total kWh (displayed amount)

77.0 = Lifetime MPG

50.5 = MPG (HV)

27 = kWh /100 miles

All the data itself and lots of graphs are included. It's really nice having a resource like that available now. We've needed something to easily refer back too. So often, there's been claiming about the plug-in model that were way off base but couldn't be disproven by simply supplying a link. Now, we can. Detail from very tank refill and every recharge is listed. The daily results are especially informative to see illustrated. Variance from real-world driving needs is very easy to see, clearly confirming that the generalizations about per-day usage are way off. There is no pattern. Life is not that simple. It was fun watching all that play out. Each day revealed a little bit more information. Watching the influence of seasonal change tells quite a story too. There's much to consider when it comes to everyday driving. Looks at the information I have available to consider your own particular circumstances. This webpage is where you the free downloads are available... [annual report](#)

3-12-2013 **Lies & Hate.** When that's all we have left, you can finally breath a sign of relief... and it now looks like that's all there is. It's quite unfortunate to have some dishonesty still, but thankfully that's easy to disprove now. As for the deep emotional response, those are to be expected. It's an outcome of change, confirmation things are happening beyond their control. Without getting too detailed, since there's plenty of lie & hate examples I could provide, we'll try to just stick to facts. Even though Prius PHV was only available in 15 states and in them for only 10 months, the total for the year came to 12,750 purchased. Worldwide, the sales total was 27,181. We're not really sure if that difference of 14,431 was exclusively in Japan, since a few must have been sold in the United Kingdom, but we do know that was only 11 months' worth of availability. Long story short, the total for Volt was still higher: 30,090. That's why those final desperate comments are being made. It won't be much longer before those attempts to greenwashed will simply be overwhelmed by the truth. Some love would be nice too. It was quite frustrating dealing with all the enthusiast rhetoric. But in the end (like when the tax-credits expire), vehicles designed to appeal to the masses which are also profitable will be the winners. That's what we can properly call "superior".

- 3-13-2013** **What Happened?** I'd consider it well timed. Someone on the daily blog for Volt, which rarely ever actually has content about Volt anymore, tried to greenwash about the plug-in Prius. It was one of the subtle attempts, despite using information that clearly didn't represent real-world data. I was intrigued. That type of desperation is the very thing I had just blogged about. So, it was a good way of summing up and moving on. I'm not expecting it to make any difference or for anyone to even respond; it was just a nice way to draw attention to the fact that it still happens. After all, going down with a fight is how some people achieve closure: Raising doubt was surprisingly effective in the past, but not anymore. It's now easy to challenge vague claims & dismissals with lots of detail. The internet empowers and continues to improve. Examples can be backed with references, confirming it really is what was stated. Follow up is not only possible, it's expected. People researching a purchase will do searches, watch videos, ask questions, work their way through the rhetoric. They'll reply with actual information, not just parrot a comment or make a generalization. What happened here?
- 3-14-2013** **Not Price.** It's simply not worth responding anymore. Just let it go when you read something like this "*It wasn't until the 2nd gen Prius and the cut in price that sales really began to rise...*" The price started out the same, then halfway through that first year price was increased by \$300. The real reason was the design delivered more power and greater efficiency in a larger vehicle. Switching from a sedan to a hatchback made a world of difference too. Volt's lack of a middle seat, very little legroom in back, and it not offering flat cargo area are a convenience factors often dismissed, something GM could clearly benefit from if the enthusiasts stopped claiming it was fine the way it is. Of course, the other part of the increase in sales was the reputation that had already been built up at that point along with the obvious gesture of continued investment on Toyota's part. If GM could send a clear message and stop with all the over-promising, Volt may stand a chance. Then again, enthusiasts becoming the barrier is a growing problem. Proof of that was the recent comments posted about price. So many sounded off that battery-capacity should not be reduced or a smaller battery offered as a second choice, it makes stating goals just about impossible... hence all the mixed messages. Clarity would be quite helpful. Though, some still either don't know the history of price or are in denial about that. Without understanding reason, it's difficult to make any progress. But when I ask, it just ends up becoming an argument... since ending up being proven incorrect is rarely ever taken well.

- 3-14-2013** **41 Degrees!** Although it is suppose to get cold this weekend, down to the single digits again, we had a brief taste of warmth today. My EV range estimate even went up as a result. I had seen quite a few "*10.5 miles*" values lately. Today, it was 10.9 miles. I remember the same drop & rise pattern last year, following cold then warm. It's part of the experience owning a plug-in vehicle. Winter reduces range. Consequently, the range estimate will reflect it. As Spring arrives, I'll see the value climb into the 11's. Low 12's will come later. I don't expect to see 13's, since I do so much HV driving. Those who primarily drive EV will though. Some will see estimates even higher. Of course, that has nothing to do with actual EV range. I routinely drove 13 & 14 mile distances with EV on a single charge, despite the fact that the estimate was only in the 12's. That's just the way it works. For that matter, it works the same way with traditional cars. You get "*distance to empty*" value with them too and they are also just estimates. MPG varies. So does the consumption of electricity. Fortunately, it improves as the weather improves. That's always something to look forward to, even if it is just a guess when and how many degrees.
- 3-14-2013** **The Irony.** I really get a kick out of how Volt enthusiasts use to sight the engine starting up as a Prius PHV weakness. Now that it's emerging as a strength, they stop mentioning it. That abrupt change to silence is clear confirmation they didn't have all the facts. Well, better put would be saying they didn't listen to all the facts. We presented them over and over again. But their outright dismissal prevented any consideration. Finding out that a brief burst of power from the gas engine to help out the electric motor is actually a wise design choice makes them sound hypocritical if they say anything. The nature of that behavior actually being a feature to point out as a strength to those researching the approach makes it ironic. Talking about a backfire. It's more efficient overall to save electricity for cruising, to take advantage of the engine briefly. Prius makes that easy to do to. Pressing on the pedal usually just results in EV driving. All you have to do is push a little harder, to make the bar on the Eco-Meter jump into the power-zone. With the engine already warm, it only runs for a few seconds. Having it shut off so quickly impresses those taking test drives. What was supposedly a weakness is clearly proving otherwise. Ha!
- 3-15-2013** **Research Funding.** The big news today was the plan to use revenue from federal leases for offshore drilling to fund research for automotive batteries and biofuels. The expectation is to provide \$200 million per year for the next decade. Considering how much we've spent on defending oil-reach nations, oil subsidies, and the automotive bailout, that choice would seem to be rather trivial. It's a good investment in the future and a rather small amount of money in comparison. Even so, there are still some opponents. That's hard to believe considering those other reasons combined with the price of gas. Why haven't we been doing that all along. Simply switching to domestic drilling and creating a new pipeline from Canada makes no sense. There should be something related to renewable energy sources too... and that's without even considering the environmental benefits. Needless to say, there were plenty of comments about this posted online. Long story short, it's a political issue... lots of finger-pointing and blame, rather than actually trying to accomplish something. It's sad.

- 3-15-2013** **Market Share.** The spin-doctors are at it again. They limit scope to give a false impression. Stepping back to look at the big picture reveals they are up to the same old nonsense again. Sadly, some simply thrive on the attention that gets them, which means there's no solution. They'll just keep misleading. They don't care about greenwashing. This was today's example: "*From hybrid cars Toyota's market share is falling...*" That almost seems objective, until you look at who posted it and remember the replies the previous times. I typically ignore those posts. But every now and then, it's better to respond than to allow them to influence innocent newbies. I chimed in with: The larger numbers get, the smaller the difference becomes. Also, it's called percentage spin when the market as a whole is not taken into out. The competition is traditional vehicles, not other hybrids. 892,519 Prius were purchased last year... which means fewer traditional vehicles were sold. Remember, the purpose is to replace mainstream sales, not compete within a niche.
- 3-16-2013** **The Disconnect.** We've been wondering when it would finally happen. Turns out, it's right on schedule. 2 years is the limit. Something big must happen in the third year; otherwise, new technology loses its "newness" and people simply move on. That was overwhelmingly clear with Two-Mode. Sales the first & second year were so far under expectations, attention shifted over to something else instead. Volt became the center of attention. Enthusiasts were captivated by the potential. They didn't let realities of business hold them back either. Cost and market need were carelessly disregarded. It was the very same thing that happened with Two-Mode originally, back when it was going to crush Prius. Later with Volt, it became a "*vastly superior*" campaign. Now that Volt has faded away from having under delivered to such a huge degree, promises from the next generation have become the focus. Now, we are seeing that same baseless hope emerge... again. Anticipation of increased EV range and increased MPG after depletion with a total absence of cost concern is dominating discussions. It's truly amazing to watch the very same behavior repeat. They learned nothing from the past. There's a disconnect between reality & hype they don't want to see.

3-18-2013 **Frustrated, part 1.** We've been seeing the same thing over and over again. So, I climbed up on the soapbox... Setting of expectations is incredibly difficult for any type of plug-in vehicle. With a pure EV, some owners find out and accept the reality that the range displayed is only an estimate and only delivers that value under certain circumstances. It's a source of frustration, but they learn about the factors involved and adapt. In time, many enjoy their vehicle again... but certainly didn't anticipate there would be such complexities. The thought had never crossed their mind prior to purchase. When a gas engine is introduced to the situation, matters become even more confusing and far more incorrect assumptions are made, especially with Prius. Notice the pattern that has emerged? Virtually even complaint about dropping EV estimates share the same thing in common... no mention of MPG. Prius PHV is a plug-in hybrid. It's not an EV. The purpose is to deliver a significant MPG boost, not electric-only driving. Owners become transfixed on the EV range estimate. Some have driving routes that bring it way down. Others simply drive in an inefficient manner, believing more EV is better. They forget about the purpose of the design. They figure using the engine as infrequently as possible is best. They end up seeking out help online. Some of those owners are receptive to the information provided. Some just aren't interested and really only want to vent. Unfortunately in this case, the owner stating *"Either Toyota is mis-representing the product, or there is something very wrong with my vehicle"* doesn't give us much opportunity to respond. It gives the impression that it's already too late to provide feedback. Will the owner be receptive to switching focus to the purpose of increased efficiency? Considering how many times the EV range was mentioned and the total absence of MPG data, the feeling is, no.

3-18-2013 **Frustrated, part 2.** It's frustrating for all involved. As active forum participants, the repetition of the same complaint is frustrating... despite the fact that most new owners end up pleased with the responses. It's having to jump through the same hoops every single time and the new owner not having taken the time to do some searches first. Oh well, my first post was immediately proceeding with this: Thanks for unknowingly allowing me to climb up on the soapbox. I hope we can help you out. Welcome. Specifically for me, I've watched my EV value go down. Now, I'm watching it go up again. In my circumstances, it's the result of seasonal change. Temperature fluctuation is a major influence for me, up here in Minnesota. Long distance travel without the opportunity to plug-in is another factor that will drop the value. In the case of a battery-pack delivering roughly 2.7 kWh of usable electricity, it doesn't take much to qualify as "long". Notice that you didn't tell us how many miles your daily drive is either. Hopefully, you'll get past the frustration and begin to see how well thought out the design actually is. There's much to appreciate after discovering how many factors were taken into consideration. Simple things like the ECO button's benefit when it comes to heating & cooling easily get overlooked. Give us more info and we'll do the best to try to help.

- 3-18-2013** **Frustrated, part 3.** The discussions continue: Expectations depend heavily upon audience. That's why the "Who?" question has been asked over and over again and continues to be. Prius PHV is a plug-in hybrid. Toyota aimed squarely at middle-market and you can clearly see what they are working to deliver. It's intended to become a high-volume business-sustaining vehicle for mainstream competition in the near future. That's certainly not same as an EV. True, you do get the electric-only driving experience from Prius, but that's not the purpose. Engine running is a normal part of operation. It will use some gas. The point is, that combustion will be cleaner and the efficiency will be better. All we can do is continue to share our own experiences. No matter what information EPA or automakers or dealers provide, it's not going to convey anything more than a generalized measure. Owners are the only ones that can exchange detail to make help those making the purchase decision. They can relate, making sure "Who?" really understands how the vehicle will function.
- 3-18-2013** **Frustrated, part 4.** The activity on that thread quickly died down. I got a few likes, then people moved on. Only so many people can cry wolf before responses become refined and attention wanes. My conclusion was to simply provide detail from my commute this morning. The solution is often to just present real-world data. The original poster rarely follows up with their own. And if they don't bother, most everyone else won't either. Lack of detail usually indicates the person hadn't considered or wasn't aware of all the factors involved. Simply raising awareness does the trick. Their complaint ends up being satisfied without us ever finding out what the true situation actually was. That leaves you hanging, but at least they end up being able to draw a conclusion. Here's that data from me... 17.3 mile commute today. 55 mph maximum 36 minutes driving. 32°F outside. Cabin-Heater set at 68°F. Heated-Seats off. Headlights & Foglights on. Driving through fresh snow. 10.7 miles was the EV estimate upon leaving the driveway (video-camera setup consumed 0.2 mile). Drive-Ratio reported: 9 EV and 7 HV. End result: 127 MPG.
- 3-18-2013** **Expecting Miracles.** The cycle has begun. Observing hope emerge from rumor is disturbing. It feeds itself, setting people up to expect a miracle without anything to actually support it. The belief is that somehow the engineers will deliver... despite evidence showing that's an unreasonable assumption. Volt's past had that unfortunate history. Enthusiasts got excited about a concept and talked about it so often, the "group think" convinced them it could be true. That turned into a disaster. So many of the original goals fell short, discussing purpose resulted in hostile responses. It's happening again. They are repeating the very same hopeful assumptions. This example in particular caught my eye: *"If the Gen II Volt can step up to 45+ miles of EV range and 45+ MPG in charge-sustaining mode, while cutting the price at the same time, that would be a game changer."* It seems cautiously optimistic... until you think about the detail. Even if battery costs come down dramatically, there's no way to offset the entire tax-credit difference and increase range... which would only retain the current price. To get it even lower and also deliver an improved engine in just a few years would require divine intervention. That simply is not realistic. Then of course, you encounter this: *"Volt 50/50 – 50 miles all electric – then 50 more per gallon of gas!"* It's that same senseless cheerleading of the past. That's how the over-promise situation gets out of hand. They clearly haven't learned from the past. Ugh. There's only so much that can be accomplished in such a short amount of time.

- 3-19-2013** **No Long Frustrated.** That owner ended up going to the dealer and had his computer reset. All it actually does is just revert the EV estimate value back to the default of 13.4 miles. His response to that was posting this: *"I'll let everyone know if it starts to deteriorate again."* Sadly, that's a naive statement with total disregard for the information we had provided. Some people just plain don't want to face facts; they just want their original assumption to be proven correct. In disbelief to his attitude, quite curious what his next post will say, I responded with: There's a 100% chance of that. The estimate is a dynamic value, always adjusting based on your recent driving. My first long-distance driving trip, the value plummeted since I couldn't plug in while on the road. When winter changed to spring, I watched the estimate go up. From spring to summer, it went up even more. In my fall, it dropped. In the winter, it dropped even further. Now that it's warming up again, the value is going back up. That's what the estimate is supposed to do. It reflects the conditions. What good would it be if it never changed?
- 3-19-2013** **Dishonesty.** That's the ultimate source of finality. The cries of superiority coming from the Volt daily blog were truly amazing today. I called someone out on the claim that the best Toyota could do was deliver 6 miles of EV. The response was a long post that went on and on about the regular model Prius. It wasn't even relevant. There of course was attacking of the messenger, nothing's complete without that. But the best was basing their conclusion on a single owner's comments and some random observations from undisclosed sources. The original claim was avoided entirely. There was nothing to support it, nor was any acknowledgement given to the fact that the very same topic was recently brought up and another member confirmed that was not correct. He just plain didn't care. It's the same thing on this particular venue as there was on the big GM forum late last year. It's was started the whole hope nonsense in the first place years ago. The only way Volt could be made to look good was to misrepresent Prius. Things went downhill from there. That's beginning to happen again. I'm intrigued by how it will play out, especially since there isn't much of a need to participate there anymore. The audience is so limited and so bias, what difference would it make? With so much real-world data available now too, readers can confirm on their own that the information in the posts isn't honest.

3-20-2013 **So Familiar.** Nothing constructive came out of those blog postings. It turned into an opportunity to attack & insult Prius and proclaim superiority for Volt. Watching that deterioration of attitude was spectacular. It was like witnessing a disaster. You cannot believe the situation could get so bad so quickly. The outcome was so familiar, I was beside myself. To watch someone who had in the past tried to be fair & balanced turn to misrepresentation like that, you can't believe it. Greenwashing on that level goes beyond dishonesty. He just plain didn't care anymore. It's the very same thing we've seen elsewhere. Enthusiasts are not in any way interested in the well being of the masses. Having a vehicle available for middle-market is meaningless. They can afford more and are happy to pay for it. Even the idea of cost-reduction sickens them. You can tell how deep their dislike for business goes. Any attempt to bring up the topic of high-volume production or making profit makes them cringe. Volt is the vehicle they and GM wanted, not what was needed. It must stand out as special. Becoming a common, everyday vehicle for ordinary daily transportation without anything making it unique would sour the appeal. Volt must not under any circumstances transform to a run of the mill product... the very thing Prius is now. They see the compact, hatchback, and wagon models of Prius everywhere. They know that success was achieved through careful attention to cost... something GM clearly did not do with Volt. The tradeoff is not a conciliation they are willing to accept, hence the responses growing hostile. They know that inevitability can only be fought for so long... and are irrationally lashing out as a result, exactly what we've seen before in other venues. Resistance is futile.

3-20-2013 **What a Relief.** Knowing the "third year" effect would play out in an abrupt fashion was difficult to prepare for. When sales are bad 2 years in a row and the competition is rolling out lots of alternatives, it's pretty obvious to expect rather intense fallout. On the big GM forum, they don't even discuss Volt anymore. The explosive exchange of messages ended in December. They gave up, betting the farm on ELR coming to the rescue. It was suppose to be a mid-cycle upgrade, often referred to as the "1.5" generation. That didn't happen. In fact, it was such a big disappointment, almost nothing was posted about it. With some much built up and an instant death, there was nothing to support Volt anymore. That's a major reason why Toyota is simply focusing on existing markets for the plug-in Prius. The PHV model will establish itself in pockets around the country. In the meantime, the thought is that Toyota will be able to reduce cost some. It may not be reflected at all from a price perspective when national rollout finally takes place, but that would definitely sweeten the appeal for dealers. It would give them the incentive to keep more in stock. Salespeople would make more commission from each sale. That's important for a vehicle intended to appeal to the mainstream, especially without a dependency on tax-credits... quite unlike the situation Volt faces. All I can say now is, what a relief. The disaster GM created for itself does not seem to be having a negative effect on the efforts of Toyota. For that matter, it looks like Ford won't be harmed either. Phew!

- 3-20-2013** **Ignoring Prius.** We don't often here anything from the big Ford forum. Today, that silence was broken with this: "*Like the Roman Senate upon Julius Caesar, the Ford Focus toppled the 10th generation Toyota Corolla in global sales in 2012 with 1,036,683 compared to less than 971,601 units.*" That was a declaration of victory, finally taking away the leadership position Corolla has held for ages. But like many situations, the story changes when you have all the facts. The reality that the c model of Prius took sales directly away from Corolla was never mentioned. Nothing in the article nor any comments ever considered that. Toyota's goal to replace traditional vehicles with hybrids was conveniently absent. Excluding such vital information like that is greenwashing. They don't care though. There's no place for facts when you seek bragging rights. All they want is a number that's better than the opponent, regardless of what it actually represents. Limited the scope of competition is what they thrive on. That's nothing new. We've seen that with plug-in vehicles too. Enthusiasts don't want to consider the market as a whole, just their own particular view. Ugh.
- 3-21-2013** **Cold Pass.** I got stuck behind someone who actually fit the land-yacht stereotype. It was a beautiful end-of-winter day out, so I totally understood the draw. The driver was a man who appeared to have been retired for a number of years and had one of those old-school very, very long cars. He was clearly enjoying the drive. But when doing that, pull over if traffic builds up behind you. Doing only 28 mph in a 40 isn't exactly contributing to a smooth flow. Anywho, when we got to the small city along that country drive, he increased speed to 30. What the heck! Through town, where he could have easily let me pass by pulling over for a moment, he was now going faster than before. Geez! Following that, it got worse. The speed limit changed to 50 mph, but the fastest he got up to was 35. It was a test of my patience... and a golden opportunity. That entire drive was in EV. I had a very, very cold engine. What would happen if I dropped the pedal? That should result in a sudden surge of electricity to allow the engine to gracefully start with the motor holding combustion at 1500 RPM for the cleanest possible warm-up. Merging onto the highway, that's what I routinely see on the ramp. There's no need to drop the pedal then, medium is enough. In this situation, I was about to request maximum, but only would briefly. So, I did. It was finally time to pass him. That burst shot me from 35 to 57 mph. And sure enough, the engine did indeed hold at the warm-up level. It was surprisingly smooth as a result. That made me enjoy the overall experience too, a nice drive for the both of us.

- 3-22-2013** **Spring Arrived.** Yeah! One of the undeniable signs of Spring having arrived is MPG increasing. That's easy to see with a regular Prius, but difficult with the plug-in model due to the normal variance being much larger. There is something else related to the plug though. It's the EV estimate. That range increases as the temperature increases. It doesn't have to be outside high temperatures climbing much either. In fact, it's been colder in that respect lately. It's the thermal warming caused by the growing intensity of the sun. Interior temperature is a pleasant warm now after sitting out in the bright afternoon catching rays. That's quite a noticeable recent change. The extra warmth reduces electrical resistance in the battery, which is what MPG ends up lower when there's still snow on the ground. Li-Ion doesn't work as well when it's below freezing. The cabin temperature of the Prius is well above that now. As a result, I'm seeing that estimate climb. Today, it made it to 11.3 miles. That had been just a long ago memory. In the early Winter, seeing 10's became the norm. Now, 11's are what I'll get for awhile. Eventually, 12's will return. The actual EV distance will exceed that from time to time. But the miles estimated doesn't fluctuate as much. Anywho, long story short, I have officially said goodbye to values starting with a 10. Yeah!
- 3-23-2013** **Gone.** It's pretty easy to confirm that closure has been achieved when seeing what I've seen. Nothing! It's as if Volt doesn't even exist. Discussions on the big GM forum are gone entirely. There is literally no mention anymore. That's exactly what happened in the past with Two-Mode. Sales continued, but the outlook became so grim, nothing more could be said. Constructive posts weren't possible at that point. The niche was pleased, but there simply wasn't any way of expanding the market. There were no aspects of appeal to reach to a larger audience. It became trapped as a specialty vehicle. Hope was transferred to the next generation... which all these years later, still hasn't been delivered. I suspect Volt will "die" the same way. When a competitive design actually is offered, it won't bear any resemblance to the one currently available. Remember BAS, that first assist hybrid GM offered? The next generation got renamed to eAssist to disassociate from the past. Of course, it shared a number of the same shortcomings, so it didn't matter. Some of Volt's fundamentals much change. Enthusiasts know they've become the barrier now. The goals to achieve mainstream sales are not what they want to endorse. That means focusing on what they like and disregarding everything else until later... the very same approach that got them into this mess in the first place. Oh well. At these blogs won't be packed with their spin anymore.
- 3-23-2013** **Online.** Sometimes, a bit of "did you know" is needed on the big Prius forum too. Some people really don't. Fortunately, that audience is receptive to constructive rebuttals. But reading this does stir temptation to interject more than is really necessary: *"I find this to be one of the most combative and self-righteous automotive-based on-line communities in which I participate. Even the bilious vitriol in The Car Lounge pales in comparison to some of the hit-and-run poo-flinging which goes on around here."* Clearly, he hadn't been exposed to the same things I've encountered. Curious to find out what comments would follow, I posted: Haven't been on the GM forums or blogs, eh? Go there and bring up the business success of Volt. You'll get attacked personally and relentlessly bombarded with responses referring exclusively to performance & engineering. Being an enthusiast venue, they just plain don't care about accounting/profit or products for the mainstream. That bit of perspective helps with the understanding of posts here where the original-poster has basically already made a decision prior to starting a thread and doesn't respond to feedback.

3-23-2013 **Failed.** It would be nice for these to be closing thoughts, but odds are it will drag on a bit still: "Enjoy the trophy. Some of us simply want a mainstream choice." What else could be said when dealing with attitude like this: *"Then Toyota, like an angry little child dragging its feet, made an attempt at a plug in vehicle, and failed miserably. If you want a target to throw your "price", "masses", etc stones at, look no further than the PiP. What a joke of a car. A plug for single digit EV miles, why even bother. My question to Toyota, is when will they release their Volt knock-off? It's only a matter of time, and I bet the day that they do, you will praise them for developing a brand new "synergy" of power-trains, that no one else could ever accomplish."* Those are basically the words of hate & blame, excuses rather than deal with actual need. I responded with: Based on what goals? They delivered a plug upgrade for their popular hybrid without weight or cargo compromise. They kept cost within the stated target. They achieved efficiency well above traditional vehicles even after depletion. How is that a miserable failure? As for the *"why even bother"* comment, that is pretty obvious for everyone to see. My annual average went from 50 MPG to 77 MPG. The benefit of adding a plug & capacity is undeniable. With respect to a Volt knock-off, what does that mean? Adding capacity is simple. The early model Prius plug-in pointed out the ease of which sub-packs could be used. Capacity can be doubled by just bridging in a second pack. Ford's C-Max Energi shows how that could be implemented too; it's basically a matter of trading off weight & cargo space. The degree to which GM is defended in the name of pride is troubling. All that's been needed from the very beginning is something to replace traditional vehicles; instead, we just get efforts to prove superiority. That want sacrifices well being of the automaker. They still must pay workers & suppliers, as well as remain competitive. Joke all you want. It's not a laughing matter though.

3-25-2013 **What Really Matters.** When the argument is lost, rather than accept and move on, the topic is rapidly shifted over to something else. In this case, it was: *"Let's see, how much emissions are spurted out by every cold start/stops of the Prius engine?"* The response to that was pretty straight forward, just remind him of the topic at hand... as well as point out what had just been attempted: That's exactly what I meant about misrepresentation. No matter how many times details of the startup process are shared and the PZEV emission rating pointed out, it's as if that never happened. As for sales, the goal is replacement of traditional vehicles. It doesn't make any difference whether it's a vehicle with a fuel-cell or a large battery-pack. If it remains just a trophy winner, what's the point? Looking at the entire automaker production of cars, like GM with Volt, it's quite a daunting challenge. So, it's understandable about all the resentment toward Toyota for having progressed to the degree they have with Prius. 892,519 last year is quite a sizeable chunk of overall production. Keep using words like *"pathetic"* to describe that progress. Meanwhile, we do have the genuine worry of how many Malibu, Impala, Cruze, Sonic, and Spark that are still being purchased.

3-25-2013 **Constructive?** Strangely, you do get someone proclaiming "superior" to actually listen. Whether or not anything is heard or not is a different matter. But it sure beats not having any dialog at all: GM had experience from EV, Two-Mode, and BAS prior to Volt. They all contributed to engineering & production knowledge of motors & batteries, as well as improved engines. Toyota had none of that when Prius was designed. As for the cherry-picking, excuses don't change the reality that traditional vehicles are the true competition. GM's own line-up is Volt's greatest enemy. Continuing to believe Prius is the competitor causes harm, yet some still don't see it. Heck, those numbers posted made it obvious. The plug-in Prius is only available in 15 states; yet, you repeatedly treated the sales counts as if the entire US had access to them for purchase. Step back and look at the resources GM is expending on traditional vehicles. Volt is hurting as a result of its own enthusiast supporting it as a niche, rather than pushing for something that actually pushes it into the mainstream. The downplay of numbers and calling this stage "*infancy*" rather than acknowledging GM's own past is evidence of that. When the tax-credit expires, the absence of that massive subsidy will make the situation even worse. We all know the effort of getting cost down enough to offset the difference is a daunting challenge. Getting down even lower to actually make it competitive with the increasingly popular small cars GM offers would take a miracle. Making it a top-seller in the line-up anytime within this decade, how would that be accomplished?

3-25-2013 **Infancy.** Imagine if Volt would have been promoted as the next generation of vehicle now available today. Rather than all the downplay & excuses, they could show us that car of the future everyone has been waiting decades for. It's that trophy-mentality holding things back. For a technology to become commonplace, to be so ubiquitous that it is seen everywhere, it cannot stand out. Enthusiasts want it to though. They are the barrier, the very thing they tried so hard to prevent. It was a self-fulfilling destiny they were warned about. Lessons of the past were shrugged off, dismissed as not relevant to the situation. Now, they are stuck, still somewhat unaware of what transpired. Saying the technology is in a state of "*infancy*" still is so counter-productive, it's hard to imagine anyone would ever do it. Computers have been in a state of advancement for decades. Each new step for them is called "*progress*" instead and that has worked remarkably well. Everyone sees what is currently available and knows more is to come, but they purchase it anyway. It's part of a natural cycle. Why are some in the automotive industry so dead-set against that with vehicles? Why not increase capacity as it becomes affordable? Forcing people to pay a very high premium to get more now makes no sense. That is certainly not what the computer industry has done. They always offered a choice, featuring the lower capacity as the option for the masses. Just think of how different things could have been. Instead of following a well-proven formula for high-volume sales, the decision to intentionally disassociate was made. Now the consequences are becoming evident.

- 3-25-2013** **Fireworks.** It certainly was exciting watching them fly today. This is what started it: *"When he said this I explained to him Toyota Hybrid technology relies on a small electric motor that is only capable of under 12 mph speeds and that the electric motor shuts down and lets the gas engine take over completely over at speeds over 12 mph. He looked shocked. It seems hybrid owners have their heads in the sand and are stuck on stupid."* That was both incorrect and insulting. Coming from a Volt owner on the forum dedicated to Volt (where I am only a lurker), several other owners sounded off. Each polite attempt to correct him was responded to with fierce resistance. It was quite clear his hate ran deep and facts weren't going to get in the way of his slander. Reality is, Prius uses a 60 kWh electric motor which operates at 650 volts. That offers a top electric-only speed of 46 mph for the regular model and 62 mph for the plug-in. Personally, I'm most impressed by my climb out of the river valley at 55 mph using just electricity. That's far more power than the 12 mph he claims. It's too bad someone didn't just refer to YouTube for a video showing how the system actually operates. I'm flabbergasted that someone would be so bold to think that such blatant dishonesty would go unchallenged.
- 3-26-2013** **Goals & Success.** Looking forward means learning from the past. That next step really can't happen until you know which direction to take. It's been a major problem for Volt and a complete non-issue for Prius. Toyota had a clear vision and set that course. A friend of mine stated GM's path as this: *"Priceless experience in developing cars that don't sell. The Volt carries on a proud tradition."* We honestly don't know what will come next. It's a huge mystery with a growing sense of urgency. Cost must drop significantly. The dependency on a large battery-pack compromises much. It's not like Prius, where you know there's a high probability of increased capacity with the next. Volt is already at the supposed end-state and somehow must rapidly make it affordable. I joined in with this: They all had something in common. Unfortunately, every attempt to point that out was met with fierce resistance. It was a simple matter of stating what the goals were. Not being able to clearly define success was a sure sign of trouble was to come. When you don't have understanding & agreement of what's trying to be accomplished and by when, there's no way to achieve any type of finality. This is why there is so much attention focused on the next generation now. It's also why there so much abhorrence for the vehicle which had goals stated and did indeed achieve them.
- 3-27-2013** **Something's Wrong, part 1.** In disbelief, I posted: Wow! With so many videos available and so many reports illustrating how far a kWh of electricity will allow the plug-in Prius to travel, it blows the mind that someone would post false information anyway. That's very encouraging. It shows there's worry about merit alone being enough. What other reason could there be for such obvious misrepresentation? We all saw that original post which clearly excluded 5 of the 11 miles of electricity available. So what if the engine starts up and runs briefly at mile-marker 6. That doesn't mean the entire capacity of the battery had already been consumed. It simply means a high-power demand was not fulfilled by electricity alone. The engine shuts back off and another 5 miles of EV travel occur. The spreadsheet omitted that fact. We all know it too. We see the concern the true information causes. No one is fooled by the effort to distract & avoid. And attempts to dismiss just show desperation. It's sad that the situation has come to this. But it's not like we didn't see it coming. Remember how success had been defined prior to rollout?

3-27-2013 Something's Wrong, part 2. Still amazing by such blatant greenwashing, I was left wondering of something was actually wrong. Why would there be such intense responses about a claim that is clearly not true? With Volt attention having diminished to virtually nothing, was this attempt to draw back attention or what there a big picture issue that I hadn't even noticed? I push hard on the hostile venues to find out, since they gladly welcome that type of participation. The members there provide lots of feedback... some of it quite valuable. But you really have to look for it... because they clearly aren't aware of the issues. It's a matter of someone exposing a clue that ultimately informs us of what's really going on. Anywho, this was my response: The battery-capacity listed by the EPA is 11 miles. The window-sticker clearly shows that plug-supplied electricity is available is for 11 miles. What the heck do you believe that 11 miles means? My guess is the group-think here has convinced everyone that the 6 means something other than what it actually does and no one bothered to actually look up what it really represents. That kind of assumption makes sense too. It's a common trap to fall into and no one wants to admit they made an error afterward.

3-27-2013 Something's Wrong, part 3. It finally hit me! What if those intense exchanges of words were based on a misunderstand? That would explain a lot. We've seen that type of passion before. When someone has incorrect information, they can unknowingly spread it. In fact, that's the basis for greenwashing. You convince someone else that a situation is different that it actually is and they end up passing along false beliefs. However, sometimes it can be even more simple than that. To test my theory, I started posting detail about the determination of Miles-Per-Gallon-Equivalency for the plug-in Prius:

$$(\# \text{ EV miles} + \# \text{ HV miles}) / ((\# \text{ kWh} / 33.7 \text{ kWh}) + \# \text{ gallons}) = \text{MPGe}$$

$$(6 + 5) / ((3.19 / 33.7) + 0.022) = 94.3$$

0.2 gallons per 100 miles

$$11 \text{ miles} = 0.022 \text{ gallons}$$

29 kWh per 100 miles

$$11 \text{ miles} = 3.19 \text{ kWh}$$

Guess what? The immediate impression I got from that was that there were a few individuals that seemed to be totally oblivious to what those numbers actually meant. It was the clue I had long been looking to undercover. Yeah!

- 3-27-2013** **Something's Wrong, part 4.** Continuing my new found quest, I interjected a dose of reality... to find out what priorities really were. After all, it wasn't clear whether or not this exchange was only just an opportunity for more bragging or if they somehow actually did envision a clear plan for the future. My question was about product-line. Rather than responding to their bait about Prius, I asked about GM's intent. Sadly, all they did was echo back the same question with: *"Damn that's a weak argument. Could you please provide an analysis of PiP sales with that of Malibu, Impala and Cruze? After you do that could you please explain your point?"* Having already done that for the same audience quite a few times in the past, I knew it was bragging. But why? Something still seemed wrong. I asked: Replying back by simply replacing Volt with PiP makes it overwhelming clear how unwilling supporters are to address the actual problem. As long as they have a scapegoat available, they don't feel the need to face the reality of the situation... Malibu, Impala, and Cruze are kicking Volt's butt in sales, despite the benefit of a large tax incentive. No matter how much you flaunt the EV range of Volt, that doesn't change. GM's only high-efficiency offering cannot compete with its own popular cars. That makes the situation very, very different from Toyota, where Prius actually does. Stay in denial all you want. Continuing to refuse to acknowledge the big picture only makes the situation worse. Have you ever considered the reality of GM getting cold feet, that Volt funding could get reduced due to low sales?
- 3-28-2013** **Something's Wrong, part 5.** It really was! I actually had figured out what was wrong. Yeah! This was the comment which ultimately confirmed my suspicion: *"And it clearly states "All-Electric range = 6 miles". That's what's been said here all along..."* It was what I had been waiting to see. Ultimately, I responded with this *"Belittling Prius won't fix GM's product gap."*, since the posting had degenerated to the senseless trophy-mentality we've been dealing with for years now. But I also took the time to be constructive and make my point: Notice how everyone stops on that? Not looking at any of the other information provided is the problem. They assume it means something it doesn't.
- 3-29-2013** **Something's Wrong, part 6.** Assumptions are often the underlying source of problems. Uncovering there are any is a major challenge though. In this case, I was dealing with an audience who didn't understand how the numbers were derived. The measurement value they kept quoting was one of many; however, all they saw was just the one. Not even acknowledging there were other quantities to take into consideration was the confirmation. In two of my previous posts, I included a link to a scan of the window-sticker itself. That showed all the numbers. They didn't address them though. They kept getting dismissed. That's called cherry-picking. You cannot just select the data you like. You must acknowledge all of it. When I provided the detail, showing the calculations and explaining how each played a role in the final result, it was totally disregarded. Outright avoidance is usually a clue that information isn't actually being understood.

- 3-30-2013** **Something's Wrong, part 7.** It makes so much sense looking back at the situation now. Not actually understanding how the Prius PHV works and believing it is trying to achieve the same thing as Volt would contribute to an endless stream of debates. No matter how many times we'd point out it was a plug-in hybrid, designed to deliver a MPG boost through the blending of motor & engine, they would always respond with how poor of an EV it was. You'd scratch your head wondering if any part of what you'd post was actually being read. It would get to the point where you'd be truly amazed how misguided some of the claims became. Why would they even make such statements, knowing they were clearly not correct? Turns out, they had no idea they were spreading false information. Their actions were without consideration of all the facts. It was thoughtless reciting. That explains a lot! Not stating goals allowed the nonsense to ensue. Bragging dominated threads because they weren't interested in detail. Fixated on just one particular number prevented any type of constructive discussion. Of course, I got quite a bit out of it. Knowing your audience is priceless. My effort to figure out who they really are made quite a difference. You cannot take that next step without.
- 3-30-2013** **Very Snowy Commute.** 17.3 mile commute today. 55 mph maximum 36 minutes driving. 32°F outside. Cabin-Heater set at 68°F. Heated-Seats off. Headlights & Foglights on. Driving through fresh snow. 10.7 miles was the EV estimate upon leaving the driveway (video-camera setup consumed 0.2 mile). Drive-Ratio reported: 9 EV and 7 HV. End result: 127 MPG. Watching that drive afterward brings back interesting memories. Dealing with wet, lumpy, slippery roads isn't something everyone does. I've done that countless times over the years though. With a Prius, the efficiency was always a nice benefit from being forced to go slower. Having plug-supplied electricity to augment the situation makes it even better. Removing a surprising amount of the stress from the unpredictability and increased drive time. Video like this will come in handy later, as people research the sale of a new vehicle. The consideration of winter commutes raises lots of questions in forums & blogs. It will be nice to point back to this particular one then. You can see it now... [Very Snowy Commute \(dashcam\)](#)

3-31-2013 **Questions.** An attempt to be constructive emerged out of nowhere. I was intrigued by the unknown poster, though disappointed since it was the same old approach. Notice how they are forced into a particular perspective: "*Why do you think that so many Volt owners would buy another Volt, as was asked by CU Reports, and why are so many of them previous Prius owners? Do you think that it is because they feel that the Volt is a reeeeaally goooood car? Or have they just drunk the Volt kool aid?*" It's the classic problem of niche owners not understanding vehicles for the masses. It was an either/or choice, no other viewpoint could be possible as far as they are concerned. I just shook my head and replied with: Volt enthusiasts don't express interest in there being a product for middle-market. So no matter how many times comparisons are made, they completely miss the point of delivering a high-volume business-sustaining vehicle. It's that simple. Enjoy your Volt, though recognize the fact that it is not configured for mainstream need. It's a specialty vehicle. In that respect, it does a nice job of fulfilling that particular role... which there's nothing wrong with. But to think that it in any way it can take on the true competition of GM's own cars like Malibu, Impala, and Cruze, you're not addressing the problem at hand. The purpose of Volt has changed; it has been recast to serve a different purpose. The original vision transformed from what was actually rolled out. The reality of cost & engineering proved much more of a disconnect with the market than GM understood. That's why the question of "*better*" doesn't makes sense to even ask. It was always this other question (to direct focus back to purpose) that irritated the heck out of some: *Who is the market for Volt?*

3-31-2013 **Expected Announcement.** We know that sales of Volt have been flat... which is a really bad sign for a vehicle in its third year... especially one so heavily hyped. With the approach of Earth Day stirring interest in affordable clean & efficient vehicles, that puts GM in a very uncomfortable position. Sales results for March will likely be released today tomorrow too... which just happens to be April Fool's Day. That makes for an interesting formula of circumstance. Based on previous history, that likely means some type of announcement will be made. After all, anticipation has been a powerful tool in the past. Of course, that has led to unrealistic expectations... ultimately contributing to mindless hype. The reputation for "*over promise, under deliver*" was well earned. Temptation was too great. Rather than keep quiet about innovation, anything related to market advancement was carelessly flaunted... despite to basis to support it. Consideration of things like cost were simply brushed aside. Having learned from the past, it's quite reasonable for that cycle to repeat. We'll likely see the emergence of such a situation soon... unfortunately. Someday a miracle will happen, right?

- 4-01-2013** **Really?** It appears as though that prediction of how events would unfold was spot on... or was it? Supposedly, there will be another model of Volt offered, one that actually addresses cost to deliver an entry-level plug-in choice. Offering more seating room along with more battery-capacity has been the magic solution that enthusiasts have long dreamed of. Doing that for a much lower cost would be the miracle part. Of course, I'm just reading the introductory portion of the blog posted today. Those are my initial impressions, documented before continuing on to read the second half of the article. Sure enough, upon reading further, there was nothing but wishes being fulfilled... a very good reason to pause for consideration of facts. (Think about the upcoming Cadillac ELR for a moment.) That's the very trap which happened in the past, taking a leap of faith without looking. You get unsubstantiated comments leading to unsupported hope. With only nuggets of info, each sounding too good to be true, you should question the situation. Yet, no one is taking the time to ask how that will actually be achieved, no one even gets a chance to ask for detail. Needless to say, the timing was likely taken advantage of. Nonetheless, even being a cruel April Fool's joke, it does still bring up the issues of concern. Why not start out the month with a sense of humor? Everyone having a good laugh would be an effective way to move on. Somehow we have to overcome the past.
- 4-01-2013** **Progress.** It can be painfully slow. Reading a Detroit article today about the New York Auto Show currently underway, it's like traveling back in time. Now that pretty much every automaker has plans to rollout hybrids of their own, the same old comments from years ago are being posted online again. They act as if there is something to prove still, like Toyota's success is somehow in an entirely different category. That's actually true in a way, since the technology itself must be different to avoid patent infringement. But the expectation of them remaining a niche for many years to come is a stretch. The misconceptions are gone. That was a major obstacle to overcome. We've successfully done that. There is the genuine problem of the moving target though. Since traditional vehicles continue to improve, it makes the introduction of a new hybrid difficult. Those other automakers have to scramble to catch up. Only Toyota is far enough ahead for hybrids to be seen as a common choice among their product line. Resistance is no surprise. The reality of internal competition is a major challenge... as GM is currently finding out the hard way. Fortunately, we have the example of Ford demonstrating how to prevail over that. Progress is difficult. At least there is now a shared effort to deliver something, rather than the past where some automakers simply didn't care.

4-02-2013 **Disappointed.** Sales results were revealed today. Tesla & Leaf did pleasingly well. Volt did so bad, enthusiasts we using "*disappointed*" as the adjective to describe their feelings. That sentiment latest 11 hours... then they turned to their scapegoat. I couldn't believe what had been posted. Someone listed monthly Prius sales from over a decade ago, generation this response: "*Wow, those number are really cool! Prius sales absolutely plummeted in summer 2003. I am surprised Toyota didn't give it up at that point.*" That's spin so desperate, it's hard to know how to even respond. Toyota was clearing out inventory then. So much interest for next-generation model coming in the fall had already been expressed, it was in everyone's best interest to ensure none of the older model would be left by the time rollout began... hence the plummet. They excluded that information though. It was presented as if Prius had become a market failure. To make matters worse, they used quantity matching to justify such low sales of Volt... as if all else was the same. Again though, a vital piece of information was withheld. In that case, it was the fact that there wasn't a tax-credit available for Prius, only a \$2,000 deduction which amounted to about \$300 to \$400 for the typical person. That's a tiny fraction of the \$7,500 buyers of Volt get. Needless to say, the greenwashing made enthusiasts feel better. Misrepresentation obviously doesn't matter to them. Any words of encouragement will do at this point.

4-02-2013 **The Real Issue.** When a leading expert makes a comment like this, you should take notice: "*I think the research in the world is largely misdirected. What I mean by that is that the conventional approach for battery research is: 'Let's find the coolest chemistry. And then we publish the paper and somebody else should figure out how to make this device cheaper.'*" That is most definitely the approach we've seen from a certain automaker, though actually a bit worse... they rolled a vehicle out that way. There was no regard for cost. There was just hope for a breakthru in the near future to eliminate subsidies and make it competitive. In other words, rather than keeping design with affordability in mind, a risk was taken that a miracle would vindicate the effort. That's quite a gamble. It's unlikely to payoff. What of the odds of a technological discovery happening soon? Implementation alone consumes a great deal of time & resources. Reliability studies (very important when it comes to warranties) cannot be hurried either. It's a recipe for disappointment. To make matters worse, reputation could be tarnished in the meantime. Too bad the industry didn't invest heavily in the use of inexpensive materials. Gambles like that would be unheard of then.

- 4-03-2013** **Downward.** Yesterday's news of disappointing sales for Volt brought owner comments to a new low. I understood the hostile replies to me directly in the past, since no matter what I said all they ever heard was "Prius", even if that wasn't what I posted about. They just assume you are somehow expressing brand loyalty, rather than actually stating a point about automaker product-line and the basic need for sales & profit. Their disregard for everything else is disturbing: *"Let's see your prius do 143mpg! I think deep down he knows the Volt is better than the prius and he just hates that he got the wrong car. Yes priuses used to be the best for gas mileage but that was the early 2000's. There are so many others out there now. I am really seeing now what people mean by how prius people are. I lost a lot of respect for my uncle. Very sad. He can take his 50mpg, I'll take my 143."* Those were the feelings expressed online about a family encountered over the holidays from a Volt owner about his uncle who had just purchased a Prius. Naturally, none of the comments following that new thread in the Volt forum addressed the plug-in model. They just reflected the same sentiment. It's all about MPG. Consideration of the usual mainstream purchase priorities, like cost or seating, are simply ignored. I'm amazed they don't see how smug those comments were. Attitude is trending downward.
- 4-03-2013** **Sales Trend.** When dealing with a group convinced you're trying to promote the competition, it's best just to post data about their own automaker. Of course, even then, they'll likely either spin the intent or just disregard the information entirely. We'll find out soon enough what the reaction is to this: Consider the big picture, GM's car offering. Notice the sales trend? 18,539 Malibu; 14,766 Impala; 23,260 Cruze; 1,478 Volt. Thinking that resources are abundant and heavy investment in Volt (as we know it) will continue, that it's just a matter of waiting, is not taking the situation seriously. Whether or not the technology delivers has nothing to do with the market... something supporters haven't been wanting to face. Now into the 3rd year of sales, it's pretty obvious the competition from within GM itself poses a very real problem. Volt is not aligned with what needs to be produced & sold. Consider what it means for dealers to sell only 1 per month. Consumers are simply buying the other choices available instead. Those offerings are far less expensive and much more in line with their priorities.
- 4-03-2013** **Topic Change.** Reaction to the sales counts was neither spin nor disregard. Instead, a topic change was attempted. When all else fails for Volt, they fallback to enthusiast appeal. The belief is the speed & handling will convince people the extra cost is well worth it. That's obviously not the case. GM numbers for March clearly show preference for traditional vehicles instead. Why can't they see that? Acknowledgement of fact shouldn't be so difficult. It boggles the mind how deep the denial runs. Oh well. I just abandoned the effort with this: So rather than address the issue, the choice is to change the topic. That's constructive. No one has asked the question about MPG itself... How much will result in high-volume sales? There is a point of diminishing returns. More isn't necessarily better. Striking a balance between MPG and cost is required. Is the plan really to just wait it out and hope for the best? What if cost isn't cut enough, for the sake of keeping MPG higher than people are interested in paying for? Where is there any proof that 200 MPG is better than 150 MPG? 125? 100? 75? Think about how people have settled for vehicles that deliver MPG in the 30's, despite the fact that gas is sometimes \$4 per gallon.

- 4-05-2013 The Announcement, part 1.** That inevitable distraction from disappointing sales results arrived yesterday. GM had a press-release stating: "*The typical Volt owner who regularly charges the vehicle is going 900 miles between fill-ups of the gasoline engine that powers the Volt's on-board generator. That avoids about \$1,300 a year at the pump.*" Not a single enthusiast or owner remembered GM's promotion from 2 years ago claiming 1,000 miles. None questioned how the \$1,300 was determined either. What was Volt compared to? How many miles per year? What was the price per gallon of gas? GM basically just threw a number out there and they all accepted it at face value. That's scary. I drove 18,477 miles last year. My entire gas expense for that was \$840. So, it certainly wasn't a comparison to another plug-in hybrid. With a regular hybrid, at 50 MPG and \$3.59 per gallon, that same distance would have been \$1,327. But that doesn't make sense, since that distance would have meant the Volt drove roughly 5,000 miles using gas. At 37 MPG and \$3.59 per gallon, that would have been \$485. Needless to say, there are countless of scenarios which could have been explored. They didn't bother though. It was all about bragging rights.
- 4-05-2013 The Announcement, part 2.** The reaction on that daily blog was quite predictable. On the big GM forum, I was rather curious. Since my focus there was always automaker success... sustainable high-volume profitable sales... they never liked me. The MPG trophy was of no interest. Their fanboi taunting fell on deaf ears. I simply didn't care. That's why they always tried to divert discussion to Prius, hoping to stir an emotional outburst. That never happened, which frustrated them. Talking about accounting matters and choices for everyday consumers had no place there. It just stirred anger. So, this opportunity to gloat & taunt about MPG was too much for them to resist. Sure enough, I personally got called out too. Fortunately, I don't play that game. It's a waste of time, though reading the posts themselves can be constructive. These are my favorites quotes from that particular thread: "*Volt is pure awesomeness. I'd buy one, but they are out of my price range.*" That's a common theme, much like autoshow desire where a person likes the showcase vehicle but ends up buying the mainstream choice. This was especially telling: "*Volt is a great idea that was total blown in execution.*" Not much else can be said about that. GM really messed up. Sales prove it. And this one summed the situation up nicely, coming directly from an owner: "*I love the Volt, but after a year I'd say a Cruze Eco or Cruze Diesel would be a better fit for how I drive and the overall cost ratio.*"

- 4-05-2013 *The Announcement, part 3.*** It sure would be nice to hear from the other automakers more. Tesla is getting a lot of attention, but that's because it's the little company that proved successful. GM thrives on the spotlight, so there will always be something from them. But doing a quick check, news from them is mostly about their new next-gen full-size trucks and the Camaro Z/28. Their ability for them to stir interest with efficiency cars is almost non-existent now. Volt is too expensive. People clearly aren't interested. Ford runs the same old C-Max television commercial endlessly, but sales of the Fusion hybrid are actually just a little bit higher. So, that situation is a bit odd. We haven't heard anything from Hyundai or Honda lately. Nissan does make a peep from time to time. But ultimately, you've got the quiet giant called Toyota leading the pack by a very wide margin... hence so much ill sentiment by others. Just finding out that Prius c is now officially the top-selling vehicle in Japan and the regular model holding the second position, there really isn't much to say. The hybrid technology is most definitely mainstream and a primary part of the business now. That's poses a massive amount of pressure on the other automakers. They cannot argue hypotheticals with such a solid example success. That's why no matter what I post, they always twist it to somehow apply to Prius.
- 4-06-2013 *Recognizing Change.*** With such strong trophy-mentality clouding judgment, seeing what's happening on the larger scale can be difficult. You get the impression of overwhelming success. Focus on engineering alone will do that. They believe more is better, regardless of cost. The idea of balance is a joke. Enthusiasts laugh at thoughts of offering less, so more people will be able to afford it. That's an unacceptable tradeoff. Strangely, they are adamantly opposed to the well-proven approach of improving capacities over time, to keep the cost-prohibitive nature of newer technology from becoming an issue. In other words, they just plain don't care about middle-market. In their mind, any well designed vehicle will become mainstream... despite the reality of that not being true and the fact that many ubiquitous products require a very, very long time to take hold... even those with short service lives. Vehicle replacement will take much longer than they care to admit, we're talking decades. Long story short, it's easy to recognize change when goals aren't clear. Simply ask questions like "*who*" and "*when*" and "*how many*". We witnessed the much hype Two-Mode fade into just a terrible memory of misguided priorities... because the answers to those questions didn't address ordinary consumers. The very same thing is happening with Volt. Its obsession with the highest possible MPG closely resembles Two-Mode's obsession with power. More was better, regardless of cost. Sacrifices made to achieve that soured its appeal. People ended up buying other vehicles instead. Sound familiar? What happened to the "*game changer*" we were promised?

4-06-2013 **Balance.** That's what makes a vehicle mainstream. Common needs of the masses are identified by high-volume purchases. If you need more than average power, you buy a truck. If you want more than average performance, you buy a sports car. If smooth & quiet is your thing, you buy a luxury car. It's not rocket science. The difference between mainstream & enthusiast should be obvious. Of course, the concept of an online forum not being a venue for die-hard supporters is a bit of a oxymoron. Somehow though, Prius was able to overcome that. Offering balance of power, performance, smooth & quiet while also delivering MPG well above average and emissions well below average frustrates the competition. Reading posts on the big Prius forum for only a few minutes is all it takes to confirm many of the participants there are not enthusiasts. They're just ordinary people with an interest in something better than the traditional choice. Look at buyers of other offerings. Is that true for them too? The imbalance is pretty obvious. Being part of a niche is fun & rewarding, but misrepresenting others to conceal that fact is harmful. Rather than pushing automakers to configure choices to match priorities, they just endorse a one-size-fits-all solution that doesn't actually match need. Ugh.

4-06-2013 **Now That It's Over.** Resources spent documenting the transition were well worth it. Many people find reading a relaxing pastime. So, it's not too far of a stretch to find out some write for pleasure. Getting back to the "good old days" of writing about daily Prius observations instead will be nice. The absurd nature of Volt craze was a unique moment in history, a time we won't ever see again. How often does a new offering ever stand alone like that? It was the only plug-in hybrid available and hype outweighed the hype well beyond anyone's imagination. Rollout turned into a disaster with new spin all the time. Keeping track of what happened when and how the claim was actually stated could have been easily lost. Looking back, situations quickly get confusing. Having noted those details as they were all unfolding was great. Witnessing plans & hopes fall apart made you very curious what would happen next. It was a real-life drama... with a predictable ending. We all knew Volt didn't match the needs of mainstream consumers. The effort to make it different from Prius meant compromising purpose. Purchase priorities for middle-market are quite particular. Convincing us that they would change so much, especially without evidence to support it, was unreasonable. Adaptation on that scale is painfully slow. There's decades of history clearly showing that. We can now look forward to automakers rolling out more realistic offerings. Heck, maybe even GM will join in. After all, there is a shared goal of increased efficiency and reduced emissions, with the need to continue to be competitive and make profit.

- 4-07-2013** **Consequences.** It's intriguing to watch Volt enthusiasts coming to grips with the situation. Snippets like this were so vague, no one is even bothering to respond anymore: "*delivers what GM promised*". We all know those supporting Volt prior to rollout were so horribly vague about goals anything could have been delivered and they would have praised it. The rest of us are well aware of what really happened. That's why a consequence we're seeing now is silence from the outside world. From the inside, on the big forum exclusively for enthusiasts, it's a different story. Reading responses to this there tells an interesting story: "*He called me a Bald Faced Liar.*" That vague nature of replies is now coming back to haunt them. How many times do you have to warning them to include detail? Enthusiasts became so smug with all those "*vastly superior*" claims they simply didn't bother with anything else. When an owner said he'd be saving about \$2,000 per year on gas, the name-calling could have easily been avoided. They didn't learn though, the advice was disregarded. That's happening now, finally. The person hearing that automatically thought it was in comparison to other choices available at the time of purchase... not his old Isuzu Trooper which only delivered 15 MPG. Well, duh! Any new vehicle is better than that. But having excluded such a vital bit of information, it was to surprise to get such a harsh emotional response in return. It's the same thing GM is still doing. Their \$1,300 claim wasn't explained at all. There was nothing whatsoever stating what the comparison was to. Intentionally, that's considered greenwashing. Unintentionally, there are still consequences.
- 4-08-2013** **That Button.** Mid 50's for MPG on the highway make using that HV/EV button a no-brainer for me, since I routinely drive well beyond battery-capacity. Saving electricity for when it can be better used is a nice option. The fact that the engine consumes electricity during warm-up to make it both cleaner and more efficient makes the replenishment of it later using gas is pretty much a wash. Adding a plug to an already well thought out system is what gives Toyota the edge over competitors. Makes you wonder when everyone will figure out why that was such a sensible approach. And memories of naysayers claiming there was no advantage of the hybrid components while cruising on the highway are still so vivid. We'll never know if they didn't have a clue of what they were talking about or were just lying to impede progress. Only now, as we start the second year and still only have rollout to 15 states, are we seeing some interest building. There's always first-year jitters anyway. Assumptions make it worse. There have been efforts to misrepresent too. Watching that change is reassuring... especially since we've seen other technologies stumble as time progresses. Long story short (guess I climbed up on the soapbox there) is that you can't go wrong just giving it a try. Not pressing that button, you'll still get great MPG. Pressing it, there's a chance of squeezing out even higher overall efficiency.

- 4-09-2013** **Photos & Video.** There's a collection of them I haven't had a chance to sort & organize yet. Slowly, I'm getting a change to go through them and pick out favorites. A highlight from Winter was a drive home after a pretty nasty snow storm. Travel was starting to resume again, after basically everything shutting down entirely, but the going was slow. That allowed the opportunity to take a few photos, capturing what some people never see and we here in the north try to forget during the warm season. There's also two sets of display screen photos. I use those to show detail of the drives captured on video. The filming has become somewhat easier too. Catching the sun when it's low allows dashcam (single camera) footage, rather than needing the complicated setup required when it's really bright out. Anywho, here's those webpages showing what I now have available to share... [photo album 182](#) and [video - winter phy](#)
- 4-10-2013** **When?** Also having hybrid counterparts, the plug-in hybrids offered by Ford & Toyota don't really include a question of when... since the choice is a package selection, a feature rather than exclusive vehicle. There is far less at stake and far more opportunity. That's only the case for them though, due to the push for high-volume production & sales. It's different with other automakers. When is being asked. There was a lot of attention on GM in the past. That was due to so much over promising of Volt. It ended up under delivered... based on their own self-imposed measure. Those events are history now, labeling the first generation rollout not achieving "*game changer*" status. Had it been presented as a niche right from the very start, a top offering rather than something that would "*leapfrog*" the success of Prius, things could have been different. We see that from the approach Tesla took. Model S has become a very popular choice outside of the mainstream. Fisker attempted the same. Results were different. Intent was the same though. Nissan is unique among the EV offerings. The hope really is to make it a car for middle-market. But unlike the others, pricing was given a very high priority and when was immediate. With Fisker about to file bankruptcy, when with it is clear. Tesla is doing fine as is, despite the high price. So, it has a "when" that really doesn't come into question either. That's what sets Volt apart. It's quite a shift to go from unrealistic promises with a firm rollout date to not saying anything anymore. The uncertainty could, if carefully considered, provide a path of less resistance for the next generation. When though?
- 4-10-2013** **Charging Stations.** By the end of the month, there will be roughly 6,000 of them available to the public nationwide. How many would be beneficial this year? How many more next year? How much should it cost to use one? How long is appropriate time for usage? How will goals be measured? How are we going to get answers to these questions? Needless to say, there's no way of knowing. The situation will change over time too. Right now, using them is for the most part a pleasant experience. There are some instances where a non-plug vehicle will park in a spot. There have been a few reports of EV owners being quite rude to plug-in hybrid owners too. Overall, it's been nice though. Even the conflicts online about Volt don't carry over to real-world encounters, since there's a huge difference between actual purchases and automaker intent. Charging stations are an uncertain topic, coming from a third-party with interest in gaining patronize by offering a plug. More seems to be a good idea.

- 4-13-2013** **52 MPG.** No complaint about that. 176 miles of almost all highway driving and still having 70% of the EV miles left, with 52 MPG as the result, is great. I wondered what that weekend escape would bring, especially with it still very much Winter here still. Tomorrow, a snow storm arrives. Today was a pleasant trip that confirmed the plug-in Prius delivers outstanding efficiency even when you don't plug it in. What else can be said? The naysayers claiming the extra weight of an unused battery (or in this case, barely used) would result in a large penalty were wrong, very wrong. It feels good having confirmation that the engineering we studied carefully delivers well in real-world implementation. The greenwashing assumption attempts are dead. Yeah!
- 4-15-2013** **Tax Day.** Like many others, I filed my federal income tax and waited the credit return from having purchased a plug-in vehicle. For Prius PHV, the maximum amount you can collect is \$2,500. Not everyone qualifies for the full amount though. Some are denied it entirely... many by mistake... since the process is still new and there has been confusion with expired credits. Some owners were finding out the money wasn't allowed for any particular reason. That's why I waited. They ended up spending many hours on the phone trying to get the error corrected. So, there may be a delay, if claims are flagged for review to avoid mistakes. My e-file went just fine, but I may have caught the process on a good day. A delay certainty is a test of patience... like many things related to Prius. Fortunately, those waits are well worth it.
- 4-16-2013** **Energi Sighting.** The C-Max emblem caught my eye. There was something different about it. Logic supports the belief that it was the plug-in model. Unfortunately, there wasn't enough time to confirm. We were both turning corners in opposing directions. All I got was just a quick glance, enough to notice and hope Ford is making some progress in these parts. Rollout has been slow. Acceptance is expected to be mild initially anyway, so no big deal. Near the end of this year, things should heat up. Until then, new market penetration takes place. I look forward to that... especially since the choice of sacrificing cargo area for the sake of increased capacity presents quite a bit of uncertainty.
- 4-17-2013** **Engine size.** Reading a thread on the dedicated Volt forum about engine size has been intriguing. The majority of participants think smaller is better... despite the proof from Prius that larger can actually be more efficiency. It's strange hearing some of the debate points. Most fall apart due to a single fact, the reality of cost. How do you justify the expense of development? Sharing a block & piston size with a traditional vehicle only takes you so far and requires lots of time to optimize for hybrid use. The components within, the valves, the timing. It gets complicated. The concern of "*too little, too slowly*" are finally being seen. The lust for EV allowed HV to be neglected. Consequences no longer need to be pointed out, they are quite obvious. Thankfully, the discussion was fairly constructive. That's progress.

- 4-18-2013** **5 Million Sold.** That's a lot of Prius. Toyota's goal to make it a mainstream vehicle, to the extent of replacing sales of traditional vehicles is difficult to deny now. I'm so glad to see this particular milestone being reached. Having to point out that purpose was maddening. All those claims of Prius only being a "*halo*" vehicle and losing money on each one were absurd, blatant denial that an automaker would ever take such a risk. Long term, it hardly seemed a risk. That was simply the natural advancement of propulsion systems for vehicles, when done proactively... prior to need. Waiting until gas prices get ugly to begin is an entirely different matter. That reactionary approach is trouble... which is exactly what we've been dealing with. Perspective & Timing making a huge difference, as did the approach. Now, it should be obvious.
- 4-19-2013** **\$3.39 Per Gallon.** We do anticipate the switch from Winter to Summer formula gas to result in lower prices. But watching the price of a barrel of oil drop below \$90 was quite unexpected. Why that happened is a bit of a mystery. You can imagine what that does for interest in hybrids. People now perceive that \$3.39 as an improvement, better than before. They become accustomed to it, settling for the purchase of a smaller traditional vehicle as a replacement for their guzzler instead of seeking out a hybrid. Perhaps that shift is what's influencing oil. Slowness of change does bring stability. Sharp demand pushes up prices. Seeing people settle for an adequate solution rather than embracing change certainly won't stir up the market.
- 4-20-2013** **291 miles.** Watching that trip from Northern Minnesota back to south of the cities result in an average of 59 MPG was great. We had to take the long way around too, since we were picking up a car along the way. It was a cold Spring day, having just got lots of snow 2 days before. Most people would still call that Winter, but it did make a scenic day for travel. I hadn't anticipated efficiency to be so good. It sure was nice though. That was my farthest single-day drive with this Prius, without having plugged in. The drive was entirely engine-only. Of course, electricity from the wall really wouldn't provide a big boost coming from only a 4.4 kWh battery-pack. So, it sure is nice having such an efficient engine. Long story short, I enjoyed the trip.
- 4-21-2013** **Trust.** It's pleasing to read posts from newbies on the big Prius forum. In the past, we've read about people going to a Toyota dealer with the intent of purchasing one of their traditional cars, then coming home with a Prius. Turns out, that's their first encounter with hybrids. Some simply never have the opportunity to see one up close. Now, the reach has expanded. We are getting reports of people going to look at a regular Prius and ending up with a plug-in. That's good news. It shows trust has been established. That's really important in a world where there's lots of greenwashing & assumptions. The worst is still the portrayal/belief that Prius PHV is a short-range EV. The large emblem on the car itself stating that it's a "PLUG-IN HYBRID" along with the information on the window-sticker doesn't get through to some people. Thankfully, the rest see the plug as an enhancement to the regular Prius experience. The larger battery offers increased electric power & range compared to the model without a plug. And since that results in lower emissions and higher efficiency, mission accomplished... since that's what middle-market has wanted all along. They trust that is what has been delivered. I trusted their sensible purchase decision-making would triumph in the end, over the rhetoric claiming EV was of paramount importance.

- 4-21-2013** **EV Importance.** The sensible is often not the voice of the internet. More likely than not, you will hear from an enthusiast instead. They deem different things of importance, most notably EV. Keeping in mind they aren't representative of the masses, there's nothing wrong with that. It is frustrating though when they don't realize their own statements don't match the mainstream. For example: *"What Toyota doesn't seem to get is that a lot of people like me are interested in the experience of driving EV mode, not so much the efficiency. They should follow Ford's example with the C-Max and give an EV mode that locks out the ICE for those who want it."* Had he qualified what *"like me"* actually meant, fine. After all, we do know that specialized configurations will be offered later. Prius doesn't seek out that audience though. So the *"Toyota"* reference is misrepresentative. Toyota does in fact know that; just look at what they reveal at auto shows. None of those plug-in vehicles carry the *"Prius"* label, but they do indeed entice the enthusiast. Anywho, I replied with: Don't overlook the reality of capacity tradeoff. Toyota's effort to reach an extremely wide base of consumers by sticking to a size that is both affordable and doesn't intrude on storage is a very big deal. Appealing to the mainstream is far more difficult than pleasing a niche. And with the price of gas is down to \$3.39 per gallon, demand for EV isn't going to be very low. There is of course the reality of battery life too. Taking advantage of the engine during times of high demand doesn't please the enthusiast, but it does ensure longevity.
- 4-22-2013** **Road Trip.** Yesterday was my longest no-charge (HV only) trip ever. The temperature averaged 40°F. The driving was almost entirely highway (55 - 70 mph). I was thrilled with the results... 291 miles, 59 MPG. That heavily supports the *"Solid 50"* goal following depletion Toyota set to deliver. It proves Prius is very much still a remarkable hybrid even when there isn't any plug-supplied electricity available. You can imagine just how uncomfortable that makes the competition, especially when you consider the affordability of a system with only a 4.4 kWh capacity. The plug-in feature can easily become as simple as a package option.
- 4-22-2013** **Redemption.** When you argue with someone over and over again, stating their estimates are missing vital points, it's reasonable to finally give up... hoping for the best. Well, sure enough. It happened. Though, the situation is still a bit frustrating. A very stubborn Volt enthusiast continuously posted his calculations, excluding important factors. But whenever I called him on it, stating without the numbers were an ideal, he'd attack. His assumption was that my intent was really a covert way of promoting Prius. Today, he posted this: *"Now that I own a Volt, I believe 55 EPA miles of AER would be more appropriate, for many reasons: 1) Many trips are longer than I realized. 2) Cold weather significantly lowers range. 3) My driving style also lowers range."* How many times should I have tried to make it clear that he wasn't taking them into account? He kept stating 40 miles of All-Electric-Range would be delivered under all circumstances. Now he knows how wrong that actually was. But rather than post an *"I told you so"*, I refrained... even though I was quite entitled. There were plenty of links and quotes I could have used to. Why bother. I simply replied with: Sounds familiar.

- 4-22-2013** **EV Estimate.** Those posts continue to emerge. For example: "*I, too, bought a PIP several months ago and every time we plug it in and then get in to drive, the "total miles charged" is less and less; starting at 11 and now down to 8.4. After reading all posts I still don't get it??? WHY???????*" We try to be constructive. This was my response: The value starts at a default value. As you drive and conditions change (like outside temperature), the value will become an estimate based upon your own particular circumstances instead. It will adjust accordingly as time progresses. It will still only be an estimate though. Primary purpose remains the same. That value simply gives you a rough idea of how much electricity is available. Whether or not it is consumed for EV or to boost HV remains an unknown and continuously different variable. MPG is still improved nonetheless. New owners tend to obsess with the estimate, which is great... since that is actually a secondary purpose. It draws you into the ownership experience, stimulating a heightened awareness of how the system actually works. That's something no manual or pamphlet could achieve. Heck, even the online exchange of "how it operates" isn't as effective as firsthand observation. Enjoy your plug-in Prius. If you want to learn even more, purchase an aftermarket gauge. Using it, you'll be able to see capacity as a percentage rather than miles. That really adds to the understanding.
- 4-22-2013** **Diesel Deception.** It's so annoying to read an article with a title like this: "*Diesel Chevrolet Cruze to get 46 mpg, matching Toyota Prius C*". As you would expect, it came from a Detroit publication. Only disclosing the highway estimate is greenwashing. No amount of spin will cover up such a blatant attempt to mislead. To make matters worse, the combined value is only 33 MPG. That's so low, what's the point? In fact, that may have been way the gas model of Cruze wasn't mentioned. With the price of diesel so much more expensive, it's difficult to imagine the car selling well. But the opportunity to spite the competition was too much to resist. The article itself seemed desperate. You got the impression of being equal on all measures. Clearly, that's not the case. MPG for Prius is far better. Prius emissions are cleaner too. It's really unfortunate. But on Earth Day, that type of deception was to be expected.
- 4-22-2013** **Freaky Old PHV.** Think about the condition of the plug-in model gas-engine many years from now. It will still have quite a bit of life remaining! We could see some freaky old PHV, especially if the owner decides to replace the battery-pack after the warranty is long past expired. Imagine how cheap 4.4 kWh would cost then. It would be a simple effort. The brushless electric-motors continue to operate just like they were new. Aging doesn't happen with those components. Only the combustion side suffers from reduced performance from excessive use. The gas-engine isn't used hard or much. It has an easy job and should be able to deliver for a very, very long time. Heck, there's no belts in the system and the timing is controlled by a metal chain. The 0W-20 synthetic oil as a lubricant will help minimize wear. It's a design that traditional vehicles simply cannot compete with. Having a plug makes it an even better hybrid.

- 4-23-2013** **First Owner.** The big Earth Day news for Volt ended up being an article which started with: *"In December 2010, retired airline pilot *** become the first Chevy Volt owner in the world. Since then, *** has racked up a decent amount of miles. But it's not the mileage on his Volt's odometer that's the story here. Rather, it's that ***'s Volt is averaging over 450 miles per gallon of gas consumed."* I was in dismay by how blatantly such vital information was just summarily omitted like that. Turns out, over the 2.5 years of ownership, he only drove a total of 13,700 miles. That's quite the opposite of decent. That's so far under the norm, it skews results heavily. Just think if I only drove 5,500 per year like that. My resulting MPG would be amazing too. It's frustrating to see misrepresentation. People cannot expect the same outcome. They get the impression that it could happen for them though. Ugh.
- 4-23-2013** **Buick Riviera.** We got a strange concept vehicle from GM yesterday. The reveal was so vague, it didn't actually tell us anything. The whole day I scratched my head wondering why the supporters didn't ask questions. Supposedly, it's just the plug-in version of Two-Mode again. That didn't make any sense... since some supporters now contradict their own original statements about Volt, saying it evolved from Two-Mode after all. Claims of starting fresh have vanished. But with that being the case, what the heck was this? It was a confusing mess. Of course, mixed messages is nothing new. No clear path is what we've been dealing with for years. Anywho, I thought I'd make mention of the concept here. It reminded me of the original announcements for Saturn hybrids. The story changed so often, I had to refer back to my logs to figure out what was said and when.
- 4-24-2013** **Spark EV.** Rather than having to deal with a concept reveal, we got an actual new vehicle rating from GM today. And with all the other automakers so quiet, this news got the spotlight. The estimate officially from the EPA was the upcoming Spark EV would deliver 82 miles of range. That's reasonable. Supposedly, price will be too. Of course, this is a total contradiction to what we were told prior to Volt rollout. Remember all the *"range anxiety"* marketing? They promoted the horrors of electric-only vehicles. Now, they'll be selling one anyway. It's that mixed message problem. Each encounter, you get a different interpretation of intent. Anywho, the rollout itself certainly will be interesting. Spark EV doesn't address the product gap (no real hybrid), but it does expand choice and further production of batteries.

- 4-25-2013** **That Never Happened.** Someone asked about the HOLD button for Volt today on the big Prius forum. I mentioned the history of resistance to it and how nice things are now that we have finally moved on. Almost immediately, there was a claim saying that never happened. My blogs are loaded with quotes from enthusiasts fighting against it, stating it was unnecessary and there would be no benefit. Over and over again, I heard that even mere mention of it was really an endorsement for Prius. It was relentless, repeating the message that it was uncalled-for. But the more real-world need became understood, the less the purity of EV from a vehicle with a gas engine available made sense. Why would you intentionally waste electricity? Knowing the button would be offered in the European market made the situation worse. The spin was that there were EPA regulatory concerns preventing the button from being offered. Today, that same claim was made, complete with a reference link. Of course, if you took the time to read that webpage, there was no such information. It's a greenwashing trick, since very few people ever actually click to check. Long story short, that button is now a standard feature for Volt and there wasn't ever any reason not to offer it... other than the fact that the plug-in Prius was rolled out with a HV/EV button, a feature very similar to HOLD. In the end, it still comes down to pride. Being similar to Prius equates to failure as far as they are concerned.
- 4-25-2013** **He's Back.** The situation of actually deal with a genuine forum troll is rare. You'll see brief attacks, when someone creates a new membership id, posts something to stir trouble, then vanishes. That happens all the time. What doesn't is when someone comes on openly & actively, but counters whatever you reply. The bait is simple, since the discussion almost immediate wonders off-topic anyway. About a week ago, the biggest problem the Prius community ever had to deal with returned. He was initially a hard-core pusher of biodiesel. Post after post endorsed that and belittled Prius. Eventually, he gave up and switched focus to Lupo, which is now known as a disaster vehicle for VW. But back then, people weren't well enough informed to understand the problems and most of the documentation & reviews weren't in English. We ended up overcoming his greenwashing. He ended up purchasing an original model Insight... which is how he introduced himself recently on the big Prius forum. He seemed to be Honda owner looking for a replacement for his aging hybrid. I knew who he was. No one else did. But I kept quiet, hoping for the best. Unfortunately, things got weird quickly. He started calling Prius owners Honda haters. He wouldn't acknowledge replies to his posts either. It was just one odd question after another. Then things really took a strange turn. Supposedly, just yesterday his Insight just get rear-ended by a Prius. What are the odds of that? Now people are starting to wonder. I still haven't pointed out his trolling history, though I did search the old forum to have a few of his old posts handy for reference just in case.

- 4-25-2013** **Spring Expectations?** That question is far more complicated to answer than you ever imagined, still fulfilling to learn about though. The fact that Prius PHV is a plug-in hybrid means some plug-supplied electricity will also get used for HV driving, not just EV. Seeing blended miles like that make interpreting the improvement associated with warming weather extremely difficult to quantify. Fortunately, you will notice the change, but getting detail from everyday observations is quite a challenge. The transition from Winter to Spring to Summer is something I was privileged to document last year. Looking at my daily driving graph, you can see the EV miles were all over the place. There most definitely is not any pattern whatsoever. Electrical resistance & capacity improve with warm temperatures. I've seen my continuous EV-miles distance (actual not estimated) nearly double from 9 in the depths of Winter to a high of 17 on the nicest Summer morning commute. Seasonal change is part of the ownership experience. MPG improve & degrade for Prius even without a plug. It because a refreshing reset every year, especially even when low the efficiency is still quite a bit better than traditional vehicles. Having a plug enhances that. You find it even more rewarding.
- 4-25-2013** **More Spark.** Some detail of the Spark EV was released today. It's rated at 82 MILES and 119 MPGe from the 21 kWh battery-pack. Finding that out marked the next chapter in GM history moving away from Volt as a "*game changer*" vehicle. Between this and all the attention Cruze Diesel got last week, the once heavily hyped plug-in hybrid has almost totally vanished from online discussions. That competition-from-within reality has become all too real. It's the "too little, too slowly" concern playing out right before our eyes. Measure of success comes from looking at each automaker's own offerings. Their own product-line speaks for itself. Diversity is great, but lack of direction is not. Emphasis is not focused on anything in particular. Of course, as always, it comes down to cost. Production simply won't be there if cost is too high. Mainstream volume requires the vehicle to be affordable, making a profit without dependency on subsidies is vital. It's what enthusiasts don't want to hear; they thrive on bragging rights, not accounting. From my perspective, I'm intrigued about how this will stimulate the market as a whole for plug-in vehicles. With so many "me too" and compliance rollouts, it's difficult to know how mainstream consumers will actually react.
- 4-26-2013** **Hooray!** The commute to work this morning was wonderful. 201 MPG with 0.4 miles of EV remaining from my usual route (just under 17 miles with half at 70 mph) was a welcome improvement. The warmer temperature outside made a huge difference. It was an amazing 57°F outside. That's 20 degrees warmer than it's been in months. Hooray for spring! I still remember exceeding 400 MPG on the way to work. That seems so long ago, I feel sharing those experiences requires me to start the story with: "*Once upon a time*". Fortunately, the snow does eventually melt away. And even with having to deal with the cold, having a plug clearly improved upon the great MPG already provided by Prius. It did indeed raise the bar as a realistic solution for the masses.

- 4-26-2013 Grille Blocking.** Watching the temperature climb into the 60's today was amazing. We haven't seen warmth that nice here in Minnesota since last Fall. It has been quite a long Winter here. Spring will be incredibly short as a result. We will basically jump straight to Summer. Anywho, the new high meant removing the grille-blocking from the Prius before the commute home. Since all I do is use the squeeze method, just squishing form pipe-insulation between the slots, it only took a minute. Done. Yeah! Doing that means there's no need for extra heat-retention anymore. Engine warm-up will be rapid. Of course, it's not like the blocking was a big deal. It only took 20 minutes and cost less than \$2. The dark gray among the black didn't even make it noticeable. The benefit was though. With the low temperatures we get around here, that extra heat was nice.
- 4-26-2013 No Arguing, part 1.** We're in the stating-the-facts stage. The time to reflect has arrived: Debt & Obligations dismissed. Many problems self-inflicted. Little concern for the future. 200 Million shares purchased by our government, then later than wanted sold back at a loss. 300 Million shares still owned by our government, stock prices still under the purchase price. All that makes accepting the consequences of the circumstances GM is in now difficult. Volt was promoted as their flagship, the technology leader intended to pave the way. 2.5 years after rollout, it's barely talked about anymore. S o many goals fell short, the decision to explore other options is becoming obvious. We hear about eAssist, diesel, and EV offerings instead. Meanwhile, the "Voltec" system continues to follow the very same path as Two-Mode. There is no clear purpose or intent anymore. GM's own production is competing with itself and there's a massive product gap, no high-efficiency choice that's affordable for middle-market. What are we supposed to expect at this point?
- 4-26-2013 No Arguing, part 2.** When a discussion focusing on bailout & sales emerges, you just keep on providing information: A quick search of dealer inventory for new Volts available provides a list of 8,543. That's a heck of a lot of unsold to worry about, especially considering there are 285 used also listed. Just think what will happen when those amazing 3-year leases begin to expire 6 months from now. It sure would be nice to see Volt on the path to becoming a business-sustaining vehicle, providing profitable high-volume sales like GM's other popular cars... Malibu, Impala, and Cruze. Heck, even their Equinox has much greater demand, despite being a small SUV. The situation isn't pretty and Volt owners are getting tangled in the mess. Sure, the technology works and it's proving reliable, but cost makes it unreachable for the masses. They just end up buying some other GM vehicle instead. That worse part is we saw this coming, but hope clouded judgment. Now what?

- 4-27-2013** **Keeping It Simple.** The current approach of restricting inventory to the initial rollout markets is proving to be a wise choice. Reasoning for that should be obvious. Think about how many times we see a new thread started here by a new owner absolutely insisting something is wrong with their plug-in Prius because their EV-mile estimate value has dropped. Those are from people who have firsthand experience driving one. Think about the scores who are only just reading posts and stumbling across hearsay. Imagine how busy that's been keeping service & training personnel. Misconceptions are quite a challenge to deal with. Keeping them from spreading makes sense. After all, Toyota has 2 major markets to deal with... the 15 states here and the sales over in Japan. Working toward clarity prior to expanding makes a lot of sense. After all, the first owners are only starting to report their first-year results now. It takes an entire annual cycle to properly represent real-world driving. The collection of that data cannot be accelerated. We must wait for it. But the reward is huge. Owner endorsements are far more influential than automaker promotion.
- 4-27-2013** **Discontinued?** A strange new thread started yesterday. It asked whether the slow progress of PHV rollout would cause it to be discontinued. That was an odd question, since each new generation caused the prior to be discontinued. Curious what was actually meant and the use of the word "*solution*" among the comments, I chimed in. After all, we know there will be something with a plug offered and we know how Toyota strives to keep Prius a product for middle-market. I posted: No one has said it was a solution. For that matter, there's a 100% chance of it being discontinued. Each generation gets progressively better. The next will offer a variety of improvements which may not necessarily resemble the prior. Heck, think about how expensive lithium-based batteries are still. Expecting better models with new or modified technology is quite realistic. Consider the state of the market, the diversity of consumers, the cycle timing, and the overall goals. What we currently have is on target. A few years from now, we'll see advancement of the system bringing us closer. The automotive industry is mimicking the computer industry now. There are on-going upgrades with changed priorities and different approaches.
- 4-28-2013** **10-Speed, Dual-Clutch.** Offering variety through product diversity is usually an excellent decision. In case one approach fails to catch on, you've got something else to rely upon still. There's a catch though, cost. In the case of VW last week, they announced their effort to offer a 10-speed, dual-clutch system for their diesel vehicles. How does increasing complexity to that extreme make sense? Adding more gears adds cost up front and warranty expenditures later. Some consumers have expressed displeasure when a vehicle shifts often. With 10 gears, there's clearly going to be more shifting. The expectation is the new system will deliver a 15-percent improvement in efficiency. That would equate to their latest 33 MPG combined estimate climbing to about 38 MPG... which still doesn't compete with a gas hybrid. Being competitive is important too.

- 4-30-2013** **Collision Avoidance.** It was one of those mornings, things could go either way. The highway merge was with a slow-poke just leaving the ramp and not a sole on the highway itself from behind. So as I got on the ramp, my pushing of the HV/EV button came with a thought. How fast could I accelerate while still within that first minute, where you get a substantial amount of electricity from the battery? That temporary state protects the engine from stress by limiting RPM. What the heck. I gave the system a substantial amount of pedal. Not having floored it, my curiosity was peaked. RPM went up to 1571. That's it. Speed jumped to 76 mph. Then, with the radio blasting and the front windows open, I heard an alert. The radar had automatically (collision avoidance is always active) detected danger and warned me of the approach. It saw the slow moving vehicle, but had no idea I was going to just shoot into the next lane. That was cool. The acceleration boost from the electricity was too.
- 4-30-2013** **Restoring EV.** I followed a thread on the big Prius forum for awhile. Some owners were saying they didn't see a recovery of EV miles resulting from their push of the HV/EV button. That electricity from the battery-pack used to ease engine warm-up is slowly restored as you drive. I've seen it many times now... and have recently paid closer attention to detail. That has indeed happened for me. In fact, the entire amount is accounted for prior to exiting the highway. That means the recharging which comes from the ramp is a bonus, making the charge-level a little higher than what I started with when the button was pushed. My guess it the small loss some have been seeing is the result of not driving far enough at a steady cruise, especially if the A/C is being used. It's nice having the option of choosing when to draw heavily from the battery-pack. Getting 50 MPG on the highway makes it a no-brain saving the electricity for suburb driving later instead.
- 5-01-2013** **Wow!** Today certainly got off to a wild start. I was beside myself when I read the daily blog with this title: *"2014 Chevy Volt: anticipation and mystery surrounds newest model."* It went on to say: *"The array of speculation surrounding the newest Volt varies from wild and imaginative rumor to more reasonable and realistic assumptions. The combination of passionate fans along with the technological possibilities associated with the car has created a platform for some interesting notions regarding the features and specifications of the upcoming vehicle..."* Funny thing is, not a peep has actually been said about next year's model, nothing at all. No one has mentioned anything whatsoever about a mid-cycle upgrade. In fact, it's been dead quiet ever since the disappointing reveal of the Cadillac ELR which will be coming at the very same time. It just plain does not make any sense... until you think about GM's approach of distracting sales results with something that will stir lots of attention. This is what sets GM apart from the other automakers. They stimulate hype. Substance can be totally absent, yet enthusiasts gobble it up anyway. It's where the *"over promise, under deliver"* reputation came from. Needless to say, the expectation is that Volt sales for April were well below that of GM's other offerings.

- 5-01-2013** **It Finally Happened.** Clearly, wanting to be constructive is no longer of any interest. The enthusiasts are in damage-control mode now. That daily blog for Volt has now officially become a venue for only posts that are cheerleading (positive) in nature. Nothing casting a shadow on the future of Volt is allowed anymore. Posts like that are rapidly deleted by the moderator. We wondered how long the status quo would last. It was 2012 year-end for the big GM forum. The blog took longer, mostly because many topics were no longer about Volt. Now, 2.5 years into sales, what else can be said? Someone brought up sales, with this snippet: "*undersold the Volt's credentials by quoting sales*". I was very curious how the numbers for last month, released just a few hours ago, would be responded to. Finding out the following reaction would be deleted within minutes was no surprise: Put in perspective, since automaker production & profit is very important, consider sales: 23,260 Cruze; 18,539 Malibu; 14,766 Impala; 1,478 Volt.
- 5-01-2013** **Debates.** Pretty much any discussion about a Volt purchase turns into a debate. It doesn't even matter where. Each venue ends up stirring plug-in attention. It's the unwillingness to consider the big picture that gets me crazy. That usually comes about from generalizations. On one particular thread today, it was: "*Why do PiP advocates always downrate the Volt and uprate the PiP in their assumptions.*" It didn't take long for someone to sound off saying they don't. Naturally, I joined in too: I'm another who doesn't. I use real-world data too, not assumptions. As for patterns, notice how Volt advocates include the tax-credit without concern about what happens when it expires? That's what sets the debates apart. There's the support in the here & now for an individual purchase being treated the same way as business diversity & profitability on the high-volume scale. They are fundamentally different. Volt holds its own on the individual level. On the business level, it has been a struggle with growing pressure. Acknowledging that would be progress. It will relieve some of the pressure, paving the way for GM to reconfigure Volt for it to appeal to the masses. Enthusiast admiration doesn't pay the bills. Do you want a praised niche or a ubiquitous vehicle?
- 5-01-2013** **Wearily Optimistic.** That's how a GM supporter stated their feelings about Volt, based on the comments made by the CEO yesterday. "*We're losing money on every one.*" was a key quote from the interview. It's confirmation that the expectation of the first generation being profitable didn't happen... and vindication of the "*too little, too slowly*" concern those well informed about Prius development & rollout had, as well as the automotive task-force in charge of GM's bankruptcy recovery. We wondered how the heck that bold claim from January 2010 could possibly be achieved with such a complex system depending upon such a large battery. Now, there's concern how this statement made yesterday will be achieved: "*This next generation, we think we can decrease the price on the order of \$7,000 to \$10,000.*" For that to be realistic, Volt will have to transform in a way some enthusiasts won't be too happy about. Becoming profitable is a very big deal. It requires compromise, something certain people have stood firmly against. Delivering a Volt that competes with GM's own inventory is required. That means it must take on attributes associated with their high-volume selling cars... Malibu, Impala, and Cruze. The longer it takes, the more difficult the challenge. MPG continues to improve for traditional vehicles. Making Volt competitive with regard to MPG after depletion increases cost. Then there's the issue of the tax-credit expiring. A reduction of \$7,500 simply holds the price at the level it is now. To make matters worse, people are growing used to paying more for gas. Time is very real problem.

- 5-02-2013 Pinched Gasket, Oil Everywhere.** I took my Prius in for a free oil-change & tire-rotation. Last time, they overfilled. The oil was 1/2-inch over the maximum mark. That's frustrating. I was obviously going to check this time. To my surprise, it was perfect, just a little under maximum! Cool. All but the last 10 minutes of my driving that day was on electricity. So, the engine had it pretty easy. But with the pouring rain coming down, I didn't notice anything... until the next morning. The garage had slight oil smell. I wanted to double-check the fill level anyway. The oil was at the minimum mark. Huh? I tried again. Same thing. Oh! Oh! Sure enough, I backed out of the garage to discover a large puddle of oil. Grrrrr. Fortunately, I wasn't stranded anywhere and the engine was just fine. Within about 20 minutes of calling the dealer, they had a mechanic on his hands & knees cleaning up the mess in my garage. We then jumped in the Prius and drove to the dealer. Only needing electricity to get there made that part really easy. Needless to say, they were extremely apologetic and very attentive. Gotta like that. I enjoyed getting to chat with the mechanic for awhile too. Long story short, the gasket (that rubber o-ring around the filter canister you replace each time) had been pinched. That allowed oil to squirt out. I lost almost all of it in just a matter of minutes. Be attentive of this when changing oil yourself. Also, be aware that the shop could mess up too. This is a very, very good reason to check the level afterward. Mistakes happen.
- 5-02-2013 Product Gap.** That's the ultimate source of the on-going conflict. Each month stirs the same old thing... some focus solely at plug-in vehicles, others consider Prius as a whole. We're lucky if a "*limited availability*" disclaimer is included. But then again, that's horribly vague. For April, the total sales of the Prius family in the United States came to 19,889. That should be enough to warrant a closer look as to why. Instead, the number is pushed aside and only PHV is discussed. It's overwhelming evident that the topic of cars for the typical consumer isn't being addressed. That's the product gap. Toyota offers something for the middle, those who want improved emissions & consumption but don't have a large budget to get that. Ford is striving to deliver the same thing. GM has a big problem in that category; there's nothing for consumers with such priorities to purchase. Fortunately, that's becoming rather obvious. The hope was the performance aspects of Volt would make it a product to fill that gap. We now have confirmation that it isn't. The choice of a model with a smaller battery-pack and/or one without a plug is clearly needed.
- 5-02-2013 Sales?** I liked answering this particular question: "*You keep saying that but what do the sales numbers tell you?*" 158,069 Toyota division. 19,889 Prius family. 12.6 % of their US sales in April were Prius. Demand remains steady and a decent chunk of traditional production has been replaced by Prius. As for Volt, it desperately needs to diversify. The current configuration falls well short of the mainstream minimum (5,000 per month). It alone (no battery-size choice, no hybrid-only version, no midsize model, etc.) is clearly not enough. Also, let's not overlook the reality that there are 8,612 new Volt listed as dealer inventory right now. That's roughly a 6-month supply unsold. There's also 272 used Volt listed. Lastly, consider what will happen with the 3-year leases begin to expire the end of this year. What does that tell you?

- 5-03-2013** **Who?** Through all the spin, that question persists. It's very important. I restated the significance with: When a technology matures, being capable of delivering high-volume profitable sales, business calls it "*mature*". Enthusiasts label that very same situation "*obsolete*". The usual trophy response is no surprise. We've dealt with it for years. They see affordability as a low priority, an engineering effort that will come later. In the meantime, they downplay that cost shortcoming and belittle the competition. Fortunately, that approach has proven to fall apart about 2.5 years into the rollout. At that point, the market begins to lose interest and moves on to something else... which is exactly what we're seeing with Volt now. That's why audience is so important. For sales to grow, it must appear to the masses. There's a disconnect between enthusiasts and middle-market. Evidence of this come from the raising-doubt tactic, when sales don't meet expectations. Looking at Prius, we see that the C and V models did not steal sales away from the regular model... despite countless claims that would happen. Instead, they reached out to a new variety of consumer. The plug-in model will do the same thing. The mature technology enables that growth. Looking at Volt, we don't know what the heck to expect. Hearing the next-generation goal of price \$7,000 to \$10,000 lower makes you wonder how it will actually be configured and what that will do to new & used sales in the meantime. Knowing that the tax-credit of \$7,500 will expire by then, there's still the question audience still remains. Who?
- 5-04-2013** **Expanded Rollout.** As nice as that sounds, there are some things to consider. So when I encountered this, I gave it some deep thought to make sure all the most recent elements were taken into account: "*You want to boost PiP sales? Sell them across the country!*" Knowing that PHV is actually just an upgrade option, the economies-of-scale and real-world data benefits still apply even with rollout limited. I pointed out the situation with: As much as I'd like to see more around here, that's not really a good idea yet. Just look at how many "*range*" discussions there are still. Only within the last 2 weeks have we been able to get a handle on effect winter has on capacity. Prior to that, there were only a handful of us (literally) that had any real-world data to share, and that data was extremely limited. Waiting for an entire annual cycle to pass is mandatory. There's no way to accelerate that collection process. Then there's the act of actually spreading the word. It means we couldn't realistically expect the next phase of rollout until Summer 2013, which would be complicated by end of model-year clearance. To further complicate matters, we have Volt, Leaf, Tesla, along with the C-Max and Fusion plug-ins all sending their own particular marketing messages to consumers. Sadly, waiting until Fall really is a sensible choice. In the meantime, we can establish some clarity about what to expect from a plug-in hybrid.

- 5-04-2013** **Sales Reaction.** It was summed up with: *"This does not bode well for the volt."* I contributed: Two-Mode followed the same path. It faded away at the 2.5 year mark, when sales fell far below expectations and there was no clear next step. The technology did actually work. But it was complicated, expensive, and wasn't as efficient as hoped. It ended up being abandoned. Being told things are fine and we only need to be patient is allowing that history to repeat. Rather than giving GM a kick in the right direction so it stands a chance of meeting ordinary consumer needs, there's an effort to prevent conclusions from ever being drawn in discussions. Wanting success (profitable high-volume sales) means being willing to adjust. Not making an effort to try to align with market priorities is a red flag. Some simply didn't care. They preferred the gamble on hope. Standing firm with the range & horsepower regardless of cost was a dead giveaway of trouble to come. Now, sales are a struggle and there's no alternative available.
- 5-05-2013** **Abandonment.** Sometimes, there are a few who just don't get it: *"The two-mode hasn't been abandoned."* It stems from all the polarization, resulting in a perspective of absolutes. Not allowing for anything between success & failure contributes to all kinds of problems. Imagine if that was the way children were graded in school. No more A, B, C, or D. Either you did great or you did horrible. Seeking out opportunity to improve should be obvious. Though, that does require taking what you learned and leaving the rest behind... which is abandonment. Scary, eh? No. Anywho, this is how I replied: As for Volt, it won't be abandoned either. What has been is the *"game changer"* motto. Volt supporters commonly argue *"failure"* and *"cancel"* to distract from the goal of this generation becoming a mainstream vehicle. They'll bring up Prius as a change of focus and keep conclusions from being drawn. The purpose is to prevent the pattern from being recognized. Reality is, Volt enthusiasts are going to be disappointed with the next generation. GM will come to terms with what is actually needed and transform accordingly. The required balance will finally happen. If it doesn't, Volt will be one of those vehicles people admire, but rarely ever actually buy. 5,000 sales per month is quite a challenge... and only the minimum criteria. To have a vehicle become a source for business-sustaining profit, quite a few more must be purchased. Like Two-Mode, we now see the current approach is not capable of achieving that. Sales at the 2.5 year mark make that overwhelmingly clear.
- 5-05-2013** **Diesel Desperation.** When you don't have any data to support a claim, it's a bad sign. When you make a generalization you know isn't true, that's desperation. It's amazing how many times this same assertion comes up: *"The diesel does well in the city and much better than the hybrid on the highway. Don't go by EPA ratings as the hybrid ratings are extremely optimistic and the diesel ratings are very pessimistic."* Reading the forums, it's easy to see that numbers are all over the place. What basis could you confirm findings anyway? After all, what does *"hybrid"* actually refer to? Notice all the adjectives? How do you quantify *"well"* and *"better"* and *"extremely"*? The complete lack of effort is a dead giveaway the comment is emotional, not scientific. Fact is, I haven't encountered a diesel able to do 50 MPG in both city & highway. Mine can, without plugged supplied electricity. And of course, taking advantage of the battery-pack, there's no contest. My overall average for last year was 77 MPG. The emission rating of PZEV is another fact to consider. The diesel vehicle doesn't achieve that clean of a rating... not even close.

- 5-06-2013** **Priority Change, exposed.** Remember the "*Who is the market for Volt?*" question? The outcome to asking that question yet again (Google shows I already did 43 times on that website) was a link clearly stating it is Leaf, Prius, Prius PHV, and Fusion hybrid. That seemed rather odd. Normally, nothing of substance ever results. Checking the publication-date, it was obvious what had happened. GM's strategy isn't the same anymore. All that vague "*game changer*" spin had caused a new plan to finally emerge. Originally, we were led to believe Volt was the future of the automotive industry, that the first-generation model would take the market by storm... easily achieving the 60,000 annual sales rate by the end of the second year of sales. Since that obviously wasn't going to happen, and apparently not even feeling confident about the 45,000 revision either, focus was directed outwardly at the direct competition instead. Notice how shortsighted that was. The plug-in hybrids from Ford weren't even mentioned. Tesla was outright dismissed too. I got a kick out of how the new plan was exposed. It was intended as a rebuttal. I used to confirm priorities changed.
- 5-06-2013** **Priority Change, response.** Hearing today that our government will finally be selling back the remaining 300 million shares of GM stock (at a substantial loss), it was worthwhile to poke the bear. I responded to this: "*Why do you suppose these guys come here and go through this schtick?*" The Volt owner's distaste for Prius is blatant, referring to it as the "*P-word*", that his effort to prevent discussions about it actually causes people to do exactly the opposite. I used it as an opportunity to post: Since we answer that question on a regular basis, why keep asking? Notice that the following has absolutely nothing to do with the "*P-word*", yet it was treated as if it did: "*Wasn't the market for Volt those who would otherwise purchase a GM car like Malibu, Impala, or Cruze?*" We know the answer to that too. The first generation Volt was intended to become a mainstream vehicle. That's why annual production capacity of 60,000 was discussed so often and the ability to ramp up to 120,000 mentioned. Now well into year 3 of production, that hope has been abandoned in favor of a second generation Volt reconfigured to attract the buyers it intended to reach originally. Do we care that the "*too little, too slowly*" concern came true? Not really, unless the next offering doesn't meet the needs of middle-market either. Not understanding the reason why reinforces the posting, until the true problem is finally acknowledged. GM is competing with itself. That should be overwhelming clear at this point. Strong interest in their traditional offerings is pushing Volt out of the minds of consumers. They see it at the dealer as a curiosity, then end up buying a GM car instead.
- 5-06-2013** **Priority Change, attention.** The other reason GM is getting so much attention today is that all of the eAssist cars built before December 2012 were just recalled. That's 38,197 of their second-generation BAS hybrid... a good reason to distract with talk of the second-generation Volt instead. Oddly, if it puts the design on the right track and changes priority to actually be something for the mainstream, that type of greenwashing is acceptable. After all, no supporter wants to admit having made a fundamental escape. Providing them with an avenue of escape is a sensible. They switch focus to the future by allowing current problems to pass with argument. It does make you wonder how far the system changes will go. GM is not afraid to rename a technology to make it appear to be new. That's misleading, but most consumers only focus on details in present anyway. The point is to get the automaker back on track. And though a terrible approach, it could still work.

- 5-06-2013** **Priority Change, analogy.** I really enjoyed reading: *"This reminds me of the shop that added toppings to their hamburgers at no cost. It still was a lousy hamburger! I prefer steak, even if it cost more. Same for the Volt against the pip. Toyota added a plug to the prius but it is still a lousy car!"* References like that often backfire. In this case, it most definitely did. All along, my point has been that mainstream consumers are ordinary people who don't have the same purchase criteria as enthusiasts, who are willing to pay much more for their vehicle. Of course, my drive to the coffeeshop today without any EV available, delivered 62 MPG. On the way back, it was 64 MPG. My overall average for the day, recharging at home at work and driving a total of 51 miles, was 114 MPG. I could have pointed out how un-lousy all that was, but didn't bother. Instead, I responded with this: Thanks for the analogy. It perfectly fits the situation. Most of GM customers only buy hamburgers. They aren't going to purchase a steak, no matter how delicious it is. Why Volt supporters still don't accept that is baffling. Fortunately, GM seems to have recognized the priority difference and will be adjusting their menu accordingly. Enjoy your steak. The rest of us will be eating hamburgers, with plenty of money left over for fries, a frosty drink, and dessert.
- 5-07-2013** **Priority Change, reality.** It came crashing down yesterday. They didn't want to address goals. They didn't want to discuss need. They didn't want to face reality. We're returning back to the days of unsubstantiated hope, where being realistic wasn't required. GM will somehow deliver a significantly less expensive Volt without any decontenting. As if by magic, the current problems will be solved and the other automakers won't be able to match. Bring up the fact that the competition was actually GM's own traditional vehicles infuriated. Their anger was quite clear. The challenge of actual change was simply too much; instead, they chose to stick with bragging rights. It's an unfortunate position. Rather than supporting the automaker by making the tough decisions easier, they played the smug card. Predicting how that will play out is trivial. We've seen this very same situation unfold several times now. The signs are obvious. Yet, they don't see them. Priority change is a sign of weakness, an admission of failure. The decision is to just hope for the best.

- 5-08-2013** **Television Commercials.** The advertising of C-Max is getting annoying. It's not the fact that there's always a comparison to the v model of Prius. In fact, that's quite welcome. Having Ford indirectly point out that Toyota has more than one Prius size available is nice. The trouble comes from "*47 MPG Combined*" message. Knowing how much of a stretch that is, the pending lawsuit, and the misleading EPA numbers in general, you'd hope they wouldn't put emphasis that. Setting more realistic expectations is better for everyone. Heck, they could even just safely claim the MPG is better than Prius v. But to flaunt the value like that, it could do more harm than good. After all, such mismatches are why the 2008 revisions were introduced in the first place. Unfortunately, the measurement adjustments didn't go far enough. Besides the high-speed and stop & slow driving conditions not matching real-world well, the fuel used for testing is pure gasoline. Very few use that anymore. Almost everyone is using E10 now. So no matter what you do, your results will always be lower. As a basis of comparison, the numbers still work. But consumers are using them for that; they believe those big numbers represent an expectation... even though the smaller numbers and the including explanation clearly state they should not be. So, it's easy to imagine how little information is actually conveyed from a 30-second television commercial. Of course, that is the nature of promoting a product. Marketing doesn't usually have much educational value. It's used to draw attention.
- 5-09-2013** **Monthly Stir.** This time, it was drawn out. Bad monthly sales results stir lots of online debate. We got the usual flurry of excuses from Volt supporters attempting to draw parallels to early Prius history. You know how it goes. They only sight the bits of history they like and dismiss anything you attempt to remind them of. That keeps the posts flying for awhile, then activity abruptly ends. The inclusion of what's now being referred to as the "*\$10,000 price drop*" got far more attention than it deserved. There was nothing of any substance. It was just like in the past when claims of "*nicely under \$30,000*" were gleefully tossed around. Not having anything to support that goal actually being achieved should be worrisome; instead, they celebrate. The hope for 50 MPG and a 40-mile range were looked forward to the same way. It's the "*over promise, under deliver*" playing out again, right before our eyes. Yet, they don't see it. They believe it's all quite realistic and those saying otherwise are just attempting to undermine that success. Factors like cost are simply dismissed. Examples of the past are considered unpatriotic. The attitude is quite troubling. Lessons of prior shortcomings were clearly not learned. Rather than setting reasonable expectations, it's the same old hype all over again. Unfortunately, the monthly stir makes it even worse. Ahhh! Here we go again.

- 5-10-2013** **EV up & down, seasonal effect.** How many threads have you encountered over the WINTER complaining about EV range dropping? Only a handful of owners last year had the opportunity to experience the climb SPRING brings. As a result, there was a lot of frustration from many and very little real-world data to work with. To make matters worse, Prius PHV is a plug-in hybrid, not an EV. So when we'd try to get MPG information from a new owner absolutely convinced there was something wrong with their car, they'd get defensive saying we weren't taking their range concerns seriously. Now, we have the real-world data available. My own EV estimate & range has increased as a result of the seasons changing. Winter literally ended just last week (bad snow storms). Spring has sprung here. The last 3 days, the estimate has risen from 11.3 to 11.6 to 12.1 miles. The resulting range has increased as well. Not as consistently matched, but range is well above the 9 miles of EV that I experienced during Winter. The previous three days have been 14.7 and 14.2 and 14.1 miles. Spring has clearly ushered in much better results. It makes me wonder how those who had complained will now respond. Getting an endorsement from them would be great. We need owners who closely observed the seasonal effect.
- 5-11-2013** **Smug.** Some never learn, holding firm with their perspective. As a result, the same missteps are repeated over and over again. Thankfully, there are very few of such individuals now. Here's one, who made this comment yesterday about Toyota: "*Their pathetic attempt at a PHEV, that only gets minuscule EV miles, is pointless.*" Calling the choice of limiting battery-capacity to an affordable size that tells us the product-gap GM has will continue to remain unfilled. This particular Volt owner simply doesn't care though. Those adjectives make that overwhelmingly clear. You don't say "*pathetic*" and "*minuscule*" and "*pointless*" without being smug. They are meant to insult & belittle. Using them is no surprise. Car enthusiasts magazines wouldn't be caught dead endorsing a family sedan back in the days when Prius was first rolled out. All of them, the entire category, was looked upon with the same smug. They simply weren't interested in middle-market vehicles. This is why Volt is so difficult to promote. They treat it as a niche but want it to be mainstream. That's a direct conflict. Those enthusiasts are their own worst enemy. Endorsements much come from ordinary vehicle buyers instead. That's why I provide so much real-world data, complete with logs, photos, and video. Seeing all that, people can decide for themselves if my driving resembles their own. They can make judgment without any influencing adjectives. It's only those who are desperate that choose to disparage in such a way.

5-11-2013 **Up To The Chore.** Remember that saga a decade ago? There was a debate on a single thread that went on and on and on. It was the status quo (anti-hybrid) fighting Prius, attempting to prove it wasn't up to the chore. After nearly 2 years of failing to do so, the moderator finally declared that it was. The same type of thing has been going on for Volt; however, it's proving not to be. After years of excuses, the most important factor still hasn't materialized. Sales are just stumbling along. Without consumer support, what's the point? The goal of replacing traditional production with the new technology hasn't been achieved. The annual quantities were not met. Volt is really the second-generation design of Two-Mode. Looking closely at the system, it's pretty easy to see how GM took what they learned from the first and implemented improvements. Admitting that was painful for enthusiasts, since it meant confessing that the effort to compete has actually been going on for a very long time. But now that details of the next Volt are emerging, it's quite evident the design is really third-generation Two-Mode. In other words, there's another redesign on the way. GM will take what this rollout taught and use it to deliver a system better matched to market need. Volt wasn't up to the chore. This is why no matter what is said about GM's own product-line and the gap they are attempting to address, Prius is always brought up as a rebuttal by Volt enthusiasts. When nothing is even said about Toyota, that success is mentioned anyway. It's quite an endorsement for having reached the mainstream... overwhelming proof that subsequent versions from GM will be aligned to middle-market priorities. The current attempt to entice & convince didn't work. Too few were willing to pay the premium to satisfy want; instead, there will be a shift to focus on need. It's about dang time.

5-12-2013 **Facing Reality.** Middle-Market consumers don't have money available to purchase a Tesla. If they did, the automotive industry wouldn't face such a big struggle to make high-efficiency technology affordable. This is why the example of Prius is so often discussed. Toyota's effort to deliver a plug-in hybrid using only 4.4 kWh of battery met the objective. Going from 35 to 75 MPG, driving the standard annual distance of 15,000 miles, you'd use 229 gallons less of gas. At \$3.89 per gallon, that's \$891. Using my own real-world data, including recharging losses, that comes to about \$206 worth of electricity at 0.12 per kWh. The difference is roughly \$685 per year. That easily covers the goal making the system cost-competitive with traditional vehicles. As price drops for lithium battery-packs and the price rises for gas, the appeal of 35 MPG fades. GM is now painfully aware of how important that affordability aspect of a vehicle really is. They thought the thrill of EV driving alone would compel mainstream buyers to spend more. That didn't happen. The sacrifices made for range & power weren't enough. Even the explanation of savings hasn't worked. There's quite a challenge being faced and we are stuck waiting several more years for the next attempt to attract the masses. In the meantime, people are just purchasing 35 MPG vehicles with the intent of driving them for the next decade. This is what the *"too little, too slowly"* concern was all about. The *"we'll find a way to lower costs later"* approach is clearly not working. The design must address cost right from the start, initially rolling out with an affordable configuration, leaving the opportunity for capacity increase later when prices drop.

- 5-13-2013** **What's Next, part 1?** Reading that daily blog for Volt as a lurker now, rather than an active participant, is interesting. Like on the big GM forum, discussion depends heavily on enthusiast spin, due to lack of new content. They'd provoke those who supported something other than the status quo to keep threads from dying out entirely. When that begins to fail, they speculate about the future. Attempts in the past ended up stirring unfounded hope, a sense of triumph without actually having accomplished anything there even being support detail. That's what got me blogging about Volt so much in the first place. Enthusiasts would bet the farm on a long-shot. Despite terrible odds, they'd pounce on anyone who questioned their judgment. Needless to say, I certainly don't want to get involved with that again... especially now, with so much real-world data available. Though, I am curious what they have to say. Watching mistakes repeat is quite educational.
- 5-13-2013** **What's Next, part 2?** Despite today's topic asking the question of what's next, no one brought up Volt's own past. Having come short on so many goals, validating the vaporware predication, learning from the past is pretty much taboo. It's simply not talked about. They go to great lengths to avoid discussing it. We know that Volt came about from Two-Mode having many shortcomings of its own. Ironically, the heavily promoted "in transmission" design simplicity (intended to make adaptation into other vehicles easy) ended up far more complex than ever imagined. So, GM decided to abandon the approach. Rather than redesign, start fresh. It was a sensible move. Too bad cost wasn't a priority. They ended up with an expensive system that was still inefficient. Needless to say, GM is choosing to abandon again. That's great; however, enthusiasts are unwilling to acknowledge the steps actually needed to achieve that. The reality that Volt will become quite different isn't welcome news.
- 5-13-2013** **What's Next, part 3?** Watching Prius prevail yet another rollout cycle was obviously rough for those who genuinely thought there was a chance of catching up. Unfortunately, rather than wanting to participate as partners, they became combative competitors. We knew that wouldn't end up well. Since the very beginning, it was made quite clear that the actual competition was traditional vehicles. They didn't want to hear that though. Finding out firsthand that was indeed the case turned out to be quite a painful lesson to be learned. The Volt enthusiasts simply did not want to listen. The idea of GM competing from within seemed too absurd. The advice was dismissed as attempts to promote Prius... even though Prius was clearly at the forefront of the battle against traditional vehicles. Now, they know. GM's own product-line, cars like Malibu, Impala, and Cruze, are attracting consumers away from Volt. The evidence is overwhelming. The numbers easily confirm it. Loyal buyers aren't interested in such an expensive plug-in hybrid.

- 5-13-2013** **What's Next, part 4?** Having to wait very long times for Prius advances is always worth it, but what happens in the meantime certainly is a test of patience. This Fall, rollout of Prius PHV will proceed to the other states. That's what is next for Toyota. That's what so many have been waiting for. Of course, those interested have also been waiting for data. Getting that takes time. We all knew it would require an entire year of collecting. Each season must be experienced... and posted about in great detail online. Only now are we seeing the results of that. First anniversaries are being celebrated. Of course, even those owners must wait until Spring concludes. You cannot judge midseason either. All 4 must be consecutively observed in full. Then, proper conclusions can be made and stories compared with others. There are so many variables involved, the 12-month minimum is a necessity... which is why so much emphasis was placed on the second year for Volt. Now being halfway through the third, results speak for themselves.
- 5-13-2013** **What's Next, part 5?** Basically, we see both GM and Volt enthusiasts stepping away from the spotlight. Tesla is shining brighter than ever. It's quite remarkable how sales & stock are so strong now. Heck, I have even seen the Model S twice recently. I see Nissan Leaf on a regular basis too. To my surprise, even two C-Max Energi have caught my eye already. When Prius PHV joins the mix, it will be a joyous occasion. It's been quite lonely. But I certainly have enjoyed gathering so much real-world data in the meantime. We'll see both the variety & quantity grow. Eventually, the Honda Accord plug-in should make an appearance around here too. That's not expected until after the hybrid model gets rolled out in early Summer. The outlook is definitely changing. With Volt having reeked so much havoc, this new stage certainly is a welcome one. There was much worry that the rhetoric would damage the market. Thankfully, not much harm seems to have been done.
- 5-14-2013** **Chaos.** It's like watching a train wreck. You cannot help but to be fascinated with the disaster GM created for itself. We already knew Volt was a mess, a collection of misplaced priorities. Enthusiasts love it. Mainstream consumers aren't interested. The next plug-in hybrid to be rolled out by GM will be the Cadillac ELR. Turns out though, it won't be identified "Voltec" technology. In fact, there's already a marketing effort underway to make it clear that ELR is not a variant of Volt. Talking about mixed messages. What the heck is it then? Of course, with the CEO of GM having recently confirmed that Volt is not profitable, what difference does it make? Knowing money is lost on each one, it's a good bet that GM production won't grow. It was a declaration of niche, a clear statement that the next generation will be quite different. Think about how much will have to change for that \$7,000 to \$10,000 price drop to be achieved. The change will actually have to be more, to rework cost from being a loss to profit. Accomplishing so much, in so little time, without the expectation of the design or configuration or operation being fundamentally altered would truly be a miracle. That's not realistic... and the enthusiasts can no longer deny it... hence the chaos. That have no clue what to endorse anymore. Today's daily blog was an amazing array of uncertainty. This is why I lurk now. There's no need to post. Their failure to state goals has left without a clear purpose. Conflicts from within is a big problem, exactly as they had been warned about... but chose to dismiss.

- 5-15-2013** **\$4.19 Per Gallon.** One rather thought-provoking sign of the economy recovering is the price of gas shooting up. That reason typically is stronger demand. Knowing that the DOW has exceeded an all-time record high and continues to climb tends to support that as well. I certainly wasn't expecting a spike like \$4.19 though. It may very well be the highest I've ever actually seen it. Since our oil comes from Canada and the ethanol is produced local, prices are usually lower than just about everywhere else in the country. Despite that, we still have a surprising number of Prius on the roads around here. Seeing gas expensive now will add to it. I get people driving by giving me the thumbs-up sign already. I can't imagine when more discover the plug-in model. It will be like back in the good-old-days, when I'd get stopped in the parking lot to answer a fluffy of questions from someone who was curious about Prius. PHV could end up proving to be timed perfectly. Summer usually keeps the price of gas high. Building up demand for the national rollout would be great.
- 5-16-2013** **Much Ado.** For awhile there, the most common response to addressing business need was asking a rhetorical question. That's when you know they do actually see the problem but simply don't what to acknowledge it. Studying the market worldwide, it becomes easier to see. For example, Toyota won't release the plug-in model of Prius until 2016 in Australia. That information to easy spin. Rather than point out how the market there has always experienced a delay or pointing out that they are just waiting to rollout with the next generation model, those hoping to mislead & undermine claim the wait is due to sales elsewhere. Another example is looking at what purchase priorities are in other countries. Here in the United States, there is still an obsession with speed & power. That allows focus to dwell on average price, rather than middle-market price. There's a big difference. They draw you into arguments. They claim all the huff is much ado about nothing, that we just need to be patient and things will just naturally work out. Preventing conclusions from being drawn is a big concern when things aren't going well. It's an effort to stall. They know a business decisions must be made. The next step cannot be based on just hope.
- 5-17-2013** **\$4.39 Per Gallon.** Seeing the price of gas continue to rise was quite unexpected. Fortunately, I'm focusing more on plug-in observations. Actual EV is holding up well. 14.6 miles yesterday and 14.7 miles today. Estimate EV has climbed to 12.6 miles. So far with this tank, I'm at 532 miles with an average of 115 MPG. The driving-ratio is 53% EV and 47% HV. That's good stuff. It excites me to see such great results from a small battery-pack. Being able to squeeze out efficiency like that with 4.4 kWh from just ordinary driving is very encouraging. It's easy to scale a system up. Adding more capacity doesn't take much effort. The other way around doesn't work the same way. A system like Volt is heavily dependent upon the battery being that much larger. That's because it wasn't designed to blend well. Using its engine is much less efficient than with Prius. That means reaching mainstream consumers is a much greater challenge. With an abundance of time available, no big deal. With the price of gas already at \$4.39 in an area of the country where is it normally much less, that's a big problem. Think about how much a gallon costs on the West Coast. Solutions that are both high-volume & profitable are needed today, not years from now.

- 5-18-2013** **Desperate.** A long article from a Texas publication concluded with this paragraph: "*What did we buy to replace the 2003 Prius? A new Honda Fit, Sport model. It doesn't get the 40-plus miles per gallon of a hybrid, but at \$20,000 it cost about \$10,000 less than most hybrids. It's also fun to drive, has great visibility and very flexible seating/storage. We figure the \$10,000 difference will buy a lot of gasoline.*" Withholding vital information is just plain wrong. I don't know how else to describe such blatant misleading. That type of greenwashing is shameful. The base price of c model of Prius is \$19,080. That's less than his \$20,000 choice and delivers better efficiency. The disturbing part though is it was presented in a misleading way. This was the title: "*Hybrid went the distance, and then some*". From that, you get the impression it was the sharing of a positive ownership experience with along with an endorsement. Instead, it ended up being a recommendation not to purchase a hybrid. Sadly, we're likely to see more of that type of desperation to keep traditional owners from switching to hybrids. The price of gas is influencing what people say and do.
- 5-18-2013** **Arguments.** Reading quotes like this fascinates: "*There are two die-hard Prius owners who frequent the home page main article section that will argue with anyone they can that the Prius and the PiP are far better than the Volt. The rest of the world simply does not agree with them.*" Knowing that isn't true, what is the appropriate response? They just plain don't care. The actual arguments have been that GM must alter Volt to become attract sales from ordinary people. Even when Prius is never mentioned, that's what they hear anyway. The idea of offering a model of Volt with a smaller battery-pack and a more efficient engine for blending horrifies them. It's the typical enthusiast reaction. They fear what they cherish will vanish. The idea of diversification scares them. So, they argue against those who appear to be fighting them... basically, lashing out at anything they can to prevent change. Their perspective actually makes sense too. From their point-of-view, engineering is all that matters. They have no idea how big of a role economic or accounting factors actually play.
- 5-19-2013** **Drawing Conclusions.** Now being 2.5 years into rollout, it is appropriate to draw some conclusions. Too bad if it angers a few individuals. That next step won't be successful unless you look back at the previous thoroughly. Buy patterns is the topic today. A constructive look at the numbers isn't encouraging. Hopefully, we'll actually get some decent discussion. Wanting to see the next step taken is a good reason to allow the past be analyzed. No more pointless resistance would be great. I stated the situation this way: Autotrader has 293 USED and 7,808 NEW listed. Cars has 259 USED and 9,294 NEW listed. That's roughly a 5-month inventory of new and a reason for concern as used leases begin to expire. Volt enthusiasts tell us to continue to be patient, wait for the next generation... which should be offer system improvements and much lower cost. Doesn't that tell us that new sales will be flat in the meantime and resale values will later plummet? It's quite obvious that GM needs to diversify. The thought that power & speed would stimulate strong sales clearly didn't work. Those traits didn't appeal to the mainstream enough to justify the purchase. We hear from countless scores all saying price must be lower. The best-case scenario has been stated as \$10,000 less. Taking into account the \$7,500 tax-credit won't be available then, that isn't promising. Knowing history, expecting best-case isn't realistic. Also, let's not forget the climbing price of gas and the upcoming efficiency & emissions regulations. As automakers add more hybrid & plug-in choices and pressure from traditional continues to grow, what should we expect?

- 5-20-2013** **Finally.** Remember the IPO of GM way back in 2010? The government selling back those remaining 300 millions shares of stock helped to push the market over that original \$33 price today. The news made headlines on quite a number of publications. Investors liked hearing that. Good thing too. The uncertainty left people hesitant. There had been much disappointment along the way too. That concern of "*too little, too slowly*" came true. The money lost was officially considered a bailout. The automaker can finally move on now though. We're all better off with it being over. Of course, there is still the mess of what step to take next, but financial recovery is done. The struggle to remain competitive will get proper attention now... at least we hope. This year will be pivotal. With other automakers already leading the way, their "*game changer*" plan will obviously need to be revised. It took far longer than many expected. We're glad some type of resolution happened. Let's take a constructive look at 2014 now.
- 5-20-2013** **Lithium Batteries.** The other big news today, this morning before the stock-market opened, was a reassertion that Toyota will be expanding their use of lithium based batteries. That's a big deal. In my Prius PHV, even without plugging it in, efficiency is higher compared to the regular model... despite the additional 123 pounds. That primarily comes from the Li-Ion pack being able to capture & deliver more power. That means the regular model will see an improvement by simply switching from the current NiMH pack. The report today was that the production will soon be increased six-fold. That translates to 200,000 units per year. It's hard to know exactly what that means in terms of usage & availability, but any type of expansion is good. Currently, only the plug-in model and the 7-seat model use lithium. What else will. Perhaps there will be a big PHV push later. After all, economy-of-scale often results in cost reduction. Having a design which doesn't compromise cargo area sets Prius apart from the other plug-in choices. A drop in price would stir more interest. That's a good thing when reaching the mainstream is a major priority.
- 5-21-2013** **Best Tank.** I've been watching the MPG climb. It's been around 120 for several days now. That's fantastic! Of course, this morning's commute was somewhat unpleasant. The temperature went from the upper-50's and lower-60's we had been enjoying lately to just 46°F. Fortunately, that didn't affect the average MPG much. With nearly 800 miles on this current tank, I'm still going to see a jump in lifetime MPG anyway. Watching the value drop over Winter was unpleasant. I know, complaining about efficiency at 75 MPG is a bit on the absurd side. But then again, this could have been my best tank ever. Seeing the efficiency that high without doing anything special is really exciting. I'm just driving it. I even let the battery cold-soak before plugging in again. At work, that's minimum of 4 hours. At home, it's a wait of at least 1.5 hours. That allows the chemicals to rest, which contributing to longevity. Anywho, I'll be filling up the end of the week. I'm looking forward to it.

- 5-22-2013** **Coffee Talk.** Once a year, I met with a friend from the West Coast. With his extensive automotive background and my interest in Prius, we usually talk about that as the coffeeshop. In the past, lots of it involved the drama known as GM. It was like watching a train wreck. You're horrified that anything could be so bad. But now that the disaster has long passed and there is no hope for current efforts, we simply talked about other stuff instead. 2.5 years into Volt sales, it's quite clear executive decisions made a mess of what could have been a contender. Consumers certainly haven't endorsed it as a "*game changer*" and just 3 weeks ago the CEO stated each was losing money. Not being profitable means not much will happen until the next-generation rollout. In the meantime, I'm having a blast with my plug-in Prius and we're looking forward to availability in the other 35 states coming this Fall.
- 5-23-2013** **Range Anxiety.** Nothing is being said about it anymore. At one point, GM was about to bet the farm on "*range anxiety*", to the point of protecting the slogan with a trademark. It was the fundamental selling-point for Volt. That's why there was no intention of selling an EV in the United States. The idea of an electric-only vehicle was preposterous. Nissan was laughed at. Since then, reality has set in. Not only has Volt lost the spotlight for GM, it's to the point where pricing is competitive right from the start. Chevy Spark EV is getting all the attention now. It will roughly \$2,000 less than Leaf. Of course, it's a smaller car. But at \$28,305 before the \$7,500 federal tax-credit, that's definitely going to fall into the affordable category. Long story short, the philosophy & approach GM took in the past has completely fallen apart. It's an effort to diversify and pave the way for a realistic model of Volt later, not the trophy vehicle we currently have. Change is difficult. But steps are now being taken.
- 5-24-2013** **Next-Gen Prius.** A spy photo surfaced on the internet today. It was just current model with camouflage, but that didn't stop people from speculating what it concealed. Realistically, testing out new design, operation, and features this early is to be expected. That's not a big deal. All automakers take their prototypes out into real-world conditions for detailed verification. Testing the major revisions is complete and they are now in the tweaking stage. That sure excited some people. Needless to say, on the big GM forum, it provided an opportunity to slander Toyota. Nothing constructive whatsoever came out of that. It was just a sad stream of insults. But now with Volt rarely being discussed there anymore, that type of reaction was to be expected. Comments posted about this mule sighting were quite sensible on the general automotive blogs, sprinkled with ugly comments, of course. There's no getting around the "*judging a book by its cover*" problem. Realistically, it doesn't matter. We still have another year before any information will actually be revealed. The thought is the next generation Prius will be a 2015 model. So, waiting is still involved.

- 5-25-2013** **Too Small.** Another Volt owner gave into the reality that the seating room in back is too small. This one wouldn't be caught dead in a Prius, so naturally the switch was to a C-Max instead. Oddly, it was just the regular model rather than the plug-in. But then again, we do know that Volt leases will begin to expire later this year. Most of them were for just \$199 per month. Finding another deal that low isn't at all realistic. There is a growing chorus of those considering the rear legroom and the lack of a middle seat a problem for Volt. That's a very good sign. It shows a sense of acknowledgement that consumer priorities are different from what GM delivered. Realigning to better match is a win for everyone. It's really unfortunate it took so long. But then again, it should have been obvious that a compact couldn't compete directly with midsize cars.
- 5-26-2013** **Receiver Hitch.** The strap-on bike-rack has worked great on my Iconic, 2010, and PHV model Prius. Each functioned flawlessly on many long vacation trips with 3 bikes on that high-adjustable plastic rack on back. There was never any concern about stability or spoiler contact. The ability to easily disassemble it for in-car storage/transport could be handy at some point too, especially since my group of biking friends is growing and we'll need a second car. That being said, I just bought a 4-bike hitch-rack on Friday, to go with the hitch I ordered on Thursday. Having that larger capacity with the ability to lock was a nice upgrade. Back with my Classic Prius, I had a hitch rack. It was convenient, but the rack itself was quite primitive compared to what's available nowadays, if willing to pay... which should be a no-brainer for exercise/recreation equipment I'll have for the next decade or two... especially with early-season discounts. It will be nice being able to easily load the bikes & cargo at the same time, since the hatch can open & close with the hitch. That's obviously not the case when it's physically resting on the bumper and pulled up against the glass with the strap-on type. Transporting 4 people means lots of cargo to carry inside. So, that's handy. I'm really excited about the increased opportunity a receiver hitch offers.
- 5-27-2013** **2014 Outlook.** With the 2014 Car & Truck guide from GM now available and the size of unsold 2013 Volt inventory roughly 5-months in quantity, the outlook isn't good. We know the design isn't profitable and there are no changes coming for next year. Adding to that the reality of leases expiring, causing a used inventory of low-mileage Volts to enter the market without tax-credit assistance, there's nothing supporters can say anymore. Enthusiasts still belittle & insult, but they aren't constructive and disagreement with supporters is rather obvious. It's quite a mess... the very thing we had concerned about. That "*too little, too slowly*" is overwhelmingly confirmed at this point. Just like with Two-Mode, sales proved to be the ultimate decider of how success or failure. On the Volt forum, the situation is described as a "*fizzle*". Rather than being a game-changer and leading the industry, it is struggling to survive. On the big GM forum, the sentiment is marketing made a terrible mistake with its push of Volt as an EV with a backup generator. Publicity should have called it a "*reinvented hybrid*" instead. After all, having an engine and blending at times very much makes Volt a hybrid. Needless to say, sales are expected to remain well below the mainstream minimum of 5,000 per month.

- 5-27-2013 **Battery Longevity.** The topic came up today. It's different with Prius PHV than electric-only vehicles. With them, there's no engine to protect the system and you want to utilize maximum capacity. You won't see that from a plug-in hybrid. They have a design capable of protecting & prolonging. It gets confusing those. Operation of electric-only vehicles isn't well understood by most people. They make assumptions. That in itself is difficult to deal with. Translating how that differs in a plug-in hybrid becomes quite a challenge, especially when they aren't aware of what to look for. Highlighting the basics is what we're attempting to do now.
- 5-27-2013 **Battery Longevity, HEAT** is the biggest enemy, as many have already sounded off about. Obviously, parking in a situation that will cook the car should be avoided. I face the windshield toward the sun and place a reflective insulated shade in the window. Cracking the windows is also a sensible idea. While driving, take advantage of the A/C. It's remarkably efficient. When you're comfortable, the battery will be too. Remember, it uses cabin air to cool itself. Heat contributes to aging.
- 5-27-2013 **Battery Longevity, DRAW RATE** is another very helpful longevity suggestion pointed out. That's good advice that's easy to overlook. You should keep the draw from the battery low. Seeing the bar on the Eco-Meter higher means you're putting greater demand on the battery. Speed doesn't matter either. 60 mph is no big deal if you're only using a small amount of power. Acceleration from a stop is the heavy-hitter. Avoid that by taking advantage of the engine. Don't be afraid to press the pedal hard. The engine will shut back off surprisingly after it's been warmed up.
- 5-27-2013 **Battery Longevity, COLD SOAK** is something you can do to prolong battery-life as well. A battery ages from stress of use, that includes the charging process, not just usage. Toyota made this easy by providing a recharge timer. Many owners don't realize the benefit the delay provides though. Allowing the chemicals within to cool & rest after use is what "*cold soak*" refers to. If you will be plugging in immediately after use, use EV upfront and finish off your driving in HV mode. That way, the battery is only used lightly prior to recharging.
- 5-27-2013 **Battery Longevity, CHARGE LEVEL** is an aspect of battery-life you don't have to be concerned about. 100% (the "FULL" level) is what most owners won't ever encounter. Recharging automatically stops at 85% and that's all the higher the indicator shows. That 15% buffer at the top protects the battery. 23.5% (the "EMPTY" level) is when the plug-supplied electricity is fully depleted. That protect the battery at the bottom, preventing deep-discharge from ever happening. So unless you routinely drive down mountains after plugging or drive after having run out of gas, there's no reason for concern.

- 5-28-2013** **Each Month.** The results of plug-in sales show how the market is taking shape. Dedicated electric vehicles, like Tesla's Model S and Nissan's Leaf are doing well. Ford's Focus and Honda's Fit are almost completely unheard of. That begs the question of how GM's Spark EV will be accepted, especially knowing how small it is and how competitively priced it will be. Both Ford's C-Max & Fusion plug-in hybrids (the "Energi" models) seem to be off to a good start. But then again, there's always that initial surge prevents determining actual demand accurately. We have Toyota's Prius PHV too (obviously), but that is still only available in 15 states. The intentional rollout delay that seems more and more sensible as time progresses. Rather than deal with all the mixed messages being set now, continue to refine sales & support first. That should help avoid some of the confusion currently taking place in the market. Understanding the 9-month is easier. Each month brings increased clarity about market perception & reaction.
- 5-29-2013** **Climate Change.** Witnessing the outcome of that monstrous tornado in Oklahoma has brought out the worst in some people. They still use "*global warming*" as greenwashing proof, claiming that doesn't make any sense considering how cold Winter is still. They'll even go as far as admitting Summer storms are more powerful and more frequent. All they need is that "*not warmer*" information to dismiss everything. In reality, we know that misnomer must be acknowledged. They don't want to though. Fear of change is powerful. And now with the sales of Volt really becoming a struggle, there's yet another excuse to not bother trying. It's amazing. It's like we've been transported back to a time when people absolutely insisted the world was flat. Without 100% of the population agreeing, they felt they can claim it's all just a shame. We're back to the "*raising doubt*" situation. Reading recent comments online, it's easy to see the same old "*environmental hazard*" rhetoric. But what's different this time is the number of Prius owners sounding off about how many years of clean, efficient, trouble-free driving they've experienced.
- 5-30-2013** **Tomorrow.** Toyota has already pre-released sales information about Prius for May. No specific quantity was actually disclosed, since there's still one day remaining for the month. But it they did state was that results would be better than May last year, which supports the strong demand we've been observing. That makes tomorrow a day of great anticipation. Of course, we won't know details until the start of next week. But with the inventory of Volt such a hot topic now, everyone is well aware that this is a turning point. In fact, even GM's monthly distraction from sales confirms it. Today, their big news was the first Cadillac ELR coming off the production line. Volt has vanished from the spotlight; sales results have been well under expectation. Additional proof of that came from the Spark EV price announcement. Honda immediately responded with a very enticing lease offer for their Fit EV. Toyota's approach of heavy emphasis on cost is clearly paying off. GM's decision to delay cost-reduction until the second generation is not working out to be a wise choice.

- 6-01-2013** **Intentional Distraction.** Sales of Volt falling well below the mainstream minimum of 5,000 per month has been making the path to profitability an extreme challenge. When the tax-credit expires, then what? The efforts to reduce cost aren't expected to even cover that difference. Without a hybrid counterpart, how will volume be achieved? Short production runs make sales even more difficult. Needless to say, the situation is a mess. To make matters worse, GM now faces a similar situation to what Toyota did years ago... and they are well aware of grossly blown out of proportion that got. The dashboard layout was setup with cosmetic appeal more of a factor than practicality. That resulted in the placement of the power & mode buttons very close to each other. Pushing the power button twice shuts off the vehicle. Guess what owners have inadvertently been doing while attempting to change modes... shutting off while driving. That's dangerous. GM's response has been to not acknowledge it and focus (intentionally distract) on their other offerings instead. Hopefully, that means a fix will rapidly be deployed. We'll see. The last thing they need is a stream of bad press from not addressing the issue. Knowing a solution can be just a software change (and well aware that this suggestion is to make it work like Prius does), I posted the following: Improving it shouldn't be a big deal either. To force the power off on a computer, you hold the power button for a few seconds. Why not update Volt to do the same thing?
- 6-03-2013** **It Happened.** The estimate value we've been using to determine how many months of inventory there were remaining of Volt turned out to be almost exactly what the actual sales were. That number was 1,600. The sales for the month of May were 1,607. The amount available for sale was 9,100 still. That's not good. In fact, it is so far below the needed 5,000 per month, all we can do is expect excuses and talk about the next generation. This model is a disaster. To make the situation even worse, there's the possibility that the Osborne effect may have been deliberate. That's a consequence of focusing too much what comes next, killing the current product as a result. Oddly, that would be a good way to restart Volt, just establish it all over again because the original version faded away. Anywho, there's no chance of "*game changer*" hope anymore. That particular dream is dead. There will be a mix of choices available from a variety of automakers. Heck, even the "*halo*" effect won't apply. Too much emphasis on engineering and almost total disregard for business spelled doom right from the start. Lack of balance like that rarely ever turns out well. We said it would happen and it did.
- 6-03-2013** **New Hitch & Rack.** SI tried out my new receiver-hitch & bike-rack this evening. It's quite solid and the hatch can still be opened, even with a bike on and its handlebar sticking out. That setup should do well carrying 4 light to medium weight bikes. I really don't care about a MPG penalty when it comes to recreation. Summer is way too short to let opportunity slip away. I have a plug-in model Prius too, so efficiency is kind of wash. Clearly there's going to be a big hit with 4 bikes on back, 4 people inside, and a bunch of cargo. Today's drive was 24 miles with about 4.5 miles of suburb driving, the rest on the highway. I also had 6 miles of EV available. The result of that one-way drive with a single bike on back was 65 MPG. It's a nice alternative for those who want a handy 4-bike lockable rack that doesn't make contact with the car. It's expensive though, about three times the price of a 3-bike strap on rack.

- 6-04-2013** **Failure.** No more spin or arguing. The horrible attitudes are gone too. Just like Two-Mode 2.5 years after rollout began, it's easy to see how things went wrong and the lack of demand. However, with Two-Mode, there was a profitable platform to leverage from. That meant the high-efficiency purchase choice for consumers was a model option, not an entirely unique vehicle. Prius uses that approach with PHV. The plug-in is just a package variation. That provides lower risk and higher potential. It's a win-win. GM certainly could use that now too. Sales of their Silverado pickup are amazing. 43,283 were purchased last month. Malibu does offer the package variant, with the eAssist system. Sales of the regular model were 18,899 and the hybrid at 1,695. That alone puts the situation with 1,607 into perspective. Looking at the rest... 23,055 for Cruze; 22,918 for Equinox; 16,061 for Sierra; 10,841 for Impala; 9,523 for Sonic; 9,243 for Tahoe; 7,929 for Camaro ...you can see the numbers for their variety of popular offerings are far outselling Volt. The reality of GM competing with itself is quite clear now. Those smug enthusiasts see that traditional vehicles are indeed the competition, just as some of us have been saying for years. Their hostile attacks on Prius owners who understood what the market needed are now an embarrassing part of an ugly past. It's too bad we had to endure their lack of willingness to consider the big picture. Now, they cannot avoid it.
- 6-05-2013** **Simple Statistics.** I let that daily blog for Volt have it today. This is what set me off: *"Gasoline saved by the cars that are being tracked to date, Chevrolet says, is in excess of 10.42 million gallons."* Compared to what? Put in perspective, there were 23,461 Volts sold last year. It's extremely difficult to offset the 237,758 Cruze; 210,951 Malibu; 218,621 Equinox; and 169,351 Impala from the same year. Then when you take the 418,312 Silverado and 157,185 Sierra into account, the rosy picture painted looks rather gloomy. Consider the impact the 81,247 Sonic made when it comes to saving gas. Consumers obviously have. That's just traditional vehicle comparison. Take into account the impact regular hybrids models contribution. The 147,503 Prius; 40,669 Prius V; 35,733 Prius C all obviously use less gas. Even without a plug they have a noticeable influence compared to the industry MPG average that was used to calculate that 10.42 million gallons. Adding a plug contributes to greater saving, but diminishing returns and cost required makes high-capacity unrealistic for the masses. There's pressure growing to take that reality seriously. The first generation of Volt clearly did not address those factors. It's becoming quite evident what the *"too little, too slowly"* concern pertained to as well. There's a variety of growing competition now, resulting in missed opportunity for GM. The situation can no longer be dealt with by stating a few simple statistics.

- 6-06-2013** **Simplistic Replies.** That posted resulted in rather explosive reaction. Pressure had been building up. It was a great way to wrap up the sales results for the previous month. My favorite quote from the thread was: "*A journey of a thousand miles begins with a single step.*" Two people posted it. No one participating actually wanted to address it though; instead, they use comments like that to dismiss your posts. I find their brutish refusal to consider the big picture confirmation that there is desperation to hold on to the few bits of what remains. Admitting that there were missteps is difficult. Facing the need for change will inevitably include emotional outbursts. All that was expected. I'm thankful it's over. Phew! They attempt to simplify the situation. I point out there are many other trees in the forest. In this case, I did it like this: Haven't you noticed when I ask for details about that journey, the request is evaded? That cliché makes the situation sound like there is no competition and an abundance of time available. Reality is, there is no guarantee the destination will be reached. How do you know it is the correct one to invest so many resources into? After all, the need for diversification informs us that there is more than just a single journey.
- 6-07-2013** **Done.** The effort yesterday, as the personal attacks were coming to a close, was to direct all focus onto the next generation of Volt. Naturally, they wouldn't acknowledge any advancement of Prius. It was exclusively about how GM will be making a superior product. Taking place on both the big Prius forum and that daily blog for Volt, it was quite intriguing to witness the same comments from the same people getting replied to in two very different ways. The one was loaded with bragging & insults, nothing of any constructive nature. The other, there were attempts have a true discussion. Sadly, the hypocritical nature of certain responses and the rather obvious use of favorite greenwashing techniques caused that to breakdown rather quickly. This morning, all that came to an end though. On the blog, the fixes GM needs to do to make to improve Volt were given "*simple*" labels were looked upon with the same type of hope that led to the problems they have now. Strangely, that is actually a tiny step forward. At least they are now acknowledging what we said prior to rollout. The blog stated the shortcomings this way: "*Price is too high*" and "*Interior room is too low*". That's progress, even though we had to wait for them to learn that the hard way. And of course, they won't admit it was what we had been saying all along. Acceptance only comes from the enthusiasts feeling they drew the conclusion about what needed to be done on their own. I find it quite a relief. Distracting from problems which have become so obvious at this point wasn't worth their effort. They see that now. So, we can call this decade's round of "*up to the chore*" postings with a different conclusion... No.

6-07-2013 **Higher Sales.** It's very much a mixed blessing not having PHV in the spotlight yet. Collecting lots of real-world data prior to that is by far the preferred approach anyway. But it's rather lonely with so few of us. But then again, those few become well versed in how the system actually works in the meantime. With so many misconceptions still, some being intentionally spread by those who want to undermine the greater spread of batteries & motors, having that is rather important. Fortunately, word is slowly getting out. My 17-mile commute includes 9 miles above the 100 km/h (62.1 mph) threshold. People assume that the battery-pack is only used during the slower portion of the drive. That certainly is not the case. You still get a substantial plug-in boost even at the faster speeds. That's pretty easy to see too. My first 0.5 mile is EV. The following 9 miles is in the 65 to 70 mph range, depending on traffic. Today, the screen displayed 119 MPG when I finally slowed down where the highway changed to 55 mph and the engine stopped. I ended up parking with the average having climbed up to 205 MPG. But the assumption that EV is limited and MPG is low as a result isn't an easy belief to overcome. Sales will climb as the people discover how PiP actually works. Higher is better. Faster isn't necessarily a good thing though. The catch is what sells. For Prius, it's simply the plug-in model of the existing generation. For a certain other plug-in, this current generation isn't expected to see a sales increase. Much of the industry experts are expecting numbers to remain flat. No growth is bad. As Prius PHV is rolled out to the 35 states this Fall that still don't have it yet, the hope for sales climbing even in the current 15 states is realistic. Meanwhile, this temporary lull while we wait for the first owners to finally celebrate their first year of ownership is a test of patience.

6-07-2013 **Scare Tactics.** Here in Minnesota, I remember the fear most of the rest of the country had when E10 was rolled out to other states. At that point, we had been using it for over a decade. All the claims of engine problems to expect never had any merit. If they did, we would have already encountered them. Instead, nothing. E10 worked fine. It reduced emissions, but at the cost of a minor MPG drop. Studies showed the MPG difference would plateau with higher blends. So as we moved to E15 and E20, there wouldn't be that aspect of impact. That meant research could focus on the long-term effects of using those higher blends. Turns out, there weren't any. Nothing ever emerged revealing problems. Yet, the association representing Big Oil recently stated this: *"E15 could leave millions of consumers with broken-down cars and high repair bills. It could also put motorists in harm's way when vehicles break down in the middle of a busy highway."* I was amazed to read that. What are they implying will happen to the engine? Not a shred of detail has been provided. What could possibly be so bad increasing the blend by 5 percent? Why aren't they just presenting the evidence to support the claim? Convincing people to fear something with showing them what to actually be afraid of isn't the slightest bit constructive. It scares me that some people will actually believe them without question. Accepting claims without knowing why is scary.

6-08-2013

What Really Happened. The approach for high-efficiency vehicles using batteries with more than just a tiny integrated motor was to develop a competitive hybrid, something with a traction motor strong enough to propel the vehicle at suburb speeds. Toyota figured out how early on. Ford took awhile, but then followed in similar fashion. Honda is only now doing that, after having struggled for years. Then there's VW with a first model that's actually worthwhile. We think Hyundai & Kia have potential in that regard too. Nissan chose to go all EV instead, abandoning their plans. The only other mainstream automaker is GM, who chose a very different path. They won't be offering anything in the category without a plug. That's why there has been so much pressure lately. That's also why the enthusiasts haven't cared about engine efficiency for Volt, expecting no model to ever be available with anything less than a "40 mile" capacity is a necessity. That's quite a gamble. But it does provide bragging rights so intense, MPG results can drown out any attempt to reason. Concern for joe consumer simply isn't there. They are the ones who never understood "*too little, too slowly*". The economic aspect still doesn't matter. So, when discussion turned to what the other automakers were doing, the posts became hostile. Fortunately now, there are nothing but pointless arguments. But 6 months ago, *whoa!* The reason is easy to see now too. Prior to that, Toyota was the only player of consequence. Including Ford didn't make any difference. Then came C-Max Energi, their first plug-in model of a hybrid. Mentioning that, just Ford alone excluding Toyota entirely, invoked rage I hadn't ever encountered before. It was ferocious. Up until that point, the supposed enemy was an automaker from Japan. Mocking them was easy for GM supporters. But to have a fellow Detroit automaker make GM worry, that was a very different matter. Now Ford offers another plug-in hybrid, Fusion Energi. That too is attracting unwanted attention. That situation makes basically anything you say about GM status not of a cheerleading nature a statement of hate. The Volt enthusiasts are baffled why there isn't praise for their plug-in anyway. Rather than looking at the big picture, taking into consideration business & consumer needs, they are truly amazed how anyone could question the success of Volt. Of course, some are just simply looking for a fight. Winning battles is much more important to them than ending the war itself. Fortunately, there are far more quietly happy Volt owners who couldn't care less and welcome other plug-in hybrid offerings. They see the real need. They recognize what must be done. To them, I thank. Their support is appreciated. To the few who refuse to embrace change, goodbye. Mainstream consumers are still waiting.

6-10-2013 **Endless Debates.** They are a sign of change on the way. When the same old argument is brought up again and again, even though clear evidence to the contrary is repeatedly provided, you know the person is desperate to prevent conclusions from being drawn. Only a handful of such individuals remain anymore. Their persistence to challenge well established principles would be admirable if there was something to support their claims. But then they bring up the same old talking points and nothing else, you have to wonder if they ever took the time to actually study the situation. Being guided by principle alone doesn't work. They're learning that the hard way. The market is far more complex than they ever imagined. It's what happens when you take a class like economics or accounting. You have no idea how many factors are at play until being taught what to look for. This is the very reason why venues, like online forums, are typically a poor mechanism for sharing detail. They are great for research. You'll stumble across all kinds of issues you'd never imagine otherwise. But the short nature of posts and the difficulty to follow a topic presents a great challenge... and fuels the opportunity for endless debate. Fortunately, one of the things you are taught to look for is that type of repetition. It's a sign something isn't right.

6-11-2013 **12.9 Estimate Miles.** The EV estimate value was a hot topic up until recently. Those miles kept dropping. New owners absolutely insisted something was wrong with their new plug-in Prius. They wouldn't accept the fact that the number was only a generic default. They wouldn't accept that the actual miles would change as the seasons changed either. They refused to accept the fact that they purchased a vehicle that didn't deliver consistent results. In other words, they came from the naive world of traditional vehicles where owners believed MPG was consistent all year long. Not having a gauge in the vehicle to display such detailed performance information is a totally new concept to them. Now they know. Now they understand. Now they enjoy. But to see their panic & frustration of the past, you'd never believe it was the same person. This change of heart came from there now being a large enough set of owners to have experienced a full annual cycle. They confirm what the few of us had been saying all along. We'd watch our estimate values plummet in Winter. My dropped to less than 10 miles at the worst of the extreme cold, here in Minnesota. Now, I'm seeing 12.9 estimate miles. The actual miles are even further. For those who have the opportunity to live in warmer climates, they routinely see estimate values as high as 17 miles. Batteries are sensitive to temperature, just like combustion engines. Knowledge is power. Lack of it can lead to confusion & anger. It's best to study. Research, rather than just complain. Fortunately now, there are enough posts on the same topic to make that easy.

- 6-12-2013** **250,000 Sales.** Just a few months ago, we were told the hope for a quarter-million sales of Prius in the United States for 2013 didn't look realistic. Boy, have things changed. Recent growing interest has put expectations back on track. That is now looking to be quite doable. There's a new advertisement campaign starting and the confusion caused by Volt is subsiding. To think of how much of a mess GM made of things... That situation is why Toyota held back. It was frustrating. But then again, the delay allowed time for the rewards of having real-world data readily available prior to nationwide rollout. After all, that is exactly what the Volt enthusiasts insisted upon anyway. They were quite adamant we wait a full year first. For Prius PHV, the extra 9 months is a bit annoying... but benefits of not having got snarled in the GM mess should be obvious. Marketing a hybrid as an EV was a big mistake. Even some of the once hostile supporters now acknowledge the damage that choice caused. Seeing the success Ford has been having recently is what made them come around. Admitting Toyota had anything to do with the outcome simply isn't going to happen, ever. Mention of "Prius" still upsets. But with a family of them demonstrating growth and the ability to sustain sales, that makes sense. That measure of success is what true change is all about.
- 6-14-2013** **30 Months.** That duration marks judgment time for the success or failure of a rollout. We watched the mighty Two-Mode evaporate at that point. Every argument and support effort imaginable had been done to keep it relevant. Nothing worked. It was simply too expensive. Cost was by far the biggest shortcoming. Having inventory piled up was confirmation sales weren't able to meet expectations. How can a product not making a profit and heavily dependent on tax-credits possibly become a regular offering? Needless to say, it faded away to become just a page in history books. Volt faced that very same trouble, and more. Beside the problem of cost, it came up short on seating room and depleted efficiency. With an inventory of over 9,000 unsold, we knew something rather drastic would have to happen. It did too. 3 days ago, GM slashed prices of 2013 models by \$4,000 and 2012 models by \$5,000. That was an undeniable sign the hope to reach the mainstream minimum of 5,000 per month isn't going to happen. What was shocking was finding some 2012 models still available. Clearly, there are a few dealers simply aren't interested. Why bother? Seriously. Everyone is abandoning this generation of Volt. Even the die-hard supporters have given up. It certainly has been a shock to see those who had been fiercely disagreeing with defending just last week become silent. GM produced a vehicle they wanted to sell, not what they needed to sell. The evidence is overwhelming now. Purchase priorities cannot be dismissed in favor of trophies. Reality can be cruel, but it's not like warnings weren't abundantly provided.

6-17-2013 **Stopped Production.** We all knew there were serious problems with Volt demand. The large price reduction to deal with the massive build up of inventory overwhelmingly confirmed that. Finding out that GM is no longer sharing production information takes us to an entirely new low. It's amazing things could be so bad. But witnessing the denial of the situation certainly made it clear the issues were not being addressed. It started 3 years ago with the design itself, when the direct-drive ability (HV mode) wasn't revealed until someone inside accidentally mentioned it and there was an immediate refusal to clarify. Then came that absurd publicity event, where a Volt was driven 1,776 miles over the 4th of July weekend. GM absolutely refused to reveal what the MPG was. That didn't make any sense. Why in the world would they withhold information so vital to a high-efficiency vehicle? We didn't find out the answer to that until just before rollout began. The numbers showed a very heavy dependency on plugging in. Without that electricity, Volt was just an ordinary car. That's why the idea of a smaller battery-pack was so intensely fought against, despite the reality of cost being much too high for mainstream consumers. Then came the plug-in Toyota Prius, the plug-in Ford C-Max, the Nissan Leaf, and Tesla Model-S. Heck, maybe even the plug-in Honda Accord had an influence. With the choices growing, each showing more market potential than Volt, the loss of interest became an inevitable reality. It was only a matter of time before the supply issue could no longer be explained. We were told every excuse imaginable. The hype is gone though. There's nothing left to promote it as "*vastly superior*". The end has arrived. This chapter is closed. Will GM be able to rollout a new Volt in a few years that actually addresses middle-market need. Who knows? All we know now is that this was did not.

6-18-2013 **Few Sales.** The failure of Two-Mode to take the market by storm, despite years of hype, was something that Volt enthusiasts staunchly evaded. That just plain did not want to acknowledge their favored efficiency technology could have the same outcome... even though it was clearly following the same path. The similarities were blatant. The biggest match was the complete disregard for cost. Both systems were expensive, doomed to lose money on each sale until the next generation was rolled out. That dependency on lower cost without unambiguous means of how that would be achieved was a dead giveaway the struggle to overcome such a shortcoming would bring intense pressure. But rather than learn from the past, they chose to hope for the best instead. That failed miserably. How could the same approach result in a different outcome? The belief was this market would immediately embrace plug-in vehicles, to the point where consumers wouldn't hesitate... even in the face of a high sticker price. They were wrong, very wrong. Not having a non-plug model of the vehicle made that bad situation worse. Fighting against the idea of second offering with a smaller capacity battery-pack for rapid cost-reduction basically sealed its fate. The lack of enthusiast endorsement for such a simple rescue effort was so ironic, I was beside myself. They chose the high-risk course, rather than support automaker attempts to widen appeal. They claimed they had no influence on GM decision-making, despite overwhelming evidence to the contrary. They demanded patience instead. Don't react to the growing problems. Stay true to the original concept, regardless of the benefit change could bring. As a result, few sales have caused a wide-array of problems... without any suggestion of how to recover.

- 6-18-2013 Looking Back.** Put blatantly, Volt was a disaster. Sure, it worked. But sales fell far short of expectations. Remember the assurances from GM that production capacity was able to deliver up to 120,000 per year. That was assurance to keep people from worrying about fallout from supply not being able to keep up with demand. Instead, quite the opposite happened. Inventory piled up with any interest from mainstream consumers. That hope of being a top-selling vehicle didn't materialize. It was a bad situation that continued to get worse. There was an intense desire to appeal to middle-market without any support to actually make it match priorities. In other words, the expectation was change on a very unrealistic scale. The idea of taking smaller steps, rather than just one large one, didn't have any backing. After all, being able to flaunt awards is much more rewarding than seeing the parking lot at the grocery store filled with their vehicle... so common, it wouldn't stir any praise or even recognition. They wanted the success of Prius but not the standpoint being ubiquitous carries. That conflict of interest prevented progress. There was no agreement upon goals. It was a situation with no next step available. Looking back, that's easy to see now... so much so, few will admit to ever having contributed to the problem. It's difficult to acknowledge you were actually the barrier to success. Of course, it's not like they weren't warned. Those who don't understand history are doomed to repeat it. You cannot overcome without addressing directly. Think that will finally happen?
- 6-18-2013 Silent Schooling.** I got out of work early today and to take advantage by stopping to get a haircut. The barbershop is located in a strip-mall, next to an off-campus classroom for local high school students. When done getting my hair cut, the Prius was surrounded. None of the kids were paying close attention though. They simply stepped aside as they saw me approach. I didn't say anything. I just got in the Prius and silently backed away. Suddenly, one of them looked up with a bewildered look on his face. The lack of engine sound replaced by the pedestrian warning had him captivated to the degree that others stopped and looked too. Since I had the window open, I smiled and yelled out: "*Yes, it's electric!*" They replied back with smiles. That was cool, an educational experience they hadn't anticipated... which was ironic, since the class taught there was driver's education.
- 6-20-2013 Downtown Commute.** I work in St. Paul, the smaller of the Twin Cities. I'm able to sneak in from the south, avoiding most of the metro area traffic. That's really, really nice. I'd despise having to deal with the nightmare conditions countless thousands of others have to face routinely... which pales in comparison to other areas of the country. I couldn't imagine long, frustrating drives like that. Anywho, today my girlfriend had a concert performance clear on the other side. That meant punching straight through the Minneapolis commute during the peak of rush-hour. I decided to delay my departure a little. Turns out, that was a wise move. It took here and extra 30 minutes by leaving earlier. Nonetheless, I had 2.5 miles of crawling through painfully slow, dense traffic. It sure was nice doing that with only electricity. Funny part was, the relief of having cleared the mess, I forgot to turn the engine back on (switch to HV mode). That left me cruising along at 60 mph in smoooooooooth silence. It sure was a happy ending to a nasty experience. The craziness of the constantly changing speeds and all the people coming & going through lanes would be maddening on a regular basis.

- 6-21-2013** **EV Estimate.** That value continues to climb as the temperature climbs. It is now up to 13.3 miles. That hasn't affected actual EV miles of travel though. That seems to have leveled off at 14.6 miles for my morning commute. As for the drive home, I have no idea. The afternoon high finally feels like Summer now. Temperatures in upper 80's to low 90's is becoming routine. It's about time. I've been looking forward to using the kayaks. Anywho, that heat means using the A/C, which consumes electricity. It's important to keep the battery-pack comfortable the same way you'd like to feel. They are cooled by circulating cabin air through the case. So, I use the A/C when cruising out on the open road. It's remarkably efficient too. Even when in HV mode, efficiency on the highway still averages about 55 MPG. When using EV-BOOST mode at high-speeds, the MPG is well over 100. That makes tracking the actual efficiency a challenge... not that detail matters. The point of delivering a significant increase is clearly fulfilled. Long story short, complaints from Winter have overwhelming been confirmed as unnecessary concern. There really wasn't anything wrong. That truly is what's expected to happen with each seasonal cycle.
- 6-21-2013** **Hype.** It's what Volt thrived on. That daily blog depended upon vague & exceptional claims. The essential component of survival depended on people believing in the unbelievable with no way of actually checking information... a situation doomed from the start. The facts simply didn't match the hope. Disregard for need made those bad circumstances even worse. How could so much be achieved in so little time at so little cost with so little actual real-world experience to support it? Enthusiasts truly thought a miracle would be delivered, an answer to their prayers. After all, the engineering itself was sound. But with so little business backing to make the desire feasible, the expectation of high-volume sales made no sense. It was mismatch of want & need to an extreme that would require a true miracle to succeed. Risk was too great. That risk was taken away. It turned into a disaster. What a mess. Now the price of used Volts is dropping. There was a Detroit article today pointing out how quickly value has been lost. Depreciation at a rate much faster than both traditional vehicles and hybrids is not what you want when attempting to build a reputation for a new standard.
- 6-22-2013** **Celebrate?** I've made it overwhelmingly clear that I won't endorse any vehicle offering improved efficiency. Improved emissions has always been the higher priority. That's why I was against diesel from the very beginning. Lack of potential is another. That's why I was against ASSIST hybrid from the very beginning. Both proved to be wise choices too. The FULL hybrid has been cleaner and offers plug augmentation. It's been a winning solution. Anywho, this comment was made today about the plug-in Accord hybrid: "*In my view, any car with fuel economy 2x above the national average should be celebrated.*" Obviously, I couldn't resist interjecting some comment: With a base price over \$40K, we should hold off on the celebrating. A certain other plug-in taught us how critical being affordable is as a priority for the masses. Mainstream acceptance requires a business-sustaining cost. It cannot have a dependency on tax-credits either. The new approach to hybrid design & efficiency obviously shows promise though.

- 6-22-2013** **Thoughtless Responses.** There's nothing like hearing this at the gas station: "*Hey, I didn't think that car took gas.*" It was an experience a Prius owner recently had. Encounters like that are sticky situations. You aren't sure how the person saying it will actually react. More often than not, they'll blow off whatever you have to say. That can be good if the message is still conveyed. All you need to do is just leave them with something to think about, something they hadn't ever considered. Change is slow. You have to start somewhere. I joined in the discussion with: Quotes like that come from those who never bother to take even a moment to consider how Prius actually works. They typically dismiss it as small & weak without any other thought. That's a huge improvement over responses of the past. Back in the early days, over a decade ago, I encountered some people who absolutely freaked out. They honestly believed the government was going to force them to give up their monster-size SUV. It was a genuine fear that resulted in anger and unwilling to listen. Of course, still to this day, detail isn't being addressed. But at least the general message is getting through. That parting comment of "*it takes me 5 gallons to start this Tahoe up*" may have made him laugh, but the upset of his wife was confirmation that the choice to guzzle isn't acceptable as it was in the past.
- 6-22-2013** **Super Hybrid.** I liked reading that description of PHV. It derived from this: "*Avoid much more than 40 mph during this stage, because then fuel consumption will spike for relatively little gain in speed.*" The discussion was about modes & efficiency. I posted: In most cases, that is indeed the case. However, there is the exception of a well-timed switch from EV to HV mode. As already pointed out, the system strives to maximum use of the battery-pack during cold engine warm-up. With the regular Prius, this is difficult to quantify without having a tachometer available. With the plug-in Prius, the behavior is quite pronounced. It's obvious. I've been taking advantage of this, waiting to push that button until just prior to the approach a steep hill climb or highway entrance ramp. That way, the engine speed is restricted to 1500 RPM, rather than exceeding the usual 3000 RPM that type of power demand would require. It's been working well. I can get up to speed without the engine straining (high emissions & consumption) and still have reserve power, just in case. I have dropped the pedal to the floor in those scenarios, to confirm the system will override that green behavior. It does. Calling Prius PHV a "*super hybrid*" seems a very effective way of conveying the design objective. You have a larger battery and a plug, but the intent of the system is still very much one of delivering significant improvement at an affordable price rather than calling it a short-range EV.
- 6-22-2013** **Still Trying.** When you read this, what are your thoughts: "*Volt combined economy of 37, Prius Plug in 50 . ' Very misleading journalism. The PIP is using electricity blended in to achieve this rating. If the Volt blended in the electricity it would be 65 mpg.*" That's greenwashing, twisting information to make it seem like misleading so it will be disregarded. Without plug-supplied electricity (regular HV mode), the plug-in Prius does indeed deliver 50 MPG. With electricity and the engine running (we call that EV-BOOST mode), the MPG is well over 100. As for Volt, where the heck did that 65 come from? The reference is literally the first I've ever seen. Of course, we have absolutely no clue what was actually meant by "*blending*" in this case. That's how greenwashing works. They are excessively vague, hoping you'll make an incorrect assumption. Long story short, certain Volt enthusiasts & owners are still trying.

- 6-23-2013** **Gone.** Even that daily blog on the Volt website isn't about Volt anymore. The discussions, debates, and arguments of the past are gone. This is exactly the way things played out with the demise of Two-Mode. The pattern is so remarkably similar, even that isn't talked about. The design approach didn't reach the masses. It did not reach mainstream sales volume by the end of the second year. What we currently know as Volt has become a vehicle for those interested in unique historical opportunities. There's no doubt the next generation model will be quick different. What GM wanted to sell did not match what consumers needed... for that matter, what GM needed. Thank goodness that is over. Such a misalignment of priorities was a fiasco in the making. The best we could hope for was a graceful conclusion. Let this model fade away into memory. So when the remake is rolled out, it won't have this ghost from the past holding it back. In other words, rather than being "*vastly superior*" as all the hype had endlessly proclaimed, this new model will be a member on the team. The true opponent was traditional vehicles, not other plug-in hybrids. Hopefully, that lesson is learned. Most likely, those enthusiasts of the past will remain silent about failed goals & reputation and will simply focus on what needs to be done instead. After all, letting pride dictate decisions again will only set them down the same path again.
- 6-24-2013** **Struggle.** Without Volt being the headlines from GM anymore, we're seeing more attention on the pickup market. In fact, Chevy is capitalizing on that by launching an advertising campaign. The new Silverado is well timed with the recovering economy and people's general loss of concern toward gas prices. With a towing-capacity of 11,500 pounds and the reality that fact that 43,283 of the older model were sold last month, it seems as though there's a new breed of guzzler about to emerge. Reading through a "first-drive" review of this next generation model, there's nothing but this single sentence mentioning efficiency: "*It is rated at 16 mpg city/23 mpg highway with rear-wheel drive and 16/22 mpg with 4-wheel drive.*" Unlike most reviews, this did not include observed MPG. It makes you wonder who will be purchasing the pickups and how they will actually be used. Will we see these as daily commuters like we did with SUVs? It certainly does present challenges for efficiency improvement, like Honda's effort to rollout a new two-motor hybrid system. Fortunately, we do still see Prius PHV as well positioned for those who are looking for an affordable package upgrade to Prius. But Ford's attempt to do the same thing doesn't have the same advantage of there already being a popular model to compare with. There is the reality of battery uncertainty too, which naysayers will attempt to greenwash about for years still. Keep raising doubt. Tell people there's plenty of oil still. Support the high-profit vehicles. It's a recipe for continued struggle. Makes you wonder what the heck the Volt enthusiasts are thinking about now.

6-24-2013 **Just 4.4 kWh.** The importance of significantly reducing emissions & consumption in a reliable & cost-effective manner was a lesson learned a long time ago. In fact, the first hybrid rolled out in the United States suffered from not meeting those goals. Sure, the Honda Insight delivered great MPG, but the smog-related emissions were no different than traditional vehicles and the all-aluminum body & frame made the cost too high. It was the "*science experiment*" the greenwashing always claimed the Classic Prius to be. That wasn't actually what Toyota had delivered though. Prius was intended to compete directly with traditional vehicles... which is indeed what ended up happening. GM didn't do that. Volt clearly is a niche. In fact, it is still getting recognized that way. Just today, the ranking from the Sierra Club put it at the top. No one is talking about it being part of the mainstream anymore. All hope of that has been postponed, abandoned until the next generation is rolled out. Meanwhile, there's Prius PHV. It actually is a mainstream contender without any modifications. Toyota worked really hard to deliver a plug-in hybrid using a very small battery-pack. They achieved their goal of 20 km using just 4.4 kWh. That means when the cost of lithium-based batteries finally drops to the industry expectation for mass-market, Toyota will already have a well-proven system available. Having real-world data already available from a wide array of owners is a very big deal. There's nothing to change. They keep selling it, but with a lower price. That won't work for Volt. The 16.5 kWh battery-pack is over 4 times more expensive. (Remember, it is liquid-cooled instead of air. That makes it even more expensive.) A cost drop alone won't be enough to make it competitive with traditional vehicles, especially with a hybrid system (HV mode) not delivering MPG any better than one. Enthusiasts didn't want to face that reality. They thought by now, they'd be looking forward to the rollout of the first upgrade. Instead, they are witnessing clearance prices. In other words, they now realize how vital it was for the design to have placed a much higher priority on cost... a mistake they'll end up waiting years to be rectified.

6-25-2013 **Carbon Emissions.** For awhile now, I've been referring to the refusal to acknowledge the obvious growing problem we have related to climate change as the "*flat worlder*" perspective. The rather blatant rise in water-level in our oceans and the increase volume of water being precipitated is a clue something has changed. Evidence of other aspects, like storm frequency & magnitude is much more difficult to nail down. But with respect to the water, we have gathered enough data to see a new pattern emerging. That in itself should be enough to be taking the reduction of carbon emissions seriously. It isn't necessary for dramatic change (yet). But the flat out dismissal that anything at all needs to be done is absurd. Denial to that degree is a terrible thing to do to our children. Imagine how ashamed they'll be when they find out we didn't bother, even though we had the technology. To not try is a horrible waste to lead-by-example as well. How are developing nations, like China & India, going to address climate change if we don't? If we have already implemented & refined solutions, they are far more likely to begin using them too. But to just say the world is flat... Needless to say, I was thrilled when President Obama used the very same reference I've been using. We all know that cleaner electricity is possible; however, the effort to clean emissions from coal consumption to generate electricity has been faced with intense resistance. That's been part of the problem with EV acceptance. Dirty electricity has a very negative impact on promoting them as green. The same problem is being to get attention with respect to plug-in hybrids now too. It's a situation we must finally deal with. The cost of reducing carbon emissions is far less than the massive expense our children will face decades from now if we don't.

- 6-26-2013** **0.7 Miles.** To my intrigue, I saw something quite unexpected today. When the SOC (State Of Charge) level indicated 27 percent, the EV estimate distance displayed 0.7 miles. That seems perfectly normal, quite expected in fact. However, that only happens when driving in EV mode prior to depletion. What happens when driving in HV mode following depletion? Living in Minnesota and not having taken the PHV to any of the extreme altitude changes from our remote river-valley canyons, I didn't know the answer. My guess is after a few miles of decent, the regen would reflect a build of EV miles. What happens in minor situations? In my case today, the engine had started up just prior to a climb up my tiny valley. Though small by most people's standards, the climbing to the summit is pretty nasty on a bike. Sunsets from up there are spectacular though. Anywho, the act of warming up a cold engine, even on a climb, results in the generation of electricity. That meant I reached the top of the hill with 8 bars for HV mode. Rolling back down from there to my house, what would happen? Turns out, nothing. Even though the SOC said 27 percent, no EV mile value was displayed. The system is programmed to just present that as "*full*". Getting to confirm that today was nice. It keeps the interface simple... and will raise the curiosity of owners new to the exploration phase of ownership. Educational stimulation like that built into the design is sweet. There's just enough to compel the curious to dig deeper to learn more about what's actually happening. Gotta like that.
- 6-27-2013** **E15 Fear.** Were seeing more of it. Minnesota made the switch to E15 years earlier than everyone else, so it was quite educational to read about the fears people from other states would post. We already had evidence there wasn't anything to be concerned about. Supposed horrors stories coming from the E10 rollout nationwide never actually materialized. It turned out to be just fine. Seeing a label or warning about E15 is a simple case of liability. If they tell you not to, there won't be any argument about later about warranty coverage... which has uncertainties even there's no ethanol involved. Think of the contaminants that come from air & oil already. For that matter, what about those additives coming from gas-station brands? Why accept greater exposure when you don't have to? What evidence is there that going from E10 to E15 represents a tipping point? For that matter, what would actually happen? There isn't anything backing up the claims. Reality is, ethanol can be derived from waste. Economies of scale will allow us to transition from the current crop sources the majority still use. Some people are fighting that change without evidence to support it. The effort is to spread fear to impede the progress. That's really disappointing.

- 6-27-2013** **Compares.** Responses to the automotive enthusiasts magazine reviews are annoying. I thought that nonsense of the past was just an unpleasant distant memory... apparently, not. It looks like we are seeing this history repeat again. Ugh. Though, it is actually a good sign. Seeing that they cannot avoid including Prius in compares means their obsession with speed & power is again being threatened. Normally, they wouldn't be caught dead even mentioning a middle-market offering. Vehicles intended for the mainstream are not what their audience ever cared about. They were the voice of niche. Being uncommon was what they thrived (and profited) on. Prius most definitely does not fit that mold. Yet, it's getting attention anyway. They feel threatened by change and left out by not including to. Doing that increases circulation of their publication as well. So, that's what we are seeing... again. This was my response to the content itself: The short-sighted compares are troubling. When has the one-size-fits-all approach ever worked? Connect a battery with the capacity of Volt to a vehicle using the larger HSD configuration. What happens? Reduce the capacity of Volt's battery to make it affordable for the masses. What happens? What about the overall emissions? What about the reality that Volt is smaller inside than Prius? There are so many problems with comparison, it difficult not to address the reality of cherry-picking. What will replace traditional vehicles? Isn't the point to become mainstream, not to win trophies?
- 6-27-2013** **Next?** It's really difficult to see what will happen next. The end of May, unsold new Volt inventory available was about 9,100. As of this moment, it's shown to be 8,245. Based on those numbers, it looks like even just matching May's sales of 1,600 will be a problem. Despite the \$4,000 price-drop, sales didn't increase. In fact, they did the opposite. GM's decision to build what they wanted to sell rather than what was needed is clearly backfiring. Sure, the system itself is winning awards, but what the heck is the point of that? GM consumers are still buying their traditional vehicles instead. Mission not accomplished. GM has a long-running "*over promise, under deliver*" reputation. How do they avoid falling into that same trap again? With so much pressure to overcome the shortcomings of this generation, telling people they will and false hope leading to unsupported hype like it did last time is very easy. Being realistic about expectations doesn't attract headlines. Dealing with lots of unsold inventory makes a bad situation even worse. What's going to happen?
- 6-28-2013** **Dead Giveaway.** Some don't take defeat well. They attempt to alter goals & definitions to make it look like they are still doing ok. We see that as desperate. I made that quite clear when the question of "*mainstream*" was asked yet again: For over a decade, the measure of "*mainstream*" has been a minimum of 60,000 per year (5,000 per month). That is how the Iconic Prius was gauged. It met that volume criteria and enraged those who attempted to label it as a "*stop gap*" solution. In fact, that is the very reason why GM set the Volt goal of 60,000 for second year sales and stated production capacity of 120,000 would be available for the third year. Knowing that large automakers, like Toyota, Ford, and GM, each sell a number of models of traditional vehicles easily exceeding 5,000 per month, it only makes sense to measure hybrids the same way. After all, the point is to replace those traditional vehicles with hybrids. The fact that this information conveniently gets forgotten and re-asked on a very regular basis is a dead giveaway there's an effort at play by some to undermine. We are being overwhelmingly clear & concise: *5,000 per month*.

- 6-29-2013 Audience, dying.** That question of "*mainstream*" stimulated constructive discussion. That certainly was a welcome change. But then again, the staunch antagonist that had been harassing (more than just trolling, personal attacks) those on the big Prius forum has vanished. The assumption is that he was banned. Whatever the reason, not being there anymore makes civil exchanges of thought & observations much easier. The first example was this question: "*Is the prius slowly dying?*" It came about from seeing some well known Prius owners trying out Volt and Tesla. Being well aware of how a mature technology is often labeled as "*obsolete*" by competitor enthusiasts, I responded with this: Knowing your audience is vital. Seeing some enthusiasts or supporters switch to something with larger battery & motor doesn't represent anything with respect to ordinary consumers. That's why there are different grades of vehicle. It's also why claims of "*shortcomings*" don't actually make any difference. If you're simply looking for an improvement over the regular Prius, the PHV undeniably delivers. It's not attempting to be an EV, which is why direct comparisons to a plug-in like Volt don't make any sense... they clearly aren't intended to appeal to the same audience. BTW, what speed is the traditional vehicle dying?
- 6-29-2013 Audience, cues.** This was posted as a follow-up to the discussion on that thread: "*All this means is that Toyota will have to take cues from their competitors and decide which way they want to market their vehicles.*" I was happy to add: Hence the delay of the nationwide rollout. Volt made it quite clear that high-capacity plug-in hybrids won't be accepted by the masses anytime soon... low sales, even with tax-credit and price-slash incentives. There's obviously a market for them, but that category is a niche for enthusiasts rather than a solution for the mainstream. It's a long-term effort that leave a massive product-gap in the meantime. Toyota is well positioned to fill in that gap. Prius PHV is an augmentation of the existing platform. The under-utilized 60 kW traction motor gladly gobbles up the extra electricity the bigger battery provides. It's not a paradigm shift either. Consumers easily understand the capacity increase and plug pushes MPG quite a bit. They'll enjoy the EV mode as they do now with Stealth mode... because it's a Plug-In Hybrid. Much of the current struggle Volt is dealing with was self-inflicted. That sounds like a harsh assessment, until you realize that also means there is an opportunity for self-correction. GM will take cues from its own mistakes to reach the audience it couldn't on this current attempt. The catch is, they must be clear about who the vehicle is intended. The cue to us from supporters was the "*Who is the market for Volt?*" question continuously being evaded. That unwillingness to answer was a dead giveaway audience expectations were not being met.

- 6-29-2013** **Ranting.** It's starting to get bad, not the slightest bit constructive and without any merit. It's hard to tell what the intent actually is. But I thought I'd humor this particular rant that included "*isn't worth the money*" and "*if PPI was that great, why didn't Toyota*". You never really know what the person's motive is until attempting a discussion, so I tried with: That's called anecdotal reasoning. Step back and look at the big picture. There is currently no way to justify any plug-in vehicle. For that matter, even the "*worth*" of a hybrid continues to be challenged. Sadly, part of that comes from giving no value to the reduction of emissions and non-renewable resources in those "*worth*" analysis calculations. Fortunately, purchase priorities are changing for some. Toyota took the balance of battery & cargo sizes was taken quite seriously. As with the cost of gas, battery cost will swing in favor of that configuration. Without any incentives, the approach will be profitable and reach the masses. That's a very, very important aspect typically dismissed by those only looking at the immediate present. The current effort is to establish the existing rollout markets and to better spread the word about real-world experiences. Introducing more new owners at dealers who are also new would be counter-productive. Expansion prior to finishing up with the first batch of owners would spread resources too thin, especially when dealing with an ever-changing mindset about plugging in from the political arena.
- 6-30-2013** **Bike Rack.** 106 miles yesterday, my first long trip. 2 bikes on back were on back. Since I have the plug-in and there was 5 miles of EV available, my resulting 51 MPG doesn't directly apply to the regular model. But I can comment on how well the rack itself performed. It's definitely the way to go for convenience. Being able to easily load and lock the bikes while still having the option of opening the hatch is great. The rack connected to the Prius via only the hitch mount works well. It's secure, doesn't impair visibility much, and won't ever make contact with the car itself. It stashes away inside the hatch well too, an unexpected benefit I can take advantage of. It is expensive though, nearly triple the cost of a strap-on rack. But I consider it worthwhile if used often over the course of many years. Long story short, I pleased with the choice.
- 6-30-2013** **0.8 Miles.** I finally got an opportunity for some serious regeneration observation. My girlfriend and I went out on a biking trip. There was a plunge into the river valley. It was spread across about 3 miles and dropped a few hundred feet. Starting in HV mode with nothing left in the battery for EV, the decent began. When it got to that 0.7 miles of mystery I encountered the other day, my attention was peaked. Sure enough, that next tenth-of-a-mile increment did the trick. The indicator on the display switched over from showing a full HV battery (8 individual bars) to a solid presentation stating 0.8 miles of EV. That was cool. I still wasn't at the bottom yet either. It ended up recharging the pack to 1.4 miles. The remainder of the drive to the parking area for that long, beautiful trail out in the country along the river, shrouded by large trees, was all in EV as a result. The drive back out later was too. That sure was nice. For those who actually live in areas with rolling hills or mountains can actually do what has been coined as "*stacking*". Where rather than using up that EV right away, they save it and continue regenerating. The miles keep going up. That's something I'll never see around here, but I could simulate the same by saving the regen that comes from braking. On a road trip, that could come in handy. Around here though, I'll just plug in.

- 7-01-2013** **Change.** We went from being "*vastly superior*" to direct comparisons of plug-in hybrid with more seating & cargo room, greater efficiency following depletion, nearly a quarter the battery-capacity, a third the tax-credit, and only available in a third the states. It wasn't too long ago that a few outspoken Volt enthusiasts had described it as "*pathetic*". Things have undeniably changed. Reality of business need has become difficult to avoid. The mighty have fallen. We all know middle-market consumers don't have purchase priorities that match what Volt has delivered but do match Prius PHV. That's an ugly fact that caused some to insist we now wait for the next generation and hope for the best with nothing but vague claims that cost will drop substantially and configuration will not be compromised. How is such feat possible, especially without the competition also achieving similar results? It doesn't add up. It's time to get serious. The rhetoric isn't getting any traction anymore. Inventory piling up without a plan "B" available is putting a lot of pressure on Volt. There isn't a smaller capacity or a non-plug model to offset. It's a one-size-fits-all gamble that hasn't been paying off. Enthusiasts can argue that point all they want, but it falls on deaf ears... since that only confirms what we had been saying even before rollout began. GM must offer something for the masses that's profitable and doesn't depend on tax-credits. It's essential those requirements are met. Good luck with that next generation.
- 7-01-2013** **Lithium-Sulfur.** That was this month's distraction from upcoming sales numbers. The release of those counts always causes a stir. So, focusing on something else has become the routine. There was actually a really well done write-up this time too. It was an article detailing the potential of battery technology currently being researched. Lithium-Sulfur was the type showing the best opportunity. With roughly 4 times the capacity of the current Lithium-Ion, that would indeed be good news. Something like that is many, many years away still. We won't see automotive-grade availability until long after the rollout on small recharging portable devices first. They pave the way, since cost & longevity is so much less of an issue for them. Like everything else, there's waiting involved. The topic itself is more of a curiosity than anything. But it is compelling enough to be a worthwhile distraction... which is what was wanted today.
- 7-01-2013** **The Wait, tomorrow.** Sales results get posted tomorrow. The mark the end of senseless battling. With the "*game changer*" hope clearly not being fulfilled, it's over. The electric-only plug-in, Nissan Leaf, has kept in pace with the plug-in hybrid Chevy Volt. We expect that to go unchanged, despite the heavy discounting. The market isn't ready. Hybrids should do well, which is why Prius stands out. Adding the option of a larger pack with a plug doesn't change the equation much. The formula for success (penetration into the mainstream) doesn't require any major rework. Volt enthusiasts don't believe that though. They're still hoping for a miracle... soon. With the production of the 2014 model starting in just 2 weeks, the inventory listed online of over 8,000 still is a very real problem. Needless to say, using scapegoats to keep discussions from drawing any conclusions is the key for them. I simply responded to their undermining efforts with: Regardless of what I post, it just ends up being twisted. The pattern is easy to see. I'm done playing the game. It's overwhelming clear that Volt does not match consumer needs. No effort to divert attention will change that.

- 7-02-2013 The Wait, competition.** Shortly after the numbers were revealed, it was clear there would be major problems. Online arguments would get intense if we allow them to get off-topic. After over 2.5 years, it is clear that waiting is the only option for Volt. That means allowing the plug-in Prius to catch up in the meantime. And since its audience is middle-market, rather than being for niche buyers, that's a very real problem. Awaiting a sleeping giant isn't what the enthusiasts had in mind. It's their own fault. They always considered Prius PHV the competition. Now they fear when it wakes. I responded with: Traditional cars have always been the competition, not other automaker hybrids or plug-ins. Cruze, Malibu, and Impala continue to dominate. That's the reality of the situation.
- 7-02-2013 The Wait, wake up.** Needless to say, they were angered. I simply added: So as long as sales of Volt are better than Prius PHV, all is well? Wow! Some have definitely lost touch with reality. Here's a wake-up call, other GM sales for June: 32,871 Cruze; 23,645 Equinox; 21,288 Malibu; 17,255 Impala; 43,259 Silverado. Attempts to divert attention away from the cold hard fact that those profitable traditional vehicles are absolutely crushing Volt won't change anything. They are just excuses to feel better about a really bad situation. GM doesn't have an alternative available. Want to compare to Toyota? How about acknowledging that they could easily follow Ford's approach of sacrificing cargo room for more battery, which would increase both range & power. Then there's the fact that Toyota already offers an HSD system which pairs a larger motor with a larger engine. There is also the reality that the system is extremely efficient even without plugging in, as well as profitable. Take all that and offer it in a body built as an alternative configuration. What will GM do?
- 7-02-2013 The Wait, hotcakes.** Ignoring the spin coming from Volt support, I shifted to the problems by one particular new Prius owner. He was lied to by a salesperson. Being misled about a purchase hurts. All that incorrect information steered him away from the plug-in model. His lack of willingness to acknowledge how far off some numbers we resulted in a series of posts with generalizations and emotional outburst... not exactly what we call constructive. But considering his thread was titled "*Plug-in Prius is a rip off*" there clearly has been some improvement. Fortunately, the moderators quickly took down his thread, seeing how it lacked any effort to address facts. Rants aren't welcome. Questions are though. He finally came around and posted: "*There has to be a reason why they are not selling like hotcakes.*" That's far more appropriate. We can be receptive to that. Still, there is worry that the message will get through. Dealing with buyer's remorse can be a problem as well. But at least there is now an attempt to exchange information. I provided: There has been a major greenwashing effort to convince people that the plug-in Prius is an EV with just a 6-mile range and the battery is useless at speeds faster than 62 mph. Seeing that and confirming consumers were misunderstanding how plug-in hybrids operates, Toyota decided to slow down the rollout. Focus on initial markets has become the priority now. Real-World data has always triumphed over efforts to mislead.

- 7-02-2013** **The Wait, more is better.** No more waiting. It's over. I was actually surprised how quickly the Volt enthusiasts backed down. Their antagonistic efforts on the big Prius forum seem to have been abandoned. Not getting what they had hoped for allowed the constructive discussion to begin. I liked reading this: "*Unfortunately, the original question about what would cause the PiP sales to improve is still elusive.*" True, we did provide information about that many, many times already. But finding it amongst the rhetoric is tough. So, I was happy to restate it again. Of course, that too involves waiting: Time is needed more than anything. The first-year jitters combined with simply not being available are barriers that will overcome themselves. No redesign is needed. Prius PHV is already configured to match middle-market purchase priorities. We knew the misconceptions related to batteries would be a challenge to deal with. Fallout from the first attempts was the uncertainty, hence the delay faced now. Fortunately, just the act of taking that next step of national rollout will stimulate sales even in the markets already established. Selling a car that will basically be thought of as an appliance will never make an enthusiast happy. Acceptance of vehicles they consider dull & boring to achieve business-sustaining sales isn't taken seriously. Arguing with them is a futile endeavor. The only thing it actually accomplishes is to provide confirmation that priorities were correct. As the dust settles, those who didn't understand what was needed will grow silent. Dealing with that more-is-better nonsense is a pain, but it's nothing new. We've been through it many times in the past.
- 7-03-2013** **The Wait, rehashing.** Today's discussion was pointless. It was just the same old questions being asked again... the ones already answered in that very thread. They literally don't have anything worthwhile to say anymore. The antagonists are aren't stirring attention and those who want to help aren't accomplishing anything. It has all come down to the need for real-world data from ordinary consumers. That means Volt faces quite a challenge. Many of those owners take great pride in the fact that they are not common. They have a special vehicle that they have consistency promoted as "*well worth it*" for quite some time now. That contradicts the goal of being affordable. It's a self-defeating effort which has finally been take in. At least the wait for that is over. As for the rehashing of content we have covered countless times already, we're not going to bother. It's pretty clear the time would be better spent on things like educating new owners instead. They share experiences and request feedback. It's fun to fill in the blanks for them too. They gobble up information from owners who have had their Prius longer, especially when it comes to the plug-in model. Needless to say, that's what I'd rather focus on anyway.

- 7-03-2013** **3 million.** That was the big number published today. It's how many Prius have been purchased worldwide. I find the number and the timing thought provoking. Exactly 3 years ago, we were suffering from the extreme smug. Remember that "*Freedom Drive*" publicity stunt for Volt? The hope that stirred was truly remarkable... but was filled with red flags. We got little warnings during that event that things weren't quite right... but were assured that 3 years from now, the "*vastly superior*" vehicle would triumph. Turns out, the opposite happened. Prius is holding strong and Volt is just barely hanging on. It never ceases to amaze me how evading priorities ends up costing supporters dearly in the end. Sure enough, we watched that very thing unfold. They didn't want to address what achieving middle-market acceptance would take. They were excited about a niche, hoping it would somehow become a mainstream vehicle without having to change to meet the priorities of those consumers. Prius was designed with "*middle*" audience in mind. The 3 million sales confirm that goal of matching their needs was fulfilled.
- 7-05-2013** **Disappointment.** How do you respond to this: "*My disappointment with Toyota is they dragged their heels and let the other guys jump out ahead.*" The expectation was that Toyota would have rolled out a plug-in hybrid that took the market by storm and followed up with an equally impressive electric-only vehicle. To this particular individual, cost didn't matter. He figures a worthwhile product will justify its price tag. I strongly disagree with that, obviously. But he doesn't see the importance of directly targeting middle-market. That doesn't leave to debate with. His perspective & goals are simply too different. That meant reflecting back upon the tried & true instead. So, I posted: How do you know? PHV is a mid-cycle release. It didn't make sense to go all out, especially knowing there's lots of great feedback to leverage from by limiting the release. After all, that approach worked extremely well with the Classic model. The next generation isn't too far off when you consider when design finalization must be completed.
- 7-07-2013** **Reviews.** They certainly stir a lot of attention. The addition of a plug to Prius is most definitely doing that... especially since there is no standard whatsoever on how the electricity usage is actually reported. They write whatever the heck they want, without any detail, and just label it as an "*observation*". That's extremely misleading. But then when you consider the lack of any standards when it comes to comparing MPG anyway, the situation is understandable. Basically, the automotive reporters are still geared toward appealing to emotion rather than focusing on being practical & affordable. This is the quote that got a number of us riled up: "*But in normal hybrid mode, fuel economy dropped to 43 mpg, one less than the regular Prius.*" Needless to say, we didn't know how that conclusion was being drawn. My response was: I just got back from a 425-mile vacation, without ever plugging in. 270 of those miles were with 2 bikes on back, 2 people inside, and a bunch of cargo. The A/C was on the entire time. The other 155 miles were driving around, sight-seeing and stuff. The A/C was on the entire time. 8.87 gallons were used. 47.9 MPG was the end result. Even that extreme example delivered better fuel economy. It's frustrating to read such reviews that mislead & confuse. They clearly don't have an informative method of comparison established yet.

- 7-07-2013** **Blocked Vent?** The temperature was in the 90's. The Prius had been baking in the sun while we enjoyed a long lunch. We jumped in, I fired up the A/C, then we headed out. About a minute later, the dashboard lit up with warnings. Hmm. Was it that misleading door-ajar message? I had only encountered that one time ever. It was so easily rectified, I wasn't able to confirm either. I pulled over, asked everyone to open & close their door, then restarted the Prius. That would have been a nice observational opportunity. But unfortunately, I noticed the back passenger had also shifted position at the same time. I asked if she had been leaning up against the door. Her response was "*Maybe.*" I asked if she was aware that the vent could have been blocked. Her response was "*Want vent?*" Needless to say, the restart had already shown all was well at that point. So, there wasn't anything else left to observe. My guess is the battery-pack had sensed it wasn't able to breathe and sounded off a warning concerned that it wouldn't be able to cool itself later as I drove. The lesson learned was to raise awareness of the vent adjacent to the back seat. Mention of it in the past obviously wasn't enough.
- 7-08-2013** **Silence.** *"It's interesting how tight-lipped GM has been on the 2014. Either there is nothing to report, or they don't want to show their cards. Production starts next week, you think we'd hear something."* That quote posted by a die-hard enthusiast of Volt on that daily blog sure caught the attention of some people. June sales were strong, due in large part to the price-reduction, but that provides no indication of what to expect for July. It could have easily been a surge, the opportunity some sitting on the fence had long awaited for. After all, we know some PHV owners did the same thing. We know also though that the effect is temporary. We know that won't result in a large quantity either. GM won't be able to unload roughly 8,000 Volt still in inventory soon enough. Call me anti-GM or anti-Volt for pointing out the facts, but don't disregard that in the process. Toyota has the flexibility of just producing regular models instead. The ability to switch battery-packs offers a big inventory protection (profit retention) approach GM simply doesn't have with a plug-in only Volt. Prius doesn't have a one-size-fits-all risk like that... which is why we hear anything but silence from it. This is an important time in history. We truly don't know what will happen next... other than the inevitable spin that will follow from those who will claim the choice was an obvious one. What will it be? The silence makes us wonder. The outcome of what happens in the near future is very important.
- 7-08-2013** **Avalon Hybrid.** I saw my first today. It was quite unexpected too. I was just walking along the street and noticed that the car I approached was a new large Toyota sedan. I looked close at the interior space and dashboard arrangement. It wasn't until I backed up to look at the entire side of the vehicle that I noticed the hybrid emblem. Cool. I like seeing the HSD system implemented on a larger vehicle so covertly. It provides Toyota with lots of real-world production & support experience well ahead of the anticipated demand. They can refine the system in the meantime, improving efficiency and reducing cost with little to no attention. That's preparing for the future. Just think what that larger system could offer when the price of battery capacity finally drops significantly. Having something already well proven waiting for the upgrade is a good plan. It helps out a lot with product-diversity too.

7-09-2013 **Perspective.** There certainly is a wide variety now. Much of it stems from goals. When they differ, typically you'll find that the person isn't seeing needs the same way. The influence of urgency never matches either. For example: *"I just see Toyota's handling of the iQ has evidence that they aren't taking a plug-in market seriously."* That little electric-only vehicle is a niche offering, not intended for the mainstream. True, the audience is middle-market, but plan isn't for it to become a business-sustaining product. Not all vehicles must be profitable and sold in high-volume. Volt gets a lot of fallout because it was intended to be just that, but came up well short. That isn't the purpose of iQ. It is the purpose of Prius though. This first implementation of PHV will not only establish expectations, it will also pave the way for easy rollout of the next generation, while at the same time deliver sales well in excess of iQ. Needless to say, I did respond, but there really wasn't a whole lot to say: Compared to what other traditional automaker? Nissan is basically alone. None of the others have made any dent in the market. We also know that attacking middle-market head on rather than approaching via a niche pretty much always gets the same assessment. So, it's somewhat of a red herring until the cost drops enough to make either viable for high-volume.

7-10-2013 **True Colors.** It didn't take long for the owner who was supposedly making an effort to be constructive to finally show his true colors: *"I have nothing against the PPI or the technology. Pay for your own car, losers."* Calling out in an insulting way like that and claiming we were stealing enraged those who had been patiently trying to discuss issues with him. I posted: We've been through virtually every angle, to no avail. It started off with a thread claiming the plug-in model was a *"rip off"* and got worse from there. When you express no interest or value in our reduction of emissions & oil-dependency, that's one thing. But then when it turns to flag-waving & insults, that's quite different. We all see how much employment Toyota vehicles generate in the United States just with the traditional & hybrid vehicles. Add to that the opportunities the plug introduces, it simply makes no sense for such terrible attitude... especially when there was a very clear effort to make the design match purchase priorities of the masses. At least there is this thread now to voice opinion, rather than deal with off-topic interjections within other discussions. The big question though is: Why? My guess is not having any background information about how the market actually works. After all, many enthusiasts don't. That experience with a dishonest salesperson made the situation certainly didn't help, but lashing out at us doesn't either. To specifically address the *"loser"* comment, haven't you noticed that no matter how much some of us have an issue with other automaker offerings, we always make a sincere effort to treat owners nicely without stooping down to name calling? Use ignore if you don't agree. Post information showing your stance actually does address the needs of both business & country. Provide suggestions for improvement. Just don't resort to vague generalizations, disregard for the big picture, or remarks that clearly aren't constructive.

- 7-10-2013** **Scapegoat.** The follow-up to the "losers" insult was: *"So basically, you guys are getting someone else to pay for your expense to make this feature look like it's a good buy."* The logic of considering the true cost of gas and the penalties of the resulting pollution fell on deaf ears. He just plain did not care. He got misled by a salesperson, missed out on the discount opportunities, and now wanted to take out his frustration on us. He needed a scapegoat to feel better. We weren't happy about his short-sightedness. But making it personal took the "rip off" argument to a whole new level. I tried to remain constructive though: The point of the tax-credit is to help rapidly establish the market. If used well, by the time it expires, that cost differential will have been eliminated. In other words, the \$2,500 some of us get will be matched by a \$2,500 drop in cost. The so-basically fails to acknowledge that purpose... which is realistic for Prius PHV to fulfill. Enough, or should we also point out oil is still heavily subsidized?
- 7-10-2013** **Decontented Volt.** Those few still left on what remains of that daily blog for Volt aren't happy when someone else echoes the same message I've been conveying for years... The current configuration of Volt isn't enough; another model must be offered. Of course, whenever I expressed that, they'd spin it to mean GM should abandon the current model entirely. Even though that most definitely not what I have said, that is what they hear. After all, posts are always assumed to somehow be related to Prius, despite that never have been mentioned. They don't want Volt to become common, since then it won't stand out anymore. That loss of being special undermines all that they've worked so hard to endorse. It's a losing battle. Becoming mainstream requires uniqueness to be forfeited. That's too great of a penalty in their mind. So whenever an affordable model is mentioned, they get very defensive. I finally chimed into the discussion with: This group has been dead set against GM offering a second model of Volt for years. They know something affordable & profitable for the masses to purchase is a necessity, but they'd rather gamble on the next generation than address product diversity. Of course, the current inventory situation and the topic at hand (upcoming 2014 models) will force change anyway. So, it's a basically a moot point at this stage. The time for being proactive has already expired.
- 7-11-2013** **Fundamentals.** How many times can the same comments be brought up? The purpose of antagonist is to undermine, to prevent conclusions from being drawn. So, any kind of doubt that can be raised or point that is no longer in context will be exploited for that purpose. It would be quite maddening if you were willing to play that game. I do only for milking out information that otherwise wouldn't be surrendered. They get desperate sometimes, unwittingly revealing a weakness for the sake of winning an argument. Sacrificing the war for a battle never makes sense. But then again, their intent isn't sensible anyway. My choice was to post: Still trying to buy time and completely disregarding all the other excuses, we are finally down to the fundamentals. Prius was configured to achieve profit without change, and it did. Volt most definitely was not, and will not. Quite a bit of reconfiguring is needed still. That's a fundamental difference you cannot just overlook or dismiss.

- 7-12-2013** **EV Confusion.** Sometimes, a bit of exposition is helpful: Prius PHV is a plug-in hybrid. That means the engine shut off when it isn't needed. While in EV mode, you are telling the system to draw as much electricity from the battery-pack as possible. While in HV mode, you are telling the system to draw less. Switching modes changes tolerances, it doesn't prevent. As some have pointed out, even while in HV mode, estimated EV range will slowly drop. The system is seeking out efficiency opportunities and taken advantage of them when they are found. That's what is supposed to happen. This is why there is still an "EV" symbol even while in HV mode. When it illuminates, that informs you some capacity which would otherwise be used for EV is being consumed. Technically, that actually is EV mode, since the engine isn't running. To avoid confusion, as it is a feature of HV mode available in both the plug-in and regular models of Prius, those of us wanting to keep things straight call that STEALTH mode.
- 7-12-2013** **Direct Confrontation.** A new discussion thread was created to deal with the problems we've been having with the "*rip off*" poster. His attacks on PHV quickly turned to lashing out at individuals. We wanted to know more, but not at the expense of other threads. So, a new one was created exclusively to address the issue. I joined in with: This thread has turned out to be quite informative. I was scratching my head wondering what in the world motive could be. The ardent nature of messages didn't match the words actually being posted. Facts were being dismissed and ignored. It didn't make sense. Why lash out at owners rather than just the technology itself? We ended up finding out there is a strong resentment for those having received credits & rebates for their purchase. Since he didn't have that opportunity, the reaction is understandable. It's not reasonable. There's simply no place for insults like that. But having those feeling is though. Paying more for less happens sometimes. It's frustrating. Being a victim of misleading makes the situation even worse. There isn't much we can do to make things better. Life isn't fair. That sucks. You have to focus on positives. Make the best of the situation. After all, having a regular model Prius is still quite nice. Resale value stays high. MPG is well above traditional vehicles and all the other hybrids without is plug. You are still contributing to reduced emissions & consumption.

7-12-2013 **Stuff happens.** It's hard to believe some posts come to this: "*But you are not entitled to make up your own 'facts'.*" It's not surprising though. Some people make up their mind and you are stuck with them unwilling to even consider anything else. A number of us have had it. He has declared PHV a failure and that's that. I sounded off with: Rather than just provide information, we get conclusions drawn for us and they presented as "*facts*". Toyota hasn't even expanded rollout beyond the initial markets. Yet, we are told the game is over already. The outright dismissal of purchase priorities, like helping contribute to a better world by supporting the effort to reduce emissions & consumption, there's nothing but arguing about financial return. That type of absolute isn't constructive. Add to that the childish name-calling and complete disregard for consumer understanding, it's basically a futile effort to attempt reason. This isn't anything new to Prius. We've been through it many times in the past. What makes it different now is the scale. Offering a plug-in model changes perception of the regular model. That's great for the ordinary consumer driving a traditional vehicle still, but it puts those who considered the purchase the plug-in and ended up getting the regular instead in a difficult position... especially if their decision was heavily based on financial points and they now see their original calculations in error and substantial rebates reducing price. Long story short, the resulting spin is a manifestation of buyer's remorse we simply cannot do anything about other than allow him to vent his frustration. Those "*facts*" will be drowned out by the real-world data contradicting them. So, there really isn't much to be concerned about.

7-12-2013 **Excluding Business.** Sometimes it is rather pleasant to just deal with PHV outlashing. The rhetoric with Volt is really getting old. Some just plain don't care about the business aspect, so they exclude it entirely. It boggles the mind that anyone could intentionally be so short-sighted. But here it is: "*We (not you) are talking about the technology and engineering here. This is what has leapfrogged the competition.*" It's that same definition of success they've evaded all along. You ask for goals, they respond with praise for the design. I've had it with this too. So, I posted: That trophy-mentality is what pushed Volt in the wrong direction, encouraging GM to deliver a car enthusiasts will praise. The consequence is a vehicle not drawing interest from the mainstream, piling up as unsold inventory on dealer's lots. Had that "*we*" embraced the idea of GM diversification by offering a second model of Volt, one much less expensive and configured to match purchase-priorities of the masses, the situation currently being faced wouldn't be so dire. Focus on technology and engineering only has consequences. That blatant dismissal of business need is now proving to be a poor choice. In the meantime, the competition is striving to deliver what GM did not. The leapfrog opportunity was missed. We could see GM join in with the next generation offering. But there won't be a trophy for that. They'll be a partner in the effort to phase out production of traditional vehicles. To those who that upsets, just do a search of 2013 models still available for purchase. The majority of consumers, middle-market, simply aren't interested. Their needs & budget are quite different from the "*we*" here. Those of us here referred to as "*you*" will continue to remind about the realities of a business needing profit and what happens when the tax-credits expire. As for the frog, notice how hot the water is getting?

7-13-2013 *"too little, too late"* I couldn't let that particular summary slip by. Those defending GM on the big Prius forum are basically just providing damage-control at this point; there's nothing to actually hope for anymore. It's counter-productive not drawing conclusions at this point anyway. But pride is a big barrier to overcome and anything we say to that effect ends up making us sound smug. So, I tried to convey the situation with: *"too little, too slowly"* was the concern expressed by the auto-taskforce when the bankruptcy recovery was being planned and throughout the years that followed. We were assured there was nothing to worry about. Now all we get is a stream of excuses without any plan. Neither Two-Mode nor BAS/eAssist were able to reach beyond initial rollout. What makes this effort with Volt different? We see small cars and diesel as the current push from GM. How does a hybrid offering fit into the mix now? The clock is ticking. When the \$7,500 tax-credit expires, that difference must be made up for by GM... since even with it, the main complaint is price is still too high and no profit is being made. Many people, especially some participating on this thread, forget that traditional vehicles are the true competition. GM is competing with itself.

7-13-2013 **Absolutes.** You gotta like this: *"If the car is not capable of electric only max power then there is NO all electric range. The EPA, CARB, etc, should see it this way. They should only provide blended MPG and gas only MPG numbers."* That effort to support purity is still going nowhere. Being horribly vague, it won't. But that's what those pushing generalizations do. They want you to think in terms of absolutes. The hybrid approach of taking advantage of whatever the situation presents messes up that effort. Nonetheless, I had to respond with something: Finally, something constructive to discuss. Thank you! With everyone else -1 voting to make comments disappear rather than actually address them, that is a welcome change. Unfortunately, the term *"max power"* doesn't actually mean anything. For that matter, there is no *"max speed"* either. It's all quite vague and differs amongst audience. No standard has ever emerged. The measure of maximum doesn't reflect upon real-world results anyway. As for your suggestion, the *"blended"* would need to be divided into 2 separate categories... before & after depletion. The latter is what we currently have available from the EPA. They don't provide anything direct with respect to MPG while plug-supplied electricity is being used. That's because you wouldn't be taking into account all fuel consumption, only what the engine is doing... hence the MPGe value. While blending with plug-supplied electricity, I see efficiency averaging well over 100 MPG. What does that number tell the consumer wanting to know more about how the system works?

- 7-13-2013** **Blended & Purity.** There are a handful of bitter & resentful Volt enthusiasts still. Having lost the ultimate test of success, achieving mainstream sales, they seek out ways to vent their frustration. You can tell their emotional distress runs deep too... which means reasoning won't work. Logic is outright dismissed. They just want someone else to suffer at this point. Having been proven incorrect is an uncomfortable place to be. But to attack others makes the situation unacceptable. The way this has manifested itself is in the form of misleading. Among Volt's strongest traits prior to the actual design having been revealed was the belief of purity. The engine would only be used as an emergency backup and would never provide power directly to the wheels. Well, that obviously fell apart. It never had any substance to support it anyway, but hope is a mighty powerful influence. Anywho, those few individuals still frustrated are lashing out at the plug-in Prius by attempting to create a misconception about blending. Succeeding with that would make Volt still stand out. They want you to believe blended operation causes an extreme MPG drop. It doesn't. But making people assume there's a huge penalty is there hope. I simply responded with: Think about what "*blended*" actually means. It's just an indication of at least 1 injection of fuel was utilized. That's all. So even if the engine shuts off just a few seconds later, the drive is no longer considered pure electric. What about when the heater is needed? In other words, the EPA estimates don't tell us the whole story. Notice how there isn't a usable-capacity listed?
- 7-14-2013** **Unwatch.** They did every possible thing they could think of to prevent conclusions from being drawn. It didn't work, since my purpose was to draw conclusions. I wanted to know who the troublemakers were. With the venue the big Prius forum, it was important to find out who would keep trying to raise doubt and would ask the same questions over and over again. They clearly didn't want to be constructive. They just wanted to level the playing field, to undermine success to allow time for mistakes to be corrected. Well, too bad. I now know who those Volt antagonists are and have put them on ignore. That's not something I like to do. I want to have very good reason not to listen to what someone has to say. But when there are so many others would genuinely want help and these particular individuals are just wasting your time, it's ok. So, I did. They I draw a conclusion they hadn't anticipated and could do nothing about. I simply ended a post with "*unwatch*". There's no way for them to respond to that. They knew I had moved on. And since virtually everyone else had already, there was no audience left. The thread came to a screeching halt.
- 7-17-2013** **Sick Week.** I came down with something nasty and have been stuck at home the past few days. My driving is for nothing but food, mostly runs to keep dehydration from becoming a problem. The convenience of not having to leave your car to get a tasty drink sure is nice, doing that using nothing but electricity is even better. Anything I desire is easily within range of the battery-capacity. I'll be sick for a least a few more days. So, this week is going to be really odd for the statistics. Getting out for some fresh air is a plus. Not having to deal with the daily commute is too. Missing out on Summer activities due to being sick sucks. The weather has finally taken a turn for the better, perfect for getting out on the kayaks. Yet another thing I can do with only electricity, though I'd gladly use some gas for the sake of recreation. Taking advantage of when the outdoor conditions are beautiful and your health is good really will be important to me this year. In the meantime, cough & snuffle. Blah.

- 7-18-2013** **Battery Longevity.** It's nice being able to switch over to answering newbie & research questions. Today's was about battery longevity: The careful avoidance of both high & low for battery-level is a major contributor to longevity that other rechargeable devices just plain don't have. Using the timer, to take advantage of cold-soaks, is another. It could take several years before even a small drop is noticed. I certainly haven't seen anything. In fact, the consecutive EV miles from driving my morning commute with a cold engine seems to have increased a little. I'd attribute that to break-in of the drive components. The battery itself hasn't ever raised any concern. Of course, I never immediately recharge and the interior of the car rarely ever gets super-heated from the sun. The system is designed with long-term use in mind. Only recharging to 85% rather than 100% is obvious confirmation of that. The same goes with the low-end, always starting the engine at 23.5% to ensure deep discharging never takes place. It's intended to deliver many, many years of service without much degradation.
- 7-18-2013** **After All.** Hearing that GM has formed a committee to watch the competition is no surprise. We already have confirmation that the huge price-slash on Volt resulted in a surge of sales, nothing to show sustainability was achieved. Looking at the online inventory, the purchase-rate has slowed to a crawl. GM clearly has reason to worry about high-efficiency sales. On the traditional side, GM just announced the intent to significantly increase production & sales of their vehicles like Cruze & Sonic. There was also official word that the next-generation of Cruze would be delayed by a year to capitalize on recent strong consumer demand for it. In other words, that question of knowing your audience is coming back to haunt GM now. They didn't understand who the consumers were and truly believed the "*if you build it, they will buy it*" approach would do the trick. That obviously didn't work. This market isn't what they had anticipated. Turns out, some of the naysayers really were contributing good advice after all.
- 7-19-2013** **Finally.** All the nonsense coming from Volt is over. With inventory on dealer's lots still high, despite deep discounts and high tax-credits, there's nothing to spin anymore. The blind hope that was impairing the market is gone. Toyota intentionally steered clear of it. Many misinterpreted that choice, which is why there was an endless stream of comparisons with GM rather than evaluating each automaker's own product-line. Now, it is confirmed as having been a wise move. I was truly amazed how misunderstood the market was. So many enthusiasts didn't have a background in economics, all arguments ended up focusing solely on engineering... which ultimately meant having to wait. The world today clearly reveals what GM wanted to sell is not what GM needed to sell. Those same enthusiasts who were horribly smug have stepped down, admitting that the "*vastly superior*" approach didn't work. They see the next-generation of Volt as being quite different. We are finally transitioning to constructive, far from the hype of the past.

7-20-2013 **Tesla's Influence.** There's a new thread on the big Prius forum stirring the pot in a new way. This was the post I especially liked: "*That article brings up no surprises at all. GM is nervous with Tesla, plain and simple. Yeah, one could call Tesla a disruptor, so be it. Innovations like Tesla is good for business and consumers.*" It made things clear the mixed messages of the past are even more of a problem now. I chimed in with: That lack of acknowledgement for the obvious is what has made Volt a topic which attracted so much attention. Enthusiasts went to extremes to tell us Volt was not the same as the plug-in Prius, then contradicted that very claim with direct comparisons. So, you'd ask who Volt was intended for. They'd evade the question. Eventually, when sales faltering could no longer be denied, focus on audience changed. We were led to believe the purpose of this generation all along wasn't to reach the mainstream, it was to tap into a new "*electrified*" market. That sounded reasonable... until Tesla's success became apparent. WHO IS THE MARKET FOR VOLT? That's the question Volt supporters have come to despise, since they truly don't know. The fear is that GM is completely reconfiguring the next-generation, sacrificing certain design aspects enthusiasts praised for the sake of it being able to appeal to middle-market. It's what should have happened originally. They just didn't want to admit the disconnect in priorities, hoping circumstances were change in the meantime. Seeing Nissan, Toyota, Ford, and Honda all taking the need for high-volume profitable sales seriously, while watching the success of Tesla, is far more of an influence than any of our preventative advice prior to rollout. GM knows now. The uncertainty of who is costing them quite a penalty. Forming that committee to observe confirms the worry they should have had all along. Better late than never?

7-21-2013 **Customers.** There are only a handful of Volt defenders left now. The others have shifted over to the how-can-we-change-for-the-better side at this point. To those who insist they know better, our posts are few and far between. Today's was started with: "*When a manufacturer launches a product, it is mandatory that the organization KNOWS and UNDERSTAND its' customers. GM is struggling with this all along.*" I contributed: Prior to rollout, Toyota established direct relationships with those hoping to become owners. They'd provide detail about how the system operated, intended goals, and targeted audience. We'd become the well-educated contacts to assist with the rollout process. It was a win-win situation. We had the opportunity to ask both the lead executive and top engineer of the Prius project questions. They worked surprisingly hard at being as forthcoming as possible. Concepts very new to the industry, like in-motion startup of an engine using a motor-generator and emission-cleansing to achieve the SULEV rating, were carefully explained. I was delighted by the level of information they were willing to share. It was fantastic... and a very different approach from what GM chose to take. The relationship held strong throughout sales of the Classic model. When the Iconic model was introduced, we still had an open communication line to ask questions and get answers. By then, Toyota's own internal education program tapped into that owner relationship to ensure everyone knows and understands. That proved to be extremely effective too. Who did GM include in the committee they just formed? Will there be an opportunity for consumer input? Or is this just another example of "*only GM itself*", leaving those who don't work for GM but have helpful insight without any way to provide input? A post this week from a die-hard Volt owner who previously owned a Prius stated the situation this way: "*We all know Volt's problem is price and profitability.*" That type of candid feedback is long overdue, something Toyota went to great efforts to avoid and successfully did. Cost was treated as a very high priority and continues to be. The design was configured to be enhanced overtime, as pricing would allow, rather than necessitating a new generation. Pointing out the risk taken and the lack of flexibility doesn't achieve anything anymore, nor does identifying the product-gap. It always boils down to knowing and understanding customers. Just look at how "*want*" and "*need*" are defined to see the lack of clarity still. The struggle will continue until those mixed messages cease.

7-21-2013 **Cost of Gas.** Here in Minnesota, we get our oil from Canada. That makes the "*paying terrorists*" argument about oil dependency self-deprecating, immediately informing us the arguer likely didn't actually research the situation. It's a handy credibility measure. That's important, since here coal is quickly being replaced by natural gas and ethanol is produced locally. We've been experimenting more with wind too. It makes the state more accepting to change than others, which is clearly confirmed by the number of Prius on the roads. Gotta like that. Anywho, the Keystone XL pipeline controversy has recently revealed a new problem for us here to seriously consider. The purpose of that pipeline is to provide a means for Canada to export their oil to other markets, like Europe and Latin America. Doing that would open up demand, resulting in the discounting of supply close to the source (like here in Minnesota) to come to an end. The price of gas would go up. The prediction is somewhere between 20 to 40 cents per gallon. Seeing that happen could easily result in even more of a boom in the effort to drill in North Dakota. This certainly puts some perspective on the need for hybrids by the masses. Our obsession with oil isn't a comforting thought. We're still not taking the cost of gas seriously.

7-21-2013 **Diesel.** He asked: "*What is the future? I think it's still better than the plain old gasoline engine. I live in the present and diesel works fine for me here.*" Knowing he was a diesel owner, I could resist joining in this particular discussion: Diesel = Fine = C. Getting a grade of just status quo isn't exactly a good sign for the future. We really need to strive for a better tomorrow. Comparing to plain old gasoline isn't constructive. Some of us have been driving hybrids for over a decade already. Hybrid = Very Good = B. Plug-In Hybrid = Great = A. Let's not overlook how dirty diesel actually is either. Requiring a urea system to cleanse emissions just to bring them to the level clean enough to meet minimum allowable criteria is embarrassing. We shouldn't have to lower our standards for diesel that much when SULEV & PZEV ratings are so easy to achieve with hybrids. As far as the "*Fossil-Fuel Mileage Champ*" title of the article (for this discussion) goes, excluding hybrids fueled only by gas is quite an omission... especially when the regular Prius delivers greater efficiency in every category... not to mention that it offers a larger interior than Cruze diesel too. And with such a massive difference between highway & city efficiency, overall MPG is going to be far lower than the advertising will inevitably lead people to expect. 46 highway. 27 city. Combined is only 33 MPG from the diesel. That's dramatically lower than the 50 MPG combined from Prius. What makes diesel compelling? The reality that it costs more per gallon than gas is a big deterrent (not to mention refilling the urea tank, roughly 7.5 gallons every 15,000 miles, or the upfront premium). That makes the fun-to-drive argument a wash when there's a gas version of the same vehicle available.

7-21-2013 **Ethanol.** Even though I've driven each of my Prius over the past 13 years using nothing but E10 for fuel, some people just plain don't like the idea of blending gas with any ethanol at all. There's a fear it will somehow damage the vehicle (despite no evidence to actually support that) and the frustration of losing about 3% of your MPG potential. Fortunately, mixed in among the message a constructive question emerges. Today it was asking why pure gas is still used for EPA estimates. That's a legitimate thing to consider. Several of us replied back with information. This was mine: Listing the wide variety of Ethanol blends would quickly become a nightmare, especially when E## only indicate an up to value, not an exact quantity. It can differ from fill to fill. E15 and E20 testing has been going on for years now, due to upcoming mandates. Including them next to the E0, E10, and E85 values currently in play wouldn't really benefit anyone, nor would the extra expense for the testing. The situation is confusing enough already anyway. Keep the ultimate purpose in mind. The EPA estimates don't actually represent a MPG expectation. They are really only provided as a standard basis for comparison.

- 7-22-2013** **Wow!** I recently compiled a list of posters simply not worth wasting time on anymore. They'll end up on ignore. If something worthwhile comes from them, other members will point it out. Then I'll join in; otherwise, it's clear their motive is to simply just keep discussions from ending. Remember all those years ago, back when that wild "*up to the chore*" debate captivated so many? That was their goal... preventing people from drawing conclusions. Today, there was a fresh attempt with this: "*I thought you said when prius phv sales started gm sales would stop.*" It was a completely fictitious comment. I never said any such thing. He knew it too, since the next post twisted the words with the hope of getting me to respond... hence the term trolling. They just keep trying. I'm simply not interested. There are so many newbies, those researching hybrids, and those deep into the ownership experience that I'd enjoy responding to instead. It's exciting to be able to help them out. Sadly, they too have to make an effort to ignore the rhetoric. That's why the more experienced try to quickly squash their attempts to undermine. I must admit, today's provoke was a good one. I was surprised anything so blatantly obvious would be tried.
- 7-23-2013** **Short Trips.** There was a strange new thread started recently. After a number of people got frustrated with the new member's behavior toward replied, I joined in: It's always fascinating to see someone attempt to bring about new discussion by presenting something already well proven in a new way. Antagonists do that to raise doubt and prevent conclusions from being drawn. They enjoy the ongoing exchanges, but their polarized views and credibility attacks make it pretty easy to see intent. Newbies are a different matter. You don't know if they are simply poorly informed, don't have the background to follow technical detail, or just feel the need to prove something. We do our best to get the facts out and hope for the best. In this case, the "*short trip*" problem has always been the efficiency penalty caused by the first few minutes of driving, due to the engine warming up. It meant a brief drive somewhere, like just a few blocks to the local store, would result in really low MPG. The only way to avoid that was doing short trips while the engine was still hot. Of course, with the availability of a plug-in model, those nearby errands can be run with just electricity. In other words, there is no myth.
- 7-24-2013** **Not Right.** When you get the feeling something is wrong, how do you respond? "*It isn't something we could avoid no matter how far we drive on any given day. So my point was why some people would give false impression that short trips are bad. Well, short trips are bad, I agree to that but it is not something anyone could avoid.*" Reading that left many frustrated, including me. It was as if the poster simply didn't care what you had to say. Being that close-minded is really odd, especially in the forum venue. Owners try to help each other out, not provoke each other without any clear purpose. Me, I ignored the banter and attempted to draw focus back to the comment actually made with: That's the rub... you can avoid them. We tell owners to run their errands while the engine is still warm. That will result in less gas being used than driving later after the system has cooled down. You plan to stop by the store on your way home or combine several trips into one. Also, don't forget that the plug-in model provides a solution to the brief drive penalty. So, there really is a difference that is being directly addressed by the upgrade. The thing we can agree on is how poor of an efficiency measure MPG is. It doesn't represent how much fuel is actually being consumed. It's just a end-result calculation with no reference to distance traveled.

7-24-2013 **Each Month.** We know that is the ultimate goal for every vehicle; it's either niche or mainstream. Each category has its own merits, but they are mutually exclusive. A niche vehicle doesn't have to generate business-sustaining profit, but a mainstream vehicle does. So, it's quite appropriate to treat them differently. A select group of individuals introduced a new category, the "*early adopter*" phase. These are the particular individuals who stir trouble every single month, which is really getting annoying. The rest of the Volt supporters have acknowledged Volt is actually the second-generation design of Two-Mode. Having seen that information in great detail, it wasn't be a deal for them. But the antagonists just plain don't like that, since it puts this stage into perspective. Remember how different expectations were back in 2007? Remember how they changed dramatically in 2010? Think about how much they've changed since then. How are they going to convince the world the third will cost dramatically less without having undergone a major transformation? Resistance to even the idea of a second model (a smaller battery-pack and more blending) is quite intense. No matter what you say about the importance of profit & choice, it just gets twisted into a series of excuses... each month. We want that to end. Ignoring posts doesn't work though. They just attack Prius PHV to stir attention. It's why this moment now is so important... prior to national rollout, while Ford is beginning to gain traction, and GM is attempting to clear out old inventory. The 2014 model years represent change. Unfortunately, this is how we have to deal with the situation in the meantime: Volt is a polarizing topic. The suggestion of offering a second model gets labeled as "*hate*" and is treated as if you are calling the current model "*failure*". It's an absolute. There's no in between. You are either for or against. Long story short, we will continue to see that until GM breaks out beyond the one-size-fits-all approach. The need for diversity causes a lot of pressure. It's a normal and quite predictable response by supporters & enthusiasts. Prius PHV is not like that. It coexists with other models. The idea of altering battery-pack capacity is commonly posted about. There aren't the avoidance issues as we see with Volt. There isn't worry that all will be lost when differences are later introduced.

7-25-2013 **Growing Pressure.** I'm delighted to see Nissan Leafs popping up here all of a sudden. I saw 3 today. One of them is now sharing the charging-stations at work. The others sightings were just random on the road. I've seen a few others throughout the week too. As you could imagine, that does contribute to the frustration Volt supporters are feeling. That particular electric-only vehicle was supposed to have the "*range anxiety*" shortcoming. Turns out, some consumers don't see that as a problem. Consumers obviously don't see a problem with hybrids that don't even offer a plug either. That growing pressure from both ends in the mainstream arena is becoming uncomfortable. The question of "*Who?*" is being answered by them, with a response that contradicts their arguments in favor of Volt. To make matters worse, that's a good endorsement for PHV when it finally rolls out nationwide. The priorities of price & practicality outweigh the features Volt has won many trophies for. Engineering recognition doesn't necessarily translate to business success. They're finding that out the hard way. Middle-Market doesn't care much about awards, with the exception of reliability. They want a good buy, a vehicle offering an all-around balance. Nissan's focus on that rather than offering longer range is proving to have paid off. Toyota's focus on price, interior room, and depleted efficiency should pay off as well. This is why there has been a continuous push on GM to offer another model of Volt, one that strives to offer a balance instead. We don't have to point that out anymore either. The piled up inventory combined with other choices getting attention... like GM's own Cruze, which has been selling extremely well lately... speaks volumes. We don't have to say much anymore. The pressure does all on its own.

7-25-2013 **Banned Troll.** Remember the "*rip off*" poster? He was the new member, who immediately upon joining the forum, attacked the plug-in Prius owners. Remember how he called us out for "*stealing*" from others? It was quite bizarre. His abrupt disappearance didn't come as much of a surprise. We figured him vanishing like that was the result of being banned. I was thankful. Some who doesn't even try to be constructive is worth wasting time on. Oddly, another type of attack started almost immediately after that other ended. It was quite bizarre too. We never get back to back problems that way, which made me wonder. This time though, the arguing was against Prius in general... that "*short trip*" penalty, presented as a myth. It stirred the forum in an odd way. Why bring up something already so well proven and call it incorrect? Valid points were being presented, but they were all red herrings... not actually related to the topic. How could anyone begin fighting everyone with nothing to gain by winning? It didn't feel right. Then I noticed a familiar statement in the newest post. The myth topic suddenly shifted to stealing. It included a nearly word-for-word sentence about PHV sales too. That's one heck of a coincidence... or was it? Could that be the same person, back with a different identity? After all, that's how trolls got around bans in the past.

- 7-25-2013** **Dream Machine.** It's hard to believe anyone would actually make a comment like this: *"Wouldn't the PIP Prius be everyone's dream machine if the electric range was extended and the price was lowered 20%?"* For well over a half century, some people have been amazingly passionate about constant improvement. Each generation ushers in advances. It's a never ending cycle. Better is the expectation. So, there really isn't ever an ideal. I tried to convey that: Nope. The target is always moving. 13 years of Prius support make that quite clear. The size, price, speed, power, emissions, and efficiency of the current Prius is the dream machine compared to what I first purchased way back in 2000... and that Classic was a clear improvement over the original. Improvement is on going. How much can be delivered at a specific price-point is the constant.
- 7-25-2013** **Move On.** The poster of the dream machine comment followed up with: *"I am anxiously looking forward to seeing how much the "target" moves when the G4 is finally introduced."* But rather than entertain more ideas, he simple said it was time to move on. That was bizarre. What would we move on to? Coming from a topic with 350 posts, what else could be discussed? I posted: We all await that. After all, there is no way of knowing how much of a MPG improvement for HV will come. But the market mentally is it must be substantial, even though that isn't actually associated with any particular quantity. They expect more for the same price... even if the rest of the vehicle is improved across the board. Despite the reality of diminishing, people want to see a bigger number. Targeting the middle is quite a challenge. Of course, playing the game isn't too difficult. If you stick to balance, raising the bar later on things like capacity is way easier than trying to squeeze out cost-reductions. After all, we've seen that approach successfully used time after time in the computer industry. Sadly, stuff like faster warm-up speed will go overlooked by most. The efficiency related to blending likely won't get squat for attention either. But at least we do have things to look forward to. People simply don't have a background. They don't understand how the system works. For me, I get excited every time I see the reaction on people's faces when they discover that recharging is a simple matter of plugging in the charger to an ordinary household outlet. That is obviously a major misconception currently impeding growth progress. When I tell them the resulting MPG, their first question of range becomes a non-issue.

7-26-2013 Pivotal Day. Sure enough, that same troll was back. He just plain didn't care either. His goal was to undermine in any way he could. It made me think about the way I was considered way back prior to Volt being rolled out. The catch was, my push was in the other direction. I wanted more, sooner. That's quite the opposite of what happened today. It was exciting to watch the revelation come from several people, all putting together the puzzle at the same time. They knew who was attacking and why. The reason is vindicating. Prius PHV is considered a threat... so much so, this was posted on the forum dedicated to Volt: *"What do you all think of the idea of GM keeping the existing Volt pretty much as is, with a 40 mile range at \$39,000, and also offering a Volt with a smaller battery, say 20 mile range, at \$27,500?"* At this point, it has become overwhelming clear that my push for a second more affordable offering was indeed an effort to help, not to impede. Trouble is, they understand the consequences of that choice. Fortunately, some are now willing to put pride aside in favor of mainstream appeal. See, when capacity is reduced, so is the power available. A smaller battery would mean the engine would be needed at times of high demand. They'd have to sacrifice the purity of electric-only drive. None wanted any part of that in the past. Of course, some still feel that way: *"I would not give up range for anything.....period!!"* Reading that was especially amusing. They can be their own worst enemy at times. The catch is, more are learning that the augmentation of Prius did indeed deliver more power. Upgrading the battery-pack increased the maximum draw from 27 kW to 38 kW. They didn't want to believe claims to that effect. Heck, even one of the posts with that information got removed in an attempt to conceal the truth. It didn't work. To make complicate matters, they know that traction motor is capable of utilizing even more electricity... up to 60 kW. Bigger means more power. Smaller means less. What makes today pivotal is the fact that some are willing to finally talk about that. Open discussion is a true step forward. Actual progress. Yeah!

7-26-2013 What If? Someone finally asked this question seriously: *"What if it was Toyota that made a car matching the Volt in all respects?"* In the past, it was always in the form of a rhetorical accusation, intended as an insult. That was frustrating. But knowing their purpose was to bring down your credibility rather than actually listen, it was no surprise. Anywho, this is how I answered: Reputation is factor not to be taken lightly; however, the balance Toyota strived for with Prius has been a major sales draw. GM made compromises with Volt which soured the appeal for everyday consumers. Watch how the upcoming generation changes to draw middle-market interest. People have given Toyota quite a bit of grief for the way Prius looks, but there's no denying the midsize hatch is remarkably practical. Ordinary purchase priorities shouldn't be pushed aside in favor of squeezing out range or power that really isn't necessary. That will result in enthusiast sales. It isn't what you do when making a product for the mainstream, on that is expected to deliver business-sustaining profit. Hopefully, GM learned its lesson and we can just write off this attempt as a rough start. Watch what the other automakers do. Ford is especially noteworthy; seeing how their Energi models catch on will tell us a lot about potential market opportunity. Toyota will obviously be closely watching.

- 7-28-2013** **No Charging.** Today was one of those rare ones where I didn't have an opportunity to plug in. No charging at all means ordinary hybrid efficiency... for a Prius, with a lithium battery. I was quite pleased with the outcome. 35 miles of driving throughout the day. The average was 68 MPG. That's fantastic! Fortunately, I had the camera available to document details. It's nice having examples of what's possible. Variety of driving circumstances takes awhile to collect to, so the photos help serve as a reminder of when something happened. In this case, I was just doing weekend running around. I stopped at my girlfriend's place and then went over to my sister's. It was pretty basic, the same kind of driving countless others have done with their Prius... only they don't have a the plug-in system, which is a little bit more efficient, even when you haven't plugged it. See... [photo album 183](#)
- 7-28-2013** **Product Gap.** Each month has been ending with something entirely new to talk about, a rather blatant distraction from Volt's struggling sales. This month, that topic is the supposed discovery of a test mule. It appears to be a new hybrid from GM. How convenient... and hypocritical. I had quite a few of the die-hard Volt enthusiasts outright attack me with hostile posts whenever I brought up the product-gap. Now, they too are saying the very same thing I did. For example: *"The 2-mode is expensive and complicated, but GM has a huge hole in their product line. They have e-assist and Voltec and nothing in between."* To have someone who had been previous fighting that very comment now make it himself, there's some frustration. You know they'll deny it. There will be some creative way of spinning the situation. Whatever. At least acknowledgement about the product-gap is now happening. Long overdue is still better than not at all.
- 7-29-2013** **The Spin.** That product-gap quote from yesterday was posted on the forum dedicated to Volt, where I don't participate. In fact, most non-owners don't. That's what the daily blog is for. Anywho, the topic today for that blog is the product-gap. Of course, the spin is in the form of: *"Is Chevrolet abandoning Voltec, or preparing the next variant?"* That wording was carefully chosen to stir attention and draw participation. The need for something similar to what Toyota & Ford offer is obvious. Thinking Volt will be canceled isn't realistic, since it could easily survive as a niche. But the necessity for a mainstream product is putting a lot of pressure on GM. Something must be delivered. This is what the controversy has been about all along. They can no longer just hope for the best. The risk is simply too high. There must be something offered for middle-market. Only the choice of an expensive compact plug-in isn't enough for ordinary consumers. With sales of Cruze so high, there's no argument anymore about what needs to be done. No amount of brand-loyalty or flag-waving will hide the reality of GM having *"nothing in between"*. Filling that void is essential.

- 7-29-2013** **Competition From Within, part 1.** It got a bit absurd, back to the terribly misleading tangent starting with: "*So if we compare apples to apples...*" I was amazed anyone would still try that. At best, it is just an excuse for delay. So much for leap-frogging. Anywho, I responded posting this: GM already had extensive experience with electric-motors & battery-packs when Volt was rolled out. That most definitely wasn't the case when Toyota rolled out Prius. It was all brand new back then. Gas was dirt cheap all those years ago too. There wasn't concern about oil-dependency either. In fact, we were encouraged to consume it and the topic of climate-change was considered a joke. Let's not forget the government incentives either. Prius only got a \$2,000 tax DEDUCTION, which worked out to about \$350 for most people. That's not even remotely close to the \$7,500 tax CREDIT offered for Volt purchases. And what about all the support for plug-in vehicles now? There wasn't any type of cooperation like that back when Prius was new. In fact, certain automakers launched anti-hybrid campaigns. There was an array of misconceptions to deal with too. The circumstances are far more in the favor now than they were back then. Each automaker is striving to deliver something highly efficiency & clean. Even a new automaker selling nothing but plug-in vehicles has emerged. There are manufacturers of charging-stations pushing mass-acceptance as well. Calling the situation an apple-to-apple compare is not constructive.
- 7-29-2013** **Competition From Within, part 2.** I sometimes follow their red-herrings for an opportunity to make it clear who the competition actually is. They lose focus very easily. Unfortunately, some never even consider the fact that GM can be a contributor to its own problems. That most definitely is the case with Volt. So all this nonsense about comparing it to Prius of long ago makes no sense. They are trying to win a battle that doesn't actually accomplish anything. Fortunately, it's becoming ridiculously easy to see. The July sales results will emphasize that. Online inventory listings indicate June was just a temporary surge. Toyota's plan to rollout PHV nationwide the end of the year seems so wise of a decision at his point. Avoiding the mess GM created for itself should pay off. We'll be able to have constructive discussions without the endless number of distractions we're dealing with now. Anywho, this was my follow-up: Reality is, you have some good points, but Volt is getting absolutely crushed by GM's own offerings... mostly notably Cruze. Competition from within is a major challenge to overcome. Focus should be on that, not what happened over a decade ago with another automaker.
- 7-29-2013** **ICE Violations.** When a lot owner goes to the trouble of installing charging-stations for patrons to use, they too get frustrated when an ICE (that's a regular Internal Combustion Engine vehicle without a plug) parks in that spots. Those of us with a plug can't use it then, even when we are willing to pay for the service. Whether the person cares or is even aware is always a big unknown. Signs which make it clear there will be a penalty for that along with painting of the spot green should make a big difference. The state of Washington will soon be requiring that, to support the new law the legislature there just passed. There will be a \$124 fine for an ICE violation. That's great; however, it comes with the same confusion we've seen in the past. What if your plug-in vehicle is unplugged by someone else? You are then preventing the spot from being used by someone else... which the law states is a violation. It also means the dual-spot locations which do allow the opportunity to plug-share would become a problem. We understand the intent of the new law, but it's clear the passing of it came from those who haven't actually ever used charging-stations. Details of the situation have obviously been overlooked.

- 7-29-2013** **Improved Charging-Stations.** I don't have a 240-volt charger at home yet. I've been waiting for the next generation to arrive and can see myself moving in the next few years. So, it's yet another one of those situations where waiting is required. Fortunately, the standard 120-volt charger that comes with the Prius is quite nice. It's just not as fast. Luckily, the public offerings won't have to wait. In fact, where I park there is an expectation of 4 new charging-stations being installed next month. Improved ones are available, one just announced today. Maybe it will be that kind? Anywho, the manufacturer directly addressed all three of the big issues with charging-stations. The biggest was installation cost. That's quite expensive. Now, there will be the option of having one unit & circuit supply electricity for two vehicles at the same time, each getting a 240-volt connection. That will be especially enticing for station owners. For vehicle owners, the cord is retractable. No more having to deal with wrapping & hanging. Lastly, the old-school illuminated text/number display will be replaced with an actual graphic screen. That should make it more inviting for newbies. I bet the information about the charging itself will be quite informative for us that have been recharging often too. It's nice that the industry continues to push forward. Every little improvement helps.
- 7-30-2013** **Extended Range.** The concept behind Volt was to deliver an electric-only vehicle with a gas-engine that would do nothing but generate electricity for those rare events when the battery-capacity wasn't enough. That didn't work out. The 16 kWh fell well short of need in Winter and the engine actually supplied power directly to the wheels at times. So, enthusiasts changed the definition of "*extended range*" rather than being honest about the situation. They pretty much had got away with that deception too... until now. BMW just introduced the i3 REx. It does indeed deliver what Volt did not. With a 22 kWh battery-pack and an engine that does nothing but generate electricity, it's what they had hoped for. The vehicle is interesting, a 2-door compact weighing 2,900 pounds and coming with just a 647 cc (34 hp) engine. Its tank holds just 9 liters (2.4 gallons) of gas, providing roughly 87 miles following the anticipated 90-mile EPA electric-only rating. Price is expected to be \$45,200. Deliveries in Europe begin the end of this year. Here in the United States, we won't see any until the second quarter next year.

7-31-2013

Normalization. I grew up hearing stories of the Japanese automakers catching Detroit totally off-guard by a sudden surge in the price of oil. My firsthand introduction to the resulting vehicles is what people now refer to as an "ecobox". Rather than actually deliver a technologically superior vehicle, automakers simply found ways to significantly reduce weight & cost. That resulted in a number of safety & reliability compromises. In other words, the industry took a big step backward. There were attempts at genuine efficiency improvement. The introduction of front-wheel-drive ended up a win later. Eventually, fuel-injection became a benefit as well. But there are some notable failures. Cylinder-Deactivation was a disaster. I know of one friend who ended up disabling the ability; it just plain did not work. Another attempt was diesel. That was so bad, one particular automaker became the blame for tarnishing the reputation for the entire industry... yes, GM. That's why the entirely new approach to thinking about plug-in vehicles put so much weight on the importance of Volt. GM was going to storm ahead of all the other automakers, delivering on bold promises too good to be true. So, there was a very real fear that GM would again wreck the opportunity for others. After all, the disaster called "Two-Mode" was still very much on everyone's mind. Sure enough, Volt ended up being a disaster too. It even had the fundamental problems of added weight & cost... a big step backward. That's why Prius was relentlessly attacked along the way. It didn't avoid that, but setting focus squarely on what middle-market needs today with the opportunity to upgrade the design along the way. GM instead started at an end state, hoping for major technology improvements quickly... risking reputation in the meantime. That brings us to last month. 2.5 years after rollout, price was dramatically reduced. There was a surge in sales as a result. This month, the online inventory states that sales have slowed significantly... to less than what they had been prior to the price slash. The hope had been steady monthly sales of around 5,000. Instead, sales had been around than 1,600. That's a major disappointment for a vehicle which has been praised as "*game changer*" prior to rollout. Needless to say, many of us are glad the hype is over. We look forward to normalization, where each automaker is offering something reasonably competitive. Sales results for the month ending today will be available soon. With over 7,000 Volt still unsold inventory and production of the new model year about to confuse the situation, we're all anxiously awaiting what comes next. This chapter in history is over. They hoped for the best and the risk did not pay off. If we're lucky, there won't be any big penalty. We'll find out as the plug-in offerings from the other automakers progress forward.

- 8-01-2013 Perspective & Goals, Toyota.** Slow and steady growth. A four models of Prius are pushing deeper into their markets. The plug-in is still limited, but that concentrated focus is informative. The antagonists just plain don't agree with that. They believe spreading out availability as much as possible makes more sense... regardless of how thin that stretches resources. How they think that's sensible is beyond me. But then again, I don't focus on short-term gains like much of the active participants online do. I step back to consider the big picture. In this case, it's with July sales. Put in perspective, the Liftback (regular model) ranked 4th in Toyota's product-line here at 15,252 for the month. The top 3 were: 34,780 Camry; 24,462 Corolla; 19,538 Rav4. In other words, it's quite clear that Prius is well established as one of the business-sustaining products. Profit with high-volume sales has been achieved. Selling less were the other models of Prius: 3,428 V; 3,797 C; 817 PHV. In Japan, C (known as "Aqua" there) is actually the top-seller. Then it's the regular model. Camry & Corolla follow. Anywho, it's quite clear that Toyota will continue to push to gain more Prius sales. That goal should be obvious at this point. I'm looking forward to the national rollout of PHV. It will stimulate increased sale of pretty much every Prius, even in the markets with heavy penetration. The current delay has proven a wise move. Lots has been learned in the meantime. But patience is trying. The wait will be worth it though. We've seen delay pay off in the past.
- 8-01-2013 Perspective & Goals, GM.** The struggle with Volt continues to get worse. Despite the huge discount (\$4,000 price reduction) last month, sales growth was not achieved. It only caused a temporary surge, then returned back to roughly the rate it was prior to that. July results were well under what was hoped, especially considering the month started with around 8,000 unsold still in inventory. Put in perspective, the position of Volt only qualifies as a niche in GM's product-line, clearly not a significant part of the fleet: 42,080 Silverado; 25,447 Cruze; 18,507 Equinox; 16,582 Sierra; 12,915 Impala; 12,473 Malibu; 7,969 Camaro; 7,855 Terrain; 7,616 Traverse; 7,119 Tahoe; 6,181 Suburban; 6,055 Sonic; 5,569 Express; 4,963 Enclave; 3,847 Spark; 3,621 Verano; 3,446 LaCrosse; 3,176 Encore; 3,143 Yukon XL; 2,790 Yukon; 2,548 Captiva; 1,788 Volt. With such an obvious indication of what the true competition is, there are obviously some priorities & goals to reconsider. Traditional vehicles are a major portion of GM sales. How will they break away from the mess they created? Some other choice must be offered. What will it be?

8-01-2013 **What Benefit?** The topic of why Toyota didn't sell PHV sooner has become a hot one. None of the people arguing take the cost of lithium batteries into account. They just figure the more that are sold, the better off Toyota will be. Waiting for the affordable price-point to be hit is a factor completely oblivious to some. That makes me crazy. There are risks to selling at a loss. When those risks are unnecessary, why take them? I don't see the problem waiting until the 2014 model year for national rollout. It's a sensible business approach. Too bad those arguing online rarely, if ever, consider that aspect of manufacturing. It's all about the engineering. That lack of balance should be obvious. Clearly, it isn't. Anywho, this was my post about the timing: Looking at the big picture, V & C have become well known in the meantime. Heck, the C model has been the top-seller in Japan for awhile now. That established the acceptance of Prius variety. While at the same time, work has been underway to prepare the market for the plug-in model... in other words, educate consumers. Haven't you noticed one of the top complaints about GM's approach with Volt has been the lack understanding, not having taught consumers how it works? What benefit would there have been rolling out this Spring as originally planned? Waiting until Fall doesn't appear to have been a loss. In fact, the success of Tesla & Nissan in the meantime appears to be a gain. The growing popularity of full EVs makes the decision to purchase a Prius with a plug easier. There's no intimidation factor then. In other words, Toyota is positioning itself rather than having just plunged in. That's a sound plan for reaching the mainstream.

8-01-2013 **Advertising.** There isn't much you can actually convey in a 30-second television commercial. Yet, that is still what we learn much about our world from. That medium tantalizes our short attention-span, giving us just enough to want to find out more. That more part is where venues like online forums come into play. Some still don't see the value in that though. Others feel empowered by the wealth of information so readily available. That catch is, you have to be aware of those trying to mislead. After all, that is a basic part of the advertising process. Online, it gets taken to a whole new level. So, there's a very real disconnect. Fortunately, that is fairly well understood... which means we can actually have some relatively constructive discussions about it. What information do consumers really need to know? I got a kick out of this comment: "*Toyota ads are 'normalizing' the Prius saying how it is 'for everyone'.*" Isn't that the point? Once a vehicle achieves mainstream level sales, that's exactly the perspective you want. With all intimidation eliminated, resources no longer need to be spent on special efforts. That label of "*normal*" is the ultimate goal. Coincidentally, remember what I stated just yesterday? Having choices of "*something reasonably competitive*" is what we should all be striving for. Sadly though, that's not what gets much attention. The everyday type ads blend into the noise of the daily routine... which is confirmation of it being normal. To think that Prius has come so far, it no longer stirs. That's good. Owners have come from be environmental extremists to just someone living on your street. Yeah!

- 8-01-2013 Warm-Up Costs.** Each generation of Prius has delivered notable improvement. Augmentation from the plug took it a step further. It's quite fascinating on my commute home to climb out of the base of the river valley, in the on-ramp that turns into a truck-lane due to the steepness, with a cold engine running at just 1500 RPM. I simply get up to flow of traffic, about 60 mph, and merge in. It's this remarkably smooooooth climb. Right before I reach the top, the boost runs out. RPM then ramps up to 2300. What a difference that electricity makes. With the next generation, we are expecting more mitigation. Increased thermal-efficiency should cut down on warm-up time. So when you do have a cold engine start, there's even less of a penalty. Of course, even in that extreme example I have, that initial warm-up efficiency is still over 50 MPG. Seeing that even higher in the future will be great.
- 8-02-2013 Spin.** No matter what happens, there's always a reason to justify it. We've been taught to remain positive, regardless of the circumstances. That's a fundamental part of our culture. Unfortunately, you end up with an endless stream of excuses as a result. In fact, it becomes so bad, you get nothing but spin at some point... which is where we are today. GM just slashed another \$1,000 off the price of Volt. The market is saturated and there isn't any other option available. GM bet the farm on an inflexible design. They lost. Supporters are now in dismay. It's not like Ford or Toyota, who both have hybrid platforms capable of delivering a variety of configurations. This is just like Two-Mode. It's falling apart the same way. We all saw the warning signs. Some of us acknowledged them. Others fed what ultimately became spin. Ironically, they will end up accusing you of the very thing they are guilty of. It's quite fascinating. Long story short, Volt is no longer a disruptive force. The barrier it once had been is gone. What a relief. Changing the game was the goal. That didn't happen. It mostly just confused consumers. And it turns out, the efforts of the other automakers the enthusiasts mocked are indeed what is overcoming the true competition... traditional vehicles. No amount of spin can conceal that anymore. Prius rollout can now proceed.
- 8-03-2013 Perspective.** Much importance is put on learning from the past. If you don't, you are likely to repeat the same mistakes and face even worse consequences. So about a year ago when the denial about Volt goals grew intense, I was thankful for having the detail available here to refer back to. The biggest issue was the claim that this generation of Volt was only intended to be an "*early adopter*" model. That perspective seemed reasonable too... if you were unaware of the past. Trouble is, the intentions of selling 60,000 in the second year were well documented as a goal with the production-capacity of building up to 120,000 by the third. That nugget of information angered the enthusiasts; it was a reminder of the struggle the shortcomings were giving them. Then came the start of the third year, this previous January when GM was supposedly going to reveal a collection of upgrades to be rolled out with ELR in the Fall. That didn't happen. Instead, it was just a repackaged Volt with some alterations. 6 months later, it doesn't take much to imagine how enthusiasts are feeling with the sales remaining flat and the variety of plug-in offerings from other automakers growing. Much opportunity was lost. What's left is slipping away. On top of that, I'm getting what I wanted all along... an ally. I looked to Volt as a player on the team, a vehicle to help out with the other plug-ins to end the dominance of traditional offerings. The enthusiasts wanted a plug-in that was "*vastly superior*" to all others. That didn't happen either. They are forced to play along. Think about what they'll want a year from now. We know their perspective will be changing. What will it be?

- 8-03-2013** **Looking Forward.** It will be very exciting to watch what happens to hybrid popularity as their plug-in counterparts draw more attention. Currently, the plug-in hybrids are so rare, most consumers aren't even aware what's actually available. Seeing charging-stations in parking lots will go a long way toward promoting them. That raising of awareness will instill a sense of normalness for the regular hybrids. Rather than being identified as "*green*" or "*alternative*", they'll be looked upon as the obvious next step in automotive standards... like the way we saw front-wheel drive become the norm. We're at that tipping point where changing the mindset of the market won't take much effort. No one is questioning business viability or technology reliability anymore. It's all well proven at this point for the regular hybrids. With each automaker offering high-efficiency choices, the tables will turn. Gas prices will continue to climb. Commutes will continue to get slower and more crowded. It will become harder to justify the purchase of a non-hybrid.
- 8-05-2013** **EV Distance.** Morning commutes taking the river route are quite pleasant. The top speed is 55 mph. So driving that way can easily be done using nothing but electricity... which is exactly what I've been doing. After all, the 70 mph has been the route to avoid. With heavy construction on it right now, the traffic is awful. The alternate route is a nice steady flow. That flow stops at the highway entrance to cross the river. It involves a wait at a merging light. That means some days require lots of stop & slow for that short distance to use the bridge. Fortunately, the drive prior to that was only 13 miles. It leaves the Prius with just enough EV range to get through that wait. Having that much further along the way, I could be stuck motionless waiting for the engine to warm-up. Instead, I'm just creeping along using only electricity. It makes that route the preferred... especially since there isn't always a wait. Sometimes, I can just drive right through. For the crossing itself, I fire up the engine. Spending only a minute on that 55 mph section of highway and the following acceleration to merge onto the 50 mph road afterward is perfect for warming. When done, the engine shuts back off and I resume more EV driving. Think about how many don't have anywhere near that pleasant of a morning commute. It works out really well for me.
- 8-05-2013** **Profitable.** The question finally got asked: "*How profitable is the Volt now?*" It's a very important one. Sales don't mean much if the vehicle isn't profitable. Losing money on each means volume will stay low. Automakers cannot afford that for long. But with such an intense effort to downplay expectations, it's no surprise that being a "*halo*" became an acceptable outcome. Becoming known for selling a premiere fuel-sipper, but selling guzzlers instead, is a doomed plan. The business cannot remain competitive that way. Fortunately, many are silently acknowledging that reality now. I commented: For some perspective, take a look at the big GM forum. While those here have been persistently pointing out reasons for being patient and waiting, members there have moved on. Volt simply doesn't get attention anymore. The daily blog has gone the same way. Discussions are now about other topics. Other plug-in choices, like Tesla, are stirring far more interest... and are demonstrating the potential for sustained profitable sales. Transforming engineering success to business success isn't going well for GM. The pressure of economic realities are forcing choices to be made. What the outcome will be is anyone's guess. The one thing we know for sure is that the market is rapidly expanding and the clock is ticking. When the tax-credits expire, each plug-in must be able to support itself... competing directly with traditional vehicles.

8-06-2013 **New Owners.** We routinely get them on the big Prius forum. A few join specifically for the purpose of figuring out why their MPG is so seemingly low. It's pretty obvious too, when a new name with only a single post starts a thread. You can tell, they didn't do much (if any) research about the measure of efficiency prior to their purchase. So, we do what we can to try to help. Here's my contribution to that this time: There are many factors that prevent MPG from what people expect, based on the big numbers on the window-sticker. New owners aren't aware of them until they start driving around with their new Prius, which has a display and begins to point out those factors. Assumptions don't make themselves known until they seek advice online. Efficiency has always been that way. Most people have no idea though. In fact, they usually aren't even aware that the window-sticker also contains small numbers too... specifying a range, trying to highlight the reality that result will vary. Fortunately, even under the worst conditions, Prius still does better than other vehicles at their best. It's too bad that new owners don't have data prior to their purchase available for comparison. Their previous vehicle didn't have a display. They had no idea things like temperature, short-trips, tire-pressure, or winter-formula fuel could make such a difference. So, all we can really do is assure the new owner their Prius is just fine and encourage them to explore the technology. Drive something other than the daily routine. Watch the difference it can make. Also, give the new car some time to break-in too.

8-06-2013 **Price Drop.** It certainly hit the fan today. Wow! There was flat out denial too. The situation is beyond a disaster. GM announced the price of the 2014 Volt would be \$5,000 lower, making it the same price as the clearance price of the 2013. That got those claiming this was only an "*early adopter*" phase in quite a tizzy. They've done everything possible to forget that GM had once projected sales of 60,000 for year #2 and would have production-capacity of 120,000 by year #3. Seeing sales significantly lower than that without any alternative approach available leaves nothing but the desperate act of selling at a loss. Of course, there were even attempts to make us believe cost could have dropped so dramatically, profit would actually be made. Reminding them that earlier this year the CEO told us money was lost on each sale fell on deaf ears. Fortunately, words of wisdom are emerging all over the place now. The forums have suddenly come to life after the disappearance of Volt. This was my favorite summary of the predicament: "*At least as far as the bread and butter market is concerned, the Voltec solution seems to be dead in the water, especially once the government no longer contributes \$7,500 per car. There have been plenty of 'moonshot' type of products that were technological marvels, but that ultimately failed because what people were willing to pay for them didn't match what they cost to make. The Volt may turn out to be one of those products.*" What else can be said? Remember that price target GM set, then subsequently disregarded? Today was a brutal reminder of why delivering that was so important.

8-07-2013 **Nicely Under \$30,000.** The primary reason Volt was labeled as "vaporware" right from the start was its price, range, and efficiency targets didn't make sense. How could so much be delivered in so little time? Having a price of "*nicely under \$30,000*" was absurd for 2010. There's no way a battery that large could have a cost low enough. Then to also deliver a 40-mile range even in Winter along with 50 MPG following depletion, it sounded too good to be true. Some of us took that as a warning. Others celebrated a victory soon to be achieved. Sure enough, it didn't end up being delivered. 2.5 years after rollout, it still hasn't. Yet, there's more celebrating. This morning, I read: "*That puts it BELOW the average price paid for a Prius in the US!*" It was from one of the most troubling of troublemakers. He just plain doesn't care about production-cost or tax-dependency. It's all about beating Prius. So what if GM losses money on each sale. So what if selling the vehicle requires government assistance. Supporting a product that sustains the automaker isn't his concern. He just wants bragging rights. That's amazing. Think about how unlikely it is that \$5,000 could have been dropped already. A cost reduction like that without any visible or operational change to the vehicle, in such a short amount of time, doesn't make sense.

8-08-2013 **Settling Down.** The usual undermining techniques aren't even working. Attempts, like diverting focus, are failing to hold the discussions attention as they did in the past. Antagonists can no longer prevent conclusions from being made. There's simple too much evidence available now. That's good news. Being able to have a somewhat constructive few posts is quite an improvement from just a week ago. It will be interesting to see how things proceed. Here's the direction the discussion went this evening: Supplier information has been provided over time for us to consider. And yes, there is indeed a benefit from volume. However, we've seen there can be a penalty if you want the increase right away. The extra work is usually welcomed, but overtime pay comes with it. There are sometimes limited supplies of raw material too, requiring a premium if you want more quickly. Long story short, the underlying effort to downplay is going well. Some contribute unknowingly. Others do it quite intentionally. It even comes from the automaker itself. Notice the doubt being raised? Meanwhile, the clock is still ticking. We know progress is being made when goals are clearly being set & achieved. For Toyota, it is clear. We know they are pushing for higher engine efficiency and lower plug-in cost. Both criteria are based upon the models currently available and the method being taken to deliver that has been spelled out. For GM, all we've been told is a general order to reduce cost from \$7,500 to \$10,000 without any idea how that will be accomplished. In other words, how is what's happening now different from the past? Seriously. There's a lot more in common with the blind hope of the past than anyone cares to admit. There isn't any accountability either. If very little is accomplished, oh well. We have emissions & dependency issues to deal with still. What about those? How long should we wait, for what, and for who?

8-09-2013 **Change.** Addressing this should be very interesting: "*The GM haters need to get over the fact that the Volt is not a complete flop, and that it is a more compelling car to the public than the Prius plug in.*" My response was: They did get over it. That's old news. Comments have since changed to it needing to be affordable. Back when Volt was rolled out, the cost for the battery was between \$800 and \$1,000 per kWh, not including controllers or liquid cooling. That puts the price of 16 kWh of capacity at a very minimum of \$12,000. Cost has since come down by then. How much? That's a big unknown. Half would be remarkable. Volt is a hybrid with clutches. Adding the battery-pack makes it a costly product. 3 years isn't much time for a significant reduction. But consider that actually happening. The plug-in Prius only uses 4.4 kWh and doesn't use liquid cooling. Cost of lithium batteries dropping will benefit it too... making it compelling by becoming affordable, the very thing people have been asking for. Mainstream consumers are looking for a plug-in option that doesn't require paying a large premium. That's why GM set their "*nicely under \$30,000*" target. That's why Toyota set their \$3,000 to \$5,000 package-option target. What part of that doesn't make sense from what we are seeing now?

8-09-2013 **FUEL-CUT while in EV-BOOST.** Since introduction of the plug-in model Prius, those wanting to undermine its acceptance have been exploiting the misconception related to the 100 km/h (62 mph) threshold. Unfortunately, we haven't had a good way to prove the system doesn't actually work as they implied. When traveling at speeds faster than the threshold, the engine RPM isn't 0. That gives the impression the engine is running. We can point out how little horsepower is required to maintain travel at higher speeds, but that message is difficult to convey when there isn't anything observable to support the claim. Fortunately, I made an unexpected observation. My morning commute started with an errand that needed to be run, rather than just jumping on the highway like I'd usually do. That meant approaching from a different direction at a slower speed. Further altering the routine, I got stuck behind a string of traffic slowed by a big truck. The end result was cruising along with an engine not fully warmed up yet. Since my speed was 65 mph, I was in EV-BOOST mode instead of EV. That means the engine was spinning, but not necessarily consuming any fuel... the aspect of operation we've never really had a good method of proving. Even though the RPM readout was 992, the temperature of the coolant wasn't rising. In fact, it was dropping! That's basically impossible for a combustion engine... since they are so terribly inefficient, losing most of their energy from fuel as heat through the exhaust & cooling system. But there I was, watching the coolant temperature drop. It was a new bit of evidence confirming the engine was in FUEL-CUT mode... only spinning, without use of fuel. It takes very little energy for the engine to spin without any compression. There's just unimpeded air passing through. The power from the electric-motor and battery-pack were more than enough sustain travel. Seeing the value go lower was great. I had enough electricity available to make the observation twice too, once when the temperature started at 175°F and the other 181°F. Both times I watched 7°F disappear one degree at a time before intentionally speeding up to watch it switch from dropping to rising. It was pretty exciting to stumble across new data like that.

- 8-10-2013** **Diesel.** This comment was quite to the point: "*Wow, the hate is strong in this thread.*" It was a worthwhile thing to say. After all, no one really knows what "*hate*" actually means anymore, especially with so many polarizing topics lately. My comment back was: The hate we see has some merit. That for misleading marketing is a good example. We've seen focus solely on highway MPG often, which is clearly misrepresentative of what someone with a mix of driving will experience. Ignoring emissions was a big problem in the past. Now, we've switched to the "*clean*" marketing. It gives the impression of being greener than it actually is. You want to be honest about emissions, state the official rating. Using a vague adjective instead allows for incorrect assumptions. There's also a history of reviews & comparisons with intentional bias, where they attempt to make it look fair, but we see how the data presented doesn't actually tell the whole story. In other words, the benefit of doubt is no longer available. People have been fooled far too many times to allow claims to be accepted as-is. Without the step back to look at all that was claimed, we enable the efforts to undermine to flourish. Sadly though, that fact-checking ends up getting the "*hate*" label. But what else can be done?
- 8-10-2013** **Disassociation.** It doesn't take much to see what's happening. We've seen the same thing in the past. When a goal isn't fulfilled, those who supported it conveniently forget. Then when someone like me brings it up, they're extremely quick to dismiss or belittle anyone who would have believed such a promise. That looking backward after-the-fact makes such attitude common. Not being observant while decisions are being made is how people can be easily misled. Delivery claims aren't seriously considered; they're just accepted as if the outcome is already a given. Oddly, that's actually advantageous at this stage with Volt. Knowing the first generation came up far short of expectations, they simply move on to the second. That growing disassociation is exactly what's needed for fundamental changes to be made. Those must-have traits of the past no longer apply. New goals are created & accepted instead. It's as if none of the original nonsense ever happened. Remember the "*vaporware*" criteria? They don't. Ironically, some of those same goals will be revisited. But this time, it will be with a realistic understanding of what can actually be achieved. In the past, hope outweighed logic. Now, there will be recognition of some of the challenges the Prius owners stated from the very beginning. They assumed we were simply defending Toyota. The thought of us actually trying to help seemed an impossibility... but not anymore.
- 8-11-2013** **Asked Questions.** There's a charging-station by a nice lake and a walk across the park to the zoo. It was an excellent location to spend a Sunday with the family. The weather was great too, perfect for powering the solar-cells attached to the charging-station... making it especially rewarding to plug in there. Anywho, as I was unplugging, a small group of people stopped to watch. One asked the question: "*How do you like it?*" My answer was: "*My average so far this month is 147 MPG.*" Needless to say, they all took a step closer. Their interest was peaked. I had a captive audience. So, I kept responding their variety of inquiries. My ultimate goal is to sneak in the information about recharging not requiring anything beyond an ordinary household outlet. Most people are taken aback when discovering all that's needed is a regular 110-volt connection. They just assume some type of special installation is necessary. I've noticed that pattern. It's an incorrect assumption impeding the acceptance of plugging in at home. People simply don't realize how easy it actually is to own a plug-in hybrid. Thankfully, overcoming that particular barrier misconception isn't that big of a deal. We'll be able to tackle it fairly well... once national availability begins in a few months.

8-12-2013 **Ignoring Cost.** There sure are a lot of online comparisons popping up now. They all point out the discounts & incentives, all drawing the conclusion that Volt is a better buy than the plug-in Prius... all ignoring cost. That's a recipe for trouble. How many vehicles will an automaker produce & sell at a loss? With a niche, that's an acceptable practice. The vehicle serves as a "*halo*" to draw in sales of their other choices. It's basically spending advertisement money on brand rather than sales of that particular vehicle. So, it is effective. But if the point is to sell lots of that actual vehicle, for it to be a source of business-sustaining profit, that doesn't work with regard to the comparisons. Purchase decisions made now are based entirely on the vehicle actually being available for immediate purchase. With a loss-leader like that, only a limited amount are available... falling well under the mainstream minimum of 60,000 per year. In other words, Volt is have that identity crisis we warned about. We still don't know who the heck it is intended for. For that matter, we really don't know the purpose anymore either. Pretty much everything except the desired price is very much a mystery for the second generation. Goals are non-existent. That's quite a bit worse than the vague we had in the past. What is its purpose? Those currently ignoring cost certainly don't care. They just want to enjoy the brief moment of victory caused by the price drop. It's more of that blind-hope playing out again.

8-13-2013 **Cold Climb.** It's difficult to know how to respond to such a comment: "*I also have a hill just outside the driveway, but no other way, but uphill. If engine is cold, fast climb can totally deplete the battery, as ICE refuses to help. There are 2 solutions to the problem...*" When a new owner doesn't include speed, distance, or state-of-charge, giving advice isn't easy. They often don't realize how wide the variety of driving circumstances had be. And of course, the tendency is to forget about ever-changing factors, like temperature. Misinterpretation of intent is very easy. So, pointing out aspects of design can be very tricky. I tried though: There is no problem. It's suppose to do that. The system will intentionally protect the engine from strain. That's a fundamental part of the design. It reduces emissions. Living near the bottom of a valley and having owned each of the generations of Prius, I know the hill climb extremely well. In the dead of winter (very cold here in Minnesota), the battery-assist is quite pronounced too. I start the Prius and begin the climb. It has never been an issue. Now, I have the plug-in model. So, I'm even more familiar how the system automatically goes out of its way to limit RPM initially. Just drive it.

8-14-2013 **Conspiracy.** Even though just earlier this year, the CEO of GM stated the sale of each Volt is at a loss, we are now suppose to believe the entire \$5,000 price cut is the result of the cost having dropped that much. That seems highly unlikely. Cost dropping is quite realistic. That much in such a short amount of time is not though. But most people only hear the first part. They also like to say Volt is following the identical path Prius did over a decade ago, even though it did not experience such a large cost drop. It's a good example of how spin comes about and how people disregard some facts... like the inventory piling up. There are obviously some misconceptions about plug-in vehicles; however, profit is lost when targets are set and not met. We're seeing that play out now. Realignment of priorities is proving painful. There's backlash too. Seeing this published recently was a surprise: "*Chevy is slashing Volt prices because it has been selling a ton of pickups and wants to keep doing so.*" The enthusiasts certainly didn't see that coming... even though they were warned repeatedly. When sales don't meet expectations, it leaves the vehicle vulnerable to things like conspiracy theory. That sounds absurd until you look back at the Hummer comparisons to Prius. It boggled the mind that we suppose to believe such nonsense. Yet, they tried anyway. Needless to say, there's a mess to deal with now.

8-14-2013 **Colors.** Based on Toyota's history, we've seen color play a role in demand. It makes you wonder what other vehicles have the same type of connection. Think about the mid-cycle refresh. Most of the time, the modifications are primarily cosmetic. Blizzard Pearl, Sea Glass, Classic Silver, and Winter Gray are colors shared amongst the regular & plug-in models of Prius. Clearwater Blue is the only unique to PHV. For the regular, people also get the choice of Black, Barcelona Red, Nautical Blue... all of which are popular. Yet, Toyota doesn't offer them with the plug. Having such a current selection that lacks a standout option is a tactic we've seen in the past. They colors are all on the soft side, nothing vibrant. Think the 2014 will? It makes sense that they'd save something for later. After all, changing the technology itself sooner than each generation introduces all kinds of issues. Holding back on colors initially is a safe bet. Had you considered that as a sales influence? Most people never think of it.

8-14-2013 **Starting Over.** The sense of change is becoming much easier to see now. I was astonished to encounter this: "*To those who bought early and now see lower prices: welcome to technology and quit whining.*" It was from a Volt owner who wasn't pleased with the topic on that daily blog... which finally addressed recent sales and the price drop. Seeing that it took so long for the topic to even come up for discussion, it wasn't much of a surprise. It's yet another piece of evidence that things are different now. Anywho, I couldn't resist. It's been awhile since I posted there. The daily battles are now just a faint memory. The war has been won. Some aren't pleased with the outcome... or my reminder: The priorities originally set by GM were quite different from what ended up being delivered. Ironically, those are what they are now striving for. There's a penalty though for having diverted goals though. But who would have thought it would come at the expense of owners turning on each other. That's quite a statement to make! There's much to do still. Just because cost has come down does not mean the new price now reflects a profit is now being made. It simply means some progress has been achieved. At some point, the tax-credit will expire too. The ability to sell the technology is high-volume is quite a challenge. Reality is, there will be changes. Basically, it will be as if GM started over. The fact there's some isolationism taking place will actually make that easier. With all the other choices emerging in the market, it's not like there was going to be a loud chorus from Volt owners anyway. Just look at how much division we've seen over the idea of offering more than a single model. Long story short, Volt didn't end up being the "*game changer*" enthusiasts had hoped for. Sales have been a struggle, definitely not what had been expected. Those interested in taking the next step will acknowledge production cost and accept what needs to be done to deliver a profitable vehicle. For those still holding on to the "*vastly superior*" claim, take a look at automaker sales... not just plug-in vehicles... the entire market.

8-15-2013 **Misconceptions.** I was pleased upon reading this: "*Most people are amazed when I tell them that I plug in to a regular wall socket.*" Coming from another plug-in Prius owner, he knew all too well the very same reaction I've been witnessing. My reply was: I get the same amazement reaction when I mentioned all that's needed is an ordinary household outlet. It's emerging as the biggest misconception. Fortunately, we have the opportunity to change that. This is much different from the "*you have to plug it in*" misconception we dealt with when Prius was first rolled out. Once we figured out people didn't actually understand how a hybrid worked, we'd take the initiative to point out what was most important first. In this case, that would be to immediately mention "*regular wall socket*" when a conversation is struck up about the car. I'd often get stopped in parking lots by total strangers, since they noticed I was driving a Prius. That was the opportunity back then. Now, it will be that they notice me plugging or unplugging at a public charging-station. Before even answering their first question, I'll interject information to squash the misconception. Someday when Toyota starts specifically advertising the plug-in model, they'll include that information too. Until then, it's up to us to spread the word.

- 8-15-2013** **Gutless.** This morning, on the popular thread about Prius power, brought a story of a wife complaining about the difference between her 258 horsepower SUV and the 134 horsepower in her husband's Prius. She thinks the lower horsepower "*cars are just dangerous because they can't get out of their own way*". I couldn't resist joining in with: That horsepower difference sounds exactly what some of us experienced in the early 80's. Remember that shift from giant guzzlers to the eco boxes? That sure made people rethink how they drove. Fortunately now, the power is an overkill situation, where nowhere near that much is actually needed. So less isn't really losing anything. In fact, I routinely see individuals driving the more powerful vehicles who casually pull out into traffic at a much slower rate than you'd do in a Prius. They have it, but don't use it. As for the planning ahead, I wish more people did that. You see some changing lanes without seeing the slower moving car they just pulled in behind. It makes me wonder if there action to advance is nothing but instinct, where they don't give it any thought before they do it. That's like tailgating. In many cases, it doesn't accomplish anything. Prius raises awareness in many regards. Just think about how people don't know the factors that influence efficiency because their vehicle doesn't have a display showing MPG. For that matter, consider how small & crude the speedometer is being behind a steering wheel using close numbers and a large needle. The digital speedometer in Prius is a dramatic improvement.
- 8-15-2013** **\$107.62 Per Barrel.** Even though the price of gas is way down (just \$3.35 per gallon here), the price of oil is very high. Seeing diesel at \$3.99 per gallon is a clue that something is amiss. Looking into the reasons why, it is revealed that there is a gas surplus. The supply is unexpectedly large due to people not consuming as much as had been predicted. It's an unplanned glut which they are attempting to be resolve through discounting. Will that work? Who knows. The economy is recovering nicely, but very slowly. To complicate matters, purchases of more efficient vehicles continues to outpace the new pickup craze. Many of those new pickup purchases are claimed to be for the construction market too, which means they won't be used for daily commuting as they had been in the past... back when guzzling was stated as being "*good for the economy*". Things certainly have changed since then. The price of oil being so high is genuine reason for concern though. When the surplus is gone, then what? How high will the price of gas climb?

8-15-2013 **11.5 Years.** That's how long the average vehicle stays on the road now. It's quite a improvement over the 9 years we saw when Prius was first rolled out here. Of course, it also means guzzlers put on the road today will go on guzzling even longer... or does it? Gas prices a decade from now combined with the popularity of hybrids could swing traditional vehicles far out of favor, lowering their value significantly. Fortunately, that means the current fleet will be getting replaced soon. That will stimulate the economy, which is great news. Ironically, not having replaced them due to the economy being bad, was counter-productive. But that situation is quite understandable. Unfortunately, not everyone wanted to acknowledge that. It's the lost opportunity for Volt some of us tried to point out for years. GM needed to be ready with an affordable offering that would generate a profit. Instead, they have a loss-leader with at least 2 years of a wait before the next generation will even be rolled out. Then there's the first-year apprehension they'll have to deal with due to a number of fundamental changes needed to have been made. Both Ford & Toyota will already be well positioned for that, since their next generation will be incremental improvements. And of course, they are currently ready to offer high-volume with profit from the existing models. We are definitely at a tipping point.

8-15-2013 **C-Max Rerate.** That MPG rating from Ford reported as the official EPA values was big news today. Did you know the EPA doesn't actually do the measurements? Did you know there are two types of tests the automaker can use? Did you know the automaker can transfer results from one vehicle to another? Most people don't. And in this case, more than just those assumptions were made. The EPA itself assumed Ford knew what it was doing. The major adjustments to the rating system revisions implemented in 2008 made that easy. People went after Toyota for misleading about MPG, not realizing they had nothing to with measurement criteria. Those updates allowed attention to waver. The recent problem with Hyundai should have been a wake-up call. It obviously wasn't. Prius had hoped Ford somehow improved their system to the degree that the outstanding MPG was realistic. After all, that meant Toyota had potential to do the same. But looking at engineering tradeoffs, it makes you wonder. Prius V (the larger wagon model) sacrificed some MPG for the sake of delivering decent acceleration, despite its extra weight. Simple changes, like a different size reduction-gear in this case, make tradeoffs like that easy. Knowing C-Max delivers more power while delivering even better MPG was a head-scratcher. How did Ford achieve that? Turns out, they didn't. The announcement today was that the EPA value for combined will officially be lowered to 43 MPG. That's quite a drop from 47 MPG. As a result of this, all those who purchase a C-Max will be issued a check for \$550. Interesting, eh? Thank goodness Prius real-world results actually match those estimate values. Of course, will consumers know that. Hmm?

- 8-16-2013** **Energi vs. PHV.** There was a review published today, one comparing Ford's C-Max plug-in to Toyota's Prius plug-in. With both being hybrids striving for optimum efficiency, you'd think there would be mention someone in that article about efficiency. Nope. There was nothing whatsoever about MPG. All it went pointed out was electric-only range & operation. Total absence of the ultimate outcome, the resulting overall efficiency, is a terrible excuse for journalism. The fixation was entirely on "*Electric Range*", which completely disregards the fact that those are plug-in hybrids. Their purpose is to optimize, to squeeze out the highest possible MPG by blending electricity & gas... which the writer clearly didn't understand. Heck, just a simple drive with the Prius in HV mode will reveal that or EV mode at speeds above 100 km/h (62.1 mph). You can clearly see that plug-supplied electricity is being used to achieve MPG clearly not possible from the no-plug model. Yet, when you look at the display, it won't register any of those miles as EV. They'll be counted as HV. Reviewers not bothering to carefully observe will just report what's displayed, not even questioning why EV is so low. They know a full-charge was available when they started. What the heck do they think happened to it? Are how can they possibly not notice the MPG on that same display? Needless to say, I wasn't pleased about what had been omitted. It was review written by someone who didn't understand how the technology work or even what the purpose was. That's very disappointing.
- 8-16-2013** **That Misconception.** This snippet was included in the comments of that comparison review: "*...and expense of installing the up-level chargers at home*". People keep making the assumption that more than an ordinary household outlet is needed. It was mentioned the time each takes to recharge us a 120-Volt connection. Yet, some don't see it. Either that or they are intentionally spreading that misconception. We've seen worse greenwashing many times in the past, so there is no benefit of doubt anymore. Question everything. I'm beginning to think this particular issue is a major influence on sales. Spreading the word that just a standard socket is all you need could make quite a difference. You plug the hybrid in the very same way you do with your phone in the evening. Just connect the charger it came with to the wall. There's no expense. It's just a basic charging device included with the purchase. True, you can install a faster charger at home. But what's the point if you're just recharging overnight anyway? A full recharge using the 120-volt only takes 2 hours and 20 minutes for me. For 80% capacity, it takes 1 hour 45 minutes. The recharging is no big deal. People assume it is.
- 8-17-2013** **Leaf Cutoff.** It isn't everyday you end up hitting the brakes and blasting the horn. To do that to an electric-only vehicle, most people never have. Today, though, it was me doing that. There was Nissan Leaf. He totally cut me off. The driver was so preoccupied with, apparently the screen information inside, he didn't even notice I was next to him on the turn in the adjacent lane. He pushed right into mine. Had I not been lagging behind a little bit, I would have been hit. When I got on his side, he was still looking down. It was frustrating to see such poor driving behavior. But sadly, that's what happens when a technology catches on. Drivers of all types will buy it. Oh well. I seriously doubt that will ever occur again. Makes you wonder what other stuff we'll see over time. Progress includes a wide array of changes. This was one example of technology acceptance, complete with a stumble along the way. Over time, it will become something we take for granted. Some day.

- 8-18-2013** **Whoa!** You knew someone would think this: *"As with all technology, I knew that the price would drop over time. However, I am furious that GM cut the price by \$5K raising the specter of value and marketability. GM marketing seems to remain a one trick pony and short on long term strategy. For the record, I'll be expecting my \$5,000 rebate check from GM – it is the right thing to do!"* None of the enthusiasts using the new-technology argument ever addressed the possibility of an overnight drop. It was always expressed as a gradual process over a long span of time. With the abrupt change we all just witnessed, it was a very real possibility someone would get screwed in the process. But to openly vent their feelings, that's a big deal. Their analogies never covered this situation. It's bad enough finding a markdown somewhere, at some unexpected location due to some unique circumstance. This is actually clearance time, after all. But knowing the MSRP for the new model was slashed across the entire nation and that new 2014 inventory is now available... what should the response be?
- 8-19-2013** **Bike Trip.** I took advantage of having that new lockable hitch-mounted bike-rack again. Being able to toss bikes on the back of the Prius while retaining access to the hatch from both sides makes the convenience factor of spontaneous trips a dream come true. We decided to escape up north for the weekend. It worked out great. Seeing MPG in the low 40's is a result with mixed feelings though. That's far lower than I usually see. Not being able to plug in and driving over 225 miles with such a big aerodynamic disruption on back sure brings down efficiency. Having the A/C run the entire drive hurts too. That's still an improvement upon what other vehicles deliver at their very best. But I've grown use to a higher standard. Easily getting over 50 MPG without plugged-supplied electricity sure is nice. Getting over 100 MPG with the plug is even better. In the end, Summer is too darn short. When you have the opportunity, take advantage of it. Enjoy. Lifetime MPG isn't affected much by those escapes anyway.
- 8-21-2013** **New Reviews.** They are getting better for PHV. It's about time those writing articles for publication about the plug-in model actually convey a decent understanding of how the technology actually works. In this case, a writer expressed his findings starting with: *"I recently drove a 2013 Toyota Prius Hybrid Plug-In which is essentially just a Prius whose nickel-metal hydride battery pack has been swapped for a far more potent lithium-ion pack. The Plug-in Hybrid comes with an easy-to-use external charging cable and the car's batteries can be fully charged in three hours from a simple household 110-volt outlet or an hour and a half from a 220-volt plug."* That certainly got my attention. It was correct & concise. How about that!?! Of course, it went bad from there, fast. It gave the impression all benefit was lost as soon as you accelerated hard or beyond 62 mph. How can someone writing a review drive the car and not report information about vehicle operation or even MPG results? Leaving out such vital detail makes no sense. What's the point if all you do is just mention vehicle specifications? That doesn't accomplish anything. People already have that information available in abundance. Observations from behind the wheel is what reviews are suppose to provide.

- 8-21-2013** **Power Outage.** I came home to a dark neighborhood. We had a mini-blackout. 30 of the homes in the vicinity were without power. I went into my warming house (it had been a very hot & humid day) to find the phone-number to contact the electric company. While in there, I unplugged the recharger for the Prius... just in case. You never know if a surge could potentially flow through the system in a situation like that. We virtually never lose power, since all of the line are underground. Unfortunately, when the power was finally restored, I forgot to plug it back in. So early in the morning, when recharging was set to start, the timer failed. I got an email telling me that. It was a morning I just happened to be up early on too. So, I heard the beep on my phone... but didn't bother to check. Ugh. I so easily could have rectified that error. Bummer. I was right there, doing laundry in the utility room next to the garage. Grrr. Needless to say, I was surprised when the engine started as I was pulling out of the driveway later. No electricity was available. Fortunately, my 25.4 mile drive over the course of 5 hours resulted in a 56 MPG average. That's hardly anything to complain about, but having plug-supplied electricity would have pushed MPG into the 100's. Oh well.
- 8-22-2013** **Arguing Semantics.** The same old problem resurfaced. We are again seeing certain individuals rebuttal with definition quarrels in an effort to avoid facing facts. Today the comment about Volt MPG not being *"any better than similar-sized traditional vehicles"* erupted into a semantic argument. Rather than just acknowledge efficiency isn't even close to that of the choices being offered by automakers as models much improved over their standard product-line, they distract with non-constructive detail. Evading the point is nothing new. We see it all the time. But in this instance, it didn't even make any sense to argue. What would that achieve? So, I'll just change the way the information is stated, as my post stated: I'm changing it to *"doesn't deliver hybrid efficiency after depletion"* and now everyone will know why. Ford's plug-in hybrids are bigger, yet deliver 43 MPG. How is that even close [to 37 MPG]? Toyota's plug-in hybrid is bigger too, and it delivers 50 MPG. Notice how many Volt supporters are also pushing for higher MPG with the next generation? Clearly, the current isn't enough. Give the rest of us a break.
- 8-22-2013** **Enough.** This was the response to my post: *"When is anything 'enough' ?"* I was surprised that was brought up, since that had been the mantra all along with the *"40-mile"* range. But with the recent price debacle, it's realistic to expect pretty much any new angle to be attempted. I followed with: It's when major sacrifices are made, abandoning goals for the sake of drawing attention. Those types of tradeoffs are not worth it. The purpose of achieving profitable high-volume sales is too important to simply postpone. Notice how the computer industry has so successfully rolled out well-balanced devices that could support capacity upgrades later, as the cost reductions would allow? They set price-points and stuck to them. There weren't dramatic & unexpected drops all at once without an upgrade, as we've seen with Volt. With computers, mp3 players, and phones, they've all offered increased memory & battery-capacity as that technology improved. The *"enough"* approach was a carefully thought out and quite predictable process. And as much as certain Volt owners grumble about it, that is indeed the approach Toyota has taken with Prius. Capacity will increase as cost warrants, keeping price at the clearly established *"nicely under \$30,000"* target consumers have expressed as an important purchase criteria. GM didn't stick to that very criteria they helped to establish; they didn't recognize the *"enough"* tradeoff.

- 8-22-2013** **Inevitable.** You cannot post something in favor of Prius on the daily blog for Volt without the expectation of an intense response worded to give the impression of being constructive. It ended up being: *"The PIP is so uncompetitive I wouldn't be surprised to see Toyota abandon it. And if I'm Toyota I'd be very concerned that GM marketing will actually get on the stick and the Volt will start eating Prius for lunch."* There was also a blatant greenwashing attempt, where the person intentionally tried to mislead about range. But that isn't worth anything more than just pointing out the desperation. I responded to the uncompetitive comment with: The choice of battery-capacity prevented the sacrifice of seating & cargo room. It also positioned it to have a cost within the typical range of upgrade options, what we normally see among model differences. We know that Toyota is directly targeting mainstream consumers for profitable high-volume sales with Prius. Adding the choice of a plug but keeping the size to 4.4 kWh keeps it affordable. It also retained MPG, by keeping the influence of weight to a minimum. The competition for Prius is ordinary traditional vehicles, buyers who would otherwise purchase a car like Camry or Corolla. Who is the market for Volt? How many times must that continue to be asked? What is its competition?
- 8-22-2013** **Outcome.** That poke on the blog, intended to serve as a reality-check, ended up just drawing out the worst of the enthusiasts. Those wanting to move on pretty all have already. The remaining cling on to bragging rights. It was a great opportunity to illustrate how bad the situation has got. There is an undeniable divide between those who want progress and those not interested in change. It's an outcome they seem content with. I see that progress on a regular basis following threads on the big Prius forum. The effort to establish that long-awaited partnership is becoming easier to see. They understand that battery-capacity alone won't solve the many problems Volt is having toward the goal of reaching everyday consumers. They know mainstream priorities are quite different from those who purchased a Volt in the past. They see how important it is to allow the design to be altered to achieve profitable high-volume sales. As for the others, they are being left behind. I replied to the rhetoric this way: It never ceases to amaze me how smug some responses are. Crush like a grape? Really? Since when does that superiority attitude represent ordinary GM customers? Of course, just ignoring the problem enables it... giving silent approval. So, that isn't good advice. Focusing on the goals of Gen2 would be the appropriate response. Notice how some are making an effort to guide discussions in that direction?
- 8-23-2013** **Greenwashing.** This particular comment yesterday provided a great feeling of vindication: *"The specially developed Goodyear Assurance FuelMax LLR tires are also designed for performance per GM engineering specifications, and greatly contribute to a fun driving experience."* The hypocritical nature of certain Volt enthusiasts is quite remarkable. They'll say one thing, then later say something else which totally contradicts it. We see outright greenwashing too. A few are still attempting to mislead about EV range, claiming the 6-mile value listed on the window-sticker is the official EPA measure... even though the rating information included clearly states the overall value is 11 miles. They just hope you won't actually fact-check what they are saying. The definition of "blend" is quite clear; it simply means the engine may run briefly. That lack of purity is what they attempt to exploit... again, hoping you won't do any verification. Fortunately, the data itself tells the story. In this case, it's a simple matter of checking. I stated the situation yesterday this way: If those tires contribute so much to the driving experience, we should point out that the plug-in Prius uses those very same tires.

8-23-2013 **Rear Seating.** I had no idea just how limited the rear seat in Volt was until playing with one at the State Fair today. On my previous in-person opportunity, I only looked at legroom. Seeing Volt offered nearly 2 inches less room for knees (specifically 1.9") quickly ended my check. I didn't bother to look at anything else. It was obviously smaller than Prius. I should have continued with a detailed inspection. Looking at room for feet. I noticed just how low the back of the front seats were in Volt, when adjusted for me. The top of your feet get pressed against it. There's no extra as there is with Prius. That discovery came as quite a surprise. I hadn't ever considered that particular comfort measure. Another totally unexpected observation was noticing how low the top of the door was. I'm just 5'8", an average size man. So, finding out I'm too tall is quite out of the ordinary. There isn't a seat adjustment available for the back either. When I turned to look out, all I could see was the roof of the car. To see out the window, I actually had to duck down. That certainly isn't the situation in Prius. Last but not least, there's the lack of a middle seat. Some families, especially those who children have friends, will find that too much of a compromise. That extra seating comes in handy from time to time. Long story short, the appeal to mainstream consumers is clearly in favor of the regular model Prius (and the plug-in). Prius is a midsize car. Volt is compact. There's no contest which one offers more rear seating room. It's strange how GM decided on a size which clearly limited its appeal to the masses.

8-24-2013 **Diminishing Returns.** It's quite a twist when a Volt enthusiast asks a Prius owner: "*Lets be real, where is the real savings?*" How did he expect me to answer? He certainly isn't. The constant bragging about EV range and MPG doesn't tell the whole story. Sadly, responses are vague and don't address the big picture. Constructive posts just plain don't happen. Looking at the data, we see a situation the enthusiasts never want to discuss. Whenever it's brought up, they evade. I expect the same outcome this time, from... Based on the standard measure of 15,000 miles per year:

500 gallons = 30 MPG
375 gallons = 40 MPG >> 125 gallons less
300 gallons = 50 MPG >> 75 gallons less
250 gallons = 60 MPG >> 50 gallons less
214 gallons = 70 MPG >> 36 gallons less
188 gallons = 80 MPG >> 26 gallons less
167 gallons = 90 MPG >> 21 gallons less
150 gallons = 100 MPG >> 17 gallons less
136 gallons = 110 MPG >> 14 gallons less
125 gallons = 120 MPG >> 11 gallons less
115 gallons = 130 MPG >> 10 gallons less
107 gallons = 140 MPG >> 8 gallons less
100 gallons = 150 MPG >> 7 gallons less

The reality of diminishing returns is quite clear. The benefit of saving drops off significantly. Even without a graph to illustrate, it's very easy to see beyond 70 MPG doesn't accomplish much. Take a look at goals. Serious consideration need must be made. Delivering a higher capacity sounds very appealing; however, being real means acknowledging the tradeoff of expense, weight, and space. A balance of priorities cannot include such large penalty. Without achieving a large gain, what's the point?

- 8-25-2013** **Overkill.** More is not necessarily better. Some will attempt to convince you otherwise. Some instead attempt to change the topic. Today's posting attempt was the latter. I was rather frustrated by such obvious avoidance. But then again, that's great confirmation you're focus is indeed correct. In this case, the topic was battery-pack cooling, Air verses Liquid: I see the overkill statement was not understood... or intentionally diverted. The discussion is about hybrids, not electric-only vehicles. Why does a plug-in hybrid that also has a gas engine also need liquid cooling? The engine can reduce load from the battery-pack significantly. Why put a heavy burden on electric draw during times of heavy demand when it can so easily be prevented by briefly substituting low RPM combustion instead? It makes no sense carrying around an engine and a transmission to link it if the system goes out of its way to avoid using it. Hybrids achieve efficiency through the sharing of power sources. That lack of balance, depending entirely on electricity, doesn't make any sense. So what if the engine runs for a few seconds. Does the addition of liquid cooling really justify all that extra expense, weight, and complexity?
- 8-26-2013** **Heat & Humidity.** Record high temperatures here now are making things interesting. This morning's commute was 82°F with the dewpoint at 73°F, which is an extreme for Minnesota. I left work with the A/C running, something I never need that early in day. That meant the expectation of lower MPG than usual. But having 9 miles of driving at 70 mph, following the initial 1/2 mile of suburb driving, I was quite surprised when reaching my standard milestone (at the slowdown, just as the highway descends into the river valley). On a good day, the average will read 150 MPG. Today at that point, it stated 172 MPG. There was more battery than usual still left too, despite being EV and EV-BOOST that entire drive. But rather than running out of electricity shortly before arriving at work, the remainder of the commute was entirely in EV. In fact, I had over a mile remaining. 232 MPG was the overall average. There is no doubt excessive heat & humidity contributed to that unusually efficient morning commute.
- 8-26-2013** **Approach & Outcome.** I posted this today... figuring it would fall on deaf ears, but it still never hurts to point out observations. Back when Prius was first rolled out here, there was lots of arguing about need. People would claim their want was actually a necessity. Now, looking back at the SUV craze, it's easy to imagine how absurd some of the posts were. Remembering how those enthusiasts didn't take that situation seriously, the approach was different with Volt. We instead asked what the goals were and who the buyers would be. The answers changed over time. When referring back to that past, the statements are simply denied or dismissed. They shoot the messenger too. It's hard to believe they still don't take the situation seriously. History was allowed to repeat. Same dance, only the song has changed. Nothing was learned. Such a waste of opportunity. So.... what's next? Do we really just blindly hope for the best? Are we truly naive enough to not even bother specifying any requirements?

- 8-27-2013** **New Opportunity.** It's nice watching the mania with Volt finally coming to a close. The current clearing out of inventory is changing the mindset, taking enthusiasts in a direction they fiercely resisted in the past. They recognize the realities of business and understand what mainstream buyers actually buy. That's progress. It means we can focus on actual goals instead. Hooray! That got me thinking about sharing more examples of what Prius PHV is capable of. Today, it hit me how frequently I drive out to my girlfriend's home. Sometimes, I have a fully charged battery available. Since I don't plug in there, I tend to reserve some capacity for driving home later. The thought occurred to me, what if I didn't? That's not the most efficient decision. Choosing to save is better. But with a distance just beyond the range available and travel speeds at 70, 60, and 40 mph, it's compelling to find out when to use the electricity. Do I use it primarily for EV or take advantage of EV-BOOST instead? This time, my decision was observe boosting. (That's when you travel faster than the EV threshold of 62 mph, using electricity to reduce demand on the engine.) Since Prius is extremely efficient at 60 mph, traveling in HV at that speed instead makes sense; it saves the electricity for later. That way, I get over 100 MPG while traveling at 70 mph... which I did indeed. Boost is great! I'll have plenty of observation opportunities. It's just a matter of choosing when to push that HV/EV button. Details will follow. Stay tuned.
- 8-28-2013** **Growing Concern, part 1.** The rather blatant greenwashing about the "6 miles" continued. I simply followed up with: Fear of blending is so high, the response is to mislead people but how it actually works. Wow! Reality is, plug-supplied electricity is used even when the engine is running. The result is much higher MPG than regular hybrid driving. This morning's commute is a great example. 16.7 miles total. 9 of those miles were on a 70 mph highway. The temperature was 79°F and it was very humid, that meant running the A/C the entire drive. I arrived in my parking-spot at work with 0.4 miles of EV remaining. According to the computer, 7 miles were EV and 9 miles HV. The final average was 196 MPG. So what if the engine ran. The result of that drive was great and it confirms blending uses that electricity to boost efficiency. EPA is nothing but a standardized measure, not an expectation.
- 8-28-2013** **Growing Concern, part 2.** I was flabbergasted by the level of desperation. The antagonists have run out of ways to prevent rising interest in Prius PHV. They see the appeal of an affordable plug-in which doesn't require compromise. It's basically just a regular Prius with enhanced capacity & power. Still in a state of amazement, I replied to the rhetoric with: The average Joe doesn't care about AER. They care about available capacity. Their interest is higher MPG. The information on the window-sticker clearly states 11 miles of blending is available from plug-supplied electricity. That means the engine could potentially could sometime during that distance, but in no way indicates it will or for how long. These continued attempts to mislead are quite vindicating; they confirm the concern that people are learning what a PLUG-IN HYBRID has to offer is compelling. They already like the idea of the engine shutting off when not needed with the hybrid. MPG is boosted from the plug.

- 8-28-2013 *The Next Prius.*** We got our very first bit of information about it today. As anticipated, MPG will be better. Thermal efficiency of the engine will be improved. That was one of the goals Toyota stated. Another goal was battery improvement, which will also be delivered. The entire propulsion system will be lighter too. As we had hoped, the chassis will be improved to deliver greater handling & aerodynamics. Naturally, the cost will be reduced as well. For the plug-in model, there were hints about increased range and wireless charging. In other words, it's an all-around better Prius... as each of the previous generations have been. The press release emphasized the overall goal of reaching 5 million total hybrid sales for the United States by the end of 2016. There's lots to look forward too. It's good to see Toyota continuing to push, even when the rest of the industry trails behind. They clearly are not resting on their laurels as some claim. The goal of replacing traditional vehicles gets more and more realistic each step of the way. Doubt is gone about whether or not that will happen. It's more a matter of when now.
- 8-29-2013 *Planning Ahead, retrofit.*** We're getting bombarded from all sides now. Newbies are attempting to assess the situation based on what they are learning now, without any prior knowledge. It's like looking back at a major natural or political event afterward and saying that outcome should have been obvious. You cannot. Unless you are participating while the smaller events building up to the big one are unfolding, you are unaware of all the elements at play. The outcome is anything but obvious. Anywho, the pot was stirred with this today: "*The current plug-in is really just a retrofit of a gen 3.*" And of course, there was nothing provided to explain what would need to be different for it to have been considered planned. Fortunately, I was indeed a participant. In fact, I've documented those events in great detail. So, I rebutted with: It's easy to jump to that conclusion, especially with the greenwashing effort pushing that very sentiment. Looking closer though, you'll discover the current hybrid is a design under-utilized. Adding the capacity & power fulfills the affordable efficiency boost Toyota had set out to deliver all along... once battery density & cost finally dropped to a reasonable level... without having to change much beyond just the pack itself. That planning ahead allows them to take advantage of economies-of-scale while also minimizing risk in a very uncertain market. It also provided a great opportunity to rollout the first model mid-cycle. They get to real-world prove implementation with the chance to upgrade sooner than any of the other automakers staring at the beginning of a cycle. Think about all the different markets Toyota gets to gather data from, lots of it too. With a system already so well refined, does it even make sense to have the plug-in model profoundly different? Why not just switch priorities instead? Let the 4th generation grow plug demand to the point where the 5th can be offered with a plug standard and the choice of no-plug as an option. The underlying effort is to shift purchases from traditional vehicles to hybrids. Doing that on the scale of millions per year within just 2 generations takes lots of planning ahead, delivering a design already prepped for future opportunities... even if it makes it appear to be a retrofit.

8-29-2013 **Planning Ahead, reach.** Also, let's not forget how many consumers there are who simply never consider the purchase of a "*first*" vehicle. They just plain are not interested in something which could potentially lose value quickly or reveal itself to have problems. Take a look a Volt for a very recent example. MSRP for the 2014 model got reduced by \$5,000. Just think what that did to resale value and the feeling it gave owners who just purchased one for a lot more. With Toyota's rollout starting in just 15 states having strong interest in high-efficiency vehicles and not expanding to nationwide until a potential price-reduction, exposure was carefully limited. It's another example of planning ahead. They can establish the plug-in hybrid market with lower risk to reputation or disenchantment. Having started mid-cycle, it sets them up greater volume right away with the next generation. The business of selling vehicles is extremely complicated. Lots of smaller improvements on a mature platform is very appealing to those who are unwilling to pay for much beyond the basics. That's the situation Toyota has now with Prius. It's a great balance for selling a large number of them. That win-win formula is how to reach middle-market, something antagonists expend a surprising amount of effort attempting to prove false. Long story short, there's lots to look forward to from the next generation.

8-29-2013 **Planning Ahead, parallel.** They spin everything you say. It would maddening at times, if it wasn't for the fact that they deliberately ignore certain things. That cherry-picking is a dead giveaway your information is in strong support of the situation; otherwise, they'd provide reasoning (even if very weak) to eliminate it. No acknowledgement, just outright disregard, is a good sign. I especially like the continued attempts to draw a parallel to Prius development with Volt. Toyota's well planned steps have paid off. They want Volt to appear the same way, even though the circumstances are immensely different. I was happy to point out those circumstances: GM already had EV1, Two-Mode, and BAS experience when Volt was being developed. That's quite a bit of real-world motor & battery knowledge already obtained that cannot just arbitrarily be dismissed. When Toyota developed Prius, there wasn't anything prior to leverage from. They started from scratch. The situation differs greatly from Volt. And as it was so eloquently put (in this thread): "*Without that \$7500, the Volt would be roadkill.*" That clearly adds to the point of not being the same. So, why is there so much effort still to convince us of a parallel? How does having an excuse help accomplish anything? How come focus isn't on what needs to be delivered next instead?

8-30-2013 **Planning Ahead, capacity.** In a truly desperate act, the exploitation of the vague and easily misunderstood EPA rating was brought up again. It was more cherry-picking. Rather than look at everything the EPA numbers represent, they focus entirely on just one... which leads to a false impression of performance... exactly what they want. That's how greenwashing works. You reference something credible, but don't include everything the person needs to know. That way, you aren't actually lying. The omission often goes unnoticed too. So naturally, there's retaliation when someone points it out. On that daily blog, they down-vote the post. Yes, they actually choose to dismiss a fact. Even if it's nothing but information, void of any opinion, it still gets a negative. I find that so vindicating. Their decision is to stick their head in the sand, hoping it will reach -10 so it will disappear from view. That kind of denial is amazing. Anywho, the nonsense was about the "6 mile" rating again. I routinely get more than double that. It's no big deal. Heck, you can even do the math. Volt delivers 38 miles from the 16.5 kWh capacity battery-pack. That works out to 2.3 miles per kWh. Using that same factor, the 4.4 kWh battery-pack in Prius PHV should deliver 10.1 miles. Since Volt weighs 621 pounds more, it's quite reasonable to add another 0.9 miles for Prius PHV. There's a very real penalty for carrying that much extra weight. So when we look at the EPA rating, there shouldn't be any issue. The 11-mile range makes sense, even with the blend potential listing. In other words, they are taking full advantage of the measurement shortcoming. But rather pointing out how misleading the label is, they hope you'll assume it's fine. I still can't believe they try things so easy to disprove. Needless to say, I couldn't resist a reply: Capacity is 11 miles, not 6. That 6 comes from a hard acceleration during the EPA testing cycle. The engine quickly shuts off after that and drive continues for 5 more miles using only electricity. $6 + 5 = 11$

8-30-2013 **Planning Ahead, more.** There is a heavy dependency on battery-pack capacity for Volt. In fact, that is the primary selling feature. So naturally, it makes sense that all comparisons to it will be with respect to its perceived best attribute. This is why Prius PHV is constantly being forced into an EV perspective. Rather than looking at it as the PLUG-IN HYBRID it actually is, there's an intentional distortion & misrepresentation of it being an electric-only vehicle with engine-backup instead. They just plain don't care. That's because the engine efficiency is for Volt so low. Less capacity would result in a far less efficient vehicle. To make matters worse, the recent reveal that the next generation Prius will come with an even more efficient engine makes that bad situation even worse. But coming from the "*vastly superior*" enthusiasts who strongly feel less is too extreme of a sacrifice, they won't ever understand Toyota's planning ahead. In fact, after so many years of stressing that point, it's basically futile attempting anymore. Today, the comment to that affect which caught my eye was this summary: "*So Toyota is tricking consumers to save money and buy a Pip because it has a cheaper battery (smaller product). What fools!*" I found that amusing. Configuring a product to offer a balance is wrong? Wow! Of course, they go out of their way to make sure battery-pack capacity remains the focus. Allowing any of the features to be discussed is an act only a troll would ever do. Just try mentioning how small the seating it back is for an example. Some responses are downright hostile. I kept my reply simple, choosing to include a quote from another Prius owner instead, one who I hold in high regard for all the research he does. I posted: Ironically, the "more is better" approach has proven to be false many, many times. As a friend so eloquently summed up the situation... PiP design was based on a smaller battery having advantage due to lower cost, less environmental impact, higher efficiency, more space, etc. The only downside was the inconvenience of multiple recharges. The wireless charger would negate that - smart move.

9-01-2013 **Planning Ahead, practical.** How any automaker could make the decision to compromise cargo area is a fundamentally important question. After all, the primary factor for rapid attraction to the second generation of Prius wasn't the upgrade to the hybrid system. True, that was a major endorsement to the technology. But when you look back at the offerings of the time, you discover it was the only midsize hatchback offered. There was literally no competition. All hatchbacks back then were compact. Nothing big enough to be practical for a family left a huge void in the market... which Toyota happily filled... which the antagonists worked hard to conceal. Eventually, Prius was vindicated. Now, there are quite a few midsize hatchbacks available. Some automakers are even offering wagons now too. So when you look at Volt, you wonder what the heck. There's a cargo space under a hatch, but area itself isn't flat like the others. The seats don't fold down flush with the rest. The floor has an uneven drop, preventing any tall or long cargo from actually being transported. You get the impression of it being practical, but it really isn't. The area is quite a bit smaller than Prius. Oddly, Ford made a practicality compromise as well. The seats are flush either. The battery-pack for the plug-in model C-Max consumes a surprising amount of vertical cargo space. Neither seems like a wise approach to fulfilling the purpose of appealing to the masses.

9-01-2013

Planning Ahead, refinements. Reading comments recently made by those responsible for the next-gen Prius, they say we can look forward to even better thermal-efficiency from the engine, refined aerodynamics, a lower center-of-gravity, and even more interior space. They also stated the higher system will be smaller and lighter weight. I have no doubt GM will deliver a number of refinements with the next-gen Volt as well. Unfortunately, that will lead to some disenchantment among current owners. Inevitably, there will be some hypocritical responses as well. Fortunately, none of that rhetoric will matter. GM customers will be better off. I went to the State Fair again yesterday. We played with the interior of the Volt there, getting on-lookers involved. The response was overwhelming negative about how small the rear seating was. When I pointed out how low the door was, blocking my view out the window, some were amazed. They even laughed when I pointed out where my head was when the hatch was opened. That's not good coming from a man who is only 5'8" in a car intended to appeal to the masses. Prius quite a bit larger with respect to several seating dimensions in back. Obviously, GM will address that rather blatant shortcoming and it will be a total non-issue. But to get so much denial in the meantime about such an obvious issue, what the heck? As countless Volt owners have stressed, this generation of Volt is only an "*early adopter*" rollout. We all know that wasn't the original plan. It was expected to hit minimum mainstream sales volume by the end of the second year. Clearly, that didn't happen. Enough said. Let's move on... which means enough with the "*vastly superior*" nonsense already. Geez! The next Volt will be better. Why? It's because the current doesn't meet needs of middle-market. We all need to get behind support for plug-in vehicles. That means constructively & directly addressing why high-volume sales vehicles continue to dominate. You cannot just hope for the best from the next generation. It's also a moving target and bragging about aspects of design that aren't even a purchase priority for the typical Camry/Malibu/Fusion and Corolla/Cruze/Focus buyer doesn't accomplish anything. Eventually, those still arguing in favor of large battery-packs which compromise cargo storage and require a substantial premium will finally notice how counter-productive that is. Who do they honestly think that actually appeals to? The clock is ticking. Competition is growing, which complicates matters by confusing consumers with so many choices. Notice how post spin doesn't make any difference anymore? That's because decisions are going back to the basics. That means comparing 100 MPG to 200 MPG is quickly become a moot point. Things like purchase-price and interior-room will be getting much more attention. That means automakers better be prepared for the paradigm shift.

9-01-2013 **Planning Ahead, lemmings.** How would you respond to this: *"To me the PiP was a half-assed job. I swear a bunch of Toyota execs were just hanging out one day, and one said: Hey guys, Nissan and GM are coming out with EVs....shouldn't we come out with one too? I know! How about we just cram a Li-On into an existing Prius! The lemmings will buy them on the Prius name alone, even though the electric range is tiny!"* That kind of perspective & attitude still amazes me, after all these years. Ironically, those making such statements based on nothing but observations after-the-fact qualify as lemmings themselves. Having seen what actually happened when it happened tells a very different story. But knowing the poster simply didn't care, I replied with this instead: Do you have any idea how easy it is for the perspective to be different? Honestly. Some call it "spin", others call it "truth". The point is, it can be labeled as anything they want, since it always comes down to sales in the end. Without high-volume and profit, the ultimate goal of the automaker is not achieved. Investing in the future is great. We've needed the long-term (planning ahead) approach for quite some time. Question is, how much should be invested and how? Does selling a first-gen offering in low numbers and at a loss make sense? What should the second offer? Who will be the target market? Think about how simple of an argument it is claiming Volt has two separate propulsion systems. After all, GM promotes it that way... electric, then gas. Problem is, dual power-sources was the argument against Prius for nearly a decade, arguing you have to pay for twice as much. It could even be said that GM crammed a large battery-pack and added a motor into their existing platform, hoping the lemmings will buy it. We all know that Toyota could have offered greater capacity, since that is in fact what Ford did with their hybrid of similar design. Instead, they chose to stick with the balanced approach, retaining cargo space and package pricing. Noticed how they delivered the plug-in with a lithium battery instead of NiMH? Notice how they increased EV speed from 46 to 62 mph? Notice how MPG is boosted at speeds faster than 62 mph? Notice how they increased power from 27 to 38 kW? Notice how HV efficiency was increased 1 MPG despite the extra weight of the larger battery? Notice how it was all delivered mid-cycle, rather than waiting until the next generation?

9-02-2013 **72.9 Percent.** I was embarking on a vacation up north. There would be lots of opportunity for EV driving. Wanting to save as much electricity as possible, I switched over to HV mode after reversing out of the driveway. The estimated range, which started at 13.6 miles, was now at 13.5 miles. Knowing the system uses EV-BOOST during engine warm-up to reduce emissions, I was curious what the EV restore would be following that. Usually, the system will replenish that boost capacity while you drive. However, that won't happen for the sake of longevity above a certain threshold. This was my opportunity to find out what the values actually were. I hadn't ever measured that before. The "full" charge started at 85 percent. That is also for longevity. 100 shortens battery life, especially in hot climates... as we've seen with Nissan Leaf... which is why it offers a partial-charge option to specifically prevent reaching full capacity. That reduced maximum helps and even lower is better. With Prius PHV, that "ideal" level ends up being 72.9 percent. In terms of a distance estimate, with respect to my particular driving circumstances, works out to 11.1 miles.

- 9-02-2013 PHV Sighting!** During the drive up north, I saw something I've been dreaming about for a very long time... another plug-in Prius approaching. It was the color of mine, exclusive to the PHV model. Sure enough, my distant observation was confirmed up close. The emblem was clearly the larger one, stating PLUG-IN HYBRID rather than just HYBRID. Needless to say, I was thrilled. But there's more to the story. I was driving through rural Wisconsin, a state no part of the initial rollout and far from any major cities. It was either another vacationer or someone ambitious like me not wanting to wait for the upcoming national rollout. It was very exciting.
- 9-02-2013 239 Miles.** The trip was from the southern part of the Twin Cities in Minnesota to the northern part of Wisconsin, specifically the Apostle Islands. Conditions for travel were nearly perfect. It was a sunny day and so comfortable the A/C wasn't even needed. There was a little bit of a wind from behind too. I was thrilled with the results. Despite all that electricity still available (11.1 miles), the efficiency was outstanding. The overall average for those 239 miles came to 59 MPG. That's remarkable for a plug-in hybrid that didn't actually take advantage of plug-supplied electricity. This is why Prius is such a versatile platform. People have a choice of the configuration to purchase and don't even have to plug in still get efficiency well above traditional vehicles. The road-trip experience is especially beneficial, having so much cargo area in back. That convenience is difficult to put a value on though. You have to experience it to appreciate it. Fortunately, the MPG speaks for itself.
- 9-03-2013 Prius, Persona Edition.** This special edition has been elusive. I had been waiting a long time for a close encounter. That day finally arrived. We were walking around town, just sight-seeing. There it was! I had an abundance of time available and was carrying a camera too. The special black-cherry (deep purple) color and the unique alloy chromed wheels really made it stand out. The dark interior looked nicer than I had envisioned too. I like the fact that Toyota offers limited models. They add to the choices while keeping an aspect of being unique still. We'll never know how many of them are on the road. But at least getting an up-close inspection of one was nice. Not everyone gets to. For that matter, many Prius owners are even aware that variations like that even exist. It's what happens as popularity grows. In fact, that's how the market expands reach beyond mainstream buyers... something other hybrids won't even imagine for many years still. Becoming diverse is that next step.
- 9-03-2013 Another PHV Sighting!!** What the heck? There in the dark in front of me was another Prius PHV, this one also that unique light blue. I was beside myself. To see another one, roughly 125 miles from that other driving the other direction the day before, was amazing. What caught my attention this time was the silver strip along the back. That's a distinguishing feature unique to the plug-in models. Sure enough, when I walked around the side, there was the PLUG-IN HYBRID emblem to confirm I wasn't seeing things. What are the odds of such an amazing sense of timing? To not see another in roughly a year, then 2 sighting in 2 days! Unfortunately, the owner was nowhere to be seen. Oh well. I was in a tourist city anyway. So, the encounter would have likely been brief. Oh well. At least I know for a fact there are others out there, coming from non-initial states. This one was from Illinois. It makes me very excited to see there is demand-in-the-waiting. National rollout isn't only a few months away now.

9-04-2013 **Industry Sales.** Economic recovery combined with the timing of model-year clearance couldn't have been better. The entire industry saw a major increase in sales for all types of vehicles. Toyota's report of having sold 44,713 Camry last month gives a great indication of the kind of growth witnessed. That's a great number. Of course, the Prius family did something to make people notice. Monthly sales exceeded that of Corolla. It wasn't by much, but the trend of both higher counts and stronger demand is difficult to deny. That's a very big deal too, when you consider the fact that 40 million Corolla have been produced since its beginning in 1966... which makes it the best-selling nameplate of all time. The liftback (16,157) compact (5,478) and wagon (3,932) models of Prius did well. My favorite, the plug-in model, saw a very pleasing 1,791. It was a very good month. As for Volt, it still didn't reach the rate of 3,750 per month, which would have placed it at the sales rate GM was hoping for over a year and a half ago. The 3,351 that were sold were the result of \$5,000 price reduction. And since there hasn't been any news whatsoever about lithium battery costs having dropped, we have to wonder how much below cost the vehicle is now. Of course, the supporters don't care. They have recently taken the CEO's goal of reducing cost from \$7,000 to \$10,000 as a promise of \$10,000. The "*over promise, under deliver*" is fed by hope like that. It turns into unsupported hype that no one questions. It's so harmful; yet, they do it anyway. We all know what unmet expectations then lead to. Fortunately, we do have Ford pushing along. 621 for C-Max and 600 for Fusion are decent numbers for the plug-in hybrids. As for all-electric cars, Nissan did well. Leaf sales of 2,420 are making people to take notice. Tesla with Model S is the other among those getting attention. The estimate of 1,700 is a big number for a vehicle well out of the price-range of middle-market. Looking at the traditional sedan offering a hybrid model, the Camry & Fusion continue to stand out. 4,729 and 3,694 (respectively) were purchased last month. Hyundai did fairly well with 2,303 from Sonata too. Overall, the outlook hasn't changed. Overall, the industry is still struggling to gain market-share. The progress is far slower than hope and a few sacrifices have been made along the way. Now, I'm more excited than ever to watch what happens when PHV rollout nationwide begins.

9-04-2013 **Ferry Ride.** My Prius PHV crossed a small section of Lake Superior today, without using a bridge. Instead, it was with a boat. That was exciting to drive onto the Ferry... since I still had an ample supply of electricity available. In fact, there would like be enough for me to drive around on the island the entire morning using nothing but EV. Sure enough, that is indeed what ended up happening. We left the boat & dock behind, visiting the small town for provisions before setting off into the wilderness. It was Madeline Island, the only established part of the Apostle Islands. Our intent was to drive to the state park on the other side, then hike along the coast taking lots of photos and having a picnic. The weather was perfect. The location was beautiful. Exploring what nature has to offer while doing it with electricity added to the experience. We had a great time! Even the wait & ride on the Ferry back was a good time. It was definitely a unique day to remember.

- 9-05-2013 PHV Again!!!** What are the odds? This was one that Sea Foam Green color. I drove right by me slowly, allowing for solid confirmation that it wasn't just the regular model. But to add to the already exhilarating situation... it drove right by the other PHV in town, which I had only noticed again moments earlier. And since I was standing right in front of mine at the time, it mean there were 3 plug-in Prius all within the same line-of-sight. Needless to say, I absolutely could not believe what had just happened. Never in my wildest dreams did I expect to see more PHV in such a remote location. But then again, walking around town we had made remarks about how many Prius there were. They obviously work well for long-distance travel. Adding a plug to the equation make the whole situation even more fulfilling. Yeah!
- 9-05-2013 60 MPG and Added EV.** This day of vacation included some driving around, getting away from the tourist areas. We ended up traveling a total of 63 miles. Some of it got rather hilly. The speed was a mix of city & highway. We used the A/C most of the time. Despite all that and not having anywhere to plug-in, the average ended up being 60 MPG. That kind of result from HV mode only is very, very pleasing. The fact that I started with 11.1 miles of EV and ended up with 11.4 miles makes it even better. Rather than a little bit of depletion overall, there was actually addition. Who would have thought you'd get that as an outcome? Instead of using up a little bit of electricity, there was a net gain. That's sweet. I'm thankful for such a result too. Taking 450-mile trips each month is dragging down my lifetime average. But then again, there's nothing more swaying to potential buyers than data consisting of real-world experiences. Life is too short to miss out on opportunities to play. So what if I cannot plug in during those vacations. The point is those are vacations. They should be enjoyed. Today's drive was a great example. We watched the sunset on a secluded Lake Superior beach. That was totally worth it.
- 9-06-2013 More PHV.** Whoa! There it was again. I got to see the Sea Foam another time. Hope had been that I run into it twice, just like the other PHV. But for it to actually happen... Yippee! You don't expect things to work out so well. I felt quite fulfilled. National rollout will be truly rewarding. The time spent observing & sharing experiences wanting others to find those also interesting is well spent when you see them having purchased the same. I cannot wait anymore. Seeing the plug-in model available for purchase locally will be a big step forward. Having to purchase from a distant state, then drive back or hire a delivery service, isn't exactly what you'd consider the usual approach. Being able to go to the local dealer changes everything, making it far more likely to become a reality. With all the real-world data now available, from all the other owners contributing their stories too, there's lots of potential. And of course, there isn't the problem GM faces. Toyota already has a profitable path. Drastic MSRP reductions won't be necessary. The usual price, with some special sales from time to time, should do the trick.

- 9-06-2013** **219 Miles.** We weren't as lucky on the way home as the way there. It was hot this time. The A/C was needed. That meant getting in and out several times for stops along the way, into a humid outside. Blah. Efficiency wouldn't be as good either... or so we thought. To my delight, the outcome ended up being an average for the 219 miles traveled of 60 MPG. That's fantastic... but not the most interesting part. The up & down driving in that area ended up regenerating 2.2 miles of electricity. That's more than I've ever seen. It's an obvious benefit to efficiency too. The big thing though was the discovery that came along with it. The response to that electricity was quite a surprise. When the Prius came to a complete stop at the very bottom, the system automatically switched over to EV mode. That hasn't ever happened before! What the heck? I had been in HV mode since 2 days ago when running out of plug-supplied electricity. Seeing EV suddenly invoke itself without having restarted the system certainly wasn't a behavior I had predicted. Perhaps it thought there may be more opportunity for the large-scale regenerating, so it was attempting to purge the current supply as quickly as possible. That makes a lot of sense from a longevity standpoint. It's a simple way to protect the battery-pack from over-charging. Anywho, that 60 MPG certainly was nice. Learning more about the plug-in system was a nice bonus.
- 9-06-2013** **Finally.** That daily blog for Volt has been dying a slow, lingering, pointless death. Fewer and fewer daily topics are actually about Volt anymore. Most are just reposts of general news from the parent website. Ever since the founder sold it, the new owner (an online automotive group) kept it going and was able to retain many of the original members. Unfortunately, they are the same ones unwilling to embrace change. So, the transition to this new reality of a cooperative culture of plug advocates hasn't gone well. They are still fighting for superiority. Fortunately, that is finally shifting out of their favor. More and more, their posts are countered by constructive content showing they are not taking the situation seriously. Phew! That sure is a relief. Reaching middle-market won't happen until they begin to address mainstream needs. The most recent topic titled "*EV sales report*" certainly helped to do that. It pointed out detail about Tesla Model S and Nissan Leaf, the 2 leaders in EV (electric-only) sales. Also highlighted were Chevy Spark EV, Fiat 500E, Ford Focus EV, Honda Fit EV, Smart ForTwo EV, Toyota RAV4 EV, and Mitsubishi i-MiEV. Remember how GM wouldn't be caught dead selling an EV, how heavily they invested in campaigns promoting the benefit of a range-extender. Something obviously happened. They get quite angry when you speculate what. They also refuse to concede the fundamental difference this situation is compared to the original rollout of Prius. Rather than misconceptions and automakers refusing to endorse, there are a variety of choices from a variety of sources. Some are still desperately clinging to the hope of a miracle shifting preference to Volt rather than it becoming a player among a team of plug-in vehicles. I stated my observation of the situation with this simple series of questions: Notice this topic? Wasn't the point of Volt to prevent EV range-anxiety? If so, why is each automaker... including GM ...offering EV anyway? What changed?

9-07-2013

Retribution. It almost feels like that. There's no intent for anything like revenge, despite the obvious self-inflicted setbacks which easily could have been avoided. There's just this sense of *"Get Over It!"* that really cannot be achieved without making that purpose clear. So, it gives the impression of celebrating a victory at the expense of another. But then again, it's not like the outcome is a surprise. How do you deal with change? What is the appropriate approach? We're starting with stating the evidence: *"What has changed is that the old guard mindset of developing and maintenance of an automotive brand can occur through a series of conversations and 'bright ideas' developed on a napkin are dead. We will probably never know or see what business case underpinned the development of the Volt and the Voltec platform but it is evident the initial business outcomes did not occur as planned..."* I liked reading that summary. My contribution which followed was: GM didn't plan ahead. That was the very same mistake they did with Two-Mode. Watching that history repeat was unpleasant. Constantly being attacked when contributing constructive advice did help the situation either. You'd bring up business need and end up getting negative votes along with accusations of attempting to undermine. Focus was entirely on technical innovation, which GM does indeed do well. That clouded judgment, allowing the hype to get out of control. The resulting poor business decisions were supported until sales fell so far of expectations price had to be dramatically dropped. All along, the message has been to tell management what to do. All those posts telling us to just trust their choices was obviously bad advice. They didn't deliver a vehicle for the masses, because enthusiasts enabled them to build the car they wanted instead. It is disastrous outcome we need to acknowledge and prevent from happening again. Hoping production cost-reductions alone will make it profitable & competitive is yet another example of not being constructive. Those saying we should just be patient and wait have lost touch with reality. We all know GM will need to make sacrifices to get Volt back on track. The next-generation must become the vehicle it was intended to be, which means matching the purchase priorities of ordinary consumers. That requires change. Who here will continue to fight that, making *"early adopter"* excuses and *"vastly superior"* claims rather than helping GM take the next step? Ending that mindset is essential.

9-08-2013 **The Question.** It was nice to see this asked: "*Can Volt hold this 3000 cars per month sales rate going forward??*" The expectation was enthusiasts wouldn't like any answer to that. What will selling more accomplish? Establishing a reputation is great. But when all that money from the government is cut, then what? When a tax-credit was offered for Prius, it was only half that amount and sales were already triple that rate. The purpose was different too; it was to expand the market. Needless to say, there's a very real concern about cost being more than price. GM's original goal of targeting \$30,000 shouldn't have been allowed to waiver, especially by so much. Now, they are stuck trying to figure out how to achieve that... since it is revealing itself to be a very, very important goal. The enthusiast claim that this generation was really only for "*early adopters*" clashes with that question, since fewer would be better. You don't need 3,000 per month to prove the technology. In other words, the situation is quite a mess and there is no agreement upon what should happen next. In fact, asking for suggestions results in a wide variety of responses. I chose to post the following: What about the question of should they? Remember the problem of the past, where sales count was more important than making profit? Getting more out on the road sounds like a great idea, but the reality of selling at a loss and the inevitable end of the \$7,500 tax-credit makes the topic of production-cost a major concern. 3,000 per month is still a rate far short of the mainstream minimum of 60,000 per year. For Volt to become a business-sustaining source of profit it was intended to be, a top-seller among GM offerings, it needs to grow to roughly 5 times that monthly rate. Notice the recent sales of Cruze, Equinox, Malibu, Impala, and Sonic?

9-08-2013 **Based On What?** We see quite a few of these vague comments being made nowadays: "*A PIP would not work for me. I have to go faster than 62 mph and farther than 13 miles.*" But when you press for detail, they rarely ever provide any. They draw conclusions with little to no actual data. Much is still based upon assumptions, just like we saw all those years ago with regular hybrids. The few who did bother to explain their reasoning often revealed misunderstandings and incorrect information. It's amazing we ever got passed all that. So the issues with the plug-in model are only temporary. Easily available real-world data will overcome that. Thank goodness the internet nowadays is so much more accessible than it was a decade ago. Sadly though, we're starting pretty basic. Until national rollout, there aren't even enough curious people to keep online dialog following. It's still just random questions intermixed in unrelated threads at the moment. Oh well. That's a good start. With respect to the quote above, I replied to it this way: Those thresholds are don't actually equate to much. They are mostly just argument points for enthusiasts. My commute is 17 miles, 9 of which are at 70 mph. Overall MPG exceeds 150.

- 9-08-2013** **Another PHV.** Back home from vacation, I was just out doing ordinary shopping. It was quite a surprise to pull into a parking spot and notice clear tail-lights on a mid-cycle update current-generation Prius. Sure enough. When I got out of my PHV to investigate, that was indeed what I saw. There was also the telltale silver strip confirming it was a PHV. This one was white. I hadn't ever seen that color. So, I walked over and snapped a quick photo of the PLUG-IN HYBRID emblem. I noted that it had Arizona plates too. I guess other owners are discovering what a great long-distance travel vehicle it is too. To think that I've encountered 4 different PHV within just 1 week. It's quite pleasing. Waiting for the national rollout has been a test of patience. But then again, not having collected enough real-world data prior to that would have hampered the effort once it began. So, this preparation in the meantime is well spent. I can't wait for that progress to occur. We're getting close to when the ramp I park at for work installs the new charging-stations. There's much to look forward to in the next few months. Today's encounter was a good reinforcement of that.
- 9-09-2013** **Who?** On an unexpected new thread, this comment was interjected: "*It should be said/thought, that the Volt was not designed for people who drive 30k miles a year.*" The topic was a new Prius owner having traded in 2013 Volt to get it. That's something certain few particularly stubborn Volt enthusiasts said would never happen. It did. I was intrigued. That comment provided the perfect opportunity to ask again, to a new audience on the big Prius forum: *Who is the market for Volt?* That question has been asked countless times over the years. The response was never clear. It still isn't either. What about 20k per year? Heck, even 15k becomes uncertain when you consider the demands of heating in the winter. *What is the best balance of capacity & price?* That should be the question asked. Evidence that price was too high is overwhelming at this point. Capacity was too much of a tradeoff, especially when you also factor in rear seating space. So, the dilemma of what should be delivered for the next generation is still very much an issue. Taking into the expiration of the tax-credit makes a challenging situation even worse. The topic of "*designed for*" is a very big deal. Who?
- 9-09-2013** **Definitions.** I'm done playing that game. Today is my 13th Anniversary. Yup, 13 years ago I bought my first Prius. The memory of that day, so long ago, is still quite vivid. It's hard to believe so much time has passed since then. Those driving experiences have been great. I especially enjoyed the discovery process that each Prius upgrade included. Some of them really made an impression, reinforcing the belief in a better future. As you imagine, the bickering about definitions still does continue. Thankfully, most of it dies out quickly. That's a good sign. You never really squash beliefs. They just become easier and easier to move beyond... which is what it's all about... taking the next step. I chose to state the situation with: Way back when, the purpose of defining hybrid types was overwhelmingly clear. Now, most people don't have a clue what the problems even were that those terms alleviated. The ultimate point was make people aware that all hybrids were not the same. Consumers today know that. Mission accomplished. Focus has since shifted to other things, like HV efficiency and EV range.

- 9-10-2013** **Priorities.** There are some who still don't have a clue. That's why they are enthusiasts, rather than supporters. The difference is one favors want and the other favors need. Today's frustrating example of this was: "*The Prius will never achieve the overall mileage of a Volt if driven in the normal driving pattern for which the Volt was designed.*" It's hard to believe that type of nonsense persists after all this time. Oh well. I'll keep chiming it with doses of reality: The purpose of today's topic was to point out the importance of aspects other than mileage bragging rights. Automakers need to sell lots of vehicles at a profit. Volt supporters do everything they can to avoid addressing details of that reality. Notice the attempts to distract & discredit? So far today, I've driven 35.1 miles with my Prius, starting with a full charge at home and then recharging at work. 25% of the capacity remains. I'll be heading out later. The average so far is 126 MPG. That's a great result from a much smaller battery-pack, a size chosen specifically to keep cost in check and not compromise interior space. Toyota made cost a high priority. GM's decision to deliver a vehicle that clearly disregarded cost is now becoming a very real problem. The abrupt drop in price clearly confirms it wasn't a good move. Cost should never have been allowed to grow so much. They didn't take they own original goal seriously. That mistake is unfortunate. What should GM do now for consumers, between today and when the next generation gets delivered? That's a lot of time in a constantly advancing market. Selling at a lower price and hoping for the best isn't much of a strategy.
- 9-10-2013** **EV-BOOST Rate.** I've never actually looked into what it really is. After all, when you're basing numbers off of just an estimate, the margin-of-error can be quite pronounced. Anywho, I was curious. When driving around in only EV, that range estimate value is somewhat realistic... as long as you don't waver too much from your driving routine. In other words, if it says 13 miles, you're likely to get 13 miles. But when you enter EV-BOOST mode (when the engine starts up to assist), there isn't necessarily a 1-to-1 ratio of electricity. The rate is somewhat lower. But how much? To find out, I have to find a long stretch of highway where I can drive a constant speed and still have a fairly full battery available to work with. My first try was at 65 mph. According to the display, my EV range estimate had dropped 5.8 miles. I had actually traveled 7.5 miles though. The outcome was as I had expected... since I knew Toyota has improved the depletion over the early model plug-in. In fact, that was the point of having done so much real-world testing. Optimizing the system to get greater efficiency from less battery is a great outcome. My second was even better. Traveling 3.7 miles based on the estimate, actual travel was 5.4 miles. That distance is obviously just a small sample. But it serves as confirmation of rate not being a simplistic as most people assume.

- 9-12-2013** **13.9 Miles.** That's the highest EV range estimate I've ever seen. My particular driving pattern doesn't contribute to higher expectations. A few owners report seeing values over 17 miles. That would be interesting. For me, today's 13.9 miles was a record. Unfortunately, I didn't take a photo either in the morning or in the afternoon. Having seen it twice, I'm hoping it will happen again. Maybe I will. Maybe I won't. There's no way to know. It doesn't influence outcome anyway. In fact, it's just the right set of circumstances. With lots of driving while holding a non-depleted charge and the daytime high-temperature falling, the variables aren't what I normally encounter. Most of the time, the value displayed after having just unplugged is in the upper 12's. Seeing low 13's is limited to good Summer conditions. Excessive heat causes a drop. Lots of driving around without any EV available does too. But that's normal; patterns are not. Real-World driving takes you randomly all over the place. After all, life is too short to miss out on opportunity. That's why the estimate doesn't mean much. For that matter, the resulting MPG from day to day doesn't either. It's still well above what a non-plug hybrid can deliver... which is the point.
- 9-13-2013** **Endless Rhetoric.** The spinning of intent & definitions is never ending. It goes along well with the moving of goal-posts. When something doesn't turn out well, they just claim something else instead and deny claims of the past. Ugh. Today, it came in the form of: *"Just too bad they didn't capitalize on the opportunity to continue to innovate."* Coming from someone who obsesses with bragging rights, it was the opposite of being astonished... same old rhetoric. That's why range is so important for Volt enthusiasts and why such a comment would be made to disparage Toyota's effort. Targeting the masses isn't important to them, which is why the endeavor to deliver a well-balance product isn't appealing. In there mind, being "middle" is a failure. So, no matter what you say, not being an extreme is unsuccessful. I put up with the self-deprecating attitude anyway. Despite having an unreceptive audience, I responded with: Having worked hard to deliver an affordable plug-in hybrid fits the definition of innovate quite well. Keeping kWh size to a minimum, sacrificing seating or cargo space, and switching to lithium certainly qualifies. And isn't the point of capitalizing to make money on each sale? It's too bad the effort to deliver high-volume isn't considered being innovative.

- 9-14-2013** **Safe Driving.** An intriguing side-effect of having a vehicle with a display on the dashboard, showing you how it achieves outstanding efficiency, is how it transforms your driving. That heightened awareness sours appeal of exceeding the speed-limit and aggressive maneuvers. You lose interest in favor of higher MPG results. Coincidentally, that also equates to better safety. Unfortunately, not every aspect of safety is influenced. I've never seen either of the following from a Prius driver, but someday it will probably happen... Roundabouts are new here. Drivers who got their license years ago were never trained how to use them. As a result, I'm seeing a lot of vehicles stopping completely when they approach, rather than just yielding. That's a scary surprise when they halt like that for no reason. Without anyone else is even in the roundabout, that unexpected stop could easily cause an accident. The other problem which has an even greater accident potential is left turns on a red. Now that there are flashing-yellow signals at some locations, people are assuming the same allowance to turn is available for solid-red elsewhere too. I'm guessing they think that stoplight simply hasn't been upgraded yet. Whatever the case, I witnessed a driver getting honked at today for not turning on a red. People were in the crosswalk at the time too. It was a blatant disregard for everyone's safety. I couldn't believe what I had just seen. Sadly, that same intersection has those turn violations on a regular basis. It's scary knowing some people just plain don't care. At least there's some sensibility coming from Prius drivers. I especially like the fact that my particular model includes collision-detect, a feature that triggers the brakes and sounds an alarm when the radar system senses a stationary object directly in front of the vehicle.
- 9-15-2013** **Realism.** It sure is nice seeing the greenwash efforts fizzle. In the past, any victory was considered a gain. Fighting for the sake of winning a battle, rather focusing on the overall objective, isn't resulting in any progress anymore though. Looking at it another way, the audience has changed. It was easy to get Volt to appeal to enthusiasts. Doing the same for middle-market just plain hasn't been working. Mainstream buyers have very different purchase priorities. They simply aren't interested in paying a premium. Balance is vital. Prius offers that, hence the popularity it earned. As time progresses, it becomes easier and easier to see that's exactly what the plug-in model also targeted. Reveals of next generation intent confirm that. Toyota is striving to deliver a realistic high-volume & profitable solution. That idea of realism frightens those still hoping for the best from GM. The recent desperation of post content makes that obvious. As the market embraces that idea of plugging in, we're all seeing Volt goals clearly didn't match and the next generation will be quite different. Watch what happens with the 2014 model. How many \$5,000 discounted ones will actually be produced & sold? GM has been altering plans to better align with what Toyota has been doing all along. That's a winning solution for everyone... but that idea of change sure upsets the enthusiasts... until they consider how well Cruze, Malibu, Impala, and Sonic are doing. They are the true competition. Reality is crashing down. Business needs can only be disregarded for so long.

9-16-2013

Fall Approaching. It was 45°F degrees this morning. That's a sure sign it isn't Summer anymore. Fortunately, that isn't cold enough to affect the battery-pack or electrical resistance yet. I had the extra time to take the slower route to work today. It runs along the river valley, which is quite scenic. So, it's the nicer choice even without the benefit of not needing the engine. That provided a great opportunity to measure range. Just like when my plug-in Prius was new, I made it all the way to the on-ramp for the highway river crossing using only electricity. That's 13 miles. There was just a little under one mile left still. Firing up the engine at that point works best, since the resulting power can be taken advantage of prior to reaching the fully warmed temperature. Being able to some EV for the remainder of the commute is nice too. The overall distance ended up being 17.2 miles, driving directly to the charging-station, rather than hiding in the lower level until the afternoon... since there is no need to worry about a super-heated interior anymore. The car will stay comfortable with Fall approaching now. Anywho, the overall efficiency came to 262 MPG. No complaints about that outcome. Though, I do miss getting even better in the dead of Summer from the engine warming up faster. Seasons change. Prius handles them well. This morning's drive was a good example of that.

9-17-2013

Diversity. Watching discussion focus on new topics is quite refreshing. In the past, bringing up the topic of a pure EV absolutely infuriated the Volt enthusiasts. Their entire philosophy of the market revolved around "*range anxiety*" fear. So even when you brought up the concept of diversity, they'd get angry. Pointing out how GM could so easily reuse the same electric motor in Volt to deliver a vehicle depending on it entirely, a system without an engine, stirred hostile responses. That was truly remarkable. Now, they've embraced the idea. Talking about a dramatic change! Of course, sales of Volt confirmed shortcomings. GM's announcement to deliver a 200-mile range EV pretty much removed all doubt. So, the attitude adjustment isn't exactly a surprise. Their one-size-fits-all approach clearly didn't work. But then again, when I'd point out the larger motors & engine in Camry hybrid they'd get very argumentative. They didn't like that type of divergence either. In fact, any type of variety resulted in upset... especially the thought of a smaller battery-pack. Now, things are quite different. Cost and the desperation to retain attention has resulted in hypocritical posts. They're contradicting the very things they held most dear. It's the ultimate confirmation of progress. Abandoning their own principals (want) in acknowledgement of what the market actually needs is a big step forward. Too bad that journey to get here had to be so painful; however, they did bring that about themselves. After all, refusing to address the parallels to Two-Mode was their own choice. They assumed it was impossible to fall into the same traps twice. They were wrong. It happened.

9-18-2013 **That Question.** How many times did the "Who?" question have to be asked before it became obvious that expectation didn't actually match reality? Today, it was enough. The outcome could no longer be denied. It came as the result of this comment: *"70% of Volt trade-ins are from non-GM brands. In other words, most people who buy Volts are not GM fans."* When those loyal to GM don't upgrade, that's a very real problem. Isn't the goal to replace traditional production? Last year in the United States, there were 2,082,504 purchases of Toyota vehicles. 327,413 of them were hybrids. Unfortunately, there's no way to know what the trade-in percent was. But that replacement quantity is genuine progress. We know that overall Prius sales grew and Corolla fell. And that's just here. Over in Japan, the favor for Toyota hybrids is much higher. Remember the *"too little, too slowly"* concern? It's why most of the GM fans have given up on Volt. A simple look at recent posts on the big GM forum confirm that. It isn't discussed anymore. Interest has shifted to competing with Tesla and Nissan with EV offerings. With the government holding of GM stock down to 7.3% (a huge reduction from the original 61%) and the bailout money just an ugly memory now, the idea of moving on is very appealing. So, the new outlook makes sense. Nonetheless, a wake-up call to those still hoping for the best got this: Offering a product that doesn't appeal to its own consumer base should raise a red flag. In other words, people simply replacing their old traditional GM cars with new traditional GM cars is reason for concern. Why aren't they switching to Volt instead?

9-19-2013 **Missed Opportunity.** No amount of spin can cover up the reality that late 2010 was the long-in-the-future targeted date to deliver something truly competitive. That effort obviously failed. Fine. We move on from there. Right? Apparently not. Looking through the dedicated Volt forum, I read a new thread from yesterday that went on for 5 pages comparing MPG results to Prius. You'd think the plug-in. Nope. It was just the regular model. They still absolutely refuse to even acknowledge PHV existence there. That's unbelievable! The very idea they'd be so stuck in past is quite unexpected... or is it? Getting back to the basics makes sense. They know the current design is heavily dependent upon having a large battery-pack. Scaling back to reduce price & weight, as well as improve interior space, is quite unrealistic with an HV mode so inefficient. They may finally be hearing what some of us have been saying all along, since well before rollout. All those years ago, we stressed the importance of delivering hybrid MPG following depletion. Why? That should have been obvious. With such a design, the system could be offered in a variety of configurations... at little expense. Not having that flexibility means missed opportunity... which only now is finally getting realized. One size does not fit all and the penalty for taking too much time stings. What a waste. Hopefully, the lesson is learned. We'll see.

9-19-2013 **Power Request.** During engine warm-up in the plug-in model of Prius, the system runs in EV-BOOST mode. This is when plug-supplied electricity is taken advantage of. The engine is limited to 1500 RPM. The result is a reduced emissions, as well as less wear & tear on the engine. It's a win-win situation... especially when you see that first minute-segment on the display close to 100 MPG. That's a heck of a warm-up improvement over Prius models without a plug. The catch is, power is held back. In virtually all cases, there's more than enough anyway. The only time you'd need more is for those surprise situations on a highway ramp, like when someone is going quite a bit slower or faster than expected. When that happens, you just drop the pedal. Just like any other vehicle, it's a request for more power. For the plug-in, that tells the computer to override the regular process. I did that today, since I hadn't in ages and wanted to witness the outcome. The system exceeded the 1500, shooting RPM up to 3568. The Prius took off. Normally, that'd be the end of the story. After all, the warm-up process only lasts just a little over 1 minute. But in this situation, it had only begun a few seconds earlier. The assumption had always been the override cancelled warm-up from that point. Turns out, it actually doesn't. As soon as I let up on the pedal, the 1500 RPM threshold resumed. I hadn't expected that! The system was back to EV-BOOST again, despite being in HV mode... which is how I started the engine in the first place, just as the Prius entered the ramp. The behavior of that power request was quite impressive. It was more proof that Toyota really gave a lot of thought to account for every situation a driver could potentially encounter.

9-20-2013 **Spin.** We've dealt with quite a few outright lies about Prius over the years. The most recent is that the plug-in model cannot climb hills without the engine starting. Yesterday, on the way to lunch with a friend, I pointed out how it effortlessly did... using only electricity. There were 2 large inclines for us to observe firsthand. One has a speed-limit of 30 mph and the other 55 mph. Neither presented a challenge. The Prius flowed along with traffic for both... never starting the engine. But no matter how often you provide examples like that, they refuse to accept. So, we get post after post stating that isn't possible. Other claims as more difficult to dispel, especially when their origin stems from a misconception. Antagonists take advantage of that. They lead you to believe the system works differently than it actually does, like when the plug-in model exceeds 62 mph. They give the impression the electric portion is no longer available at faster speeds. It's a pain dealing with the spreading of that intentional misinformation. But we manage though, since facts supporting it aren't too hard to share. Online video makes that relatively easy, at least for those who to watch them. Some people don't. The most difficult to deal with still is the spin. That's when they alter something in a subtle way, changing the topic just enough to confuse readers with the hope to discredit the poster. For example: "*The alleged higher efficiency of the PiP-ICE is merely intellectual. Real world tells otherwise.*" No one ever made that claim. What was actually stated is that the depleted efficiency is higher with the plug-in model than with the regular. That's well proven too; we have lots of real-world data. His spin was to make you think it was the efficiency of the engine exclusively. In reality, it's the entire hybrid system. Having owned a 2010 and now driving a 2012 plug-in, I can tell you for a fact that higher efficiency is true. That better battery delivers & captures more electricity and the engine shuts off faster, both for warm-up and while driving. It's frustrating to read spin. But then again, it's confirmation the antagonist is desperate. Resorting to such tactics is confirmation nothing constructive worked. They realize what they support isn't as good as they had hoped.

- 9-21-2013** **Prius Hate.** That thread on the big Prius forum lives on. There are constructive exchanges of observations & experiences. Some find it hard to believe particular attitudes & reactions still happen. For me, in a region highly receptive to change, our embracing of hybrids is the norm. You don't encounter those extremes here. Other regions aren't so fortunate. Low resistance doesn't necessarily translate to high-volume sales though. It just means you won't encounter a backlash. Reaching those content with the status quo still present quite a challenge. But at least the hate some report doesn't happen everywhere. That's progress. The response which caught my attention started with this: *"Who says that stuff? To me the modern day Prius owner seems like a regular person just liking the car..."* It came from another Prius owner who also lives in Minnesota. So, I could definitely relate. I chimed in with: That's the rub. Prius has become a regular car. I see those saying that stuff also waving the flag, close-minded to anything not American... even if their Detroit vehicle has parts from overseas and was assembled outside of the United States, it's still better than what we drive. Neither vehicle price nor emissions matter to them. It's all about bragging rights, size, power, etc. Someday we'll get past all that. The next generation of Prius will help push that change along, reaching more and more everyday consumers.
- 9-21-2013** **EV versus EREV.** We all know what an EV is. Those electric-only vehicles, like Nissan's Leaf and the models from Tesla, certainly have garnished lots of attention lately. EREV on the other hand, most people still don't have a clue what that is. The definition is so vague, it overlaps with PHEV, those plug-in hybrids like Prius, C-Max, Fusion, and Accord. In other words, Volt marketing has fallen apart. They backed themselves into a corner so tight, there's no real category to support anymore. The actual differences to other choices with an engine and a plug vary too much for that specific vehicle to justify its own category. EV is still quite unique. Popularity of them is growing. As battery cost drops, announcements of intent to deliver range above anything that would cause anxiety are increasing. That concept of *"range anxiety"* depends heavily upon cost remaining high. Too much of a reduction opens up opportunity for very affordable plug-in hybrids... so much so, a configuration sacrificing interior space just to squeeze out more electric miles becomes a questionable tradeoff. A popular Detroit newspaper published an article today highlighting GM's new effort to deliver an affordable 200-mile range EV. This recent focus change is drawing so much attention, the once much-anticipated Cadillac ELR (a second, more luxurious model of Volt) now appears to be delayed. Rollout has been pushed from late this year to early next year. Reading the online comments posted, it's clear to see how low expectations are now. The negativity related to profit and promises of the past haunt GM. This quote from that article vindicated those who stated Volt wasn't making a profit yet: *"We'll sell more (Chevrolet) Volts and lose less money on the Volts than they'll lose on the (Tesla) Model S."* What else can be said? The lack of diversity and the need to sustain the business is pushing GM to change. As for those enthusiasts who claimed this wouldn't ever happen, they'll vanish. Progress means recognizing successes & mistakes, then moving on.

9-21-2013 **Losing Money Fallout.** Reaction to the comment about Volt losing money sure is bringing out the worst in some people. The dishonest defending is so blatant, it's difficult to resist responding. The first was: *"GM said from the start it will take at least two model cycles to start churning out a profit."* That just plain is not true. No statement was ever made to that affect. In fact, the only mention ever about cycles came after rollout and it claimed the next would be profitable. That's only one cycle. Of course, we were led to believe profit would come when mainstream volume was achieved... which would have been by the end of the second year, not cycle. Perhaps that's a misunderstanding. Perhaps it's more spin. Who knows. Arguing isn't worth it. This statement falls into that category too: *"Folks have to remember that this is new technology and it will take years to generate a real profit. It took until the Prius' ninth year on the U.S. market for it to generate a profit for Toyota."* We know that isn't true either. Profit was achieved by the end of the first cycle, when the non-hybrid, detuned engine, substituted transmission variant was rolled out to help achieve economy-of-scale cost reduction. Remember Echo? To claim that the entire second cycle (generation) wasn't profitable is truly amazing. But then again, it supports the previous claim. Defenders stick together. So what if it doesn't even make sense. Logic is often dismissed when it comes to admitting mistakes anyway. Fallout isn't pretty. It's painful to admit mistakes. That's why no arguing. It isn't constructive. The already know all too well that expectations weren't met. Identify what steps need to be taken at this point, then take them.

9-22-2013 **Distorting History.** The fallout is getting so bad, some are just making up their own version of history to justify Volt's struggle. We're well past the downplay stage now. This is what I was greeted with first thing in the morning: "*People forget Toyota with the Prius a far less ambitious car. It took 2 generations for it to appear outside Japan. And the 1st model year sold all of 300...*" That sure stirs the desire to get a coffee and starting blogging. Prius was extremely aggressive. When the United States government refused to accept Toyota into the PNGV (Partnership for a New Generation of Vehicle) program, Toyota took matters into their own hands. It was a effort started in 1993 to advance the industry, with a specific target of delivering 80 MPG vehicles. That was a very big deal. Toyota's exclusion made it even bigger. By 1997, concepts were being revealed. There was much excitement about the potential. Early prototypes were expected to follow. Toyota astonished the world then. In October 1997, they revealed their own high-efficiency vehicle. Only difference, it wasn't a prototype. It was a production model ready for rollout, which would begin just 2 months from then. Detroit automakers were absolutely blown away. Toyota was far more than ambitious than they ever imagined. Sales of the first model year began December 1997. It was only that single month long. Selling 300 of an entirely new type of vehicle in such a short amount of time was absolutely amazing. Attempts to distort cannot alter that history... which was 16 years ago! Remember how backward the industry was then? Gas was less than \$1 per gallon and the SUV craze had only just begun. As for the 2 generations claim, that's a blatant lie. Dishonesty on that scale is troubling. Many people still don't consider the first upgrade to Prius, back in 2000 for the rollout to the United States, a true generation. That was the first change. It was only 2.5 years after the original rollout. August 2000, deliveries of it began here in the United States. I got mine on September 9. In no way can any of that quote above be considered constructive... and that's not even taking into account the extensive history GM already had with motors & batteries prior to Volt rollout which Toyota did not with Prius. There weren't tax-credit incentives available either. Some are getting so desperate to prevent this version of Volt from fading away into memory, they're willing to say anything. That's sad. But then again, we saw this coming. Remember Two-Mode history? Notice the parallels?

9-22-2013 Electrification Approach. There are two fundamentally different ways to approach electrification of vehicles. Toyota is clearly aiming squarely at the mainstream, attempting to phase-out their traditional production with a wide variety of hybrids. That means reasonably sized steps (affordable choices) offered in high-volume without having to wait. The opposite extreme is delivering a small number of expensive vehicles, aiming directly at enthusiasts instead. The latter considers those owners as early adopters. That raises the question of how to reach middle-market consumers later on. It also makes you wonder how long we'll have to wait in the meantime. After all, a new traditional vehicle purchased today is very likely to still be guzzling gas a decade from now. That's a very disturbing thought many Volt supporters absolutely refuse to acknowledge. They don't see any problem with the large quantity of traditional vehicles still being sold each month. They show little interest in business profit either. Incrementing battery-capacity as energy-density and cost justifies is a concept they just plain don't want to accept. It's bizarre. But then again, the poor efficiency following depletion forces them to accept the reality of a small battery-pack being uncompetitive. In response, they like to throw out theories like "*innovator's dilemma*" and "*disruptive technology*" as reasons for the approach taken. Some factors involved make sense too. But typically, that falls into the trap of cherry picking. Looking at the big picture (the automaker's entire production) tells a very different story. 2014 will be an interesting year. Details of next generation offerings will be revealed. That will tell us much about approach. After all, the market is still quite fickle. Things like fast-recharging and charging-station availability are far from well established. Heck, even the idea of simply plugging a charger into an ordinary household 120-volt outlet is an option many consumers aren't even aware of.

9-23-2013 Trophy Mentality, post. That was the worry right from the start, all those years ago. It was the new variant of smug. The enthusiasts didn't care either. Long story short, bragging rights dwindled down to basically just EV range. Even that fell short of expectations, but at least it was still more than the competition. And since cost wasn't a priority, they'd remind you know of every chance possible. It's why the idea of a smaller capacity battery as an affordable option always resulted in such harsh reaction. It was attitude over sensibility. They'd appeal to emotion. Sadly, that sentiment still persists with a few: "*They went all in on just regular hybrid tech. Eventually they'll come around to EV's. First they need to improve the EPA rated 6 mile electric range in their Plug-in Prius. That's embarrassing.....*" Reading posts like that never ceases to amaze me. Not only does it convey a terrible attitude, it also includes greenwashing. Continued efforts to mislead about capacity is what I'd consider embarrassing. Why would any true supporter allow such blatant efforts to misinform & confuse? We call those who do exhibit that behavior antagonists. They don't contribute anything constructive. The trophy clouds their judgment.

- 9-23-2013 Trophy Mentality, reply.** This is how I ended up responding to that particular post, which just happened to be on a general blog for all hybrids: We all know the 4.4 kWh battery-pack delivers more than 6 miles, that there's 5 miles of capacity still available after that brief moment the EPA test triggers the engine. Toyota is being honest by not gaming the system to show that higher value. It's a PLUG-IN HYBRID, not an electric-only vehicle. That means the engine will run from time to time. While cruising at high speed, the EV capacity is consumed as HV miles delivering over 100 MPG. You still get that total of 11 miles worth of electricity, regardless of how it's consumed. With my Prius PHV, here in Minnesota, I get 9 miles of EV in the dead of winter. During nice days in the summer, I get 14 miles of EV. So, whenever someone refers to the 6 miles, it is necessary to question if they understand the purpose of a plug-in hybrid. After 28,522 miles, my average is 77 MPG. It's quite clear to me: the electricity boosts efficiency.
- 9-23-2013 Trophy Mentality, calculation.** Knowing his effort was an obvious attempt to mislead & confuse, I followed up with the actual calculation. After all, who would dispute facts? Naturally, an antagonist would... hence the label. Nonetheless, at least readers would have some actual detail to consider rather than just vague claims. Doing that math is simple. Too bad most people don't bother. Posting the numbers helps. Sadly though, the antagonist will pretend that particular information was never provided. We've seen it countless times already. I persist anyway. Like real-world data, eventually, people will notice the greenwashing. Here's what I submitted, using Volt's own specification for comparison: 16.5 kWh = 38 miles. That works out to 2.3 miles per kWh of electricity, which means 4.4 kWh = 10.1 miles. Then when you take into consideration Prius PHV weight 621 pounds less than Volt, it's easy to see where the 11-mile EPA rating came from. The capacity is clearly there.
- 9-23-2013 Trophy Mentality, worst.** As expected, the calculation was simply ignored. They cherry-pick, which is why the big picture is common disregarded. The response ended up being more belittling: *"It's the worst electric only range of any plug-in hybrid. That's embarrassing from the hybrid world leader regardless."* To witness such behavior. That's embarrassing. No wonder many of the supporters abandoned the Volt blogs. Now, the effort is to stir attention on the one for hybrids instead. Fortunately, forum discussions are different. There's half a chance of something worthwhile emerging. Most blogs only survive a day. Some last a few days. That's it though. There's nothing like the history threads support. Blogs just abruptly end. Participation vanishes. He kept trying there anyway. I even got a "LOL" when I posted the following: Keeping size small enough to be affordable and not compromise legroom or cargo space is embarrassing? Wow! Someone needs a priority check.

- 9-24-2013** **Accord Hybrid.** Details were revealed yesterday. There's obvious skepticism about actual MPG verses the estimate, but the 2-motor system is clearly a big step forward over the original ASSIST system. It's a little strange though, the actual operation is a little vague. The plug-in model delivers. In fact, it outperforms Volt to the point where even the Volt enthusiasts are scratching their heads. Whatever the case, the hybrid itself looks nice. With a \$29,155 base MSRP, it looks to be a reasonable competitor with the other high-efficiency sedans currently being offered. Honda appears to have reinvested well. It's unfortunate that took so long. But the market is relatively early anyway. Toyota has pretty much dominated over the past decade. Honda is smaller too, having to also deal with Ford directly. Ultimately, it should be a win for the market as a whole. There's growing demand around here as the misconceptions of the past become difficult to remember. Hybrids continue to improve. This is yet another example of that. They are no longer viewed as a niche anymore. They are here to stay. Watch for this renewed entry.
- 9-24-2013** **0.1 EV Miles.** After a year and a half of driving a Prius PHV, the act of estimating becomes second nature. I've got to the point where I'm so familiar with roads & traffic that I can watch the EV value drop to 0.1 miles and still make it home on electricity... even though I still have 2 short blocks and a small hill to climb. The act of braking regenerates enough electricity that I end up driving into the garage with only a tiny distance of EV to spare. I've grown well aware of how much the battery-pack will be replenish as I enter the valley and slow down leaving the highway. But after having driven those routes that many times, it's no longer an act of guessing. The pattern is easy to remember. I hadn't realized it would become so predictable. That make sense though. Being able to plug in after having used the capacity to the fullest is a good use of the battery. Why not? It's not like Toyota stresses it anyway. "Full" is actually only 85%. That helps to ensure longevity. "Empty" is 23.5% for the same reason. There's still HV capacity available beyond that too. So, taking advantage of EV and the button to choose when to use it works out really nice.
- 9-25-2013** **2014 Corolla.** I got to see one this evening. It is interesting to watch the non-hybrid side of Toyota take another step forward. The introduction of CVT and LED is perplexing to imagine from the perspective of having grown use to no shifting and better illumination already. What will the typical consumer simply looking for an reliable & efficient traditional vehicle think? Whatever the case, it's an undeniable move away from the status quo. Time will tell. It shouldn't take long either... with the rollout of the plug-in hybrid nationally so near. That pushes the regular hybrid even deeper into the mainstream. I'm very excited about that. It's a rather subtle paradigm shift, easing people into the mentality of expecting non-traditional improvements. Change is definitely a good thing in this case. Like the slogan: moving forward.

- 9-26-2013** **Porsche Panamera SE.** At the final stoplight before reaching work, I stopped along side an unfamiliar vehicle. It was so close, all I was actually looking at was the wheel... with an unusually nice tire and brake. Hmm? When I look up and back, the shuffle of the driver behind me caught my attention. He was scrambling to get his phone to take a photo. Huh? I looked out to see what had caught his eye. Nothing. What the heck? It hadn't crossed my mind it was the car. I simply looked over it... not realizing its importance until after it began to drive away. The engine started. Hearing that captivated me. What was I looking at? Could that be the plug-in hybrid Porsche was planning to deliver? Sure enough, the nameplate matched. As it disappeared into the distance while I turned, there weren't any other indications (like a port for plugging in) that caught my eye. Though brief, that's an encounter I won't forget... since I don't expect to see that many of them ever. The 85-horsepower traction-motor powered by a 9.4 kWh battery-pack combined with a 3.0 liter supercharged engine output a net of 416 horsepower and delivers 0-60 in 5.2 seconds. A system like that isn't cheap. It's close to \$100,000... which explains the reaction the driver behind me had when he noticed it.
- 9-26-2013** **New Charging-Stations.** To my delight, the construction in the ramp right next to where I park involved more than just replacement piping for the old drains. They were running electric lines too. That meant the postponed-from-last-year charging-stations could finally be installed. There were 4 new ones waiting there for me to rejoice about. What a great way to the end the day! These were the newer type too, the kind that can deliver two 240-volt connectors from a single line. More power to share at a lower cost is win-win for everyone. Gotta like that. Unfortunately, they won't actually get used all that often yet. Sales of the plug-in Prius still haven't begun here in Minnesota. But there are some EV owners who will take advantage of the connection from time to time, since the ramp is for the entertainment venue across the street where there are lots of evening events and seasonal hockey is about to begin. So far, I'm still the only daily plugger.
- 9-27-2013** **Twisting History & Intent.** It's worthwhile to wonder who actually believes post claims without ever doing any research to validate. Nowadays, there's a wealth of information available online, like real-world data. The reputable sources are becoming easier to find too. Unfortunately, the propaganda is quite difficult to avoid. Fortunately, the warning signs are noticeable. Whether or not casual readers choose to acknowledge those red-flags is the question. I continue to post historical tidbits, hoping for the best... Toyota strived to deliver an affordable, profitable, high-volume vehicle right from the very start. The price of the 2001 model was \$19,995 and there was only a tax deduction available back then, which equated to less than \$400 for many of us. Gas was just \$1 per gallon too. The resistance to that rollout of the technological improvement was intense; chaotic attacks came from a wide array of sources fearing the status quo was breaking. With overwhelming proof of an effort directly targeting-middle market so long ago, comparisons to the situation now are disingenuous. It's very, very different. Just look at how each automaker is attempting to deliver something. There most definitely was not that spirit of cooperation back then. In fact, some automakers fought to retain the past. It was sad. Read the blogs from over a decade ago. Looking back is not at all the same as experiencing events as they unfold.

9-28-2013 **Frustrated.** That was what the "too little, too slowly" concern was all about was my reply to this: *"My biggest frustration is that GM should be getting these improvements in the Volt sooner rather than later. 2016 is waaaay to late."* We kept getting told, over and over and over again, that Volt was going to leap-frog Prius. All the talk about reaching mainstream sales volume by the end of the second year was quite frustrating. How would that be achieved? The experts wanted to know. Those of use well informed due to having participated in the initial rollout of Prius and the following generations wanted to know too. It just plain didn't add up. For so much to be accomplished so quickly, it would take a miracle. No amount of hope can overcome so many barriers with virtually no support. That wasn't realistic. Now those very same individuals are frustrated themselves... having finally learned what we had been telling them all along. Rather than 2010, they are stuck waiting until 2016... for something that isn't even certain. There's no guarantee all the modifications being made to Volt will attract lots of middle-market buyers. It's still a gamble. Those troublemaking enthusiasts are now in the position we were all those years ago. Remember way back then? They now ask the same questions we asked. They too are concerned. Finally.

9-29-2013 **100,000 Members.** That official milestone was recently arrived at on the big Prius. It was back in January of 2008 when it growth-rate had clearly exceeded that of the big GM forum, with there was 35,599 members verses 33,301. For a single vehicle to exceed that of an entire automaker, it gave reason to take notice. Remember that it was still before the economic collapse, back when times were relatively good. The reality of bankruptcy didn't come about until and entire year later. By June 2011, a full 2 years after the bankruptcy filing and 6 months after the rollout of Volt, membership of the big GM forum had climbed to 54,800. That simply couldn't compare though to the 77,333 members on the big Prius forum. The difference was massive. It contributed to the growing rhetoric, the frustration of enthusiasts from their expectations not being met. Checking out the membership there now, it's at 62,874. Clearly, far more attention is on Prius... despite all the hype of how Volt would become a halo in addition to achieving mainstream sales. The point was appealing to ordinary consumers. Attracting middle-market has been far more difficult than imagined. Think about how little it costs a person to participate on an online forum... no money, just time. Yet, even that isn't happening. Reaching beyond just enthusiasts is absolutely vital. How will growth being achieved? What will it take to attract interest? Who will make the effort to draw more people in? It starts with interaction of people and online forums are a fantastic venue for that.

9-30-2013 **EREV Definition.** It has always been horribly vague. In fact, when pressed, enthusiasts would sometimes contradict what each other says. Everyone always knew it was an arbitrary definition anyway. So, the topic got little attention. The problem became obvious just prior to Volt rollout, since the definition itself changed. Creating a new category called "EREV" fell apart. And now that both Ford's plug-in and Honda's plug-in both fit the capricious criteria, continuing to make Volt appear to be different seems like an act of desperation. They're all considered hybrids now. Why? It's because upcoming offerings make identification clear. The industry is starting to see a vehicle labeled as EREV as having an engine intended to be an emergency backup, something only for the sake of dealing with an unexpected case of running out of electricity. In other words, the size and accompanying fuel-tank should only fulfill minimum criteria. That's what BMW is planning to deliver. It will have a tiny engine and will carry just 2 gallons of gas. The system will be underpowered when depleted, but will achieve the purpose of not leaving you stranded. Volt most definitely isn't like that. GM decided to build a complete system instead, one that delivered full abilities for driving after depletion... which is exactly what a plug-in hybrid does. Looking at it from another perspective, the engine isn't suppose to deliver power to the wheels. It should only generate electricity... which is what the Volt enthusiasts told us all those years before rollout then abruptly altered the definition upon learning Volt wouldn't actually do that. Understand the frustration & confusion? See why clarity is needed?

10-01-2013 **Back To Normal.** We knew the record sales last month were the result of model-year clearance sales combined with a noticeable upturn in the economy. So, the expectation for this month was getting back to something normal. That came as a shock to those supporting Volt. They truly thought the lower MSRP would keep sales high, even though there wasn't anything to actually support that belief. Price is a big deal, but it doesn't change the fact that other aspects of the vehicle don't met middle-market purchase priorities... like legroom in back. The good news for Prius is that its effort to deliver balance appears to be contributing to sales growth. The plug-in model is up. Volt is back to where is was before the crazy discounting. You can guess what that meant online. Comments like this: *"All I know is that this is rather disappointing. A \$5000 drop in the MSRP and the sales volume drops."* quickly degenerated to: *"The PiP will get about 6 battery miles in actual use, 11 if you hypermile."* Rather than stay focused on Volt sales, they turned to greenwashing about Prius. I easily get 11 miles, without doing anything other than follow traffic. The hope is people will believe what they claim and not ever ask any questions. It never ceases to amaze me that some would stoop to such lows, rather than just accept facts. Fortunately, sales results seem to be overcoming their efforts to mislead.

- 10-02-2013 Unfavorable Conditions.** With every possible excuse exhausted at this point, monthly sales discussions seem to be taking on a new more cooperative tone. Fewer and fewer Volt enthusiasts are holding onto that "*vastly superior*" attitude. In fact, we really only got one horribly arrogant post. It called those buying a plug-in Prius "*brain dead*" people. That insult didn't go over well either. Other Volt owners don't care to be associated with such comments. There's hope. Change is slow though. I found the following a good step in the right direction: "*Volt 2.0 and the G4 Prius will be coming onto the market under what I regard as unfavorable conditions – which is to say, gas prices that don't really bother people.*" Of course, it came from a Prius owner. But at least it was found acceptable on that daily blog for Volt. I joined in with: The "boil a frog" situation has played out exactly as predicted. Volt faced and continues to face a massive challenge, dealing with a market simply not interested in saving gas because they have grown use to paying more for it. That's why the approach with Prius, starting with a modest package option rather than a one-size-fits-all design, stands a better chance of squeezing its way into the mainstream. How GM is going to pull off such a major effort against such complacent consumer-base remains a mystery.
- 10-02-2013 EPA Wording.** Notice how supporters of a particular vehicle are quick to dismiss their EPA measurements but adhere to precise wording when referring to competitors? It's an unfortunate reality, the spin we often encounter. The recent mess with Ford and earlier trouble with Hyundai MPG estimates underscore that problem. Should you or shouldn't you consider the EPA measurements an source for real-world expectations. Originally, the purpose of the values published was to provide a standardized basis of comparison. Reading the fine-print, you'd see actual results fall within a range. People like to overly simplify though. So even with the heavy promotion of YMMV (Your Mileage May Vary), it didn't matter. They didn't care. That's what makes promoting a hybrid like Prius PHV so difficult. Antagonists go out of their way to make it even harder too. But slowly, we can see progress being made. The EPA wording was used heavily for greenwashing. Reputable websites know that and want to distance themselves from it. The latest try I encountered said this: "*11 miles, with only 6 miles continuous*". They are well aware that more than 6 miles is available and want to emphasize the total of 11 miles. That approach may be effective. It makes people wonder what happens at 6 miles. It also puts an end to the claims that more can only be achieved by special means. That's good. Overcoming those wanting to undermine isn't easy. But at least we can see signs of success.

- 10-03-2013 Plug-In Hybrids.** The underlying problem with any attempt to deliver is the need to make a profit. Lacking that, they cannot become a common choice. Automakers simply won't bother producing any more than what compliance regulations require. They must be mainstream; the design must be self-sustaining. That's why the "*too little, too slowly*" concern has always been such a big deal. The tax-credits will only last so long. When they run out, then what? Traditional vehicles competing against themselves is problem enough. That's presented quite a challenge for the hybrids. Overcoming decades of cost-reduction and consumer-confidence is still an issue. Adding capacity and a plug makes it even more difficult... or does it? Half of Ford's C-Max sales last month, when comparing models, were the plug-in. The 758 verses 1,424 is a result to pay attention to. Fusion wasn't as impressive, but the 750 isn't nothing to ignore. It's a larger difference with 2,265 in comparison. The very small amount of trunk space available makes those particular sales stand out. The 1,152 for the plug-in model of Prius is still the biggest curiosity though. Availability is still limited to just 15 states. That lack of accessibility is keeping everyone wondering... especially with the major price-drop for Volt. That put it below cost. Toyota has retained MSRP. The package option has always been enough to indicate profit, though likely modest. That's still way better than losing money from each. Next year certainly will be one for the history books. This year confirmed the necessity of affordable price. 2014 will focus on profit, especially as the 2015 models gain attention.
- 10-04-2013 Ordinary Questions.** It sure is nice reading stuff like this now: "*So, for those who have the plug in BUT regularly drive beyond the extended EV range, how much better do these "tweaks" in the plug-in version boost your overall MPG compared to those trying to hypermile in a regular Prius?*" With the rhetoric gone and the antagonists absent, we are getting ordinary questions. In other words, the curious have taken their place. Yeah! I joined into the discussion by asking: Having driven a 2010 Prius for about 56,000 miles (3 years) and a 2012 Prius PHV for about 30,000 (1.5 years), I would say you're asking an ineffective question. That's common, since few have enough exposure to even know what's possible. The better, more informative thing to ask is how much of a difference does the plug-supplied electricity makes for those of us who just drive it. For me, lifetime average went from 50 to 75 MPG. That matches up with what we had predicted, which is saying a lot considering the efficiency with EV-BOOST (when you drive faster than the EV-ONLY threshold) is quite difficult to estimate. I recharge at work too, so that makes a difference. But then again, my commute is beyond the range available and I often drive somewhere in the evening. There are many, many variables at play. It gets especially complicated when the effects of temperature are considered. Running the Heater and A/C really take a toll on efficiency. There's the variety of scenarios affecting warm-up too. In other words, the question could be: How much does the increase in capacity & power improve overall efficiency?

10-04-2013 **Surprise Encounter.** We were up north, stopped in a shopping area going from store to store. When I approached the Prius to put a recent purchase inside, a man stopped to ask me about my bikes. He had noticed the empty receiver-hitch rack then was taken aback upon seeing a 3-wheel recumbent bike inside when he walked up for a closer look. I chatted with him about both the rack and the bike inside. Seeing how large that bike was but the Prius still being able to offer seating for 3 people really impressed. He hadn't ever tried anything like that before... in his Prius. I took me a bit of chatting before discovering he was also an owner. It came in a very surprising way. In fact, the encounter came as quite a shock for him. He innocently asked what MPG my Prius delivered, thinking it would compare closely to his. When I responded saying, "*I averaged 109 MPG on my most recent tank.*", his eyes almost popped out. Realizing the golden opportunity for honest feedback, I remained silent, walked over to the front of the car, and pointed at the PLUG-IN HYBRID emblem. That made his friend, who hadn't said much up to that point, exclaim with a comment of delight. They were absolutely flabbergasted that my Prius had a plug. Later when they left, he drove by very slowly to get one last good full look. To add to the excitement, my family got to witness all that. It sure provided a good memory. I can't wait for more encounters!

10-05-2013 **Misleading Advice.** I understood what he meant, but this was far to vague to be taken the same way by everyone reading it: "*If ya have a heavy foot and like jack rabbit starts, don't buy a PIP.*" That could easily be thought to mean there's no benefit from the plug. After all, there are some who have expended a great deal of effort to make people believe the battery is useless once the engine starts. Those new to the forum often have no idea how bad the greenwashing is, that certain people will intently mislead. It's a sad reality. But then again, readers shouldn't be naive enough to believe everything that's posted. Incorrect assumptions happens quite frequently. Anywho, I retorted off with: I beg to differ. I experimented with that very premise in mine just last night to get some real-world data. Now that temperatures are dropping (it was 46°F then), I specifically wanted to find out what a drive normally all-electric would result in with engine warm-up. It was just a 3.0 mile drive. The maximum speed was 45 mph. There were several stoplights. About halfway into the one-way trip, I dropped the pedal hard to fire up the cold engine. Coolant temperature reached 130°F about a block before reaching my house, automatically shutting the engine off. The result from that drive which could have been 999 MPG ended up being 101 MPG. No regular Prius can even remotely deliver the same efficiency. So what if the engine started. During the first minute of warm-up, the plug-supplied electricity is used to keep RPM under 1500. It makes quite a difference.

10-06-2013 Greenwashing Sources. As time passes, frequent posters become established as information authorities. That's why allowing the antagonists to mislead is such a bad idea. No pushback enables them to continue undermining progress. People don't challenge those who appear to know what they are talking about. In fact, those who do question them end up getting the "troll" label. That was the reputation problem the big GM forum faced. Their own popular members ended up hurting the forum's credibility by spearing false claims. That's what greenwashing is all about. Sure enough, that very same thing is emerging elsewhere, now that plug-ins are becoming a threat to the status quo. My most recent encounter on a general blog for hybrids was this: *"You only use about 10.5 of the 16.5 KWH in the Volt. Probably 4 out of 4.4KWH in the Prius give or take....."* Then when confronted with design detail saying that actual usable capacity is basically the same 62% as Volt (he's a major Volt supporter, as well as an owner), he responded with: *"PIP owners telling me they measure 3.2 to 3.4 going in, minus charging losses you're technically looking at actually using about 3 out of 4.4 KWH. Not much."* Needless to say, there were two of us who got really upset from such blatantly incorrect statements. None of that supports his original claim of 4 kWh. 62% calculates 2.75 kWh. He got caught making up facts. Quite irritated at that point, I posted: Who is telling you that? It certainly hasn't been me. The most recent real-world recharge data (fully depleted to 85% capacity) from my ChargePoint history states: 2.911, 2.656, 2.752, 2.755, 2.872, 2.723, 2.757, 2.627, 2.777, 2.678, 2.926, 2.799, 2.832, 2.716, 2.672, 2.760, 2.787, 2.999, 2.726, 2.819. That comes to an average of 2.777 kWh per recharge, from an L2 connection including charging losses. 2.777 isn't even close to 3.2 to 3.4 kWh. Please use 2.75 from now on.

10-06-2013 Subaru Hybrid. It was inevitable that Subaru finally got into the game. What a disappointment though. The system offers a 13.4 horsepower electric motor. That's so small, what the heck do they expect to appeal to consumers? The unofficial efficiency estimate is only 31 MPG combined. True, it delivers the same 8.7 inch clearance and all-wheel drive as its traditional counterpart, the XV Crosstrek which delivers 28 MPG combined. But with such a low value in the age of expensive gas, it doesn't make sense. There's no upgrade opportunity either. It's just a simple ASSIST system. The FULL hybrid type allows augmentation, provided the choice of a larger battery-pack due to the under-utilized traction motor. With the case of Prius PHV, there's up to 80 horsepower available. That's a heck of a difference. Of course, what I found intriguing was that the estimate implied no MPG improvement whatsoever for highway. Both the traditional and hybrid deliver 33 MPG. The efficiency is only gained from city driving, 29 verses 25. There was no mention whatsoever of emissions. That's a bad sign. Smog related emissions not being addressed by hybrid systems misses the point. Being green must include the reduction of pollution to the air we breath. Carbon alone doesn't tell the whole story. But with an efficiency of only 31 MPG, those aren't reduced either.

- 10-06-2013** **Talking Points.** They are what the popular media thrives on. The big Prius forum needed a reminder of that: "*...and it is disappointing to see this talking point being raised. Let's not get fooled here folks.*" Hopefully, the newbies understood those words of wisdom that well-respected member contributed. I got to meet him in person a number of years ago. That was a good experience. Smart guy. Anywho, I added: It was "talking points" that held back the acceptance of hybrids. People didn't bother actually doing any research. They'd take that hearsay as gospel and continue on with the status quo. That attitude was quite frustrating. Thankfully, we had countless posts from new Prius owners stating their perception of changed dramatically once they got behind the wheel. The test-drive experience rapidly crushed misconceptions. Their assumptions were immediately changed by observation. They realized the system didn't actually work they way they had been told. With respect to the new rhetoric emerging that Toyota is anti-EV, that doesn't make sense to those of us well informed about Prius. Toyota is continuing to refine their motors, software, and battery. All of that technology can also be used for electric-only vehicles. Improvements to cost & power apply anything using electricity for propulsion. It doesn't need to be an EV. In fact, the diversity helps increase volume. It's a win-win some people refuse to acknowledge. Unless Toyota is pushing the envelope, claims are made that they've given up and are failing to compete. That doesn't add up. How could large quantities of those vehicles be delivered without addressing the need to be affordable & profitable while offering an array of choices?
- 10-07-2013** **Timer Misconception.** Oh! This hit me as a total surprise. I had no idea an owner could interpret the charging options this way. Rather than seeing the START and the FINISH times as 2 separate options, the belief was they were tied to each other. Having to use them together never occurred to me. But looking back at the way VCR timers were programmed, that perspective makes sense. You tell it how long to run. With a plug-in hybrid, not wanting "full" seems a bit odd. Why stop short? Why would you want less capacity? You certainly don't ever see that with other rechargeable devices, like phones & tablets. My guess is the FINISH confuses some. They likely don't recognize the convenience having that choice offers; they don't realize it's optional. Rather than having to calculate in your head how much time it will take to recharge, especially if the capacity isn't depleted entirely in the first place, you simply tell it went you'd like the recharge to be complete. Requiring both seems a bit odd for the well information. But for the newbie, it is a reasonable assumption. They jump to the wrong conclusion and sadly it sometimes takes years to discover they were incorrect. Imagine how inconvenient that would be. Instead of just pushing the button once as you leave the vehicle, they go through a series of pushes each time. Eek! What a waste. I sure hope this misconception doesn't take hold.

- 10-08-2013** **Very, Very Quiet.** Normally, the time following sales announcements is filled with spin. That rhetoric to defend the struggle was awful. Last year, I remember it dragging a little into the third week. It later tapered back to two weeks. Then finally one by early this Summer. Every excuse in the book had been exhausted. There was literally nothing else left to say. That was the end. Price slashing resulted. With a massive pile up of inventory, we all new Volt was in trouble. After all, Leaf was actually selling a little better. That didn't make any sense for those who pledged their undying support for a "*range anxiety*" solution. The plug-in Prius continued to defy logic too. Still only available in 15 states, it was maintaining a modest sales rate... actually in excess of Volt if you extrapolated quantity for all 50 states. Needless to say, as the 2014 models have approached, the defense dwindled. This time, it only lasted two days. I was shocked. Now a week later, nothing. There hasn't been a peep from either the enthusiasts or the antagonists. It's very, very quiet. Volt has vanished from online discussions. Remember how Two-Mode faded away?
- 10-09-2013** **Journalist Integrity.** The host of the daily blog for Volt certainly set the enthusiasts their straight today. He's a journalist, paid to provide quality content for discussion. He has repeatedly pointed out how the topics would cover a wide range of industry happenings related to plug-in vehicles, that the subject matter was no longer devoted to Volt alone. In other words, there is no daily blog for Volt anymore. Seeing the topics first being posted on the parent website was the clue. They are now getting reposts on what had once been a fanboy hangout. It has become a child website for sharing the same content with a different audience. They don't like that. But the host didn't like their attitude more. So, it was time to make it clear that things have changed. I'm relieved. The nonsense was getting tiring. Downvoting facts was a clear indication they weren't taking the topics seriously.
- 10-09-2013** **Deterioration.** Pretty much every owner goes through the "*it's different now*" phase. That's what happens as awareness heightens. With the regular Prius, the reaction typically comes from seasonal changes. With the plug-in model, it's less predicable. The difference is unique for each owner. They usually notice EV estimates slowly dropping. That because the default value is just a generic factory setting, typically a bit on the high side. It settles as real-world driving data is collected. And since each driver is different, there's no predictable outcome. It varies quite a bit from owner to owner. Needless to say, the drop is usually interpreted as deterioration of the battery-pack. In reality, the estimate value has no reflection on actual EV distance. But they sometimes panic anyway. Here was my contribution to the latest discussion thread started by a newbie on that very topic: 29,800 miles over the past 1.5 years is where my observations come from. No deterioration. Actual range has remained the same, taking into account seasonal variances of course. Estimate is all over the place. Fortunately, I have finally noticed a pattern. After a vacation, where I went several days milking a single charge with 100's of miles of HV driving. When you come back home and return to routine charging, the estimate goes up. Last trip, the estimate climbed to 13.9 miles. That was the highest I had ever seen it. The trip last week pushed it up to a new high this morning... 14.1 miles. That estimate is just that, a guess based on recent data. It doesn't affect actual range at all. This morning's commute was 16.7 miles, taking the fast route on the 70 mph highway. The result was the same as it always had been for these temperatures, right around 200 MPG. In this case, it was 196 MPG.

10-09-2013 Big News. Checking inventory listed online, we could see Toyota only had a little over 1-month supply of Prius PHV left. That's far fewer 2013 models to deal with than the 6-month supply GM had with Volt. So, there wasn't much concern. For me, not a single one of them was within 500 miles of where I live (Minnesota). There were still all concentrated in select areas of the country. Rollout nationwide was indeed delayed until the 2014 model. We saw that coming. It made good business sense. What also made sense was not announcing the price-drops we had been hoping for until now. Let the dust settle. After the other automakers respond to market pressure, then join in taking reaction to their choice into consideration. What possible benefit would there be from rushing? Anywho, that magic target of "*nicely under \$30,000*" has been overwhelmingly confirmed as a sensible price. We always saw the goal of offering the plug-in as a package option to be realistic with the right price. And that's exactly what Toyota announced today. The base model will have an MSRP of \$29,990 without the loss of any features. In fact, there's even a new feature added... heated seats for the cloth fabric. That's no longer limited to just the synthetic leather on the advanced model. So, even without the \$2,500 tax-credit, the plug-in is more appealing. Hooray! National rollout should go well. Having this lower price and a decent amount of real-world data available online now will really help. The advanced model saw a drop too, its new MRSP is \$34,905. I'm excited about how things are shaping up.

10-09-2013 Smog Shutdown. Imagine airports & highways being shutdown for an entire week due to smog. That's what actually happened in Beijing recently. The Chinese government was desperate to reduce the air pollution. Our smog problems here are minor compared to that. But we still have breathing warnings from time to time, days where the youngest & oldest are urged to stay indoors and avoid strenuous activities. Fooling ourselves into thinking alternative fuels are the solution puts us on a similar path. Plug-In vehicles using electricity from dirty coal plants doesn't help. Sticking with traditional vehicles using compressed natural-gas isn't enough either. We need engines delivering PZEV emission-ratings and electricity from cleaner sources. Smog is a very real problem. The growing population and increasing traffic congestion is making a bad situation even more difficult to deal. What they buy now will remain on roads for many, many years to come. That replacement delay will make the pollution problem even worse. This is why delivering solutions for the masses in the near future is so important. The vehicles must be practical & affordable. How much longer must we wait? How much tolerance do you think those inconvenienced by this recent shutdown will have? After awhile, there will be some type of ugly backlash. Cleaner is needed soon, very soon.

10-10-2013 **EV Technique.** Some of the new owner questions make you wonder. They have bits & pieces of correct information mixed with assumptions combined with confusing descriptions of their observations. It takes awhile to figure out what they are attempting to convey. Sometimes, you just have to interject another perspective to verify everyone is talking about the same thing... because sometimes, they aren't. It's surprisingly easy to get mixed up at times. Online posting has limitations. My contribution to one such thread went this way: It isn't. It doesn't. It won't. Forget what the impression you got and look at it this way: TAKE ADVANTAGE OF THE HV/EV BUTTON. The other day, I had lots of running around to do and only a single charge to work with. 71 miles was the total distance. I kept pushing that button. Whenever I was approaching a stop and upon acceleration afterward. With the slowing in EV, it would regenerate more electricity since the engine would shut off sooner. With the speeding up in HV, the surplus energy from the energy would generate electricity since the system is designed to run the engine at optimum power. The end result was 20 miles of EV display on the drive-ratio screen. That's well beyond the battery's capacity. The charge-level never exceeded the long-life threshold of 85% though. Using up EV when you can allows space for extra electricity later. It's a win-win situation. In other words, this is the plug-in version of hypermiling. You are taking advantage of a feature built into the design of the system to achieve higher efficiency.

10-10-2013 **eAssist Dropped.** Rather than attempting to push this second-generation of BAS any further, Malibu will no longer offer it. With a hybrid system offering so little, it never made much sense anyway. Dropping it is a good move, but that puts even more pressure on Volt... the only choice available that isn't traditional. There aren't any other high-efficiency options in GM's product-line. That's a lot of pressure in an increasingly competitive market. GM's on-going decision to focus heavily on a plug-in vehicle and disregard the "50 MPG" goal so many other automakers have is bizarre. Diversity is a fundamental of good business. Intentionally choosing not to compete in the highest volume category is reason for concern. How exactly will profit be made? Do they really think nothing more than a traditional vehicle with start-stop could continue to draw large sales many years from now? What will people who want high-efficiency but not a plug purchase? Watching Ford, Hyundai, and Honda all push their midsize sedans hybrids hard enough to attempt to dethrone Toyota is great. Fusion, Sonata, Accord, and Camry could all emerge as winners. Gas will continue to get more expensive. Climate change will become even more of a concern. Our trouble with oil-dependency won't go away. It's clear we need to change. Does this latest move by GM represent unspoken acknowledgement of that?

10-11-2013 Tarnished Reputation. That was the title of an article describing GM's current situation, following their announcement of Cadillac ELR being rolled out with a price of \$75,995. With a such an expensive offering and the recent trouble with lack of demand for Volt, you have to wonder what in the world GM is thinking. How could an automaker repeatedly make so many mistakes? It's like they aren't even trying to target middle-market. Where do they believe business-sustaining profit comes from? The writer of the article also pointed out how press releases have been mentioning Volt less and less as the government sells back the GM stock it had purchased as part of the bankruptcy recovery. The money lost makes it officially a bailout (roughly \$10 Billion), something supporters quickly want to distance themselves from. GM itself has clearly moved on too. There's an obvious re-emphasis on Pickups and SUVs. In other words, the draw to high-profit vehicles is becoming a problem again. To make matters worse, there's a stigma emerging in regard to Volt as a reminder of the difficult years. A return to trucks dominating the mindset of buyer's pride in American values is the theme we're seeing now. What is there to be said at this point? Hype resulted in disappoint. Demand didn't emerge. Supply didn't match the purchase priorities of mainstream consumers... which is what we all saw prior to rollout. Yet, hope persisted... even though there wasn't a next step available. The design didn't offer flexibility. What the heck does that mean for next year? 2014 promises an array of high-efficiency choices from other automakers. Will GM even compete in that market? What about our dependency on oil and climate change?

10-12-2013 What Advice? When a former plug-in Prius owner who changed over to a Volt says this, you have to ask for more information: "*That is advice that Toyota should heed as well.*" With the high trade-in value for Prius PHV and the bargain clearance prices of Volt, his switch was understandable. Though, I would like to hear about the that same decision 2 years from now as the next generation models are rolled out. Everyone's situation is different anyway, and my gripe is about the business not owners. What an automaker will produce is quite different from individual purchase decisions in the here & now. Someone had pointed out what GM could do to help Volt along. That quote was his response. So, I asked for clarification: What isn't Toyota already doing that they should? They've diversified the hybrid system in a variety of ways. Prius itself is available in 3 different styles/sizes. HSD is available with different engines & motors as well as AWD and RWD. There's also the plug-in option, which does an excellent job of presenting the next step without requiring customers change much. Toyota also kept cost-containment as a major priority... advice GM gave itself, then disregarded and is now struggling to deal with. Remember all those years hearing about the importance of \$30,000 as a purchase price to achieve mainstream volume? That is now MSRP for the base Prius PHV and reasonable with respect to cost & profit. What else is there at this time and in this market?

- 10-13-2013** **What Else?** That question wasn't answered. Instead, there were off-topic comments and this: *"GM has put much more effort into customer satisfaction for the Volt and Spark than Toyota has for the PIP."* That seemed worthy of a response. Maybe I could actually get something constructive from it. So, I tried: That's an interesting comment. What specifically does it refer to? As a computer programmer for over 20 years, I know extremely well how less can actually mean more. Not having user-calls to respond to can be an indication that they are pleased with what you delivered. You don't want the system to stand out. You want it to become ubiquitous, so common people just use it without any thought. We all know that situation extremely well from experience with the regular Prius. It is mature product, a system with all the kinks worked out already. The majority of owners are rarely ever heard from. They simply drive their Prius with content. They are satisfied. Consider it a job well done when it is used without complaint. That's how success is defined. Again, what else is there?
- 10-13-2013** **Not Get It? (part 1)** I really enjoyed responding to this: *"Do you really not get it? The point is that Toyota's entire approach to the PiP has been reactive and minimalistic."* Having a strong background in business (it was my minor in college), the accounting & economic factors that come into play are something I'm well aware of... and know well that the typical person isn't. So, I rebutted with: What possible benefit could come from being proactive and taking major risk? Observing other automaker mistakes in the emerging plug-in market to avoid making them is a wise move. GM claimed price didn't matter, people would be willing to pay for what they were offering. They were wrong. Toyota avoided association with that mistake by restricting availability, while gathering valuable real-world data from actual owners in the meantime. Now, they're using that information to expand & improve. Ford rolled out their plug-in hybrid late last year. That configuration seriously compromised cargo space, but claimed the capacity tradeoff was well worth it. We still await results of that. Based on sales so far, the impression is consumers don't agree. Toyota's choice continues to show potential. The impression I get is you believe there's missed opportunity. Having driven a Prius PHV for 1.5 years now in an area not even supporting the EV beyond being just a curiosity, I can strongly disagree. The other automakers misjudged the challenges of rolling out vehicles offering a plug. Toyota's approach makes sense.
- 10-14-2013** **Not Get It? (part 2)** The next morning, after not getting a response, I replied to that same statement again: Observing customer preference and being able to react to it has always been a strength of Toyota. The system is designed with flexibility in mind, being able to offer small improvements. That too is a strength. Why are you portraying those traits as a bad thing? Look at well positioned Prius PHV is now for 2014. There's lots of real-world data available now, enough to prevent the spread of misconceptions revealed by the limited rollout. That's reacting to actual situations, rather than guessing what could happen. A clear message is sent about expectations. We've also observed consumer price preference. Toyota adjusted price accordingly, prior to entering new markets. Delivering what matches expectations is a good thing. The build it and they'll buy it hasn't proven successful, which is why Toyota isn't doing that. Notice how it instead resembles the sidewalk wisdom? Laying sidewalks where the paths have already been worn results in dramatically higher acceptance.

10-14-2013 What They Wanted. On the big GM forum, there's a very long discussion thread about Cadillac ELR. As a result, a few of those troublemakers I use to battle with have found themselves struggling in defense of Volt. Things are falling apart for them. GM sold what they wanted, not what they needed. This new offering reinforces that mindset. Those vehicles are being regarded as indulgences for the rich. It supports what I asked countless times, asking who. On what's left of that daily blog, there's post after post attempting to draw a distinction between Volt and the other plug-in hybrids. The new Accord doesn't have a power-split device. That ties the engine and traction-motor together, not allowing for independent RPM. Either they are integrated or separated (via a clutch), with no variability in between. That makes it more like Volt than it does Prius. They don't like that... especially since it delivers much better depleted efficiency. That also supports what I had said countless times. In other words, this is quite vindicating. Of course, all I did was study history and the market, coming to the same conclusions other well-informed individuals did. We all saw this problem coming. With such an incredibly difficult industry, highly resistant to change, simply hoping people would be easily convinced to embrace the new technology was madness. Even the computer industry, where devices are far less expensive and have a much shorter life, has a difficult time getting people to change. Warnings were dismissed. Advice was disregarded. Messengers were shot. They let this happen.

10-14-2013 Planning Ahead. That happens a lot with Toyota, so much so, moves appears to be an afterthought... since the design supports it so well already. In fact, that's what antagonists have been trying to spin about the plug-in Prius. They want you to believe it came about as a panic outcome from the competition catching Toyota off guard. Those of us who were paying attention years ago know that is just plain not true. But how do you prove it when threads are loaded with red-herrings and attempts to discredit? An example of something they weren't able to spin was the 2-speed design. The reason is most likely because they didn't understand its importance. Toyota quietly rolled it out. Those of us in the know carefully watched it in Camry-Hybrid. We saw the benefit and silently rejoiced when the next Prius got the same upgrade. Having other platforms available to real-world validate the value of alternate approaches is brilliant, especially when no one is paying attention. A new example of this is liquid cooling. That's overkill for smaller hybrid systems, even the plug-in model. But in the future, there may be a benefit. Already having discreetly rolled that out in another vehicle allows for the much more visible Prius platform to get the second generation... with very few people knowing. Heck, that's how Prius was delivered to the United States. Virtually everyone assumed it was first generation. Only those doing research discovered it was actually second. Anywho, that battery-pack using liquid rather than air to keep cool is in the new Lexus ES300h. The cells are actually just NiMH. But the system delivers a combined (engine & motor) rating of 200 horsepower. So, we know the electric-draw is higher than usual, a great opportunity to study thermal effects. Toyota is willing to push harder with a platform where a more expensive design is perfectly acceptable. The experience is priceless later, when important decisions need to be made. Planning ahead pays off.

- 10-15-2013 PHV Sighting.** My commute home from work offered quite a surprise today. I was pleased with myself for having noticed a train coming, just before turning and committing myself to that wait. On the alternate route which took me through some city streets, I noticed 2 Prius parked along the road. Both were the same dark gray color and likely the same year. I assumed while driving by them the view would be identical. To my surprise, it wasn't! Always hoping to spot another PHV, my focus is aimed to see side emblem. The first said the usual HYBRID. The second was 2 lines deep. Oh! That caught my attention. Sure enough. As clear as day, it said PLUG-IN HYBRID on that one. Sweet! The rear had the distinct clear taillights (as opposed to having the red strips) and that special silver backing. It was my very first sighting in that color, as well as a being a rare circumstance... since there still aren't any available for purchase within a 500-mile radius of here. Someday that won't be the case, but it certainly is at the moment.
- 10-15-2013 Final Argument.** Remember all that rhetoric from the Volt enthusiasts. They attacked Prius PHV every way imaginable. None of their efforts worked though. In the end, they found out you couldn't belittle the plug-in hybrid by misrepresenting it. So, they switched from offense to defense. That fell apart too. Nothing could withstand the reality of slow sales... except, delay. The final argument is to convince people more time is needed with respect to when Prius was first rolled out. They've even given up on the "*early adopter*" claim now. The entire focus is direct comparison to what happened over a decade ago. The catch is, their reasoning quickly falls apart. They hope you make the assumption that all current conditions match what happened back then. That couldn't be further from reality, but that's how greenwashing works. Even if you consider the extensive history GM had with motors & batteries already, prior to Volt rollout, there's no way to deny the market is different. Even when the second generation of Prius was delivered, there was nothing that could be considered industry cooperation. In fact, most of the automakers were against hybrids. GM and VW were campaigning hard to undermine their progress. The push by Ford to dominate with SUV growth was an obvious big move in the wrong direction. It was ugly. The only other automaker in favor of hybrids was Honda, whose approach was quite different than Toyota. Knowing that Toyota, Honda, Ford, Nissan, Mitsubishi, Smart, Fiat, and Tesla already offer plug-in vehicles and other automakers have announced their intent to makes this a market quite unlike what Prius faced. There is a clear spirit of cooperation at play that there wasn't back then. Claiming otherwise is dishonest and not the slightest bit constructive.

- 10-16-2013 Sales Increase.** There are a surprising number of so-called news sources that don't disclose the fact that Prius PHV is only available in 15 states. That paints an unrealistic picture of demand when comparing it to sales of other plug-in vehicles available nationwide. Yet, they do it anyway... even when asked to add a disclaimer. They simply don't care. That same situation existed way back when Prius was first rolled out here too. Even though Toyota set a strict quota and people were waiting up to 6 months for delivery, those sources couldn't care less. They felt free to misrepresent anyway they wanted. In fact, they felt no obligation to mention that Prius wasn't new when it was rolled out here either. They pretended the previous years in Japan never happened. It makes you wonder what they'll say next year, when Prius PHV availability is finally expanded. My guess is they'll be forced to acknowledge the reason for sales numbers increasing and will pretend the limited rollout was always well known, so there was no reason in the past to ever explicitly point it out... even though now, it's still a blatant misrepresentation.
- 10-16-2013 Kicking Of The Can.** We saw the effort of the Super Committee fall apart, resulting in the Budget Sequester. That was suppose to have been the solution; instead, it became a kick-the-can response with unfortunate consequences. It taught us that cooperation presents significant challenge. So, it's hard to believe recent attempt the Republican Party made to block change would result in a kicking of the can. Not only wasn't there a final decision made, but it also resulted in additional expense... a partial government shutdown. The cost to taxpayers was enormous. Just like with other delays, there's a penalty for not responding when required. What a mess. Those supporting hybrids know this all too well. We are quite familiar with the cost that comes from resistance. Fighting progress doesn't make sense. Yet, it happens again and again. Why deal with it now when we can address it later? They take advantage of the reality that people are forgetful by nature. That allows this cycle of on-going reset. Cost is lower the sooner action is taken. Yet, it doesn't happen. Delay is often the outcome. It's maddening. Thankfully, not all automakers think the same way. Some are sensible enough to understand the "*too little, too late*" problem and respond properly... despite criticism from those not understanding situation. Don't let antagonists undermine. Don't like the can be kicked again.
- 10-17-2013 5 Leafs.** I'm seeing Nissan's electric-only vehicle on a regular basis now. But to spot 5 Leafs all in one day, that was quite vindicating. The fear of "*range anxiety*" doesn't seem to actually be a problem. The hype didn't materialize into a feature anywhere near as beneficial as hoped. Volt tradeoffs are still too much for mainstream appeal. Does that mean Leaf will overcome the daunting barrier of middle-market need? We still don't know. But the outright dislike for a plug-in offering only a battery for power isn't what actually happened. In fact, the rare sightings of I have of Tesla vehicles offer reason for pause. What is the tipping point? There's a balance of capacity & price for each consumer group. The bread & butter crowd, where the business-sustaining profit comes from, is the target. Prius PHV is designed to compete in that segment. Leaf is too. What will happen in 2014, as the plug-in market advances forward with more choices, lower prices, and increased awareness? I can't wait to find out!

- 10-18-2013 PHV Again.** Parked on the street, the closest spot next to the doors at work, there was that Prius PHV again! I was quite surprised. Was that an amazing coincidence or will it happen again from time to time? Seeing another PHV sure is refreshing. It was quite a thrill, especially considering those routine Leaf sightings for me. Searching online, there are none to be found within 500 miles of here. Toyota is obviously trying to clear out existing inventory prior to taking the next step. That's quite a difference from the approach GM took. That underscores their fundamentals of not being the same. Expectations basically have nothing in common. Prius offers a variety of choices, including a model with a plug. Diversity is necessary, especially when offering a compact like Volt. Oddly, Nissan's decision to also limit rear legroom hasn't been as much of an issue. Why is that? At least it took the priority of price seriously. Whatever the case, it really does boil down to sales. When rollout happens here, making PHV readily available, how will consumers respond? Properly setting expectations is of major importance. We've seen what happened in the past when those expectations are unrealistic. Will people understand what PLUG-IN HYBRID means, what it is intended to deliver? Will see. Today's sighting provide a bit of encouragement. Real-World data is the best way to stir interest.
- 10-18-2013 Lease Residual.** The stories are beginning to trickle out. Residual value on leases is determined at the time of signing, not when the vehicle is later returned. For Volt, that situation is turning into a difficult problem to deal with for those who leased a Volt. Those extremely low rates were very attractive, since payments would otherwise have been too high. Purchase simply wasn't realistic then for some. Turns out, purchase now problem too. The residual (price to purchase) of their current Volt is higher than simply just buying a new one... which will have higher payments and none of the previous payments would count. That means starting all over again, requiring an additional cost they never imagined. To make matters worse, the banks which provided those leases are now stuck with having to deal with that loss of value. MSRP dropping \$5,000 wasn't in the plan. They will be forced to sell those lease-returns at a loss. Oops! It was a business approach that didn't make sense. It was too risky. Consequences some of us eluded to years ago are now playing out. To add to that mess, the vehicle itself isn't selling well either. What do you think will happen in the used market as a result of all this?
- 10-19-2013 Hauling Trash.** Today was a bit on the crazy side. Some reconstruction at mom's finally began, stuff that hasn't been touched since dad's passing several years ago. It resulted in 2 very full loads of trash getting hauled from there over to my place, where I'll sort for reuse, recycle, and proper disposal. Loading so much dirty material into a car isn't what most people would ever consider. But with a large tarp to protect, why not? I've taken full advantage of the massive cargo areas several times in the past... including the transport of wet leaves to the compost. There was a stack of leaky bags loaded inside. It was no big deal. Properly packed, that large space in back has proven very handy. I couldn't imagine what I would have done with a trunk? The haul included 2 glass shower doors and a large glass window. Imagine hauling that away unbroken without a hatchback. There was a stack of wood with nails too. No big deal. It all fit just fine. Of course, that mess is now at my house to deal with.

10-20-2013 Introduction Sales. That topic is what the media is focusing on now. I see this as a sign that Volt's fade away has left the reporting industry without an poster-child, so they are finding themselves having to be more creative about article subject matter. It isn't just the writing about GM's latest fumble. That's progress! On a new discussion thread about introduction sales, I posted: Comparing hybrid sales back then to plug-in sales now is not constructive. When I took delivery of my Prius in September 2000, virtually no one understood what a hybrid even was. Online discussions up to that point were with those actively seeking out that education and struggling to get enough correct information. The misconceptions were abundant. There was a major effort to undermine too. Then came 9/11, which ushered in the "*good for the economy*" campaign encouraging consumer to purchase guzzlers. After all, gas was just \$1 per gallon with no expectation of it going up. Remember GM's push of Hummer and claim that hybrids could never be profitable? At the same time, Ford had vowed to increase SUV fleet efficiency by 25%. Neither automaker was able to deliver though. Both were forced to change. Meanwhile, Toyota triumphed. Proof of success was a simple matter of looking around on streets and in parking lots. Prius were easy to spot by the completion of the second year of sales for the second generation. As the third year was underway and high-volume already achieved, a tax-credit was introduced to push hybrids deeper into the mainstream. That provided encouragement for the entire industry... 6.5 years after introduction here. Looking at 2011 as the start of plug-in sales, there was basically only Volt & Leaf. But by then, hybrids were already well-proven and gas was expensive. The entire industry was planning to deliver high-efficiency choices. All automakers were in agreement that battery & motor usage was the future. There was no disagreement about taking that next step. There were generous tax-credits available too. That spirit of cooperation, a very different market from hybrid introduction, is why comparing to plug-in sales is not constructive.

10-20-2013 Heater & Snow. It has begun. Temperatures have been 30's in the evening and will be dropping to the 20's starting tonight. We got what counts as the first snow today. It was the round pellet type. That's not rain, so it's official. MPG has already dropped too. So, I'll obviously be blocking the grille soon. Winter brings interesting change... especially when you drive a plug-in model. Efficiency is outstanding, but you have to aware of coolant temperature to make the most of it. When the coolant is toasty warm, you can be generous with the heater and not have any concerns about the engine starting. Driving EV doesn't work as well when the coolant is still icy cold. For short trips, the heated-seats do a great job of keeping you comfortable. You have to either run the blower on LO or crack two windows to circulate outside air to prevent fogging of the glass inside. That works great for short trips, a dramatic improvement over the regular Prius. But for longer distances through the suburbs, it's best just to fire up the engine. Grille-Blocking helps reduce warm-up time and extends engine-off duration. So, that's not too bad. Toyota has does an excellent job of optimizing heat utilization over the years; however, electrical resistance due to the cold reduces capacity of the battery-pack. It a reality plug-in owners know all too well. That makes you look forward to Spring coming again. In the meantime, here comes the snowy season.

- 10-21-2013** **New Tires.** The expectation of the factory tires lasting 35,000 mile is quite realistic. Sadly though, seasonal demands here in Minnesota sometimes force you to get new ones sooner. Sales promotions make timing even more of a challenge. As I type this, my Prius is at the dealer getting its routine 30,000-mile service. There's a sale: "*buy 3 tires, get the 4th for \$1*". That's a difficult opportunity to let slip by... especially knowing the forecast for this week is evening temperatures below freezing... which means any precipitation will be in the form of snow. We basically skip Fall some years, going from Summer to Winter abruptly. That actually makes the choice of tire replacement easy though. When you see a chance, take it. So, I decided to go with Michelin Energy Saver A/S tires. They're popular choice among Prius owners. Others must like them too, since they are often back-ordered. Online reviews provide a mix of impressions. I'm not sure what to make of that. But then again, much depends upon personal driving habits & conditions. I run tire-pressure close to the maximum too. So, there will be lots of subjective observations over the next few months from me. Finding those tires in stock and on sale while at the dealer anyway is a nice happenstance. My interest in them is based on being LRR (Lower Rolling Resistance) for better efficiency and the good experience I had with that brand in the past on my Iconic Prius. We'll see.
- 10-21-2013** **Oil Change Follow-Up.** 5 months later, I took the Prius in again for an oil change. With the free changes used up, I would normally do it myself. But there was fallout from that incident back in May... when the gasket was pinched and all the oil leaked out onto my garage floor. The mechanic responsible did a great job of personally cleaning up that, but the mess ended up being bigger than I had originally thought. It wasn't limited to the garage. Oil had dripped down and got soaked up by the blotter on the plastic door under the pan of the Prius itself. That caused the door to sag, exposing a breath-hole to catch spray, which contributed to even more sagging. That reduced ground-clearance and would clearly become an issue traveling through deep snow later. Needless to say, there was an obvious problem the dealership had directly caused. To my pleasure, they replaced the entire plastic section without question or charge. That was a nice follow-up to a situation which could of had a very different outcome. I sure hope no one else ever has to deal with the same thing. But at least they'll know there are some service departments willing to acknowledge mistakes and do what they can to rectify them.

10-21-2013 **Failure Confirmation.** When goals are forgotten and definitions are changed, you have your confirmation. Being well past the time-period when success should have been achieved, the best response to that is simply ignoring it. So, that's what I did today. The claim was made that he had stated a goal of "*with at least 30 EPA miles all-electric range*" since the very beginning, way back in 2007. I know that was just plain not true. His was one of those who pushed the "40-mile" mindset aggressively for Volt. I remember that well. Whenever he mentioned it, I rebutted by asking what happens in Winter. That frustrated him every time, often resulting in a hostile response... until he finally figured out that heating consumes far more electricity than he ever imagined. His belief was that real-world EV range didn't vary. Factors like speed & accessories weren't considered. His goal changed from all-condition results to EPA estimate and from 40 miles to 30... with the hope no one would notice. I certainly did and take that as a big confirmation of failure. The enthusiasts hate labels like that. But seeing a dramatic drop in price 2.5 years after rollout with heavy dependency on tax-credits and lagging sales still, what else can be said? It's time for that "Plan B" to be used. I always stated it should have been a second model. They fought me to the bitter end, embracing the one-size-fits-all approach instead. Now what? Watching other automakers introduce their plug-in choices means there are even more challenges to face. That opportunity to lead the way has passed. Mission not accomplished.

10-22-2013 **Wild Claims.** There's always reason to be suspicious when a first-time poster comes on the forum making wild claims. We've seen it so many times now, we are always on guard. This time, it came with a story of health issues and death. That was a new spin. The other part was quite familiar... a claim about advertised miles. We've seen that in countless different ways. Each has the same thing in common though... no detail. That new member will say something to anger people, then vanish. I was especially amused with his closing comment: "*I am currently planning to get rid of the Prius and buy a 4x4.*" That simply didn't make any sense coming from a supposed plug-in owner. Needless to say, the following day brought lots of posts... none from the person who had started it though. It had already become apparent the purpose of that thread was just an attack on the forum. Having such a harsh attitude, then showing no activity whatsoever afterward indicates something is very wrong. The facts themselves didn't add up either. I was the first to respond when that thread was first posted. Immediately noticing the behavior, I pressed for detail right away: This is the text on the TOYOTA.COM website about the PHV model: "*EV Mode is great for those shorter trips. Prius Plug-in has an EPA estimated driving range of 11 miles in EV Mode, and you'll be able to cover them quickly since it's capable of traveling up to 62 mph on electric power alone.*" The purpose of Prius PHV is to deliver a significant MPG improvement. That benefit is delivered even when the engine runs and the electricity being used isn't counted as EV miles. What were your MPG expectations and what did you actually get?

10-23-2013 **500 RPM.** It hadn't hit me until today. When I take the back way home from work, the climb out of the river valley is longer and steeper. Just before reaching the top, the initial EV-BOOST runs out. That's when you get a very generous amount of electricity provided to allow engine warm-up to be a more gentle process. RPM is held below 1500. That reduces strain, both for longevity and to help keep emissions lower. Just before that boost ends, the RPM will gradually creep up. With an aftermarket gauge, you can see it in the 1700's. Shortly before reaching 1800, the RPM abruptly speeds up past 2300. Especially due to that climb, you'd expect more than just a minor audio cue. After all, traditional vehicle shifting is quite a normal event to feel. But with Prius PHV, there's nothing in that respect. In fact, that 500 RPM jump is something I've never really even acknowledge from the perspective of feeling anything. I've been so focused on the quantity itself and when that happens, it hadn't occurred to me that the lack of sensation is a benefit of the design. Things like that going unnoticed is what really endorses the design. You wouldn't want a shift in operation to be noticeable. After all, lack of behavior responses like that are what people purchase luxury vehicles for. They attribute system aspects like that as a mark of quality. The smooooooooothness of having a planetary "transmission" rather than something with actual gears really makes a difference.

10-24-2013 **October Guesses.** Reality has sunk in. The third year of sales is coming to a close for Volt. That puts those who insisted on making comparisons to the early rollout of Prius in a difficult position. They now know that history didn't match. Hope has been replaced with dismay. Even the belief that price was high to help recover development expenses has fizzled. They honestly don't understand what some of us had been saying for awhile. Here's an example: *"I guess I still don't understand the whole Volt loss debacle either. They just dropped the MSRP by \$5k stating that was attainable due to cost reductions in batteries etc. So was their news release a blatant lie? If they're losing money, and they don't really care how much they sell, why decrease the price at all?"* When that price drop took place, we pointed out how there was no evidence supporting any claim of recent major advances for lithium battery production. We also recited the words of GM's CEO stating just months earlier that each Volt sale was losing money. Yet, they believed cost had been dramatically reduced anyway. For those of us who have taken accounting classes, we knew it was the rate of cost-reduction that had justified the lower price. In other words, if it could continue at that rate, the new price would become profitable within a reasonable timeframe. There was nothing in any statement saying that had happened already. Enthusiasts simply wanted it so bad already, they convinced themselves that's what they actually heard. So now, with overwhelming evidence that sales continue to just drag along at a level well below expectations, their guesses for October reflect a sense of disillusionment. Consequences of their intense focus on engineering and blatant disregard for business are revealing themselves. Too bad some still don't understand why. Perhaps the guesses being made now by peers will help them see the reasons.

10-25-2013 Dealer Inventory. Looking at new plug-in inventory for 2012 vehicles, we just plain don't why some are still available. The numbers are so few, it gives the impression some dealers simply held on to their older ones as showroom & demo models. That makes sense. Why have to discount another when the existing serve the same purpose just fine? Inventory of 2013 plug-in vehicles tells a different story though. Specifically highlighting the end of the Volt verse Prius PHV clash, we see 1,885 Volt and 1,219 Prius PHV available. Volt can be purchased nationwide. Prius PHV continues to be limited to those initial 15 rollout states. Of course, that does give the overall impression of a somewhat level sales status. Both seem reasonable... until you look at 2014 inventory. For Volt, it's 1,753 available. For Prius PHV, it's 0. Zero tells us an interesting story. Toyota has been holding out, an intentional delay to clear out existing vehicles sitting on lots first. Why push out new ones? That doesn't appear to have been a wise choice for GM. Even supporters haven't been able to spin that to a positive. Waiting to rollout 2014 to the whole nation all within the same relative time-span is sensible. After all, dealers have a partnership with the automaker. Getting stuck with old inventory isn't helpful in any respect. More than ever, I'm quite curious what next year will bring. 2013 certainly shock beliefs to the core. Approaches have changed as a result. What will that end up doing for sales?

10-26-2013 Good Combo. He summed up the situation this way: "*Prius + Pure EV. Good Combo.*" A friend of mine recently made that very same comment; however, this was from someone quite different. Early this year, he had engaged in several intense battles with me. He was a staunch Volt supported... heavily focused on engineering alone. He felt the combination of engine, motor, and battery GM offered struck a good balance. Cost wasn't a consideration. The business aspect was something quite unfamiliar to him. It was mostly a matter of principle, an ideal. Since then, reality has changed his view on priorities. The importance of other things, like sales growth & profit, are sinking in. This comment yesterday helped to confirm that: "*I think when my lease runs out on my Volt I will switch to a pure EV: either a Spark EV or a Tesla. So I think a good combo is a Prius for long trips and a Pure EV for around town.*" He, like many, assumed my endorsement for Prius was nothing but brand loyalty. He couldn't see past that old school mindset. He couldn't believe anyone interested in vehicle electrification could fight against any plug-in vehicle offering a pure EV experience. He didn't see the sacrifice GM made to deliver a plug-in with an engine. Now, he does. Now, he understands the consequences of business decisions based on want rather than need. It's very fulfilling for me to witness such an attitude change. Too bad the struggle to get there was so intense.

10-26-2013 **Hatred, part 1.** Waiting for those incendiary enthusiasts to finally get that "*vastly superior*" upset out of their systems was an exercise in patience. Some of them outright lied. They simply didn't care. No matter how much real-world data you'd present, they'd dismiss it and say anything they wanted. Others supported them too, enabling greenwashing so blatant, you felt a bit of hatred. It made the wait even harder. But knowing that profitable sales would become increasingly more difficult, it was just a matter of time. A great example of this from 6 months ago emerged yesterday, serving as a fantastic reminder of how bad the situation had actually become: "*So if your gas tank was empty, how far could you drive on the EPA test course? Answer = 6 miles.*" Over and over and over again, it was stated that the capacity of the Prius PHV battery-pack was rated at 11 miles and that 6-mile value was nothing but the hard-acceleration point during the test. You don't have to accelerate that hard. In fact, people rarely actually do. The test includes it to be thorough. The engine shuts off shortly afterward anyway, allowing you to continue on driving with only electricity for another 5 miles. Capacity is 11, not 6. I even posted a video showing a 9-mile drive in EV with the temperature at -2°F. That's dramatically colder than EPA tests are performed, yet distance exceeded 6 by quite a bit. Some absolutely refused to accept that reality, despite seeing it on video. My commute to work taking the river route during the warm season routinely delivers 13 miles of EV. That's twice as far as the implied range... without using a single drop of gas. Again, some just plain didn't care. It was very tempting to lash out, but refuting with anything but cold-hard facts would mean stepping down to their level. I'm not going to sacrifice my integrity to win a battle; instead, I wait. That approach has been paying off recently too. The war is against traditional vehicles, not fellow plug-in supporters... even those who intentionally lie and mislead... like that Volt enthusiast.

10-26-2013 **Hatred, part 2.** It obviously goes both directions. The belief that I was attempting to undermine clearly stirred strong feelings. Worry about what that would mean later was always present in the background. But then again, the same situation already played out in the past. Two-Mode was bragged about for years. Despite all the warnings about "*over promise, under deliver*", the enthusiasts kept talking big anyway. Their boasting turning into hostility at times too. Back then, online behavior wasn't as well understood either. Conduct wasn't as well controlled as a result. Moderators are much better informed now about what to openly allow and what to keep a close eye on. Anywho, by the time Two-Mode reached the end of its third year, the technology had basically been abandoned. So few were interested in such an expensive system that didn't actually meet the needs of consumers. Sound familiar? We have been witnessing similar circumstances with Volt. What had been hoped for and what was actually delivered were dramatically different. Seeing Toyota within reach of the goals consumers had established for Prius PHV made that bad situation worse. Aftermarket augmentations, countless surveys, and lots of research positioned Toyota well for reaching the masses. GM didn't care. In fact, they weren't even interested. Volt's target wasn't middle-market. There wasn't any intention to deliver a mainstream configuration until the second generation. The "*too little, too late*" concern wasn't taken seriously. Enthusiasts now understand this. They see their hatred was misplaced. Seeing that is a good sign.

10-27-2013 Winter Ready. The lower grille is now blocked. I seal it entirely, using 1/2-inch thick form pipe-insulation. By squeezing both sides together and pushing them into the slots of the grille, they stay in place all Winter long. No glue or tape or fasteners are needed. Even with several car-washes, they don't move. It's quite an inexpensive solution to a problem we all face during the cold season... heat retention. It only cost me \$2 and 30 minutes. The result looks really nice too, if you take the time to slice out bits for the vertical supports of the grille. That way, the foam appears completely flat along the entire span. Of course, with the regular spray of sand & salt Winter brings, looking good is somewhat of a non-issue. Regardless, the deed is done. MPG will be higher as a result. Heat will last longer, which causes the engine to stay off longer. There's also a small benefit when it comes to initial warm-up. Less air is allowed to pass through the engine compartment. That's obviously a nice perk. Posts online are growing. New owners stumble across information like this asking for more info. The experienced owners happily reply. My biggest frustration is the definition of Winter itself. Those living in places where the temperature might drop to freezing on a rare occasion have no concept of how cold it gets here in Minnesota. Their perspective of "*cold*" is quite different. So when we discuss grille blocking, results are often questioned... since they don't have the same encounters. I leave my Prius parked outside while at work. We routinely go weeks at a time without the temperature rising above freezing. We also experience several days each Winter when the temperature doesn't even climb above 0°F. Brrrr! That's when grille blocking provides a huge improvement.

10-28-2013 Blocking Results. This morning's commute was at 37°F. Much colder temperatures are on the way. Fortunately, the result of my 17-mile drive was 145 MPG. That certainly isn't anything to complain about... but definitely isn't reminiscent of the 400's that I'd routinely get in the Summer. The reality of Winter is setting in. Having something simple to help retain precious heat is nice. I do find it a bit amusing though. 20 years ago, seeing cardboard attached to the grilles of vehicles was a common sight. At least now, this is cosmetically much better. Some vehicles are even beginning to offer powered louvers. Prius doesn't, yet. Perhaps it will with the next generation. Until then, it's much cheaper using \$2 worth of foam each Winter. And with a cost so low, it easily pays for itself... especially considering how long Winter is here in Minnesota... where a few weeks from now 37°F will feel down right balmy in comparison.

10-28-2013 Leaf Contemplation. Since there weren't any declarations of superiority or wild claims of anticipated strong demand, Nissan's Leaf has always been treated differently than Volt. The smug & arrogance simply didn't exist for that way. Those interested just quietly supported their plug-in choice, knowing there was much to prove initially. That's what actually mimics Prius. They knew achieving mainstream volume would take years of further refinement of the technology, but what they had already would indeed deliver to the satisfaction of enthusiasts. So, they just drove. That's quite a contrast to what we saw from GM and those who favored Volt, who pushed a trophy mentality to convince us of obsolescence. It sure is nice that chapter in history is over. Such opposites really make you wonder about market... hence always asking the "who" question. Thankfully, we are now past that. Focus is now on regular priorities, the kind of things ordinary consumers consider when purchasing a vehicle. A big one is passenger & cargo space. By dumb luck, a Leaf was parked right next to a Prius today on our morning coffee run this morning. I asked if we could stop for a closer look. I told my friends to observe the interior of Leaf carefully, then look into the Prius. The legroom difference in back was obvious. Leaf is a compact. Prius is a midsize. That works out to 2.7 inches smaller in this case... very easy to see. The seats just happened to be down in back too. That made the cargo comparison a no-brainer. Prius has a high roof. Leaf has a short one with that dramatic low swoop. It was quite obvious the Prius offered significantly more room for cargo. Feature differences like that are what helped keep enthusiasts civil. The audience wasn't the same. Unlike Volt, the target for Leaf wasn't that of Prius buyers. There was no fighting. We could actual contemplate ownership situations in a sensible manner!

10-28-2013 Historical Spin. With the present so clear now, there isn't much else to do except paint a rosy picture of the past: *"GM pitched the Volt by saying: We will just make the battery big enough to cover the daily driving distance of the average driver of 40 miles."* Knowing that was spin on what actually was said and knowing that most people won't have any way of validating that history, I was intrigued. Would that point be fought if confronted? Turns out, the answer is no. That was good to find out. In the past, arguments were made about everything. Being constructive wasn't a priority. When enthusiast could get a red-herring to capture attention, they capitalized on it. After all, that is part of the formula for hype. You do what you can increase excitement, even if it there is no benefit to the topic of discussion. I've been documenting details of each day of my Prius driving since that crazy 230 MPG claim over 4 years ago. I knew the real-world data would reveal the lack of simplicity so many of those back-of-napkin estimates claimed. The variance is enormous. People drive to far more destinations than just back and forth to work with an occasional grocery run. The proof now is overwhelming. As for the history, I posted: It was not *"daily driving"* distance. The quote stated *"commute"* distance. That difference was a major source of conflict in the early years. People drive elsewhere in the evening. Disregarding that fact wasn't constructive. Another issue was range-drop due to heater use being ignored, despite the topic being brought up over and over again. Now, the resulting kWh consumption to stay comfortable at the sacrifice of available EV distance is a matter known all too well by owners. Keep in mind that living further from work often means living closer to other driving destinations. There's often a tradeoff. Lastly, weekend travel isn't addressed either. It can vary significantly from during-the-week driving. Friends & Family don't always live nearby. Other non-routine destinations are further too.

- 10-29-2013** **EV Symbol, part 1.** The difference between this [EV] and this [] isn't obvious to some Prius PHV owners. For unknown reasons, they don't seem to notice when the symbol becomes hollow. Rather than saying "EV", it is blank at times. That's an indication of the engine running, most likely for heat this time of year. But while driving at fast speeds on the highway, the same thing happens. We're a bit mystified why that indicator gets overlooked. You'd think the pattern would be recognized after awhile. Apparently, it's quite a while for some. I provided the following information to one such owner in a thread many owners happily contributed to: Though, the same thing happens while traveling faster than 62 mph. The system switches from EV mode to EV-BOOST. That means you're still getting the benefit of extra electricity from the plug, but it's obviously going to be lower MPG than 999. Fortunately, it's quite a bit higher than what the non-plug efficiency can deliver during warm-up. As for offering electric heat, that gobbles up electricity at such a fast rate, you'd be starting up the engine anyway. Between the capacity available and the increased resistance due to the cold, the penalty is too much. Also, keep in mind that heat-pumps don't work well in extreme low temperatures.
- 10-29-2013** **EV Symbol, part 2.** By the way, that same indicator is available with the newer models of the regular Prius. The only difference is power & speed thresholds are much lower than with the plug-in. It's yet another feature showing how the larger battery-pack and plug offering is really just a package choice, that Toyota planned for the design to support such enhancements all along. Being able to update software and select capacity is the kind of flexibility needed to sustain business. You really don't know what the consumer will actually purchase. Adjusting production along the way is a fundamental benefit, a very important aspect of supply & demand. Some us understand that and really appreciate the effort.
- 10-29-2013** **Reliability.** This was encouraging to stumble across: *"I read an article on Consumer Report website and it said Prius is very reliable but Prius Plug-in is not so I am confused."* Getting feedback of bewilderment rather than blind acceptance is fantastic. What a great improvement over past encounters. Of course, knowing how to respond to someone receptive to enlightenment information is someone uncertain territory. That's new for us. In the past, those newbie posts were either outright attacks or purchase regret. That response of confusion is a step up. There's hope! Even so, you still need to be somewhat direct in reply. Being too passive may end up just contributing to the confusion. Getting their attention is what I went for: Huh? The only "not reliable" rating I could imagine would be due to lack of data, a blanket "don't know" yet statement. My ownership observations would put it at higher reliability. Think about how much less the engine is used. The warm-up process involves lower RPM and short-trips sometimes don't use the engine at all.

10-30-2013 **One Hit Wonders.** It's been rather entertaining later. A well respected member of the big Prius forum put it this way: "*There have been numerous similar posts from one hit wonders of late.*" I appreciated the way he stated the situation. Posts from those who obviously thrive on stirring the pot come and go. The pattern is for their membership to be brand new, for the thread topic they start to be somewhat controversial, and for their participation to end abruptly afterward. It's a little bit frustrating to see how they sucker naive members into worry. But then again, that's how they learn about the intent of some being disingenuous. It's too easy to assume everyone is being honest. Anywho, this was my insert into the conversation: The frequency of "*one hit wonders*" has been increasing lately. (Thanks for coining that term.) They've become rather sloppy too. Claiming 27.4 MPG is quite extreme. Even with kayaks on top, I couldn't get efficiency that low. I haven't even seen that in the dead of Winter here, during the worst of the snow-trapped traffic. It simply isn't realistic of a claim. No follow-up is a dead giveaway something isn't right. The owner facts listed don't add up either. Prius sales remaining strong, despite the dropping of oil & gas prices, as well as certain other competition struggling is good reason to keep an eye out for attempts to undermine. That wastes our time. Put ultimately, it helps point out how resilient Prius actually is. Gotta like that.

10-31-2013 **Winter Questions.** I tend to really enjoy this time of year. It's when I get to share my experience without being overbearing. In fact, people often encourage me to contribute more. That provides incentive to collect more data. I'm looking forward to filming more cold & snowy driving as a result. That's what really endorses the technology. The driving outcome speaks for itself. Being able to conquer the roads here says a lot. And since I have no choice but to drive in those conditions anyway, why not make the most of it? So, I do. Today, it was with: This will be my 14th Winter driving a Prius in Minnesota. I've experienced everything the cold season can dish out. So, I'm not sure what to say at this point. In fact, it drives much better than my mom's 2004 Corolla on snow & ice. So, there's really nothing to prove. It works fine. The key is to enjoy the slower speeds required for safer driving. MPG shoots up as a result. It's a win-win situation. Heck, you'll look at commute congestion quite differently. That nightmare of wasting gas is replaced by silent satisfaction.

11-01-2013 **Stigma, blending.** Sales results stirred up the rhetoric. That was expected. I joined in with: Rollout of PHV has made sense. Like the Original model, only select markets would get the opportunity to purchase. Like the Classic model, production was limited to size small enough to cause dismay. Since the goal of Prius has been to reach wide & deep into the mainstream, rushing the design that offers an option both affordable & profitable wouldn't provide any benefit. Let the hatchback, compact, and wagon become common first. Also, it should have been obvious that Toyota didn't want to get sucked into the struggle GM was having. Volt sales have been neither affordable nor profitable. Taking such a profoundly different approach was good reason to keep distance and prevent association. After all, Volt goes out of its way to avoid using the engine and Prius PHV takes advantage of it. That sacrifice of electricity for the sake of purity is a fundamental difference which can easily contribute to consumer confusion... in a market already filled with misconceptions. Seeing PHV sales exceed that of Volt, despite only being available in 15 states, suggests that rollout decision is working. Knowing that only 1 of those states offers credit incentives beyond the federal credit, since there are 9 others for Volt but not for PHV, further supports it. Also, don't forget that the federal credit for Volt is triple that of Prius PHV. As more people discover plug-in hybrids offer more than just an EV experience with an engine backup, it will become easier to sell. A big part of that is simply having enough owners reporting real-world data. It's ironic how there have been many attempts to stigmatize blending over the years, none of which have been able to prevent the advancement of Prius. That only slows it down... which is exactly what's needed for greater acceptance.

11-02-2013 **Stigma, reactive.** We have heard about the importance of being proactive so often, the antagonists are taking advantage of that by attempting to convince people that being reactive is bad. True, if you were caught totally off guard and took an extremely long time to actually react, that would indeed be bad. But waiting to see what others do before taking the next step yourself should be common sense. In the world of online forums though, senseless arguing is what's common. That's really unfortunate. Oh well, we have no choice but to deal with the nonsense each time it comes up: Remaining flexible has always been a positive trait in the past. If your business cannot adjust to change, you lose opportunity & money. Clearly, the greenwashing effort to stigmatize being reactive has successfully entered the mindset of some. It's pretty obvious too. The definition of change itself has changed. In the past, success was measured in terms of looking at overall production. Nowadays, automakers aren't given credit for replacing their high-volume fleet. Focus is almost entirely on trophy vehicles instead. It's really unfortunate that adapting to the market as you go isn't considered being innovative and that conclusions are drawn without looking at the big picture.

- 11-03-2013 Stigma, reasons.** Sometimes, there is an element of disbelief which contributes to your stamina to rebuttal, a backfire on the part of antagonists. This quote definitely fit that: *"The only reason Toyota had to adapt to the market is because the problems with the PPI were ones they created."* I was amazed anyone would try to make such a claim. When has an absolute ever been the case? There are always multiple reasons. In this case, there are many many many of them. We try our best though to listen to what others have to say. After all, sometimes an antagonist will reveal what they actually feel... which is what we are really after, since words are commonly a disconnect to what they are really thinking. The key is to keep discussion brief and on-topic. Then, it defeats the effort to antagonize and helps to retain some element of being constructive. I fired back with: Only! Wow! This forum is loaded with other reasons. Haven't you been reading comments owners and those researching purchase have been making? Assumptions, misconceptions, and efforts to undermine are still a problem. Simply reducing price and advertising would not have overcome that. Of course, we all know that focusing on what could have been is a red-herring.
- 11-03-2013 Stigma, innovation.** There are some who fall victim to the greenwashing efforts, totally unaware that they're preventing the spread of progress. We see it originating from the belief that innovation only comes one way. They think pushing range & power are key indicators of success, followed by price. The thought that it can come in more than one form or fashion isn't ever entertained. When an alternate method is suggested, it's just outright dismissed. Even sales are disregarded. They don't see how altering a design to target middle-market could result in any type of advancement. Factors like gas prices being relatively low don't get acknowledged either. As far as they're concerned, fuel cost doesn't even come into play. That is the result of so many years of effort from others to downplay importance... mostly because consumers are purchasing Prius regardless of what happens with the oil industry. Volt depended heavily upon the price of gas being high... making its particular configuration more appealing. The small battery-pack with respect to EV choices and the low MPG after depletion compared to Prius PHV made it quite a gamble. Being perceived as innovative required circumstances that didn't materialize. As a result, we now have a small army of supporters supporting an inflexible design not matching the goals of mainstream consumers. So, they attempt to stigmatize. That's just another technique to undermine. But lots of people are fooled into believing the arguments without doing any research themselves.

11-03-2013 Good Observations & Questions. A owners noticed the drop of in charging rate that happens after about an hour. He asked if interrupting it was ok then, since the bulk of the battery-pack capacity had already been replenished. Several of us were delighted to respond to that. I did with: That's normal for plug-in vehicles. It's why charge-to-80-percent is so often quoted. That's the capacity which the highest speed charging can used without sacrificing batter longevity. Above that level, it ramps down the rate at which electricity is drawn to ease the burden on the chemicals within. Observant owners with L1 chargers at home take advantage of that knowledge. Being aware that waiting for the final part of recharging isn't required comes in handy. New owners assume the charging rate is linear, having no idea a large portion of the capacity is replenished right away. So, they wait the entire time. Good job on the observation, right away too. And it's more difficult to notice that difference with a L2 charger. I'm sure there plenty of other owners out there who won't make that same discovery for a very long time... or ever. You now know the system is more dynamic than many realize. Sharing tips like this add to ownership experience. Go ahead, unplug before recharging is complete.

11-03-2013 Took It To The Dealer. We cringe when we read that. It's often the first post from a new member. You never really know what their intent is or how they will respond. Today, it was the owner was unhappy with the estimate value having dropped. Naturally, he made no reference to actual MPG results. It was solely a concern about that much misunderstood range of electric miles they've come to expect but never actually pay close attention too. Lots of assumptions makes responding a challenge, especially if you cannot keep their attention for long. Some just need to vent. Some are too frustrated to listen. Fortunately, some do end up enlightened and drawn more to the technology as a result. We hope for the best. Maybe they'll be more receptive to our posts than their visit to the dealer. I provided: There are countless threads about the misconceptions of how EV range is estimated & delivered. At this point in the year, maximum is no longer available for those seeing temperatures near freezing. That's how batteries work. Capacity is reduced and electrical resistance increased. Of course, cold affects engines too. So, the end of the warm season efficiency is nothing new. Remember that Prius PHV isn't an electric-only vehicle. It's a PLUG-IN HYBRID. So even when EV numbers goes down, you're still getting the benefit of the plug-supplied electricity. Those miles are simply counted as HV instead. We call that blending EV-BOOST mode. It's what normally happens when driving at speeds above 62 mph. But with the engine starting more often due to the cold temperatures, you'll see it happen when going slower too. In short, stop focusing on the EV number. Expectations should be on the resulting MPG. Notice that it's still well above what a Prius without a plug could deliver.

11-03-2013 **Interpretation.** I liked reading this: "A very common conceptual mistake is to interpret battery "EV miles available" as a fixed rational unit of measure, such as gallons or liters are for volume, or miles or meters are for distance." I joined in by adding: That is an excellent point. Back when Toyota was rolling out the early model of plug-in to ordinary consumers for review, a common discussion was on how EV capacity should be represented. Most with EV background stated range in terms of PERCENT was their preference. That made sense too, since most addresses the most misconception. However, it is still misleading. Driving fast. Accelerating often. Using the Heater or A/C. They all have a big influence on outcome. Add to that the confusion new models introduce. An increase in kWh would result in much more EV, but that wouldn't be represented by a PERCENT value. It would contribute to problems in the future. That's why Toyota chose to use MILES instead. The number still misrepresents, but it gives a better idea of what you might get. It's too bad many people don't realize MPG in their traditional vehicle fluctuates too. Have a display that provides on-going detail about efficiency is a mixed blessing. The consumers who were used to just filling up their tank with gas every 300 or so end up struggling to interpret the wealth of information the regular Prius provides. Adding a plug complicates matters. They come from a world filled with assumptions. We introduce them to new concepts. That takes time & patience to get through. Some, like the poster who recently revived this old thread, assumed there was something wrong and brought his Prius to the dealer feeling lost and unhappy.

11-04-2013 **The Engine.** When it runs, those instances are noted. Patterns are observed after awhile. Detail is often missing. Incorrect assumptions are made. Advice is provided based on that. It turns into a mess. They don't understand a mistake had been made on their part. The trap is easy to fall into too. We do our best to educate without being pushy. Today, it was this that stirred the pot: "*In addition if you want heat or if you need some acceleration the engine comes on. Hope this helps.*" That sincere effort to assist another owner should be respected. After all, the forum environment is often filled with lots of people contributing thoughts. Hopefully this was worthwhile: Actually, you just unknowingly contributed to the generalization misconception we've been struggling to squash. Heat will indeed cause the engine to start, but it will shut back off too. People jump to the conclusion and just assume it never does. To keep warm, all you need is not engine coolant... which remains that way for awhile, even with the engine off. Years ago, I remember getting stuck in a really bad snow-congested traffic jam with my 2010. I was able to creep along with the other cars in EV, watching the engine remain off for 8-minute cycles. Acceleration isn't cut & dry either. I certainly can't accelerate onto a highway using only electricity, but turning onto the big 45 mph road through town in EV is no big deal. Climbing the steep 40 mph hill by my house from a dead stop at the bottom is no big deal in EV either. But even if the engine did fire up, when warm, it shuts off immediately after the acceleration is complete... and you sometimes get a little bit of electricity replenish from the engine at the same time. In other words, the system is much more dynamic than people realize and we often don't realize our side comments contribute to confusion about how it actually works.

- 11-05-2013 Party.** Things sometimes fall apart. Certain individuals like to provide their own "leveling" information. They want each automaker to be treated equally, regardless of the situation. That's not constructive. In fact, it's quite annoying. This got me going: *"Toyota will be very late to the party."* That was obviously someone coming out in defense of GM and Volt. Thankfully, 2014 isn't too far away. That automatic resetting of stance due to a new year starting really does help... because the doses of reality we provide certainly don't for some: The goal hasn't ever been to party. It has always been to change the norm, to break the status quo. There's a fundamental difference between targeting early adopters and appealing to middle-market. Fortunately, even those who has previously exclaimed *"vastly superior"* are finally accepting that reality. Selling in high-volume and making a profit doing it, without the assistance of subsidies, is what each automaker is striving for. None have achieved that yet. So, there is no concept of late either. The rush some insisted upon and careless disregard for consumer needs wasn't anything worthwhile to pursue. Seriously, what was there to lose by waiting? A midyear rollout to new dealers may sound good on paper, but in practice it takes awhile for salespeople to learn about the new vehicle. That takes time. Waiting until the 2014 model arrives instead makes sense. Step back to look at the big picture. Toyota has been working hard to replace traditional vehicle production with hybrids. That's the point. Expanding to offer a plug will draw in both PHV and more regular Prius sales. We see how many misconceptions and how much pushback there is still. Look at where the other automakers are with respective to replacement. Business is not a party.
- 11-05-2013 Japan Sales.** Honda's Fit unseated Prius from the top-seller position in Japan. Last month, 23,281 were purchased. (There, a hybrid model is also offered.) Sales for the regular model Prius were 20,886. For the smaller model, known as Aqua, there were 19,984. So, kudos to being able to compete so effectively with Toyota. I get a kick out of how much higher the numbers are there in Japan than what we see here. That wasn't always the case. Hybrid sales in the United States were leading the industry. Japan's economic recovery combined with the need to replace caused by the multiple disasters the population faced sure changed things for the better. Someday, perhaps that will happen here. Oh well. It's not like progress isn't being made. It's just slower here... frustratingly slower. But that's still a step forward. In this case, it's a month at a time.
- 11-06-2013 Must Be Replaced.** Sometimes, I need to vent. Certain individuals online thrive on attention, so they'll intentionally cause trouble. They are what I refer to as antagonists. They will do everything they can to prevent a discussion from ending. Drawing a conclusion brings an end to their entertainment. They aren't actually like trolls though, since there is an aspect of being thought-provoking. They don't just contradict and argue for the sake of spite. They repost old talking points over and over again. Fortunately, it gets old. Drawing focus back to purpose often ends a particular debate effort. It gets tiring though... but there is an aspect of curiosity. Do they care? Anywho, I posted this: That careless disregard for ordinary consumers never ceases to amaze me. But then again, it isn't at all a surprise. Automotive enthusiast interests weren't ever focused on middle-market needs. We all know how well positioned Toyota is already for delivering an affordable & profitable plug-in hybrid. That irritates to no end those who support niche efforts. The voices of the mainstream keep pointing out what's truly important. Continue distracting all you want. Pretending the big picture doesn't matter isn't constructive. It won't change the reality of the situation. Traditional vehicle production must be replaced.

11-07-2013 History Repeating. It is somewhat bizarre when it happens so many times, you not only recognize the pattern, you can also accurately point out what the antagonist will do next. That's what we've seeing lately with the downfall of Volt. It is no longer considered "*vastly superior*" by the enthusiasts. They've officially withdrawn from that war... finally realizing surrender isn't necessary, that their conflict was artificially created by them... that the true war is competition with traditional vehicles. With the plug-in Prius matching sales, despite not having the federal or state credits like Volt, it was reason enough for this attitude change. But seeing the steady rise of Ford was a very good wake up call. I simply didn't make any sense waging battles against those trying to win similar victories. Thankfully, that took us back to fundamentals. First was attacking those who were correct all along by claiming their intent was something other than what it actually was. After all, pride still influences actions. I've seen this before firsthand. They'll imply you said something, but won't actually refer back to any quote... despite your requests to see the supposed quote. It hard to know why they don't. Often, emotion clouds memory... hence me writing blogs to preserve exact quotes. That makes searches to find the original post simple. They don't do that. They make assumptions instead, which contributes to incorrect associations. Self-Convincing is a powerful healing mechanism. Second, they spin the difference between want and need. You can clearly point out an example, like the need to be able to seat 4 people. It should be easy to point out that more leg & head room is a want. But instead, they reply with the introduction of something slightly off-topic. Today is was: "*No one needs a prius, let alone a prius phv.*" We all know there is a need for improved emissions & efficiency. That's why Two-Mode became such a major controversy. 22 MPG wasn't enough, period. They wanted a monster-size vehicle. But the necessity to improve the traditional offering was blatantly obvious. Long story short, there are some who will do everything they possibly can to prevent conclusions from being drawn. They are so desperate to retain the status quo, they are willing to say just about anything. My advice is to state facts and move on. Don't argue with them. I didn't this time. I wasn't willing to repeat that.

11-09-2013 Evening Errands. Virtually all the discussions about plug-in vehicle use focus on commuting. The drives you do after work are rarely addressed, even though those miles can add up to quite a lot and the vehicle may not have much or any charge left at that point. Of course, that would be the very reason why the topic isn't discussed with Volt. Depleted mile means very low efficiency, MPG like a high-efficiency traditional car... not even close to what Prius delivers. Anywho, that's why when the topic is encountered, it's with respect to pure electric-only vehicles instead. I couldn't resist the topic came up tonight. It was a well timed opportunity to share my recent experience: Perfect for going to get groceries? That usage works fine for a small EV, but not for what I did last night... Late in the evening, with my battery-pack fully recharged, I headed out to the hardware store. There, I purchased brackets and two 8-foot shelves. With the front seat lowered, the entire load was swallowed up by the Prius. It's no big deal carrying cargo that large inside. The entire drive was with only electricity too. That practical design of Prius is what has won over many owners. They were drawn to Prius by the emission & efficiency improvements, but it was that ability to haul lots of stuff that sealed the deal. Competitors tried to convince people that it was the unique look, that it served as a smug declaration of being green. Those actually purchasing a Prius knew that wasn't true. This is why Toyota placed such a high priority on PHV design not interfering with existing interior space. Getting a plug wouldn't mean having to sacrifice the ability to haul large objects.

11-09-2013 New Tire Update. We're seeing a lot of questions about Winter driving and tires now. This is my latest contribution to the discussion: I've only had my set for 2.5 weeks now, so there isn't much to report yet. The only snow we've got so far melted right away. Reading online comments outside this forum, opinions were all over the place. Since road conditions can differ dramatically, as well as the way people actually drive, I went with the consensus here that they'd do well. After all, I tried the HydroEdges way back when they were still quite new and had pleasing results on snow & ice. And living in Minnesota, I'll certainly have lots of opportunity for Winter driving. We got hit especially bad a few times last year, so I still have vivid memories of the factory tires. Those tires only made it to 30,000 for me, since actually reaching replacement wear-level would have been mid-Winter. I took advantage of Fall sale prices and the fact that they were in stock. I've heard backorder waits are common for them. The initial impression are these tires will get my recommendation too. Driving at 44/42 PSI, road noise was my first want-to-know. Thankfully, they were actually a little quieter. For traction on dry & wet roads, they've been nice. They seem to take corners fairly well. But the ultimate test hasn't come yet. Snow handling will tell us a lot. In the end, like most owners, I want a tire offering a nice balance of traction & wear that delivers great MPG for a reasonable price. Stay tuned for updates. Right now, I'm still trying to enjoy the final days of Fall.

- 11-09-2013 Purity & Naysayers.** There are a few that have an extremely difficult time looking forward. Still wanting to win arguments lost long ago burns them up inside. You catch a glimpse of their frustration every now and then: *"Also note that a pure series design would take a lot of the wind out of the sails for Volt naysayers. The fact that the engine connects to the wheels in some driving modes seems to create a lot of negative image issues for the Volt."* Ask yourself who cares about that anymore; even most of the enthusiasts have moved on. I pointed out: For years, Volt enthusiasts praised the purity design. Then when it was discovered that wouldn't actually be delivered, there was a huge uproar... by them, not the naysayers. The rest of us always knew about the benefits of blending and were in dismay about how that approach had been shunned. The negative image was self-inflicted and continues to be. Notice your own comment in this thread: *"Tesla feeds on the *more is better* mentality, but in the end there's really no need to haul around..."* That's another example of the same thing, image dominating discussion. It eludes to the actual problem, but ends up missing it. Heck, even a diminishing-return graph was included. The need is to improve overall efficiency. Using more electricity doesn't necessarily accomplish that. It transfers consumption from one fuel to another. The same lesser gain (diminishing return) comes from MPG. Yet, we see that being flaunted as the indicator of success. Higher is promoted as better. Real-World impact of factors like heater consumption and vehicle size aren't taken into account with graph averages. Things like weekend errand-running and trips to see friends & family aren't represented either. Everything must be improved. One size does not fit all. In other words, the hope that a small battery-capacity increase can compensate for an efficient engine isn't a real solution. With the price of oil currently at \$94.60 per barrel and gas no down to \$2.89 per gallon for some regions, it should be a wake-up call that selling high-efficiency vehicles will continue to be a major challenge.
- 11-10-2013 Always That Way.** A sign of defeat is when they make that claim. Today, it came with in an argument starting with this: *"First off, EREV has always been a subset of the plug in hybrid definition. Just like mild, assist, and full are subsets of the hybrid one."* That was astonishing to read. I was left flabbergasted. That isn't the slightest bit true. People have selective memories though. That's why I blog. Being able to easily search the past comes in quite handy. I chose to respond to that with: I have many, many quotes in my blogs contradicting that claim. They were documented back then knowing attempts to tell a different story would occur later. Enthusiasts had much different expectations. What they hoped for is not what ended up being delivered. But guess what, it doesn't matter anyway. The label continues to be vague and the official organizations have simply moved on. CARB wants significant emission reductions. *"BEVx"* is a good example. The new category is their push toward which: The vehicle must have a rated all-electric range of at least 75 miles (higher than the 50 miles required of a zero-emission vehicle); The auxiliary power unit must provide range less than, or at most equal to, that battery range; The APU must not be capable of switching on until the battery charge has been depleted; The vehicle must meet "super ultra low emission vehicle" (SULEV) requirements; The APU and all associated fuel systems must comply with zero evaporative emissions requirements.

- 11-11-2013** **Asking Questions.** That's what ultimately brought the antagonist rhetoric to an end. Everyone lost interest when they kept avoiding what was asked. Instead, they'd accuse you of what they were guilty of. It's the pattern of behavior often attributed to the end of chapter in history. In fact, you'll get accused of continuing to bring up the past because they refuse to discuss the future. I find it all quite telling. Basically, you can flush out which areas of concern they are most worried about by observing their reactions. In this case, it's the fact that Volt is no longer thought of as distinct. It's simply thought of now as a plug-in hybrid with a larger battery and a smaller body that GM is struggling to sell. Since all of the posts are taking place on the big Prius forum, you have to wonder who they think their audience is. They are supporting claims with real-world data like I would do on the big GM forum or that daily blog for Volt. Posts have been nothing but an effort to get people to not look forward... which makes sense, when there's nothing to look forward to. Think about it. How will Volt compete in a market rapidly filling up with other choices? All it has going for it is a large battery-pack. Ford, Honda, and Toyota all offer higher efficiency following depletion and mainstream consumers aren't interested in electric purity. We see Tesla & Nissan dominating the EV market. The other choices, like Focus & Spark, are barely stirring any interest. In the end, it boils down to what I had been saying all along. GM is competing with itself. When Volt doesn't stand out among the other automakers, those loyal to GM will simply purchase another GM vehicle. That choice continues to be another GM traditional offering. Malibu, Cruze, Equinox, and even Sonic are selling much better. The other offerings, like GM brand: Camaro, Captiva, Corvette, Express, Spark, and Buick brand: Enclave, Encore, LaCrosse, Verano, and Cadillac brand: ATS, CTS, SRX, XTS are all selling better too. Then when you take a look at the trucks, like Silverado, Suburban, Sierra, Acadia, Tahoe, Traverse, Terrain, and Yukon, it's quite obvious Volt barely even gets noticed. That's why asking questions works so well. They absolutely refuse to look at the big picture. By seeing that list, it's pretty obvious why.
- 11-12-2013** **Intentional Misleading.** Reading a post like this is maddening: "*The EPA rates it as 6 electric miles, the 11 mile rating is the EPA rating that uses gas to get the 11 miles. I'm not sure why most people think it's 11 miles. It says 6 miles right on the sticker albeit in a smaller font...*" I couldn't let that go, especially since it was a clear effort to reach out to a new audience on a new blogging website. I knew who it was and what he was up to: Not sure why? People keep bringing it up to confuse and raise doubt, to intentionally undermine acceptance. That should be obvious by now. We keep pointing out that the capacity is 11 miles and the fact that the EPA test breaks it from being continuous due to a hard acceleration at the 6-mile mark. The engine shuts off afterward. You continue driving along using only electricity for another 5 miles or so. On my commute taking the river route (max 55 mph), I average 13 miles continuous. In the dead of Minnesota winter, it drops to 9 miles. During the nicest days of summer, it climbs to 15 miles. So, that 11 miles is quite realistic. But it really doesn't matter. The purpose of a plug-in hybrid is to deliver a significant efficiency improvement. 1.5 years of driving mine (31,323 miles), the overall average comes to 76.8 MPG. Clearly, the purpose of the added battery capacity has been fulfilled.

11-13-2013 Moving On. The ironic nature of a person doing the most to hold back progress complaining about others doing that very thing is fascinating. We see it all the time. Do they? The contradiction should be obvious to spot. Yet, we still get this: *"Yes, I would like to move on and not continue to have past conversations."* That stirs anger, since bringing up the past is exactly what continues to happen... by him, not us. It's a not-so-typical example of a troll. The reasoning is simple too. Just ask yourself what his purpose is, why is he there? No answer to that question indicates he actually thrives on repeating conversations of the past... hence routinely bringing them back up... in defense of Volt, of course. Nonetheless, I took a stab at it anyway: What would you like to discuss? When I bring up the big picture, it becomes an all-out assault to change the topic to something other than what to sell. The most hypocritical thing I hear on a regular basis is the claim that Toyota has invested so heavily in the Prius design, they are unwilling to invest in something else. Reading that never ceases to amaze me. GM sold 42,660 Silverado Pickups here last month. How can we possibly be taking the situation seriously by ignoring that? That certainly looks like an extremely heavy investment. To make matters worse, getting acknowledgement that need requires focus on replacing high-volume traditional cars like Camry, Fusion, Malibu, Impala, Corolla, Focus, and Cruze is basically impossible. That leaves us without an audience to discuss. It started out reasonable having a profitable target being set at \$30,000. That got abandoned though. Things fell apart from there... leaving us with nothing to move on to. Past conversations were attempts to find out what comes next, to move forward. What should our expectations be for mainstream consumers, those middle-markets buyers who are simply looking to purchase a practical & affordable choice that offers higher efficiency and lower emissions?

11-13-2013 Pride & Money. We keep hearing about GM's desire to compete directly with Tesla. That doesn't make sense without context. Supposedly, that means a 200-mile EV for about \$30,000. Who will the market be? Wasn't the goal of Volt to reach the very same consumers or is this something that somehow still has range-anxiety? With all the anti-EV campaigning of the past, it's really uncertain knowing what to actually expect... which is the very problem Volt had in the early days of development. Remember how all those vague & ambiguous statements led to false hope & disappointment? What about all the hype in the meantime? Someone tried to be the voice of reason today, but an example of Volt becoming a higher performance vehicle clouded judgment. It's history repeating yet again! Remember all the excitement about 0-60 times? Ugh. Anywho, this was the comment: *"GM does not need a hotter Volt, it needs a cheaper Volt with one more seat. Given the low sales, it's hard to imagine GM putting a lot of resources into Volt features that won't enhance its mainstream appeal."* I joined in with: GM's resources will be focused on where the profit comes from. 42,660 sales of Silverado pickups last month were purchased last month. That's what provides business-sustaining revenue, which means it will continue to get the attention to maintain sales. How Volt will compete with that is a mystery. Funding a low-volume seller is a very real problem. It must change in some way to attract significantly more buyers; otherwise, it will remain a niche offering. Like it or not, that's the situation Volt faces now. Cheap gas and a growing array of choices of other automakers is a sign of greater challenges to come. The advice to just wait for the next generation to work out issues is very risky. Time is working against Volt. Talk about an SS model is a step in the wrong direction.

- 11-14-2013 Choices & Reality.** Needless to say, my comments went nowhere. Certain people have no problem dismissing facts and ignoring the big picture. That still amazes me, no matter how many times I encounter it. Hope is great. But hope without consideration of the situation is a recipe for failure. Oh well. I keep trying: Don't you see the pattern? Seriously. It's played out several times now. Maybe that isn't obvious, but the lack of any conclusion should be. It's a worldwide market which is actively changing. Toyota's improvement goals cannot be achieved on paper. So no matter how much you speculate, it just plain doesn't matter. That avenue has already been exhausted. There's nothing left. Everything that could possibly be tested in a testing environment already has been tested. Understand why Toyota's choices were made? They selected the best approaches for each audience based on research information collected and released each configuration into each region. It's real-world data that will influence the next decisions. They will observe and adapt. No amount of online posting will change that reality. The "best" arguments just plain don't work. With all the driver, traffic, distance, temperature, and other differences, there's simply no other way of finding out what's effective without actually trying. So, that's what they're doing. See it now?
- 11-15-2013 Defensive Spin.** The big GM forum is dead, there's no Volt discussion there at all anymore. It's as if the vehicle never even existed. Considering the participants are strong supporters of GM, that says a lot. They've clearly moved on. What had once been the premiere source of information for Volt, as well as the biggest contributor to hype, has grown very quiet lately. It's not silent, since content from the host website posts a copy of articles there too. But the focus is on the industry in general. There is literally no outlook anymore for Volt itself. This is why the antagonists only post on the big Prius forum now. They've turned to defensive spin. Nothing constructive comes from them anymore. At least in the past, there was some sense of direction. That's gone now. This is why I pushed so hard for so long for goals. Even if they weren't met, at least they'd have something to keep focused on. How do you promote a vehicle without a clear purpose? All those mixed messages and stance changes wrecked any aspect of cohesion they had built up. There isn't anything left. Starting from scratch next year should be interesting. Wait for a new audience. Plant a new idea... because the seeds of doubt certainly didn't make any difference. Prius remains strong. They didn't like how I concluded that long exchange about purpose either: Goals were clearly stated. Goals were clearly met.

11-16-2013 **Final Spin.** The rebuttals went no where. It's clearly over. I'm looking forward to next year. Something tells me they are not. This is how I concluded the exchange: Reading claims that the plug-in Prius had different goals is quite vindicating. It's easy to spin now, long after the fact. But I documented what was said back then, in great detail. I know how Volt was hype to deliver 50 MPG after depletion and a 40-mile range prior to that... all for an affordable & profitable price. Instead, cost was much higher, range took a massive hit in the winter, MPG afterward was much lower, and the engine didn't even achieve a green emission rating. Seeing Prius hit much closer to the mark and also be a larger vehicle makes it understandable why some would go to great lengths to preserve reputation. We even knew the damage-control effort would be so thorough, some would accuse Prius supporters of doing the very same thing. Fortunately, we know what actually happened. We know what is happening now. There isn't even much to argue with either. One of the complaints about the Volt design early on was its lack of flexibility. The platform took a one-size-fits-all approach. What business could thrive with such lack of diversity? The topic here is sales. Toyota has delivered an array of engine, motor, battery configurations. That variety of offerings has worked well to confirm the HSD design. The next step has been taken by expanding battery choice and including a plug. We see Ford striving to do the very same thing. Honda would like to as well. That leaves GM in an awkward position without a clear direction of how to proceed. Options are quite limited. That's why there is so much resistance to discussion about 2014.

11-16-2013 **New Spin.** With all the usual venues exhausted, the only outlet for comments is on the blogs for general audiences. With those, you get a very diverse set of participants. Like usual, detail & follow-up are almost non-existence. Nonetheless, it is intriguing to read what gets posted: *"Ugh, Toyota, seriously... what is this, some kind of compliance car or tax credit grabber... a 10 mile range is just barely useable, almost not even worth plugging the car in for. I don't understand the rationale behind designing it this way."* That was in response to the CARB proposal to limit ZEV credits to vehicles able to deliver full EV for a minimum distance. Since that approach doesn't take overall emissions into account, there is obviously some opposition. Challenges to the proposal are emerging, with Toyota being the loudest voice. Being well aware of design tradeoffs, focusing on technology rather than outcome doesn't please. Setting clear criteria makes sense, but at the cost of this isn't worth it. To be specific, the vehicle must unconditionally deliver full EV for the first 10 miles. I wouldn't like having to sacrifice capacity for that. It would be the loss of a "hold" button, increasing the speed threshold, and requiring electric heating. Why would I want to give up the choice of starting the engine sooner to save EV for later? It's with good intent. But the results would be a net loss. I responded to the comment with: The rationale is simple. The plug improves efficiency in an affordable way for the masses. I've been averaging 76 MPG with mine over the past 1.5 years (33,000 miles). That's an undeniable improvement over the regular model Prius, while still being able to carry large cargo in back. Efficiency after depletion is improved a little too.

11-16-2013 Delay Excuses. The beginning of this year brought hope. Ford had just rolled out the Energi option, their plug-in hybrid design. It introduced an unknown into the market. In the past, Toyota had throttled back plans to allow friendly competition to get a foothold first. That made sense. Why fight another vehicle with the same purpose? After all, sharing goals is how industry changes. The catch is, delay cannot be too long. Waiting until 2014 rollout for plug-in Prius nationwide availability made sense. Ford supporters appreciated that. Volt supporters took every advantage to exploit & undermine instead. The difference was striking. But with the next generation of Voltec planned for rollout at the same time, they had reason for that smug. Then they found out it wasn't actually going to be an upgrade (as they had coined it, the "1.5 version"). That news caused a great deal of upset, resulting in retaliation... using Toyota as the scapegoat. It was a sad display. To make matters worse, it meant increased competition. But later was all they could hope for. So, we got a slew of delay excuses. In the end, it boiled down to lack of diversity. GM decided to invest in a loss-leader, spending money on a low-volume vehicle for "*halo*" benefit. Even the most staunch of Volt supporters knew how bad that looked. GM was clearly not following the path of Toyota; the biggest delay excuse they had been using was discredited. Oops! I summarized that disenchantment with: Highlander & Camry were the variants that followed... both were middle-market vehicles... in a format quite different from Prius. One was a SUV with AWD and the other a top-selling family sedan. It's 3 years later. Rather than the next rollout being a variation of Volt configured to reach the masses, we get Cadillac ELR. What the heck?

11-17-2013 Divided Support. Now that Volt enthusiasts basically no longer exist, having been replaced by true supporters, it's easy to see there's a clear mindset divide. On one side, you've got those who have went to great lengths to describe the design & operational detail of the system. Complete with diagrams and even patent references, we have been shown Voltec is the successor to Two-Mode. Having been told GM would eventually reconfigure it for use in smaller vehicles, that makes sense. There's no conflict or contrition. They accept that as natural progression of the technology. On the other side, there are those who absolutely insist Volt is brand new, that nothing GM had done in the past applies. Seen as a fresh start, they figure it should be given at least 5 to 6 years before any mainstream expectations can be made. Separation, in their mind, provides an excuse for delay. Promises of the past don't matter. It puts them directly at odds with those other Volt supporters. As a result, the behavior is to not acknowledge their existence. Instead, they claim any remarks made on their behalf are really just defenders of Toyota and the plug-in Prius. I find that divide fascinating. It means there will be arguments about approach & goals to come. Watching that play out, while Toyota steadily penetrations into middle-market along with Ford and possibly Honda, will solidify the best-of-both-worlds decision. Striking a balance, to take a decent step forward without over doing it, is what's needed. Meanwhile, there will be Volt struggling to send a message to consumers, who will get negating claims from divided supporters. Ugh.

11-17-2013 **Realistic Focus.** Random comments like this make you wonder: "*The Volt is becoming more and more an attractive offer.*" Some people make assessments based solely upon observation. They don't actually research. They assume what they encountered is a true reflection of technology advancement. Being unaware of market influences is nothing new. That's why expectations are so often a complete disconnect from reality. Of course, some people have the perspective of an individual purchase and simply aren't interested in what everyone else has to contend with. You never know. So, I responded with a question: The current MSRP from GM isn't profitable yet though. So, don't expect it to be an option for the masses... unlike with Toyota's approach. Volt is also considerably smaller in back too. Legroom and head positioning simply cannot compete with the larger interior Prius PHV offers. The ability to carry large cargo doesn't compare either. As for the "AER" rating. People continue to overlook the actual kWh capacity. That's what matters, not whether or not EPA testing criteria is perfectly matched. In fact, people use to complain about automakers rigging their configuration to deliver maximum EPA rating results. Kudos should be given to Toyota for not doing that. The point is to use the electricity available most efficiently. Delivering a pure-electric experience under all driving conditions doesn't actually do that. Looking at real-world data, we see the overall benefit of blending... which sadly, the proposed ZEV credit qualifications don't take into account. Setting a minimum sounds realistic. But is it really worth it if the electricity isn't used effectively? Shouldn't we focus on best use instead, especially configurations with high-volume sales potential?

11-18-2013 **Basic Accounting.** With the discussions of Volt pretty much dead now, it's nice getting back to the basics. I was thrilled to finally see this emerge: "*In terms of basic accounting though, products that incorporate new technology or a novel concept generally aren't profitable until the second generation.*" Of course, I don't expect much to actually become of it. But at least the mind-numbing circular arguments aren't getting traction anymore. It certainly would be nice to get thoughts on 2014 sales & promotion. But that isn't realistic considering the lack of options available... and we know what blind hope leads to. What should we expect? I'm seeing market preparation (education, attitude, charging stations, etc.) swinging favor toward Prius PHV. The ordinary consumer is looking for a plug-in option, one that's simple & affordable. I don't hear the claims of greater capacity being a necessity from that audience. It's much like the enthusiasts of the past. They don't understand how mainstream purchase priorities are different from theirs. They lose touch with those who don't put a great deal of importance on their vehicle. Transportation that's focuses on being well-balanced & practical is what sets them apart from being enthusiasts. Why can't they see that? Anywho, I simply responded with: The catch is, that wasn't the plan for Volt. GM had planned to hit mainstream volume in the third year. They even stated a production capacity target of 120,000 with the hope of actually needing it. Falling well short of that with sales and the drop in MSRP raises good reason to ask what the intent is with the remaining years of the first generation.

11-18-2013 Dropping Temperatures. That stirs lots of participation online. New owners are especially vocal. Some are quite intrigued and willing to purchase an aftermarket gauge to learn more. This is the information I provided to one such individual today, who asked specifically about coolant temperature: 195°F is the norm for full warm operation, the usual sight for summer driving. Your observation of 190°F (88°C) is typical this time of year here. (I'm in the Twin Cities, like you.) It may or may not get higher. That all depends upon the conditions outside, travel speed, distance, stoplights, heater & defroster use, etc. Having an aftermarket gauge showing coolant temperature allows you to know what will happen when, allowing you to take advantage of heat that otherwise may have been assumed was unavailable. Avoiding engine use causes some owners to make unnecessary sacrifices. Watch what happens at 145°F in NORMAL mode with the heater on. The engine will start when it dips below that. Simply by switching to ECO mode, the engine shut back off. It's because that mode lowers the threshold to 114°F. Did you know that? Blocking the grille helps with heat retention. You'll discover how valuable that is in 2 months, when the bottom drops out on the thermometer. Fortunately, Prius still delivers great efficiency, despite low temperatures outside. In fact, watching coolant on the gauge, you'll see that EV is available even then. Add RPM values to display on the app. You'll find the MG1, MG2, and Engine values quite informative. The system is much more dynamic than most people realize. Those two motors interact with the engine in a variety of ways and their RPM frequently changes. The system takes full advantage of having a power-split-device. Enjoy that new tool for learning more about what happens behind the scenes while driving a Prius.

11-18-2013 Industry Resistance. What a great topic. Automakers fight change. We see that all the time when it comes to regulations. They'll kick & scream even to do just the minimum. Example are abundant too. It's sad. Ironically, Toyota has actually worked that to their advantage with respect to Prius. Think about how unstoppable the advancement of Prius has been. There's simply too many ordinary people that purchase them. Those are the consumers who just plain don't care about the rhetoric. For that matter, they don't even follow it. Their purchase decision primarily comes from checking out the car for themselves. Stopping at the dealer for a close up inspection and a test-drive convinces them to buy. It's a simple formula... deliver something practical & affordable. The hype surrounding Volt was amazing. I kept asking the "Who" question in dismay, wondering how that could possibly appeal to someone from middle-market. It was a vehicle with characteristics which didn't match that of other mainstream offerings. How could something so different attract enough sales? The efficiency and green approach has drawn in many for closer looks. The midsize seating of Prius and generous cargo area won them over. Adding a plug requiring nothing more than the same knowledge & outlet required to recharge their phone as a package comparably priced with other upgrades option positions it for mass appeal. Where's the resistance going to come from with that? What good would it do for other automakers to resist offering something similar? If they try to step it up by offering a system with larger capacity, it would act as an endorsement for Prius... confirming the addition of a plug is safe & reliable. Notice how the computer industry thrives on purchases of products with well-balanced features? Only the dedicated purchase systems with large capacities (storage & processor). The major just get something in the middle. How is the automotive industry any different? Think about where production & profit are focused.

11-20-2013 Morning Commute Video, appdata. Prius uses a power-split-device to allow the interaction of 2 electric motors and a gas engine. Each operates independently to take advantage of efficiency opportunities. Some are quite brief, a few seconds. Others can last much longer. Being able to adjust RPM is how the system achieves improved use of the energy available. With the regular Prius, that means all energy is ultimately derived from gas. Yet, much improved MPG is delivered anyway. Having the ability to quickly adjust is the key. Adding a plug, like the PHV model of Prius offers, further expands upon those opportunities. Most people have no what actually occurs when that happens. This video will help to reveal what those motors and the engine actually do. At times, you'll see the engine off while the MG2 (the large traction motor) provides propulsion. Other times, you'll see the engine provide some power. That power is directed to both the vehicles wheels and to MG1 (the smaller motor, which operates as a generator). When coming to a stop, MG2 becomes a generator to capture the unneeded kinetic energy. It's all an interesting dance of energy flow, continuously changing. It's also important to keep in mind that the primary purpose of Prius is to deliver cleaner emissions. The system will sacrifice some MPG for the sake of reducing pollutants from the engine. This is achieved by cleansing, using heat. That's what makes knowing the coolant temperature so important. Engine heat is used by the emission system. When it is cold outside, engine heat captured by the coolant is what warms the interior of the Prius too. SOC is the battery-pack's State of Charge. 85% represents "*full*" and 23.5% represents "*empty*". Not actually recharging the battery-pack to 100% or ever depleted to 0% helps to prolong its life. Either extreme is stressful on the chemicals within. So, the system goes out if its way to avoid that. Watch the video of my commute to work, presented at 5 times normal speed. Note the outside temperature of 25°F, which marks the early signs of Winter here in Minnesota. Parked in an unheated, but insulated, garage overnight is why the coolant shows a little bit of warmth. The engine is still ice cold when I enter the ramp for the highway. Fortunately, it warms up fairly quick. At the end, you'll photos of the dashboard displays in the Prius. They show a summary of the drive. In this case, the 16.8-mile trip resulted in an overall efficiency of 128 MPG. That works out to about 0.13 gallons of gas and 3 kWh of electricity (including charging losses). Note that the average-speed value measurement includes the time while the Prius is stopped, waiting for a light to turn green. Lastly, that screen showing the on-going data while I drive is video of an application running on my phone. It's connected to the Prius OBD-II port using Bluetooth. I setup a camera to capture that information, then just combined it with the video of the scenery from a second camera afterward...
[video: Morning Commute \(appdata\)](#)

11-21-2013 Stalled Interest. The blog has been dead, nothing seems to stir any movement... even a provoke. No one knows where Volt stands anymore. It has befallen to silence. Today, there was a new article about ELR, the Cadillac variant. The topic was it offering a "smart-grid ready" feature. Being so far removed from what ordinary consumers seek, it was no surprise this popped up in the discussion: *"Too bad GM didn't give the ELR more battery range than the Volt instead of all the stuff that doesn't really matter. For the price they want a bigger battery should have been part of the package."* That peaked my interest. Would responding result in anything constructive? That's unlikely, since the blog is known for down-voting facts. Who knows how or even if anything will come. Heck, even on the big Prius forum the discussions of Volt have stalled. Pretty much everyone has given up. So, I posted: With such heavy promotion of the "40 mile" range importance, offering more would undermine the technology. After all, there were quite a few mixed messages and a serious lack of clarity in the past. The last thing GM wants to do is contribute to that again. Put another way, they've backed themselves into a corner with respect to perception of the technology. Advertised as an EV with engine backup and falling short of the growing 50 MPG expectation, options are limited. So, we are left waiting for the next generation, an uncertainty period which contributes to other automakers building recognition of their own offerings in the meantime. Volt was a rollout with lots of risk, depending upon a quick market shift to electric. That hope didn't pan out. The concerns of cost & acceptance were proven to be factors which should have been given much higher priority. GM is stuck having to backtrack and offer creature-comforts while we wait.

11-21-2013 31.1 Million Shares. There was much celebrating today. First quarter next year was the expectation for the final sale of the last remaining share of GM still in possession of the federal government. No one really knew how long the selling process would actually take. So, it was quite a surprise finding out there was only that many left and they would be sold soon. Of course, put in perspective, that's still a lot... but nowhere near as much as the 500 Million originally purchased. GM supporters hated the stigma those shares caused. It was this dark storm cloud reminding everyone of their unfortunate past. I didn't care for them either, but my perspective was that of a reminder to the desperate measures the pursuit of profit caused. The bankruptcy was ugly. So, the shares were necessary. Sadly, we are seeing some of the same problem emerge again. Heavy emphasis on money from Pickup & SUV sales is the worry. It's a red-flag, a behavior matching the past all too well. Lack of balance is the heart of the issue. Not offering a diverse product-line should be concern for a major business. Being able to self-sustain depends upon that; otherwise, it won't be protected from market shift. In this case, it's the focus to fuel efficiency. What choices are available? GM has a massive gap between their traditional vehicles and Volt. That continues to be a very real exposure. At least the burden of being partially owned by the government is no longer an issue.

11-23-2013 Engine Use. When you first get a plug-in hybrid, you are overcome by the insistence too avoid engine use. It's a natural response. The smoooooooooth silence of just gliding along on electrons is quite fulfilling. But when the vehicle as has an engine and battery-capacity is limited, you know that gas will inevitably be used at some point. Understanding when become a question frequently pondered. Eventually, you end up making a comment just like this one in a post today: *"My view, now, is that we spend more energy than is deserved worrying about the ICE starting."* I replied with: That sums up the situation well. The point of being a PLUG-IN HYBRID is often lost to the perception of EV being the ultimate goal. The point is to deliver the best balance of features, not to maximize electricity use. My commute home this evening started with 7.7 miles of EV, despite the temperature only being 28°F outside. So what if the I was able to climb to steep hills and drive along at 50 mph without the engine starting. That's nice, but the entire trip was 17 miles long and I needed heat after awhile. So, I fired up the engine on the 55 mph portion. When I got home, the average for the day (recharging both at home and at work) was 118 MPG. What reason is there to be disappointed about that? Heck, it was only 19°F on the commute to work this morning. What other vehicle the same size & cost could deliver that under those conditions? Let's not forget about overall emissions either. Engine heat is also used to cleanse what comes out of the tailpipe.

11-23-2013 Expiring Leases. Many have wondered what would happen when those first drivers of Volt had their leases expire. The 3-year option back then was a steal of a deal. GM celebrated conquest sales, not taking into consideration what would happen afterward. The gamble was the market would be so good and resale value so high, the choice to purchase or lease again would be a no-brainer. They allowed sales opportunity to slip away in favor of pushing that particular configuration. It didn't work out. Now we are getting reports of some of them switching over to C-Max Energi. It works out to a reasonable balance of power, range, efficiency, and size... which is why Ford has always been considered an ally rather than a foe. They didn't make sacrifices as much as GM. It's sad that extremes were used for promoting Volt. The cost of that is not making itself apparent. Not being able to keep consumers from leaving is a very real problem. Volt retention was assumed. The same is actually expected for the plug-in Prius, but purchases were focused on instead and the timing is much better. After all, national rollout hasn't begun yet and the next generation will be available prior to expiration for those who actually do lease. Anywho, GM wasn't able to attract many who were replacing an old GM vehicle. That hasn't been the case for Toyota. We've seen that former Toyota owners switch over to Prius. That transition from traditional to hybrid is a big deal. Offering a hybrid with a plug helps further the reach, reducing market size of choices we want to phase out. I'm intrigued to read about more lease expiration choices. Deciding what to get is a big deal. That's why consideration of more than just the here & now has been an on-going theme. Whether enthusiasts like it or not, winning battles doesn't mean you'll win the war.

11-24-2013 **Rewriting History.** Here is yet another attempt: "*Notice how long it took the Prius to catch on. Our resident Prius blabbers conveniently forget how long it took for hybrids to be a common sight on our roads. It wasn't until the 2nd gen Prius (2004) that hybrids took off in popularity.*" You have to wonder how much of that they now believe. After all, if you repeat a lie often enough... Needless to say, I wasn't about to allow such obvious greenwashing to take place... especially when it's just an effort to defend struggling sales and falling short of several design goals. There's no excuse for misrepresenting competition anyway. Doing it by rewriting history is pretty desperate too. They only do that when nothing else works, when all other options have been exhausted. My reply to that was: There's nothing to forget. That isn't what happened. Toyota strictly limited availability. They only planned production of 15,000 in 2001 and 20,000 in 2002 for our market. There was never any intent to provide more. The high-volume wouldn't come until the next generation. People ended up on long lists waiting for delivery as a result. The 2004 model (delivered late 2003) was quite different. Right from the very start, the plan was to remove the limitation and deliver as many as the market demanded. There wasn't a generous tax-credit either. For that matter, there wasn't even any competition. Gas was cheap too. Of course, knowing the true history doesn't really matter. Claiming Volt will take off when the next generation is delivered provides confirmation that the expectation in the meantime is continued weak sales. It's by no means a guarantee of high-volume later either.

11-24-2013 **Intentional Confusion.** The level of greenwashing we witness at times is truly remarkable: "*By the way, there seems to be some confusion about the range of the Plug-in Prius.*" That statement seems innocent enough. To the casual reader, they have no clue it was an intentional effort to confuse. It's the same nonsense by the same few individuals over and over again. No matter how much detail you provide as a rebuttal, even video of an entire drive, they continue to flat out deny the information. Some just plain don't care. This is nothing new. We've heard many, many, many stories over the decades of salespeople saying whatever they want to prove a point. But online, there's accountability. It's easy to reference and follow up. So, you'd think they'd be more careful. They try, by being excessively vague. You know they got the message. You know they've seen the facts, You know they decided not to accept them. The only recourse is to posts a response. I did to that today: We've been through this countless times already. By not explaining what is actually meant, posts just like that add to the confusion. No definition of what "all-electric" or "blended" refer to makes the situation worse. The plug-in Prius offers a battery-pack with capacity of 4.4 kWh. That allows owners to drive around 11 miles total. Sometimes the engine starts. Sometime it doesn't. You still get the benefit of the electricity regardless of whether or not those miles are continuous. It amazes me to no end that no matter how many times onstructive information is provided to end the confusion, the spreading of misleading content persists. The plug improves emissions & efficiency. What the miles are labeled as makes no difference. That goal is still achieved.

- 11-24-2013 Failure Fallout, summary.** These are strange times. Volt, as it currently exists, is pretty much dead. Niche purchases will continue, but expectations of mainstream acceptance are long gone. Supporters are finding ways deal with the wait for the next generation. Enthusiasts have basically vanished. The rest of the online community have moved on. The auto show season has begun. Posts are on other offerings from other automakers. ELR, the Cadillac enhancement of Chevy's Volt, is stirring nothing but negative criticism. So, focus on that is unwelcome. Disappointment is unanimous. Fortunately, that doesn't mean the idea of plugging in a hybrid has been abandoned. It just means the expectations are growing more realistic. The timing works out well for Toyota. Their decision to wait seems to be getting some vindication now. GM took a risk and failed. There's nothing stopping them from trying again. But next time, they'll need to join the rest of the industry rather than burning bridges... again. I'm looking forward the changes 2014 brings.
- 11-26-2013 Failure Fallout, bad.** Unfortunately, there is some hate still. That's happens when what you devoted a great deal of effort toward ends up failing. Not everyone moves on as quickly as others. Some people need more time. Some people need to say their piece. Some just want to go down fighting. Some choose to outright lie, to spread misinformation, to greenwash. This example makes that point all too well: *"Either way you compare, the Volt currently has about 6 times the range of the Plug-in Prius."* I was amazed that anyone would be so bold to post a claim so easy to disprove. But when you are truly desperate and have nothing to lose, I suppose he figured what the heck. I posted the following, then waited 2 days and followed up. Here's both: Adding that information after I posted a response was quite a surprise to see. It's neither constructive nor accurate. Volt offers about 62% usable capacity from its 16.5 kWh battery-pack. Prius PHV offers the same, about 62%. But taking that value from the 4.4 kWh battery-pack is not even close to 6 times. It's only 3.75 times... $(16.5 * 0.62) / (4.4 * 0.62)$. 2 days later, still no acknowledgement of the blatantly incorrect claim. That's unfortunate. But it does serve as yet another example of the greenwashing we've had to deal with. Looking at facts, things just plain don't add up. Comparing another way... $(38 \text{ miles} / 11 \text{ miles} = 3.45)$ That isn't close to 6 times either.
- 11-26-2013 Failure Fallout, good.** Thankfully, there is a bit of redemption. When one of the biggest troublemakers ends up posting this, you can breath a sign of relief: *"BTW, one thing that irks me is that GM should have built the Volt on Epsilon II instead of Delta. Had they done that they'd have easily convinced people the price was acceptable. A car the size of a Regal or Malibu would more easily justify in everyone's eyes the \$40k price tag. And, it would have much more room. I doubt there'd have been that big an impact on range, either."* He has posted over and over again how the current compact size was just fine. Clearly, there's been a major change of heart. Over and over again I pushed the importance of appealing to the Malibu buyers... getting shunned & ridiculed each time. Now, he acknowledges it was a good idea after all. Remember all that concern about *"too little, too slowly"* we repeatedly warned about? Not understanding audience until well after rollout is costly & unfortunate. It will end up being an extra 7 years. Talking about lost opportunity. Oh well... better late, than never. But then again, competition is increasing and tax-credits won't last forever.

11-27-2013 Failure Fallout, sensitive. There was a discussion today about the growing threat Ford presents. Their plug-in hybrid delivers a top electric-only speed of 85 mph. That irritates Volt owners to no end. They were able to easily dismiss Prius PHV simply by pointing out the slower limit of 62 mph. But with C-Max Energi, the vague definition they used to distinguish Volt has completely fallen apart. Now that some plug-in hybrids are matching criteria or even exceeding which was only supposed to apply to EREV, they are at a loss about how to respond. Rather than just striving to offer the best plug-in hybrid, they wanted an entirely unique category. Each time the topic was brought up, they'd immediately dismiss it. No comparisons, period. That's yet another self-inflicted wound, something which could have easily been avoided. But when the goal is to achieve bragging rights, getting blinded by things like that is easy. After all, a goal like high-volume sales would take away from any distinctiveness. Being common isn't what they really ever wanted. So, any reference to mainstream stirred emotion. They yearned for something above & beyond all else... but failed to get it. From that new thread, this particular quote stood out: *"I'm hyper sensitive to any comment implying the position that the Volt is not superior to short range plug in..."* That mindset of wanting to be vastly superior obviously still persists.

11-29-2013 Failure Fallout, voices. Those few particular individuals I keep quoting have become well established online spokespeople. The rest of the members are enablers, cheering them on when they post misleading information and insult those attempting to provide clarification. They are the voices for what Volt has evolved into. Nothing else stands out anymore. Those mixed messages of the past prevented anything actually constructive from getting a foothold. We have no idea what the heck the purpose is anymore. This quote posted today from one of those individuals summed up the situation well: *"If Volt drivers are only getting 75% EV then the Volt battery needs another 5-10 miles of EV range to bring more drivers under the bell curve."* Notice how he used the word "If" to lead the discussion, even though it is well proven that the actual percent is much lower. The article clearly points out 62 percent from real-world data collection. That means even greater EV range would be needed. Of course, the very realization that the 40-mile range didn't actually fulfill requirements for owners undermines the supposed core goal of Volt. That number was hoped to be nearly 100%. Missing the mark by that much, especially with early adopters, is quite disheartening. They had promoted the *"range extender"* as an emergency backup... not a feature that would be used so routinely. Then when it was confirmed that the MPG it provided was sub-standard for a hybrid, they made even more of an effort to downplay the role of the gas engine... hence those voices emerging. Now, 3 years after rollout began, real-world data is making them look bad, really bad. And with a group holding pride with such high regard, that hurts, really hurts.

- 11-29-2013 Cold EV.** Yesterday, the Prius sat outside unused for a little over 9 hours. Capacity remaining was estimated at enough electricity remaining to travel 6.7 miles. It was 9:30 in the evening when I left. The condition outside was a blustery 18°F. Since I was dressed well and was out in the garage working before having left, all that would be needed was the seat-heater set to high. The drive consisted of several blocks of 30 mph travel (roughly 1 miles), then a turn onto a 50 mph road. That became a long 45 mph stretch with several stoplights, a few which caught be with red. 5 miles into the journey, that electricity had all been used up. At no time while driving those 5 miles did the engine start, despite the cold. That leaves me scratching my head wondering why some owners state their experience is quite different. Their engine starting even with the heater off and EV still available. The only thought that comes to mind is the battery-pack has a short opportunity to warm up prior to needing a faster speed. (Note that I have the entire lower section of the grille blocked, the top is entirely open.)
- 11-29-2013 On-Going Improvements.** I certainly liked reading this today: *"It does 36.4 km per litre in the Japanese cycle, but the new Aqua will top that with 37 km/l, says Toyota. They eked out an extra 1.6 km/l by reducing frictional resistance in the engine and improving motor control."* That information was the highlight of an article published about the new model year of Prius Aqua (known as the "c" model here) now available in Japan. It's a big deal since competition in Japan is so much higher with hybrids, where they strive to squeeze out improvements at an on-going basis. We don't see that here. Our market doesn't place as high of a value on engine efficiency; sadly, the bar for actual MPG is set much lower too. So, we typically only get updates from the rollout of new generations. This is what I posted on the discussion thread about the news: Minor system enhancements along the way are always nice to see. It certainly is a welcome change from the old school perception too. Remember the days when any revision to the design following rollout was given the stigma of having been delivered with a defect? The competition would spin any update as a shortcoming being fix. But now with software updates on our phones becoming routine, the thought continuous improvement is coming an expectation. Heck, even the idea of plugging in at night isn't a big deal anymore.

12-01-2013 **Unbelievable.** To think it would have come to this. That's unbelievable. Yet, it did indeed happen. Being able to look back at the chapter now closed is great. But not everyone sees it the same way: "From 2007-2010 many naysayers thought the Volt was just vaporware. This was actually a very prevalent feeling back then. That's why GM made some design decisions that were less than optimal to get it out on time. The result is a fantastic car (I love my Volt), but its heavier, more costly, and less efficient than it could be. That's why the Gen2 Volt design will probably be a very different. They now have time to optimize things properly." The twisting of events is nothing new. People have differing perspectives anyway. Some just don't want to see that. I'm happy to point them out: Those supposed naysayers already knew the engineering was realistic. That wasn't ever contested. It was the timeline that brought about the vaporware claims, not if the technology itself was possible. Delivering all that had been promised by the end of 2010 was the argument. So much was expected in just a few years, they were in dismay about the reckless attitude. There wasn't anything to support the ability to produce & sell a high-volume plug-in for a profit. Hope blinded the faithful. Refusal to acknowledge the mountain of evidence showing expectations were unrealistic for such a short amount of time caused posts to turn into hype. Cheerleading drowned out the voice of reason. Constructive discussion became impossible. Then when the end of 2010 arrived, reality of the situation became overwhelmingly clear. Lessons of the past had not been learned. It was yet another example of "*over promise, under deliver*". Those having made the vaporware claims were vindicated. Damage control caused focus to rapidly shift over to the next generation. The current would limited to enthusiasts. Mainstream ambitions were delayed. 3 years later, attempts to distort that unfortunate history continue. But at least expectations for the future have become realistic. The painful experience of recognizing the difference between want and need is over. Fallout consequences are being overcome. It is now understood what those vaporware challenges actually were and what they still are. Hope has finally replaced hype.

12-01-2013 Out Of Time. Reality has come crashing down to such an extreme, even those attacks that come from the posting of disenchanting facts have vanished. Starting the 4th year of sales for Volt has brought about the acknowledgement that it has not and will not achieve mainstream acceptance in the next few years. That challenge has been overwhelmingly transferred to the next generation, following initial rollout. Not only must it achieve the goals set, it must also garnish accolades from owners... which takes time, a lot of time. That's why this question was asked today about it taking so long even for just the goals themselves to be confirmed: *"How much time did GM need?"* It really makes you wonder how executive decisions were actually made. We know that the pursuit of profit and the draw of praise can lead to trouble. But you'd think they'd learn from the mistakes of others. Apparently, not. I chimed in to that question with: GM still hasn't decided who the market for Volt actually is. Continued mixed messages about intent holds back progress. How can the next step be taken if they don't even know which direction to go? With BMW, we see clear intent. The i3 offers a small, minimum power engine with a small, minimum range tank. Its purpose is for non-routine drives, when the owner goes outside the usual distance traveled. There are obvious tradeoffs to that configuration, but at least the audience is clear. With GM, we still don't know who the heck will be targeted for the next generation model of Volt. The current ended up for enthusiasts only, not reaching mainstream consumers as originally hoped. Some of that came from not specifying purpose. It was always just a vague reference to electric-only driving. What does that mean from the business perspective? Will the approach really be to only offer a plug-in as the high-efficiency choice, without anything to compete against regular hybrids? That lack of diversity should be a concern for those wishing to see on-going profit. It means high-volume production & sales is required. It also means having an outlet available is required. Why does GM still need more time? Who's making decisions now? When will we get answers to questions that should have been cleared up many years ago?

12-04-2013 November Sales. The entire industry did fairly well this month. Economic recovery is undeniable from this aspect of revenue exchange; however, there were many warnings about it not lasting. Truck sales are through the roof, very strong. Much of that is claimed to be as a result of the construction industry finally making long postponed purchases. New equipment, like pickups, are the kind of financial burden easily delayed. But at some point, there comes a time. That time appears to be now. For the automotive industry, that's good news. The vehicles are very, very high-profit. That puts the spotlight on Ford & GM, leaving the hybrid cars to survive without any attention. That's a challenge when some are being sold below cost, at a loss. Volt clearly falls into that category. And to my surprise, not a single thing was said about it. This is the first ever month totally silent. None of the antagonists said even a peep. That's quite the confirmation of market. It's stuck as a niche until the next generation. Meanwhile, I got a mass-email advertisement from my local dealer listing the hybrids they are selling. The plug-in model Prius was listed. Hmm? Are they expecting delivery of their first soon? That would be right on time for the arrival of the 2014. Needless to say, I'm intrigued. There haven't been any available anywhere in the Midwest. They are still limited to just the 15 initial rollout states. Anywho, there are some sales numbers for November published now. This is what we are aware of so far: 9,801 Prius liftback. 2,227 Prius v. 3,001 Prius c. 1,100 Prius PHV. 2,003 Leaf. 1,920 Volt. 2,398 C-Max. 941 C-Max Energi. 870 Fusion Energi. 68 Accord PHEV. 1,031 Civic Hybrid.

- 12-04-2013 Remember October 1997?** I really enjoyed posting this reminiscence of the past: Toyota revealed Prius then. It was an amazing technological achievement, all done in secrecy as a result of having been excluded from the PNGV program. They decided to develop an high-efficiency design on their own... and passed the Detroit automakers in the process. They had a fully functional vehicle already. That wasn't the shocking part though. What amazed the world was the announcement that it would be available for sales just 2 months later. Think about that when you consider what Toyota's next steps may be. They have a diverse & profitable offering which continues to be improved. That ultimate goal of replacing traditional production is growing more and more realistic.
- 12-04-2013 Statistics.** When discussions are led with stating percentages, be wary. There's reason to be concerned. It's easy to mislead when the numbers to provide perspective aren't also included. In this case, it was: *"The Volt's November numbers represent a 26.4 percent increase over 1,519 units sold in November 2012."* Notice the complete absence of scale. It's only a comparison to itself. No consideration for the market itself is taken. Lack of context is a key of greenwashing. Anywho, I sounded off with: With a \$5,000 price drop, shouldn't growth have been quite a bit more than just an increase of 400? After all, the monthly sales expectation set 2 years ago was 3,750 per month... which was under the mainstream minimum of 5,000 per month. 1,920 still falls well short of either. If GM had a plan "B", some other method of advancing the platform, it wouldn't be so bad. Suggestions of offering a model with a smaller capacity battery and an engine tuned more for efficiency fell on deaf ears. GM chose to invest in ELR instead, a much more expensive configuration trading off efficiency for luxury. Where the heck is high-volume production that had been hoped for? 18,200 Cruze. 14,405 Malibu. 13,418 Impala. 5,068 Camaro. 4,712 Sonic. What does that tell us about the new GM's priorities for cars? Forget about the trucks. Forget about the other automakers. How much longer must we continue to wait for something that actually competes with GM's own cars? Those traditional choices are absolutely crushing Volt.
- 12-05-2013 Change.** Yeah! The charging-station count at the ramp I park at for work recently went grew from 2 to 6. Today was the sweetest experience yet. There was a Leaf, Volt, and Fusion Energi. It sure makes the 2014 outlook something to ponder. The crazy superiority roars have succumb to sales reality. Phew! That being over is quite nice. Perhaps now, the actual competition will get a recognized and the proper audience addressed. It's hard to believe how far off track some got. We now have plug-in vehicles leading the way. That will draw even more people in for the purchase of regular hybrids. Misconceptions have been replaced with mainstream acceptance... at least for Prius. Several other automakers are striving to reach middle-market consumers too, so there's hope. It's always slower than you'd like. But at least we see growth potential for some. I'm looking forward to the rollout of Prius PHV here. My dealer sent out a mass email recently, which included mention of the plug-in model. That was a first. Online listing of 2013 inventory seems to indicate the 2014 availability is realistic. So, that might mean something. But then again, the temperature here right now is just 1°F... which is far for ideal for a plug-in. Though, I did still manage 75 MPG from driving 46 miles with 2 recharges. Anywho, maybe they'll be a surge in sales for the plug-ins this month from those wanting to take advantage of getting their tax-credit money in just a few months rather than having to wait over a year.

12-06-2013 Morning Commute Video, dashcam. With the temperature at -8°F and snow from the day before, it was a great opportunity to try out my new video configuration. I wanted to capture both the dashboard activity as well as what was happening in front of my plug-in Prius as I drove. Those 2 very different lighting situations combined with the refresh flicker of a display screen made it quite a challenge with just one camera. But I had timed it just right with the morning commute. I took the back route, which is slower but scenic. Starting the engine right away to warm the system was a must with it so cold out. That directly affects the EV range estimate, lowering it with an approximation of what that alternate use of battery power could have. In other words, the electricity is consumed while the engine is running instead. So, the computer counts those miles as HV instead. Ultimately, the measure of performance is determined by MPG, since the amount of electricity consumed is always the same. My commute to work will always use the entire plug-in capacity. That's roughly 2.75 kWh, including charging losses. What varies is the amount of gas. The more the engine has to run to provide heat for the cabin and emission cleansing, the lower the overall efficiency. On this particular drive, the total 17.3 miles resulted in an average of 128 MPG. That's quite remarkable considering the extreme conditions... [video: Morning Commute \(dashcam\)](#)

12-08-2013 Extreme Cold. When the daily high is well below 0°F, you get lots of opportunity to make extreme cold observations. There's the usual watching of coolant temperature, observing how much heat is available with the engine not running and how long that heat lasts. In cases where the rest of the system has reached the full operating level, the threshold is lower. Coolant temperature is allowed to drop all the way down to 87°F. Most owners are unaware of that on-the-fly alteration. In fact, some aren't even aware of the usual 114°F tolerance. They are only familiar with the 130°F and 145°F levels. It get confusing, even with an aftermarket gauge to help you see more data. There are simply too many parameters to make those types of observations. But in the type of Winter we are now having in Minnesota, I certainly get to. That's why I was caught by surprise to discover that heater settings make a difference during initial warm-up. Toggling between LO (that's outside air) and 65 (the lowest setting for heat), I noticed the engine RPM changing. It went up by 200 when going from LO to 65 and back down again to LO. I did that several times while sitting at an intersection waiting for the light to turn green. The same thing happened when switching from LO to DEFROST (the special button for window-only blowing). That actually impacted RPM even more, by 300. The system response makes sense. Running the engine faster will generate heat quicker... which is the very thing you are requesting by pushing those buttons. But that isn't an obvious behavior. Most people simply wouldn't even realize anything was different. But in the extreme cold, it's much easier.

- 12-09-2013** **It's Finally Over.** The last share of stock has been sold. What a relief. No matter how times we pointed out the importance of delivering a mainstream hybrid, something to directly compete with high-volume traditional cars, the discussion would ultimately get spun into it somehow really being about GM's financial struggle. It never was. The problem remains. There still isn't a choice available for middle-market consumers. We all see how the other automakers are targeting their own production, offering high-efficiency vehicles similar to and the same as existing inventory. Had GM also done that, while including Volt as a choice, the situation would be quite different. Instead, it's the one-size-fits-all approach. Why isn't the market as a whole addressed? How come is there continued refusal to acknowledge strong sales of traditional cars? Shouldn't that be a concern? When will something actually competitive be offered? Needless to say, it's nice that the government ownership excuse is gone. Having that used as a distraction from the true problem got quite annoying. There's even time still available for something able to achieve business-sustaining profits to be delivered. After all, isn't that the point?
- 12-10-2013** **Constructive Attempts?** Uncertainty is the situation now. That finality yesterday brought big change today. A new CEO for GM was announced. It was a change people from many different perspectives were happy to welcome. Focus was almost entirely on proper business, how on-going profit could be made. The well-being of the business certainly got the attention that has been lacking in the past. That obviously left Volt supporters wondering what comes next. There was barely a mention of that struggling platform. That realization of trophies not paying the bills has become a very real concern. It's about dang time! So naturally, we seem to be getting a few attempts at constructive discussion. It makes you wonder what the intent actually is though... since nothing was suggested. Still refusing to state goals is the first red flag, a warning of potential that the past could repeat again... since that's how it started before. Tired of watching blind hope led people astray, not wanting it to happen all over again, and the need to actually deliver, it's difficult to know how to respond. What's different this time is how sales is getting far more attention. So, restating the original claim seemed worthy of a next step: TOO LITTLE, TOO SLOWLY is very much on the topic of sales. The distraction was claiming purpose wasn't that. Today's shake up at the top supports the situation too. Not having any profitable high-efficiency vehicle to offer middle-market and relying heavily on trucks instead is clear evidence of not having advanced forward. In fact, it's basically a reset to where GM was prior to the financial collapse. Selling something competitive is required. Status quo is not enough. How much longer must we wait?

- 12-11-2013 *The Game.*** There is literally only one person left playing it. That shouldn't be much of a surprise. No matter what I post, it's always somehow twisted to make it sound like I'm declaring "vastly superior" for Prius PHV... which made those die-hard enthusiasts of years past for Volt absolutely furious. Now, all but he has moved on. This was today's example: *"You can claim the prius phv is mainstream and the better selling volt is not, but here you simply are making up your own flawed definition of mainstream, and of course the topic is not mainstream or high efficiency."* Pointing out that GM was competing with itself, crushing Volt with its own offerings of Malibu, Impala, Cruze, and Equinox, was information that simply never gets heard. No matter what, the discussion would keep getting redirected back to "not the same" arguments in comparison with Toyota. When Ford and other automakers are mentioned, they post gets ignored. He wants to go down fighting. No one else even bothers to respond anymore. I'm getting quite short with him myself. My response was: That's the game. I'm not taking the bait. Thanks for the quote.
- 12-12-2013 *Toyota Advancements.*** It's nice that the member posts on the big Prius forum related to Volt are gone. The playing offense to keep attention didn't work. That one person would drop bait and a few others would "like" it to show support. We still have webmaster topics to deal with on the blogs, but at least that's a different venue. It means the way is clear for those with constructive things to say to actually post them. Today, we got: *"And if Toyota fails to update their now essentially 10 year old drive train anytime soon there are a lot of new hybrids coming out right now from other brands. So the competition is good for us customers - we have other models and brands to choose from - no need to wait for the Prius."* That's good stuff, something we can actually chime it with a variety of perspectives. The days of dealing with "vastly superior" are gone. Yeah! My post to that was: That only applies to those in the market at the time. And it would be fascinating to find something actually competitive with Prius. The choices so far have taken different approaches. For that matter, HSD itself has too. The age doesn't matter. Good thing, since the cars most people are still buying use much, much older drive trains. 4th generation pretty much brings an end to the "new" perspective, that's all. It means there's nothing left to prove. The time of speculation & doubt is over. Everyone agrees the technology is clearly here to stay. Failure would be not investing anymore, to allow Prius purpose to fade. Instead, we already know the next will bring even greater engine efficiency. Having to wait a full product cycle leaves you hanging, but ultimately, that is good business.

- 12-13-2013** **Much Cheaper, intent.** When the purpose of a blog is to draw attention and stir participation, expect things like the following: "*Volt's 5-year ownership cost is much cheaper than Prius*". Upon inspection of the data itself, that situation clearly wasn't the case. But controversy of ambiguity and contradiction is what venues like that thrive on. So, it's quite intentional. My curiosity as to how that particular group (Volt enthusiasts) would respond to the insurance aspect coxed me to respond with: Since tax-credit availability is temporary and the analysis purpose is long-term, we should consider the difference without. That leaves the difference with Volt at just \$637. And since Prius clearly offers more seating room in back and a larger cargo area, that in itself is enough to make the difference a wash. What I find misleading though is the insurance premium. Why the heck is Prius an average of \$706 more per year (for a total difference of \$3,529) and who is paying such a high rate? Factoring in the price of gas really changes things. The expectation of it going up is very realistic, again, since this is long-term. Going up changes the equation... hence the need to consider the plug-in model. That raises the question of bringing region into the equation... since we all know how winter really impacts outcome. Then of course, how many owners will choose to purchase & install a L2 charger for their home. With a larger battery-pack, that's more likely.
- 12-14-2013** **Much Cheaper, response.** It was the same old trouble resurfacing again. Rather than simply state goals, it was cherry-picking. I especially liked how the reduction of gas usage and carbon emissions was sighted as important, but no mention of electricity usage or smog emissions. That reliance on the tax-credit stirs anger too. It continues to show the expectation of low sales for several years still. No clear purpose and the lack of any push for better, we end up with status quo. After all this time, why can't they see that? If you don't strive to improve, it won't happen. This isn't rocket science. It's just basic economics. To deliver a cost-competitive product, the business must work to deliver on clearly stated priorities. Now into the 4th year of sales for Volt, you'd think that would be obvious. Step away from that group of enthusiasts and those venues which cater to them. Read the comments posted in other online sources. Doing that provides a great eye-opening experience, a wake-up call for those who think all will be fine if they simply just wait. The need to be proactive, for supporters to make a large effort to share experiences and to educate others, should be overwhelmingly clear. Take a look at the recent recall of the VW Jetta hybrid as an example. Confidence in the technology isn't there. Reliability concerns dominate posts. Whether or not there was ever any problem for a customer never gets addressed. They don't look at corrective steps to prevent possible long-term issues as acceptable. The word "recall" of any sort has a negative stigma. Sadly, aspects like "fun to drive" still get far more attention.

- 12-14-2013** **Coming Soon.** National rollout appears to be coming soon. Here in Minnesota, there has been a single 2014 delivered to a dealer. Hooray! Just 1 available is a whole lot more than the none we've had. It's really encouraging to see some progress. Waiting until the 2013 inventory was pretty much sold out prior to expanding required quite a bit of patience. That opened up the opportunity for antagonist spin too, making a sensible business decision sound like something had went terribly wrong instead. Where I park for work, there are now 6 charging-stations available. I share them with a Leaf. Soon, a Fusion Energi is expected to join us. The owner has plans to add more as demand increases. That's quite encouraging... and quite a relief considering the rhetoric of the past. By the time Winter's thaw arrives, some owners will be celebrating 2-year anniversaries. That real-world data is priceless in the support of sales expansion. Next year looks really encouraging.
- 12-14-2013** **Winter Efficiency.** This hot topic of cold subject matter is an endless source of posts. Each year, it's the same thing. When will that finally change? This is the latest post I decided to join in on: *"Now, my other car, a conventional gasoline powered, small AWD SUV, is not significantly impacted by these weather conditions, and my fuel efficiency is almost the same, winter and summer."* It's somewhat frustrating that the actual MPG isn't included. That's common, but what are you going to do. It's the same thing each Winter. I provided this: That always low under any conditions is an interesting situation to consider. It amplifies & confuses the situation for those not aware of influencing factors. We see it. But conveying that message is problematic. Overcoming the 50 MPG barrier presents challenges. There's lots of fine-tuning required to take advantage of thermal dynamics. It can equate to cost & complexity, something really only Toyota is in a position to address. They will too. We can see the opportunity for Gen-4. Beyond that is a mystery. But then again, engine optimization faces diminishing returns anyway. Delivering more than a solid 50 MPG average with PZEV isn't really necessary. Shifting focus over to electric efficiency makes sense at that point. After all, the measure of "kWh/mile" is rarely gets mentioned currently. Think about how few people know what the vehicle they drive now actually delivers for MPG. Sadly, your observation isn't common. Even worse, most still just settle for low efficiency, not placing a high priority on using less gas.

12-16-2013 What It Wasn't. For many years, we listened to claims from enthusiasts about how Volt would be a game changer. Only problem, what they praised never actually got delivered. It's now a classic example of moving goal-posts. They just altered the definition rather than staying true to their cause. The hope was a vehicle that would feature a small engine, just enough to allow the vehicle to continue to be used in the rare event travel is still required after depletion. Primary power would come from a battery-pack. All the propulsion, heating, and cooling would be electric. Range would be 40 miles under all conditions. Production would be high-volume. Cost would be competitive & profitable. Things obviously didn't work out. Instead, the upcoming ELR is contributing to a great deal of supporter arguments and the market is looking at BMW's new i3 as the solution GM promised. To further confuse matters, there are some who making up false history about Prius to justify the mess. We know what it wasn't. We have no idea what it will become. We have a good understanding what the market actually needs. Problem is, time is up. The opportunity to leap-frog has expired. The early-adopter phase has passed. We're entering the second chapter now. Automakers are striving to diversify, each making an effort to attract consumers seeking new options. The choices are growing. Some will win. Some will lose. That need will become more and more clear. Here comes 2014.

12-17-2013 Gas-Guzzling Horror. A new stir to the market came today in the form of an article published stating the gas-consumption per-person in 128 countries. It brought to light the extreme difference between the United States and the rest of the developed world. We heavily subsidize oil and encourage waste. It's an embarrassing reality most here don't want to admit, hence the stir. That's not the kind of attention those who guzzle want to draw. That inconvenient truth really hurts. The kind of backlash this type of mention will result in is quite uncertain. There was a massive number of comments posted online, but things like that rarely actually change behavior. There's a disconnect between what people say and what they actually do. So even if there is anything encouraging posted, it likely won't amount to anything on dealer's lots. That's sad. Government invention must continue to change. Automaker priorities must continue to change. Consumer mindsets must continue to change. Progress is painfully slow and those purchasing now will be stuck with those vehicles for the next decade. That's the real horror story. Even with realistic solutions, it's too expensive to part with a guzzler that's still has a number of reliable service years available. We're forced to deal with waste legacy. To make matters worse, there are organizations dedicated to maintaining the status quo. It's a very frustrating situation. Fortunately, we have efforts like this attempting to influence change.

- 12-18-2013 Optima Hybrid.** My first ever sighting of this Kia offering was today. It was quite subtle, very easy to overlook. But with sales over 1,000 every month, you'd think there would be more. They rarely even get mentioned those. In a way, that's good. The fallout from the Hyundai & Kia MPG labeling is good reason to lay low. Collecting real-world data and building reputation is better than drawing lots of attention for misrepresentation. With gas at just \$2.84 per gallon currently, there isn't much demand anyway. I like seeing variety like that on the road. Each automaker must offer something worthwhile and that is a genuine attempt to do exactly that. It takes time to get it right too. Each consumer base is different. But whatever the business-sustaining high-volume product is for that particular automaker, a hybrid version must be made available. There's simply no way to survive in the upcoming market without. People won't be willing to put up with guzzlers for too much longer. Pressure from upcoming CAFE regulations will force the offering of a high-efficiency choice anyway. That means each automaker must do something to remain competitive.
- 12-19-2013 Cadillac ELR.** Watching another disastrous rollout is a interesting historical perspective. It's about to happen and you know the outcome will be bad. Why? It's because enthusiasts want the new Cadillac ELR to represent more than it was actually intended. Setting expectations well beyond design is a recipe for disappointment. Sadly, it opens up opportunity for those who just want to stop progress in any way possible to label the effort overall as a failure. Why give them that? Intrigued by the new discussion, I added: Seeing that new plug-in hybrid is an interesting topic. Rather than attempting to reach ordinary consumers (which clearly didn't go well for either Two-Mode or Volt), this time, GM intentionally created a niche vehicle. Sightings on the road will be few and far between. Being a Cadillac, what will those visiting the dealer think? Other cars available there, like ATS and CTS, have a far lower base price. It seems that will be the "*halo*" vehicle Prius was claimed to be... the difference being lots of people actually purchased Prius. GM's expectation for ELR is only 300 per month. What would compel a salesperson to sell it? The sales pitch would somehow have to address Tesla offerings. With an estimated range of 208 miles for \$5,000 less, what would you say? For \$5,000 more, the estimated range increases to 265 miles. Why bother with an engine when you can get kWh capacity like that for a similar price? It makes you wonder what comes next.

12-22-2013 **Fundamentals.** It's always fascinating when the situation ends up coming down to the basics: *"Let's not forget that after 80 years of manufacturing, GM never set a goal for efficiency in smaller sided autos."* That statement from a well-respected Prius supporter hit the automaker when it really hurts. Pointing out a fundamental issue hurts. That's why pointing out the problems with Two-Mode stirred so much anger with Volt enthusiasts. They could see the parallel, but hoped somehow the same choices would result in a different outcome this time. Clearly, they hadn't learned lessons from the past. I sounded off with: Squeezing more out of less has never been a real priority. Bragging rights about engine displacement was a very big deal for over a half century. Smaller was considered a sales hindrance to the business and a sacrifice to the consumer. Sadly, some of that mindset persists. It's the root of some advancement problems. That's why even just entertaining the idea of a smaller battery-pack stirs so much emotion. Supporters fiercely resist the idea. The fact that Toyota worked so hard to get so much irritates. Achieving 50 MPG from a 98 horsepower engine propelling a midsize car really hurts pride. Gaining another roughly 25 MPG by switching to lithium and adding just 3.15 kWh with a plug adds insult to injury. To make matters worse, a common attitude shift in our society is to now say: *"it is what it is"*. Rather than striving overcome barriers, people are just settling for status quo. That's very disappointing. What happened to our pride? We use to deliver amazing feats of engineering. So many inventions. So many benefits to ordinary citizens. There are excuses. Ugh. A fundamental change is required. Either it is proactively embraced or it will come in a painful way. Emerging from the bankruptcy recovery with a heavy dependency on profits from large vehicles and nothing competitive for high-efficiency is a red flag, a warning of trouble to come.

12-22-2013 **Will Still Eat.** Thoughtful questions are always a nice change of pace: *"With a full charge from the wall and the ICE warmed up, the PiP will still eat through about 4 miles of EV range while in HV mode. I can't figure out why... Has anyone else seen this?"* I posted this, which to my delight, generated a bunch of likes: Prius PHV is a plug-in hybrid. That means it will use the electricity in the most efficient way possible. So... you'll see EV consumption while in HV mode. It's a fundamental part of the design to achieve high MPG and clean emissions. You'll also see the EV capacity reduced to a lower level for longevity. In other words, the "full" level of 85% is not the ideal for maximum battery life. It's in the low 70's. So, no matter how much you try to sustain a capacity above that while driving, it will consume electricity to stay at that happy place. Kudos to you for being so observant and asking questions. The system is well thought out and there are many variables at play. Of course, when we provide more information, it tends to open a can of worms. But understanding what goes on and why certain approach decisions were made has to start somewhere. What I find most interesting is how rapid the transition from engine to motor is when the system is warmed up. You can take full advantage of gas to accelerate and immediately switch to electricity the moment you let up on the pedal. Antagonists spin that as a shortcoming. But with a such an efficient power-split design and a small battery capacity, forcing the system to rely entirely on electricity doesn't make sense.

- 12-22-2013 Mercedes E400.** That's the first ever non-GM hybrid using the Two-Mode system I've ever seen. For that matter, it's the first non-truck too. The encounter today was very frustrating... since the owner clearly didn't give a crap. There were only 2 plug-in spots. It was parked in one of them... not plugged in, since that hybrid doesn't have a plug. The ramp was busy with Christmas shoppers and the owner simply wanted somewhere to park. The fact that there were signs clearly posted saying the spot was only for plug-in vehicles didn't matter. The bright green paint marking the parking area itself didn't either. I asked security if they had a policy to do anything, like leave a note. They sent me to guest services. There at guest services, they sent me back to security. That got me thinking. Why not pretend I am security? I could mark the vehicle's window exactly like they would, using those same bright easy wipe-off automotive markers. (They are just \$2.) That way, everyone else would know what the person had done and no harm would come to the vehicle. It would only hurt the owner's pride. Of course, that's if you are polite. I'd simply write "*parking violation*" and include the date. Asking online what others would write, the suggestions were far less kind. That choice of action is tempting, let me tell you. When the ramp owner installs charging-stations, the expectation is those spots will be used by patrons willing to pay for the opportunity to recharge. That Mercedes owner obviously didn't care. Think about how frustrated an EV owner would be encountering that same situation.
- 12-24-2013 Start/Stop Reality.** The fact that GM abandoned the second attempt to deliver a mild hybrid made everyone wonder what would come next. Had the reality of failure finally caused a better step to be taken, for a genuine investment in something capable of being competitive to be made? Short answer to that question is no. BAS resulted in such a small return for the large cost, it required a rethink. eAssist came as a result; supposedly, it was an improvement. Instead, that was the same "too little, too slowly" outcome. So today, we got this from the GM marketing manager: "*Mileage benefits of a hybrid without the cost of a hybrid.*" It was the description of what the new start/stop system in the 2014 Malibu would feature. How the heck is that beneficial? Most people go way out of their way to avoid stops, in city driving. On the highway, they obviously don't stop. When will such a design deliver anything competitive? Needless to say, even the die-hard GM supporters are upset. Knowing that Volt wasn't able to attract mainstream buyers, they've been putting hope in Malibu. This turns of events is yet another disappointment. With Ford doing so well selling Fusion, both regular & hybrid, their usual Camry insults aren't effective. They feel true pressure now. Online comments didn't provide any encouragement either. With year-end sales results about to stir next-year expectations, there really isn't much to look forward to. The warnings were not heeded. Consequences of not being concerned about advancement for the masses will soon become apparent. But in the meantime, executives will assure everyone all is well.

- 12-26-2013** **New Attacks.** A well known Prius antagonist showed up again. He's been attacking the big Prius forum relentlessly, trying everything he can to post endorsements for Honda's Insight and VW's diesel. It's the same old nonsense we've seen for over a decade now. My guess is he returns as soon as his ban expires. You know, cause trouble until getting kicked out, then wait for the next opportunity. Those acts of desperation are absurd. It's especially bad when he starts new threads claiming something that just plain isn't true. Trolls drop bait too, but never in such a blatant way. His purpose is different, it's to fulfill a vendetta. That's harder to deal with. Even the troublemaker I dealt with recent isn't that bad. He simply enjoys debate. This guy is seeking out a fight, wanting to inflict harm. That's sad. I remember one of his attacks way back when. Nothing we tried got him to stop. Finally, I tried a direct assault... challenging him by providing encouragement. It caused panic. Some were shocked by the approach, fearing the worst outcome. Instead, he ended up falling. The arguments had little substance. I took the risk of assuming he wouldn't actually be able to support his claims. Sure enough, he got burned by his own rhetoric. I wonder how it will play out this time.
- 12-27-2013** **PHV Sighting.** To my surprise, there was another Prius PHV... just like mine... same color. That light warm blue is only available for the plug-in model. So, secondary confirmation wasn't necessary. I did take a closer look that anyway. It was indeed a PHV. Sadly, they still isn't available for purchase here in Minnesota. But then again, purchasing one now would be rather disappointing. True, you'd get over 50 MPG... but barely, due to the extreme cold. The sub-zero temperature results are still amazing when you think about it. Being tough enough to deal with Winter is great too. Summer is so much better in comparison though. I enjoy the seasonal change regardless. That cycle is refreshing. Good thing too, since it's rather lonely. Someday there will be more. Someday my PHV will be warm & clean. It always requires patience. At least I got that surprise today to hold me over in the meantime.
- 12-28-2013** **Signs of Change.** The attacks continue. I've been amused by the acts of desperation. They've been pretty bad. This is how I summed up the situation: When outdated & obscure topics are posted, it's a good sign. The pattern fits. We've seen that many times before. New threads like this one only appear when the competition has failed to deliver. In fact, bringing up references to an old survey which referred to "hybrids" in a extremely vague way is a perfect example. Adding to it by claiming discontinued vehicles could deliver the same performance confirms the desperate situation. Heck, my 1984 Omni could also deliver 50 MPG highway. But what's the point? It was a small vehicle without any safety features, a high center-of-gravity, no A/C, manual windows, manual brakes, and a manual transmission. We are now at a turning point. With Prius so well proven and other automakers struggling to offer something clean & efficient, the paradigm shift is happening. Vehicles which grossly exceeded need have went from being a symbol of prestige to having a stigma of waste. Attempts to stir discussion like this confirm the market change. It's just too bad the choices available aren't competitive yet... hence references to the past rather than looking forward. Think about how few people actually understand what a Prius with a plug delivers. No old survey can reflect that.

12-28-2013 **What To Expect.** I found it amusing how a strength will be downplayed. For example: *"The ONLY silver lining is that I do see a day coming where a low-end PHEV shouldn't be significantly more expensive than a regular hybrid is today. So vehicles like the PiP should become standard."* That emphasis on "only" gives the impression you should expect more. But given serious thought, what else could there be? The entire point of the battery/plug upgrade was exactly that. It was designed with affordability a major priority... so lots of people will be able to purchase it. That quote came from a thread on a forum dedicated to Volt, where the discussion of the next generation resulted in this post: *"Lets look at 2016, GM indicates they will release a car with 200 miles of battery range and a backup gas engine for \$30,000."* It's amazing to see posts like that appearing again. Hype in the past emerged the same way. Someone would hear about something, not get all the details or ever follow up, then expect that to be a delivery promise. In reality, that situation is quite different. GM was indeed hoping to deliver a plug-in vehicle with a 200-mile range. But it wouldn't include a gas engine. That assumption somehow came about. Probably a misunderstanding or inaccurate hearsay. Whatever the case, not only is the engine part wrong, the range potential is too. An advanced new battery technology won't be delivered. What was promised by Envia for upcoming GM production ended up becoming a case of fraud & theft. It turned out to be too good to be true. Unfortunately, that poster is completely oblivious to that reality. Instead, it is believed an amazing improvement in high-efficiency vehicle choices will be delivered in 2016. Knowing what to expect is important. Sadly, some people aren't aware of what really happens and why or even how.

12-30-2013 **Irony.** It's an interesting reality, an aspect of life some don't notice until it's too late. Today, I couldn't resist pointing it out in response to this: *"I'm sick and tired of people still talking about "smugness".....thanks to the a-holes @ South Park, it appears this meme will never go away!"* That's been a topic of much emotion & discussion over the years. Now, we can interject a new twist... and unexpected outcome for some: Ironically, that same footage is now having a positive effect. Most people haven't noticed how effective of a barrier it has become. Rather than getting attempt after attempt to insult & discredit, that single episode withstood the test of time. The misunderstood attempt to educate at the expense of supporters was so entertaining and so powerful of an opposition tool that it has prevented any other material from being created. As the meme grows older and older, less and less can compete with it. That leaves those hoping to mock hybrids with nothing but a single arrow in their quiver. They cannot prevent progress with such a limited arsenal. It's a great example of how a battle won early on can actually have the opposite effect in the long-run, contributing to the loss of the war in the end.

12-30-2013 **Original Insight.** This question was interesting: "*Did Honda stop selling the original Insight in 2006?*" It came about as the result of a original owner throwing a fit from a comment made way back then but from the eyes of today. That difference still doesn't get recognized by some. They forget how much changes in over time. This was my answer, hoping to keep the asker engaged and the owner at bay: I don't readily recall. My blogs have that detail somewhere. Back then, things were different anyway. It was more about proving the technology itself rather than focus on individual models. People seem to forget how measures evolve over time. The difference between ASSIST and FULL hybrids was a big deal through that first stage. The beginning of the second was clearly marked by the start of 2006... when the tax-credits were introduced. The purpose was to push acceptance deeper into the market. Emission rating was always a challenge to get any attention at all. Honda wasn't even pushing it. The manual transmission earned a ULEV and was the more desired model. That put the CVT earning the SULEV rating in an awkward position. Meanwhile, Toyota was racing ahead and Honda's focus was on making the hybrid Civic popular. Carbon emissions started to gain attention then too, making the true green (smog reduction) an even greater challenge. The end of 2006 brought the introduction of ULSD (Ultra Low Sulfur Diesel), which was suppose to help with that. Instead, it came up short, not being as green as hoped... hence calling it "*clean*" diesel rather than keeping focus on actual emission ratings. MPG took a hit as a result too. Long story short, these look backs at history are distorted at best. You cannot judge a time quite unlike now using current standards. Expectations were different then. Gas was cheap. The economy was thriving. People were still buying monster-size vehicles. New offerings weren't getting much serious attention.

12-31-2013 **Changing Times.** When one of the troublemakers starts to post things like this, it's a sign of change: "*Enough range for 80% of the public in even the worst winter temps. Right now the Volt drops to mid-20s in cold weather.*" This particular Volt owner joined the big GM forum to combat me... since I was supposedly posting misleading information about Volt. Ironically, he is now posting the vary same information I did back then. But being hypocritical is progress, nonetheless. So, I won't hold any grudge for needlessly being attacked. I will point out the situation though. That's how you prevent history from repeating. Having learned from the experience is a good outcome. There is finally clear acknowledge of the problem pointed out long ago. The reduction of EV range caused by the heater is significant. Stating the drop would be into the 20's resulted in a "*troll*" label. You were considered an enemy of Volt. Believing I was being constructive with the intent of keeping expectations realistic was the last thing they would ever consider... since it cast a distaste light on their vehicle of praise. Thankfully, that is no more. The impact of Winter is well known now. That's really encouraging, a definite change for the better.

- 1-01-2014** **Saw This Coming.** When recently asked this question: *"When did you decide that electrification is the end game, rather than hydrogen or some other alternative fuel, in terms of fuel-efficient vehicles?"* It was no surprise to get this statement as an answer: *"It was a gradual turning point. I've always been receptive to new technology, but what annoyed me in 2005/2006 was all of this credit that Toyota was getting for the Prius. Only the Japanese, only Toyota could do this. General Motors had hybrids like that running in 1968. We just never elected to produce them because it was a bad business proposition. That was a mistake. But I continually said, we need to do something to get GM's reputation for advanced technology back."* The heavy emphasis on reputation and the lack of actually delivering something competitive was quite predictable. With the third-year sales results for Volt about to be revealed, we saw this coming. Remember how the plan was to deliver a hydrogen vehicle to consumers by 2010, that hybrids were just a "stop-gap" solution? He was responsible for that anti-hybrid campaign as well as for Volt itself. He has since changed his mind. He was wrong. The only thing gradual about it was acknowledgement of the mistake. As for the credit, that was due to sales. Exceeding 100,000 per year in 2005 was a very big deal. Meanwhile, GM's count was still a zero. Why shouldn't an automaker be given praise for achieving mainstream volume?
- 1-02-2014** **Insurance Rates.** A new and very strong ally in the fight against climate change has emerged. Whether or not there is scientific evidence to support efforts to deal with the problem is becoming less and less important. Insurance companies are no longer willing to take that risk. Their claim data is telling a compelling story of high exposure due to our environment being altered. They don't care what the cause is. Business is hurt from all the damage. As a result, insurance rates are going up. That means, even if you are a obstinate denier, it will affect your wallet. Less money in your pocket is a strong influence in opinion. Change came about due to gas prices going up. Cause didn't matter. Filling the tank was more expensive. The outcome was modified behavior. How is this any different? Choices will be altered as a result of having to pay more.
- 1-02-2014** **0 High Temp.** The new year has ushered in extreme cold. When the high doesn't climb about zero (that's 0°F), don't expect pleasant driving experiences. Thankfully, they aren't necessarily terrible either. In fact, on the drive home from celebrating New Year's, we had to fire up the engine and wait about 4 minutes before driving. The inside of the windshield had flash froze from us unloading the Prius, opening several doors right away and leaving them opened for an extended duration. That real-world experiences firsthand, the kind of data I thrive on observing. Anywho, on the drive home, I observed the coolant temperature climbing to a high of 188°F. That was nice. It made the interior quite comfortable. People worry about the engine frequently being off or run at a low RPM causing a lack of heat. The interplay of electricity & gas is too complex to explain. The switching of energy flow is too frequent to envision. The lack of understanding how traditional vehicles actually operates contributes to confusion. Thankfully, the results are easy to see. We were quite comfortable on the drive home. I'm not really looking forward to these first two weeks of January. They typically bring long periods of cold. At least MPG will be nice and there's no worry whatsoever about engine starting. The hybrid system handles those conditions well.

1-03-2014 **Repeated.** *"If GM built a \$75,000 Super-size EREV truck, it would have been just as successful as their overpriced Super-size hybrid trucks were..."* It's quite a feeling to read former foes to now be saying what you said all along. It's too bad history had to repeat. Rather than learning from the initial effort, they wanted to see if what would happen. I recognized the pattern early on. But that was mostly due to having blogged heavily. They didn't want to believe the same mistake could be made again. They now see it though: *"Lutz was spouting this exact same BS when they decided to build the 2-mode pickups instead of a Prius fighter. Look where that got them. Tojo sold a MILLION Prii and the 2-mode sank without a ripple. I almost got to the point where I was starting to respect Bob Lutz, but this stuff isn't helping me. He who ignores history is doomed to repeat it."* Ironically, there is little posted about how that gained knowledge applies to Volt. Attention is still heavily focused on the largest vehicles. And since Volt is a compact, rather than a midsize like Prius, it's difficult to get constructive discussion going. Efforts to address high-volume profit-making vehicles still struggles for an audience. As a result, that part of history could repeat again. On the bright side, the online battles have ceased. That's progress.

1-03-2014 **On Par.** Sales results were released today. 2013 ended up being an equalizing year. Leaf & Tesla plug-ins ended up selling just as well as Volt. Purchase preference for the *"vastly superior"* didn't happen as hoped. There is now confirmation of what some of us had been saying all along, including prior to rollout over 3 years ago. Thank goodness that nonsense is over. The rhetoric slowed acceptance and worked against what some of us had been reaching out for in the first place, an ally... because in the end, it always comes down to competing directly with traditional vehicles. Fortunately, as enough time passes, even dealing with shortcomings becomes easier. Those who unrealistic expectations pretty much vanish. We saw that with the demise of Two-Mode. That was a disaster from the beginning, a series of poor business decisions aimed at far too small of a market. Volt suffered from the same problem. Enthusiasts didn't understand how complex the situation was or how long it would actually take. They disregarded warnings and focused on hype factors. What a mess. But now in the 4th year of sales, all doubt has been eliminated. Like it or not, there's recognition of mainstream-consumer purchase-priorities. The chance of a birdie is long gone and course is clear. No more arguing. Yeah!

- 1-03-2014** **Diesel Denial.** It's absolutely hysterical when an article is published in favor of diesel intentionally excludes Toyota hybrids. You have to shake your head in disbelief. How can they ignore such an obvious competitor? Needless to say, one of my friends posted a comment about that on the website, using the counts I provided. It quickly disappeared. Deleting data is remarkable. They declare victory by posting only the numbers showing their favor. How is that appropriate? Whatever the case, we know the true story. No matter what story they spin, it can't totally conceal what's going on. We know they post controversial articles to draw audiences too. Making money from such actions is rather desperate. But some keep doing it anyway. It's a nice confirmation that hybrids are winning the war too. Anywho, this was my response to that: Excluding Toyota hybrids is quite amusing. Talking about denial. Geez! Using their same criteria, by adding Toyota & Lexus like they did for VW & Audi, with counts through November... Prius - 135,291; Prius C - 39,169; Camry - 41,722; Prius V - 32,879; Avalon - 14,988; ES - 14,856; CT200h - 13,284; Prius PHV - 11,169; RX400h/450h - 10,154; Highlander - 4,798; GS450h - 478; LS600h - 109; HS250h - 5; ...the total comes to 318,902. More popular. No.
- 1-04-2014** **Categories.** Once established, they are extremely difficult to change. They become a foundational part of thinking, a mindset without perspective. That's why comments like this are such a challenge to address: *"Luxury is not something that should be "affordable" or easily acquired. Those who want and have the means to purchase a true luxury vehicle will pay the price. If you can't afford it, don't buy it."* Prius directly contradicts that category. It is an affordable vehicle that's smooth & quiet. Why must we pay more? It's the point of progress to continue to offer improvements? That simply pushes the "luxury" choice to expand into new territory, exploring new creature-comforts and drive-refinements. However, Prius is already doing that. Mine offers LED lighting, HUD instruments, and dynamic-cruise with collision-detection. To the person making who I quoted, that shouldn't be. A vehicle aimed directly at mainstream consumers shouldn't provide such a choice. Those features should be limited to the elite. To that, I say too bad. Change happens. By the way, the squirters for my headlights do a fantastic job of washing away the Winter mess of sand & salt. The convenience of pushing a button to clean while I drive is fantastic.

1-05-2014 **Mass Appeal.** 2014 brings a repositioning for Volt. There's nothing left to prove anymore. Plenty of real-world data is available at this point shows what owners wanted to convey about efficiency & reliability while also confirming plug-in supporter concerns about purchase priorities. Now that we're seeing leases expire and talk of the second generation dominate discussions. The early stage is over. Volt is fading into the mix with a variety of other plug-in offerings... where it should have been from the very beginning. The superiority arguments have fizzled into the past. Market awareness has finally become apparent. Hope that the draw to electric-drive will change buyer preference is gone. Appealing to the masses, with they priorities they hold, has been accepted. It was a wild journey... so many pointless fights... all leading back to where it started in the first place. Some have to learn for themselves, regardless of how painful of an experience it could be. Oh well. It comes down to the traits Prius has focused on all along. They were very similar to other popular sellers Toyota offered. Enthusiasts for GM found that distasteful. The thought of endorsing vehicles like Camry & Corolla was a horrible thought. But in the end, that's what is still needed. That's what the masses purchase. That's what they find appealing. Volt taking on aspects not "performance" oriented was reason for all those online assaults. What a waste. Oh well. The damage is done.

1-05-2014 **Extreme Cold.** There are quite a few posts recently discussing the extreme cold. These are different from the past though. There are quite a number of owner who have experienced Winter with more than one generation of Prius. Having that basis of comparison available was rare in the past. For the online community, it's becoming common. That's great. With the technology in Prius so well established, understanding what a generational upgrade brings is new subject matter. The same is true for handheld devices, such as phones & tablets. People simply never paid attention to detail like that in the past. Now, they they seek out the information. Seeing who is yet another sign confirming deep mainstream penetration. There's excitement from new forum members with very little technical or automotive background. I joined in the active discussion with: I've owned all 3 generations over the past 13 years. Even the 2010 couldn't compete with what I experienced today with my 2012 Prius PHV. The high temperature was under 0°F. Despite the extreme cold, which included spending over 3 hours parked in a shopping lot, the drive back and forth to home with a side-stop along the way (23.5 miles total) resulted in an average of 49 MPG. That's amazing for such nasty conditions. Being able to plug-in is great, even when the engine runs to provide heat. Today was a perfect example of how well thought out the system is. Summer is much nicer. Engine warm-up is rapid and the A/C runs using electricity. MPG is double as a result. But with a lower temperature forecast of -26°F tonight, the warm season is a long way off for me. Blah!

- 1-06-2014** **Patience.** 14 years later, it's still required. Fortunately, we have examples from years gone by to draw upon. They taught those who participated much. For those who joined afterward and refused that wisdom, they were doomed to repeat some of the failures. One such examples stings a bit still. But there's hope 2014 will quickly wash that away... The problem with Volt was it being marketed as a wide-audience solution even though it didn't match requirements of high-volume vehicles. So, even though the technology worked, there's no way it could compete. That's made progress difficult. New challenge emerge from the realization of it needing to be reconfigured for the masses too. Fortunately, emerging beyond the so-called "*early adopter*" phase is making it somewhat easier to understand the circumstances of what did and didn't draw sales. Unfortunately, it's what those of us who have supported Prius for years recognized prior to rollout. Enthusiasts simply didn't want to accept it. Toyota knew the situation would get messy and there were be fallout of sorts, hence the delay rolling out their own plug-in. It certainly would have been nice not having to wait for that choice. But experience of the past made the benefit of patience clear. Mainstream acceptance means the choice must be affordable, a reality GM only recently began to deal with. When this crazy cold finally subsides (believe it or not, -15°F was the high temperature today), we'll start to hear something about national availability for PHV. Expanding to southern states right away would be nice, but inventory overall is low. That could indicate a promotion campaign on the way. After all, that's worked well in the past for Earth Day support. We'll see. But it nothing else, only using a 4.4 kWh battery-pack means being affordable is far more realistic than others. Remember, that was a very big deal for mainstream acceptance of regular hybrids. Adding a plug means that same criteria must be adhered to... but not forever... hence the "too little, too slowly". Toyota can deliver with this current generation.
- 1-07-2014** **Debate.** The effort to stir discussion has floundered. Those few who tried didn't have any successful. Interest simply isn't there. We all see that hybrids are the goal, that their purpose is to replace traditional vehicles. With every automaker striving for the same thing, there's nothing to debate. The antagonists try to provoke with taunts of declining sales due to increased competition, but that requires ignoring the market as a whole. Success of another automaker will help stimulate interest with others. Low gas prices will be an influence too. Staying relatively low stimulates diversity... which ultimately erodes traditional offerings. Obviously, high gas prices will do the same. That's a win-win situation either way. In other words, those nasty exchanges of the past are a memory from the past... a reality some will deny ever got so extreme. They at least understood what was at stake. And even with those failed intense endorsements, that understanding lives on. Sadly though, their method drawing interest targets the wrong audience. Appealing to the masses takes an entirely different approach.

- 1-09-2014** **-10°F Video.** Preventing window reflection for the camera means covering the dashboard with a black mat. Unfortunately, that covers the vents. To keep the windows from fogging up as a result, I have to crack windows to circulate fresh air. Fortunately, I have a heated seat and heavy clothing. It worked out... and I captured great data showing what happens when you don't use the heater in extreme cold with a plug-in. The Prius was parked overnight in my unheated but insulated garage. That allowed the drive to start with the system at 28°F. Of course, it took me 14 minutes with the car running outside to finally get all the filming equipment setup. That ended up consuming 2% of the battery-pack capacity that was available. Oh well. At least I'm refining the quality of the app-data capture coming from my smart-phone. Watch the coolant temperature in relation to speed. You'll see the engine shut off (RPM of zero) a number of times while HV driving (after the plug-in capacity has been depleted). The interplay of gas engine and the 2 electric motors is quite dynamic, thanks to the power-split-device. That flexibility is how high efficiency is achieved. 8.5 miles of EV was the outcome. Then, the engine fired up with the remainder of the trip in HV. The end result from the 17.3 miles of driving with the contribution of 3.0 kWh of electricity (which includes charging losses) was 96 MPG. That's great, see: [Prius PHV - Along The River -10°F, No Heater \(appdata\)](#)
- 1-11-2014** **50 MPG.** Lacking the opportunity to recharge, I only had 10% capacity from the battery-pack available for EV. That's far from ideal on a day you know you will be running around. Oh well. At least the temperature had risen to the 20's. That's a heck of a lot better than the driving at -10°F just a few days ago. 43 miles was the total distance traveled for the day. The average worked out to 50 MPG. I was elated. That was better than I had expected considering the circumstances. Just think what it could have been if I was able to plug in. Looking at the extended forecast, the long extreme cold is done for the season. We aren't even expected to get a brief cold snap. It looks like an uneventful Winter for the rest of the season. That sure is a welcome change for the better. As a result, I can look forward to pleasant driving. What a contrast to the combat last year. Phew!

1-12-2014 **Which Generation?** It's interesting to read a thread started by someone researching the purchase of a Prius asking that question. There was a variety of responses. His openness to consider the variety of new & used choices available combined with the reality of a just a commute 2 miles each way had me captivated. This is what I contributed to the discussion: Your circumstances would make the PHV (plug-in model) a great choice to consider. I fired up the engine on mine just a little bit ago, to provide a sampling of what to expect even when those 2-mile drives aren't exclusively EV. Taking the suburb route, to ensure getting hit by as many stops as possible, I ended up hitting 3 lights red and 1 stop sign. With the temperature at 36°F, the engine warmed up and shut off 1.9 miles into the drive. The MPG then was 39. It increased to 40 at the 2-mile mark. That's a pleasing outcome for a drive that would have been 999 MPG, had it not been for me forcing the engine on. Back when I had my 2010, I clearly remember non-owners arguing MPG was horrible on short trips and have proven them misleading with actual data. The situation may be somewhat distorted with the online diversity now (wide diversity of experience and observation levels), but the blogs from back then are intact. Worse case with start-then-drive-away-immediately was around 30 MPG for short trips. For longer trips, you'll do well with any model or generation Prius. I'm especially pleased with PHV when plugging in isn't possible. Results are actually a little bit better than the regular (non-plug) model... something many had insisted couldn't be done. They claimed the "*dead weight*" after depletion would be a penalty. Toyota managed to reduce the weight difference down to just 99 pounds. Combine that with the better performance from Li-Ion batteries rather than the usual NiMH, you've got a winner. With my particular drive sample today, I ended up traveling 7.3 miles to my destination. That leaves 45% of the EV capacity available for the drive home later. The average, despite the engine unnecessarily running, came to 120 MPG. No complaints about that.

1-12-2014 **Cruze-Diesel verses Volt.** A recent article from a Detroit publisher sure has caused quite a stir. It was the typical attack from within, the same nonsense Toyota use to see on a regular basis. This time though, it's GM... which is at a distinct disadvantage. Comparing Prius to Corolla was relatively straight forward. The holes in the argument were easy to reveal. But with this, there's a third vehicle involved... the gas version of Cruze. Since that is so often misrepresented, it takes away from the credibility of the diesel model. After all, they are considered competition of each other rather than complimentary. Nonetheless, there's still lots of hybrid misleading. The most common, though less obvious, is to exclude information about smog-related emissions. Clean was entirely with respect to carbon. That's rather blatant greenwashing from the Prius supporter perspective. Oddly with Volt, not so much. You'd think they'd sight that as an advantage. Whatever. Next problem was the price. Stating \$40,000 for Volt is just plain wrong. True, we don't have any evidence whatsoever that GM is making a profit yet on the significantly reduced price. But that's no reason to misrepresent by not stating current MSRP. Following that came the MPG average stated. For Volt, it was an overall for 40,000 miles of driving. For the Cruze-Diesel, it was this extremely vague comment: *"Yes, diesel power too requires research on where you can fill up in the metro area. But averaging 35 mpg with its big 15.6 gallon tank, my Cruze would travel more than 500 miles before refueling."* Avoidance of detail and specific examples is nothing new. Antagonists do it all the time. That's a common technique used to undermine. Reading the comments posted, nothing stood out. They mostly just stated the writer's math was faulty and GM was to blame for such poor marketing. With so many mixed messages, compounded by changing goals, invited this situation. What a mess.

- 1-13-2014** **Snowy Night Commute.** I was curious how well the camera mounted on the dashboard could handle darker filming conditions. The sunset had already set on that overcast day. So, the remaining light would fade quickly. It would go from gray to black during the drive home, on my commute along the river route. Notice all the streetlights and vehicle headlights are on right from the start, even though the outside appears day like. Since fresh snow had fallen earlier and some was still falling, it was a great setting to try to capture. Unfortunately, the amount of time it would take to drive in that slower Winter traffic hadn't occurred to me until I was on my way. A few miles into the video, you'll hear rustling and then see an abrupt camera clunk (just as I drive under the bridge). That's me flubbing for the cord, then plugging in. The battery doesn't offer enough capacity to record 1080p footage at 60 frames-per-second while also broadcasting a live stream. Thankfully, it's just a simple USB connection. Anywho, learned the camera does remarkably well. To my surprise, the brightness setting on the dashboard didn't need to be up to avoid refreshing distortion from the screen. I ended up turning it down as the sky grew dark anyway. So, that worked out nice. The commute itself was uneventful. Roads weren't too bad and most people drive better this far into the cold season. It was a fairly ordinary example of Minnesota conditions after a typical snow. When I started the drive, statistics on the screen were from the morning's commute in. So, you get to see exactly what I see routinely, rather than resetting before filming. Showing the round-trip results is more informative. The driving came to a total of 34.9 miles with an overall average of 74 MPG. For just the half on the way home, it was 64 MPG. I'd consider that remarkable when you take into account the temperature was -2°F. By the way, I really like how there was just enough snow on the windshield that I could easily use the wipers to clear it. The effect at high speed (5X) is quite amusing. [Prius PHV - Snowy Night Commute \(dashcam\)](#)
- 1-14-2014** **Aluminum.** The internet certainly was a buzz about Ford's announcement yesterday, especially with comments from GM supporters. With focus shifted over to trucks and consumer pickups specifically being the primary source of business-sustaining profit, it was to be expected. The new F-150 having shed 700 pounds was a huge announcement. That surprised many in the industry. They had no idea such a major accomplishment would have been achieved. The big weight reduction was achieved by switching from steel to aluminum... which is a more expensive metal and challenging to weld. I was amused by the immediate response claiming aluminum corrosion would be a problem, so GM had nothing to worry about. They didn't realize Prius has been using for the hood & hatch since back in 2003 without any issue whatsoever. The strength & durability Ford expects owners to experience has those on the other side of Detroit really worried. How in the world will GM compete with that? It should result in a inarguably better MPG. With fuel-efficiency such a concern for those large vehicles, this is a very big deal.

1-15-2014 **Abandoned.** Remember all the hype? Enthusiasts of Volt declared it to be "*vastly superior*". They claimed vehicles with only a plug, like Leaf & Tesla, were a terrible idea that consumers wouldn't want anything to do with. For a mainstream vehicle offering both plug and engine, Prius PHV, it was endlessly mocked. They would stubborn & determined, quick to dismiss data they found unappealing. I clearly remember the first winter-driving report. It was a whole year prior to rollout. You'd think they would have an open mind, saying that experience was a work-in-progress. Instead, references to it were deemed efforts to undermine. They were wrong, on many accounts. Rollout proved it. Sales were well below expectations. Then came the first true competition, C-Max Energi. That particular plug-in hybrid wrecked their own already ambiguous definition of EREV. But at that point, the hype was already gone. They were in damage-control mode. Things continued to get worse when the Fusion & Accord hybrids with a plug came along. The backlash emerged and rapidly grew. The enthusiast market was exhausted and efforts to appeal to ordinary consumers were failing. The "*vastly superior*" rhetoric was just a memory of the past. Inventory was piling up, threatening to make a mess of the new model production & sales. The price was dropped dramatically. That didn't make much of a difference. The one-size-fits-all approach continued to suffer. Finally, it was BMW's i3 that ultimately killed it. This plug-in hybrid actually delivered by Volt originally promised. As a result, the topic as well as the car itself has been abandoned. Looking on the big GM forum, that's really easy to confirm. There aren't posts anymore... from premiere vehicle to easily forgotten.

1-16-2014 **6 Million.** That's how many Toyota hybrids are now officially on the road around the world. The most recent million only took 9 months to sell. That effort to replace traditional vehicle production with hybrids is clearly making progress... which is good news considering how low gas prices have been lately, in terms of both actual & perception. People are paying less at the pump from having switched to a smaller vehicle. That downsizing alone makes quite a difference. At the same time, they are growing use to paying around \$3.29 per gallon for gas. Reaching out to attract more buyers is an ongoing challenge. It doesn't get easier as more are seen on the road due to that moving target. Some people are simply content. Others don't want to deal with change, even if there is some interest. Mixed messages from automakers don't have either. They heavily promote their traditional vehicles, obscuring their intent with hybrids. Fortunately, Toyota often includes Prius in their advertisements. Maybe that makes more of a difference that we think. It's hard to tell. But with such limited inventory from the others, the emphasis is definitely in favor of non-hybrid vehicles. Thankfully, real-world data continues to reinforce the technology. That's something which cannot be obtained by any other means. We must wait. It will really be a great endorsement for the next-generation Prius. That should influence sales in a very positive way.

- 1-17-2014** **Change.** What can I say about it? The difference is blatant. 2014 bares little in resemblance to 2013. Remember the big news exactly one year ago? The expectation was a major announcement from GM, an upgrade to their plug-in platform. Enthusiasts were very excited about what they had coined as "*Voltec 1.5*" The reveal of Cadillac ELR would provide detail. The system was hoped to be much improved; instead, it turned into a marketing mess. The hype had no substance. It was a collection of vehicle refinements. Nothing was really done to the engine, motor, or battery. There were only adjustments to deliver a smoother, quieter, more powerful drive. The result was a backfire. The very aspects Volt enthusiasts had praised were now looked upon as less. All those remarks about being a top-class ride were suddenly usurped by GM itself. Now, a full year later, they even want to talk about it. The field has finally been leveled. That ally I looked for all those years ago is slowly becoming a reality. As a Prius owner, they thought my effort to befriend was actually a clever scheme to make Volt fail. They were blinded by fear and enchanted by hope. The result was learning the lesson in a painful way. Thank goodness that is over. Change is obvious. Hooray!
- 1-18-2014** **Obsessed?** This quote made me pause: "*Let's be honest here, most hybrid owners are a little obsessive regarding mpg.*" There were many ways to respond. I chose: Have you noticed how most of the rest of the population is totally disengaged, not even aware of what MPG their vehicle actually delivers? From their perspective, it would indeed be reasonable to use an "*obsessive*" label for our awareness. From our perspective, we show a respective disappointment for their lack of concern. I am left in dismay seeing such a large quantity of people simply not interested, claiming MPG in the 30's is good progress. That makes it even more refreshing when new hybrid owners seek out information, asking questions to learn about what actually affects fuel efficiency. That active participation may be interpreted by some as being a little obsessed. We don't see it that way. As for identifying "*hybrid owners*" based on some thread samples and perhaps some random in-person encounters, think about how many there actually are. Of the 102,284 members on this forum, how many actually exhibit the obsession? Most are just quiet owners reading posts. Toyota has sold over 6,000,000 hybrids. How many of them?
- 1-18-2014** **Dealing With The Mess, part 1.** There aren't daily topics on the Volt blog about Volt anymore. In fact, they are quite rare... few and far between. It's just industry news about electrification at this point. The enthusiasts are speaking out, finally. Now into the 4th year of availability, that's long overdue. This series of favorite quotes, in order as they were posted by various discussion participants, provided a summary of the situation as they see it: "*GM sure seems to be sitting on its ass watching the competitors fly by in terms of electrification.*" and "*All I know is that the lease on my Volt is up in May and GM has made only minor tweaks with nothing new available.*" and "*I think that there is no point in GM introducing a Volt 2 without a radically improved battery.*" and "*After seeing all the truck and muscle cars at the auto show, I do wonder if they have fallen off the wagon and into their old ways again.*" and "*I didn't overestimate the Volt, but I have apparently overestimated GM.*" They never believed this situation could happen. They thought engineering alone would triumph. They now know that isn't the case... and never was.

- 1-18-2014** **Dealing With The Mess, part 2.** This was the ultimate find, that statement which seemed an impossibility: *"GM is sounding more and more like they are going to slow-foot the Voltec technology. Pity. I really like my Volt, but back in 2007 when this site started up, there was a feeling that it was going to be so much more. Then the price went up, followed by the lowered bar on the CS mpg, and finally they fell way short of 40 miles of AER that they had predicted. Then they decided not to build as many cars as would be needed to allow for sales to expand."* He watched expectations evaporate. Posts which seemed to disparage Volt turned out to be constructive criticism. The experience has been a rude awaking for many of the enthusiasts. Hope was based on hype, not supported by either engineering or history. It was the *"moonshot"* effort botched in several respects. When leases expire, more and more just end up moving on to something else instead. So many of them assumed Prius was the enemy. They learned the hard way it wasn't.
- 1-18-2014** **Dealing With The Mess, part 3.** What happens next? The mess is bad, really bad. Other automakers are pushing forward, with clear strategies. Supporters of GM don't have a clue. The next generation of Volt is a complete mystery. No goal of any sort has been set. It's a disheartening silence. Not having any idea, nothing whatsoever, to even provide direction leads to abandonment... making us wonder who will deal with the mess. We watched Two-Mode sink to an unimaginable low. Volt didn't do so bad, but being unprofitable comes with consequences, which ultimately could lead to the same outcome... especially with this highly competitive market now emerging. Designing to be cost-effective is much different from the bragging-rights approach taken for the first generation. Rollout proved that was an unwise choice. That makes designing the next even more difficult. It's challenge enough to optimize. Changing direction at the same time presents some very real problems. The new CEO has some serious decisions to make, very quickly.
- 1-18-2014** **Dealing With The Mess, part 4.** The price of gas is considered affordable. Efficiency in the low 30's is considered acceptable. Climate change is thought of as a political game. How do you deal with that? Sighting the problems of Volt doesn't address those bigger problems. The issue of how Prius sales will increase is a concern. Will people care that the next generation delivers MPG in the 50's? Will they be drawn to refinements the next plug-in model will offer? Will they become complacent as a result of the economy having recovered? Just because a choice is affordable and proven reliable does not mean it will be purchased in growing quantity. So even with taking design into careful consideration, expending a great deal of effort trying to match consumer priorities, success is not guaranteed. Increasing purchases is the goal. Traditional vehicles must be replaced.

- 1-19-2014** **Increased Capacity.** That topic comes up often. There's a wide variety of opinions on what Toyota should do next. I put it this way: Since a major priority of the design was to keep PHV competitive with the true competition... tradition vehicles ...it's not realistic to expect a major increase in battery-pack capacity. Too much would easily push the cost out of reach for mainstream consumers. That would sacrifice both cargo-space and depleted-efficiency too. Toyota could offer an additional model with higher specifications, but that's clearly not what the masses have been asking for. I drive close to 20,000 miles per year. Being able to recharge at work is nice. It doesn't cover my entire day though, not even close. I also take frequent trips well out of that doubled capacity's range. There isn't even a pattern. Each day is different, as my daily driving graphs clearly show. Fortunately, the demands of real-world are well suited for the Prius design. Lifetime MPG is above 75. That makes the benefits of the plug, despite lots of miles per year, very easy to see. Toyota delivered a system available as an affordable choice without having to give up the aspects of Prius which made it a popular. The next generation will build upon that. We'll see improved engine efficiency and refinements to EV mode. A modest capacity increase is realistic too. But don't forget about the importance of keeping it competitive with the true competition.
- 1-19-2014** **Third Time.** I hadn't posted anything on that daily blog for ages. Content didn't have anything to do with Volt anymore. All the rhetoric & spin are just a bad memory now. In fact, I can't even remember the final attack. You know, when they down-voted a fact because they didn't like the way it portrayed the situation at hand. Gotta like that. So, I've moved on. Today though, it was ok to join in. After, many of the once die-hard supporters are now speaking their mind on how to clean up the mess. I ended up posting: After years of it being said, the concern is finally recognized & understood. Strong beliefs in the engineering allowed business aspects to be neglected. Now, consequences of that are playing out. Focus was misplaced. Hype got out of control. Consumers lost interest. That can't be allowed to happen again. Those countless posts of the past speak for themselves, confirming the required change of priorities. Do they need to be reiterated or is it enough to just state "*too little, too slowly*" one last time? At least there won't be arguments about goals anymore. The strategy tried clearly didn't produce the results expected. Both Two-Mode and Voltec were heavily promoted and neither was able to demonstrate sustainability after 3 years of sales. The conclusion for both was that redesign would be required. Is third time a charm? Don't allow history to repeat.

- 1-19-2014 Shopping.** I went to the mall today. It's been awhile. In fact, I've been avoiding it since the lead up to the gift-buying last year. Parking was still on the crazy side, even though the holidays are long over. My guess is that this was the first nice weekend we've had for awhile. That made it a good time to go out. Anywho, I took advantage of being able to plug in again. That meant an hour and a half for me to roam around in the meantime. I made the best of that, even though I didn't need to. The charging price is \$0.49 per kWh. There's no time restriction. I could stop whenever I wanted. I could stay as long as I wanted to as well... but didn't want to. After all, there's only 2 spots in that ramp and 2 in the other. 4 for an entire mall makes them rather scarce. When I did leave, there was a Leaf parked next to me charging up. I bet seeing a plug-in Prius in a state not selling them yet took the owner by surprise. Whatever the case, the people watching me unplug sure were surprised. My activity in the side-corner of the car obviously caught their attention. Long story short, I enjoyed the experience, got the stuff in the mall I had stopped there for and purchased \$1.29 worth of electricity.
- 1-19-2014 70 Cents.** The price of a barrel of oil has been in the 90's for quite a long time now. That has settled the price of gas at \$3.19 and diesel at \$3.89 per gallon. With an on-going difference of 70 cents, how do certain automakers expect their plans to significantly increase the market-share of diesel passenger cars to succeed? Beside the higher fuel cost, there is an obvious noise increase (the clutter from the engine) and fewer refilling locations. Add to that the higher price of the vehicle itself, the numbers just plain don't add up. No amount of spin will overcome that. It makes competing with the gas counterparts a heck of a challenge and regular hybrids a source of endless debate. Fortunately, it's basicall impossible for traditional diesel vehicles to compete in any way against plug-in hybrids... and that's without even having to point out the need for diesel emissions to be cleansed with urea. The on-going cost of refilling that reservoir and the trunk space it consumes is a real issue to content with regardless of what the competition is.
- 1-20-2014 Focus Energi.** An interesting rumor emerged today. It was that Ford is actively working to deliver a third plug-in hybrid option. That obviously really irritated the Volt enthusiasts, who had fought the one-size-fits-all problem for years and was only made worse by GM rolling out ELR. Offering several different size hybrids and some with different size battery-packs is exactly what needs to happen for the business to be viable. We see that happening with both Ford and Toyota. The benefits of a having the goal to offer a diverse set of choices are undeniable. Yet, some still fight the idea. Ask yourself: Why? The answer to that question should be easy to figure out at this point. They hope the market won't accept anything less than what Volt offers. They want that to be the minimum. They are learning the hard way that hasn't been a wise path to follow. The realities of business simply don't support such a paradigm shift. Over and over again we get examples confirming the differences between how the market works and how some want it to work. Ugh.

- 1-21-2014** **14 Minutes.** My driving results were skewed somewhat. It was the first day of the second half of winter. I started the cold season with the bottom grille blocked entirely. The top was open entirely, until yesterday... which I switched to 50% blocked. The real-world results were compelling right away. To my surprise, there was a quite noticeable improvement in heat retention. I had thought it would be modest. But driving alone in EV with the heater still pulling warmth from the coolant, I could easily tell it was lasting longer. I also got an opportunity to try the "wait" test. After leaving the highway, with the engine toasty warm, there was a 1/2 mile drive that brought to a restaurant. I arrived really early. So, I turned down the heater temp to 65 and the fan down to the slowest setting, then sat there. The coolant temp dropped from 188°F to 123°F. I was kept warm for 14 minutes before the engine started.
- 1-23-2014** **Understanding the Plug.** Most people have no idea how the transmission works in their own vehicle, the one they've been driving for years. So how do you answer a question like this: "*Does anyone know how the plugin transmission works?*" Pointing out the differences between a what they own and a hybrid system is quite difficult. You lose attention and are open to misinterpretation if words aren't chosen carefully. Think about how many problems understanding the difference between ASSIST and FULL along the years. That was quite a challenge to deal with. And of course now, there's difference between FULL hybrids with a plug and whatever the heck EREV supposedly is. Remember, we have to deal with intentional misleading too. That makes the situation quite a mess when you are genuinely trying to be helpful and guessing at what the person's background may be. I gave it a shot today with: The lack of gears & shifting prevents it from being called a "*transmission*" as most people know them. There are power carriers permanently connected which transfer energy in a variety of ways. It connects the gas engine and two electric motors to the wheels. They rotate at different speeds & directions to optimize efficiency. The plug-in model takes advantage of that by powering the traction motor more than with the regular model.
- 1-23-2014** **New Topic.** This was posted on the parent website: "*Is the Chevy Volt Destined To Remain GM's Niche Product?*" That one is constructive and openly welcomes a diverse group of posters. It's quite a contrast to the child website, the one specifically for Volt; that daily blog. We've seen many topics start on the parent, then move to the child later. The contrast in attitudes is stark. It's remarkable to see such differences. I'm curious as ever what the other will bring. This is what I posted to start things out: "*Who is the market for Volt?*" was the question asked countless times prior to and following the rollout. It was quite clear the target audience was not mainstream consumers, those who would otherwise purchase a popular GM vehicle... like Malibu, Impala or Cruze. "*What will the next Volt offer?*" has become the new question. Goals of the first did not match up with purchase criteria of the masses. Agreement of it remaining a niche until their are major changes is easy to get now. Expectations are better now that there's an understanding of the market. The key is being able to compete head on (be profitable & high-volume), without the help of a tax-credit. That's been a fundamental strength of Prius which has irritated GM for a very long time. Adding a plug complicates matters, making sales growth an even greater challenge.

- 1-24-2014 The Other Website.** That same topic got posted there today, on the child. The parent didn't end up stirring much debate. It was mostly a collection of various opinions. There were pros & cons mentioned. Participants were quite civil, no strong emotion in any manner. The exchanges were constructive. There was a welcome tone. Either side of the fence felt comfortable contributing. What a drastic difference the daily blog brought. Right away, you could tell it was going to get hostile. And boy did it ever! To my surprise, there was an outright lie posted: "*There is a center seat area in the C-Max Energi, but the leg room is the same as the Volt.*" Huh? I responded with the official measurements: "*C-Max Leg Room - Rear = 36.5 and Volt Leg Room - Rear = 34.1*" That was my entire post. No opinion. No comment. Nothing else. Just facts. They didn't like that at all. Whoa! Having sat in Volt and played with the seat adjustments, I know being a compact competing with midsize vehicles is a sensitive topic. But such blatant attempts to mislead lately has been a surprise. You'd think they'd just move on to something else.
- 1-24-2014 Another Example.** This was another example of unexpected blatant misleading. This one came with an insult too: "*The plug-in Prius only has 6 EPA miles all-electric range. This is so pathetic...*" How many times must the detail be posted before the rhetoric ends? Even some of the Volt supporters are getting annoyed. I was happy to provide more facts: Rather than mention the actual available capacity of the battery-pack, the outcome of a specific test is stated. That's called cherry-picking, by most. Some call that type of data omission greenwashing. Whatever the label, it's misrepresentation. As for the adjective used, that's a sign of desperation. It's a 4.4 kWh battery. Available capacity for EV mode is from 85% to 23.5%, which is 2.7 kWh. Knowing that EV driving typically consumes 27 kWh/100 miles, it's very easy to confirm the distance is not 6 miles. In fact, you don't even need a calculator to see that it's 10. And knowing that the battery-pack isn't actually empty at the depletion point, that it's still "full" for HV mode (which offers EV driving), you can add another mile. That comes to 11 miles, exactly what the detail on the window-sticker states.
- 1-24-2014 Outside Opinion.** It's clearly not welcome there. No matter how constructive your criticism, having shown acceptance of a competitor makes you an outsider and your opinion an attempt to undermine. You'd think they'd be long over that by now, that they'd recognize the need to realign to target middle-market. Clearly, that not happening. The enthusiasts still think change isn't necessary. This comment from a friend really got them riled up: "*GM wasted a \$billion chasing a market that does not exist with a car that could not sell without heavy government assistance.*" Now into the 4th year of sales, well under expectations and far from being self-sustaining in any respect, it's amazing to see such unwillingness to compromise. Anywho, this was my follow up to his post: For all those who refused to answer the question "Who is the market for Volt?" and chose to downvote instead, it is quite clear why that was continually asked. Everyone now has confirmation that the assumed target audience was far too small. GM should have been chasing their own Malibu, Impala, and Cruze customers. Enticing them to purchase a plug-in rather than one of their traditional cars should have been an obvious goal. Instead, focus was on trophies and praise. That means Volt needs to be reinvented. Changing the configuration fundamentally to grow sales is required, especially since the tax-credit won't last forever and the vehicle must be profitable.

1-24-2014 **Advocate.** They still don't want any who doesn't own a Volt. That type of resistance is amazing. Why? Heck, I park next to a Leaf everyday at work. Supposedly, there will be a Fusion Energi joining us later too. What's the big deal? Despite my obvious endorsement for both lithium batteries and plugging in, some feel compelled to attempt to discredit anyway. That's bizarre. I'd gladly welcome a Volt owner to our little slice of parking paradise. I don't have any personal gripes with purchases. It has always been the misalignment of product and market. With GM selling what it wants rather than what it needs, that disconnect should be obvious. Whatever. My effort to demonstrate plug-in vehicles for mainstream consumers are realistic continues, regardless of what a select group of enthusiasts believe. This was my sound off about the topic: Being a strong advocate of affordable hybrids for the masses, especially after so many years, it's quite common to see posts from some who make stuff up about me. It's hard to know if the intent comes from frustration or simply not remembering correctly. But since they keep inviting me to respond, I do. The delivery of a plug-in Prius which provides a significant efficiency boost without sacrificing interior space or depleted MPG and achieving it at lost cost pretty much makes anything I say sound like an endorsement for a specific brand. It's not. It's an effort to promote the replacement of traditional vehicles. It's unfortunately certain individuals still don't acknowledge that. Thankfully, it doesn't matter. I'll keep driving and plugging to help demonstrate how realistic the technology is, as well as how little it takes to purchase yourself. That's the key. Besides necessity to be within reach of mainstream budgets, there's also an intimidation factor... another reality not being acknowledged.

1-25-2014 **Rewriting History.** Attempts to pretend the vaporware claim was proven true continue. That's nothing new. Why they continue to try to rewrite history is a mystery though. What would that actually prove? I guess in the mind of an enthusiast, it supports hope that the next generation will deliver as well. The catch is, the first didn't. Yet, the claim keeps being made anyway: *"GM did deliver on the Volt from concept in 2007 to customers in Dec 2010."* With this daily topic already getting way out of hand, what is there to lose by posting so more facts, sprinkled with comments: The Volt revealed back in January 2007 is not what was delivered in November 2010. Remember that car called "Volt" we heard about initially? It would deliver 40 miles of EV under all conditions, 50 MPG after the battery was depleted, and be nicely under \$30,000. It would accomplish that without ever driving the wheels directly too. Remember all the bragging about it being a "series" hybrid, about the purity of always being electric-only propulsion? Needless to say, the "Volt" that was made available to consumers ended up quite different. That's why there's such a silence about goals for the next. Being burned so bad by the *"over promise, under deliver"* problem a second time (first was Two-Mode), it's better just to improve the system quietly. The hype of unrealistic expectations got way out of hand. It limited design opportunities too. The next "Volt" will bring improvements to widen appeal. It will disenchant enthusiasts, but that's what happens when a vehicle goes from niche to mainstream anyway. Just look at the top selling cars for a dose of reality. Those choices being purchased profitably in high-volume better match priorities of ordinary consumers. Look at GM's popular vehicles. Tell us what traits Volt should share for its sales to grow.

- 1-25-2014 Banning Hybrids.** When someone outright hates hybrids and regularly attacks the forum, how do you respond. This particular individual goes well beyond the typical troll. His motives are obvious too. He's a strong supporter of diesel and sees the threat hybrids, especially the plug-in models, are to him. This is what we got yesterday: *"I would simply ban all hybrids from using the chargers."* It was on a new thread discussing how a limited number of chargers should be used when the population of plug-in vehicles exceeds them. Some of us are amazed by his outright discrimination and choose to carefully think out responses. Here's mine: Banning all plug-in hybrids would be telling those living within EV range, too bad. And what about those who live just a little beyond it and barely use any gas? You'd also be catering to EV owners who have capacity that greatly exceeds their commute distance to recharge, even if they don't need it. When someone chooses to purchase a vehicle with a plug, they should have the opportunity to plug it in. Ride share programs have been available for decades. Why not start a plug share program? You get a number of plug opportunities per month. Owners find ways of making it work. After all, how many hours to you actually need to be plugged in? Count & Duration can easily be limited by the chargers. Think about it. If you are given 4 hours to recharge and don't unplug & repark before that session expires, another session is deducted from your account. If you repeatedly violate the opportunity, you aren't given more sessions later. It's not complicated and there's no need to ban.
- 1-25-2014 Banning People.** What happens when the posts are on the topic of discussion, when members there simply don't like certain suggestions? Some cry out for the person to be banned, even when they are polite & constructive. It's how some deal with change, or in this case, the lack of... *"I agree about the right to express one's opinion. I'd even go so far to say we NEED people like him."* That was specifically about a friend of mine. I was mentioned in an earlier post, but with hostile intent. This kinder, more objective response resulted. I replied with: The sense of balance and willingness to share goals hasn't emerged yet, despite now being into the 4th year of sales. Those negative votes are a clear indication the enthusiasts are still not ready to do what it takes to make a Volt offering for mainstream consumer appeal. They thrive on the niche status. Becoming a ubiquitous vehicle, one so common it ends up fading into the crowd, hurts the sense of pride they've grown so attached to. Trading trophies for accounting numbers is a difficult transition. Watching a vehicle be transformed from performance to practical is something enthusiasts want to avoid. They hope for a miracle in the meantime, to prevent having to give anything up. The word "compromise" has been given a bad stigma, rather than it meaning mutual concession. At some point, you have to draw the line though. Choosing to ban certain input, despite those suggestions already having already proven successful, is a choice available. That means forging on alone. Accepting the risk of taking on different goals, despite massive competition (traditional vehicles), is something others have chosen to avoid. Alliance with other plug-in owners has been easy with all but Volt. Why? Do they fear no longer standing out is too great of a loss? Unwillingness to acknowledge middle-market purchase priorities was big a problem in the past. Is it still? What will it take to recognize need?

- 1-25-2014** **2014 Change.** The new year certainly has ushered in change. Discussions have transformed. Who would have thought efforts to forge an alliance would return? I had given up on that years ago. But when that moderator of the daily blog intentionally stirred by pot by declaring Volt a niche and asking if it would remain that way, it definitely ruffled some feathers. The thought of competing head on with traditional vehicles is not something they are not ready for yet. That's quite obvious. So on the other side, the effort to find cooperation at charging-stations with other plug-in vehicles, is an issue they aren't even addressing. The choice of Volt enthusiasts to isolate from everyone is drowning out the few Volt supporters who would like the mutual aid. It's a dynamic none of us have dealt with yet. There's both cheerful willingness and staunch resistance. I get the impression that's a sign of progress. In the past, fierce denial of the need to change resulted in an abrupt abandonment. Those who fought against no longer feel welcome, since everyone else accepted change. We'll see. The year certainly is off to an interesting start.
- 1-25-2014** **Too Little, Too Slowly.** That concerned wasn't taken seriously, right from the start. Such heavy focus on the looks of Volt was a big clue of problems to come. The disastrous "230 MPG" campaign overwhelmingly confirmed it. What a mess? Not even being able to get past such basic misinformation should have set off alarms; instead, the downplay began. It kept getting worse. How could they not see that was slowing down the progression? Of course, upon debut, they were already shifting focus to the next generation. Slowing down acceptance by adding another 5 years is far too long of a delay. Yet, that was the path chosen. Consumers ended up with little in return. Hope rapidly faded. 3 years later, the thought was attitude would change and the stumbles of the past would have long been forgotten. You know, acknowledge mistakes and move on. Instead, they still resist. Making adjustments to match preferences of your target audience is a basic business fundamental. Didn't any of the enthusiasts take an economics class? What the heck? True, my bachelor's degree includes a business minor. But you'd think that knowledge wouldn't take a college focus to understand. Hmm? You'd think observation of the market itself would inform you for changes that need to be made to attract more sales. Apparently, that's not the case. Of course, there are some who are too stubborn or too proud to admit when a mistake was made. Errors happen. Get over it! Calling for delay and hoping for a miracle in the meantime isn't a good plan.

1-26-2014 **Caught Misleading.** The spreading of incorrect information generally comes in two flavors... intentional and transposed. The first is an obvious attempt at greenwashing. Sadly, we encounter than far more than you'd like to think. Thankfully, that's relatively easy to deal with. The next isn't as nice or as simple to overcome. It's when the poster mixes up details. They'll use wrong quantities and mess up timing. In their mind, the information is correct. I know when they are wrong. It's just a quick search of my blogs to confirm that. The facts are spelled out in great detail, documented when those events happened. Trying to recall them years later is prone to problems. Looking up the history written as it was happening is far more accurate. Some get irritated when caught misleading. Some make up excuses. Others pretend it never happened. Here's an example of some misleading I had to deal with today: "*As I remember the Prius in it's early years got a tax rebate which could be carried forward.*" This particular one was complicated by being so blatantly vague. But in the context of the posts it immediately following, the intent of greenwashing was obvious. I responded to that with: There was only a \$2,000 tax DEDUCTION for the first 5.5 years of sales. That worked out to \$300 to \$400 for most of the buyers back then. The \$7,500 tax CREDIT for Volt is dramatically more. When Prius did finally get a tax CREDIT in 2006, it was only less than half that amount (\$3,150) and was only offered for the first 60,000 sold per automaker. GM gets 250,000 right from the start. Expecting more on the road as a result is reasonable... which makes designation of "niche" an admission of not being up to the chore... which explains the posting behavior seen on this topic.

1-27-2014 **Chapter Closed.** Remember the "*up to the chore*" nonsense over a decade ago? It was a lively discussion thread that went on for 1.5 years. The propaganda of the time just plain could not get hybrids to die. No matter how hard they tried, proof that they were capable continued to come in and mess up their arguments. I had never seen desperation on that scale before. It was amazing, especially from the eyes of an active participant. The same thing happened again, but this time it was a different outcome... well, sort of. Rather than traditional vehicles leading the fight and losing, they actually won. Volt is technically a hybrid. GM declared this generation a niche. That official word of not being able to compete in the mainstream arena was taken two ways. Those who strongly believe Volt can with modifications look forward to the next chapter to begin. Those who feel the sting of defeat wanted someone to blame & punish. That meant Prius and those like myself would be relentlessly attacked, faced with having to deal with the same kind of desperate lashing out we've become all too familiar with. It was nasty, for them. We actually got compliments for remaining civil. Stay calm & polite makes a very good impression while at the same time allows the attacker to vent and tarnish their own image. There was definite anger this time... because Prius is a hybrid, yet it won. The fight against traditional vehicles is no where near as simple as certain individuals believed. And despite being warned, they ended up learning that lesson the hard way.

1-28-2014 **Parting Thoughts.** This is what I posted as parting thoughts on that explosive "*niche*" thread: For over a decade, the definition of mainstream has meant monthly sales here of at least 5,000 and the definition of niche was simply not being enough to be mainstream. Prior to Volt's rollout, GM set that very target (in terms of 60,000 per year). The reason made sense, volume is required to achieve production cost savings... since automakers are publicly-held for-profit businesses... and none of the excuses or claims otherwise will change that. As for the "*compared to approximately 5 for electrification*" comment, I continue to be astounded how GM supporters refuse to acknowledge the past. Development of EV1 began back in the early 90's and work with batteries & motors carried on throughout the 00's with BAS and Two-Mode. Their fuel-cell vehicles were electric too, which included battery-packs. We all know what needs to be done at this point. Cost must come down dramatically. To break out beyond niche, there is no other way. How well the technology works doesn't make any difference if few actually purchase it. That means reconfiguration is needed to appeal to buyers of GM's high-volume vehicles. They are the market for the next generation of Volt. And since we are finally closing this chapter, to all those who swore this situation would never happen, I suggest taking a course in business economics. You obviously have an excellent handle on the engineering, but it's overwhelmingly clear the influences of consumer behavior were not understood.

1-28-2014 **Ironical Timing.** Or was it? We know that Toyota was keeping a distance from GM. They've done that several times in the past. We've seen it with both Ford & Honda. That's a wise business move. If something goes wrong with consumer acceptance of a competitor's product, you don't want to be included simply by being in the wrong place at the wrong time. Heavily promoting Prius PHV while Volt was struggling with problems on several fronts was obviously a good thing to avoid. In the meantime, real-world data could be collected in mass quantity. That's priceless. In fact, it is one of the most important aspects of having a successful rollout. Anywho, a little more detail about the next generation of Prius was offered by Toyota yesterday. The timing was fantastic. Volt never materialized as a "*game changer*" like Prius. That leaves the path wide open for Prius to face the challenges of generational improvement head on. Cost is a very big deal for Toyota too. Refinements to the hybrid system design will help to achieve that. Increasing the value of the vehicle itself will too. Toyota will achieve that by delivering higher MPG through the increasing of thermal efficiency for the engine. At the same, there will be weight reductions. Switching to lithium batteries will be considered too. The goal is to make the next Prius directly competitive with traditional vehicles to the degree that it can no longer be argued reasonably. And that's without gas prices going up. If they do, favor swings toward Prius even more. I find it interesting that diminishing returns hasn't become too much of a struggle yet. Of course, it won't matter as much when the next generations successor comes about. At that point, the idea of plugging in will be common. Plugging in offers opportunity for further enhancements. But for now, we still need to wait. This one is expected the end of next year. What do you think of that timing?

- 1-28-2014** **Still.** Some of the issues still remain. You wouldn't think things like this could persist for so long: *"Nobody cares anymore about a few more mpg in the Prius. Toyota, stop chasing diminishing returns..."* when there are others saying this: *"If only Volt had a proper modern hybrid-oriented engine, they'd have got one of those instead. A gas engine that could get 50+mpg highway would have sold them."* Making hybrids stand out from traditional vehicles is a must for those who understand the market. But then again, some people don't bother actually reading what's published. They just post comments to belittle & insult. Both quotes were in response to an article with this after the introduction: *"Keeping cost down will be one of the major concerns of the new Prius."* The method of reducing costs highlighted was the making the system smaller & lighter. That naturally results in improved efficiency. It's that lack of understanding (or caring to understand) that is still a major problem. You'd think something as simple as meeting the 50 MPG target would be a no-brainer. Currently, the highway rating for Prius is 48 MPG. Squeezing out 2 MPG is well under the diminishing return threshold. In fact, it's only 4% more. The size & weight improvement alone could achieve that. The article also mentioned the engine refinement. That too will deliver a few more MPG. Combined into the next generation, the reasoning to purchase a Prius becomes easier. After all, traditional vehicles continue to represent major competition.
- 1-29-2014** **40,000 km Report.** 2 years of ownership and that many kilometers of driving prompted the report. It was from a Volt driver... one who absolutely hated me... which makes this particular situation quite ironic. His main complaint was the technology works well, so well, he's frustrated by how slow and how little GM has done over the past 3 years. Sound familiar? Even the most staunch owners are now recognizing the *"too little, too slowly"* concern. That select group absolutely refused to acknowledge the barriers Volt faced back when I was pointing them out. Now, in a very humbling way, they've learned I really was sincere and all along just wanted to help out. Being vindicated like that is strange. I hadn't even expected the denial to get so bad. What a relief that it's now over. The realization of things going bad with Two-Mode wasn't anywhere near as bad. Enthusiasts just faded away back then. This time, it was continued fighting for a dead cause. The next Volt will be so different, it doesn't even make sense to associate it with this one anymore. That's why GM declared the first a niche. Anywho, the other complaint was the size. It should have been bigger. The legroom in back really was more of an issue than he wanted to admit, but ultimately finally did. So much focus was put on performance, the most basic of requirements was carelessly dismissed. Now the consequences of each of those choices along the way are quite easy to see... 40,000 km later. Ugh. Why did it have to take so long?

- 1-29-2014** **Know Your Audience.** That topic of marketing & economics sure is making its importance known now. The example of GM having totally misjudged what people would actually buy made itself clear with Volt. The regard for need was dismissed by executives, engineers, and enthusiasts. The car delivered was based on want. Who did they think purchases would come from? Sales of high-volume vehicles are that way because they fulfill the requirements of those ordinary & plentiful consumers. Remember when Prius was still perceived as "new" technology? The primary reason automotive magazines published articles on it was the attention doing that brought. Looking through previous copies, mention of mainstream vehicles was nowhere to be found. They didn't write about Camry or Corolla. Their audience simply didn't care. They knew their audience. It was the thrill of what the new technology had to offer, not the performance in any respect. Volt enthusiasts didn't recognize that. They seriously thought the average person would care... despite the fact that they didn't share anything in common. It was yet another example of history repeating. Prius owners knew the audience and tried to point out the mismatch countless times. Warnings didn't work. They found out for themselves, the hard way.
- 1-29-2014** **Mass Market.** For the past 11 years, J.D. Powers has been conducting surveys on this very topic. They know the audience and just published results of their most recent findings. The top-5 priorities mentioned, in order of importance, for mass-market vehicles were: 1. *Gas mileage (fuel economy)* 2. *Reliability (freedom from breakdowns)* 3. *The "Deal" (interest rates/rebates)* 4. *Exterior styling (design)* 5. *Performance (power, handling, etc.)* Seeing that easily confirms the problem. Enthusiasts of Volt absolutely insisted number 5 was actually number 1, performance was the key. They also claimed number 1 was meaningless, that electric-only miles were all that mattered. Of course, overall MPG is so random with a plug, they couldn't promote a clear expectation anyway. Reliability never got mentioned, most likely due to obvious added complexity compared to Prius. The allure of the tax-credit was heavily flaunted, but the reality of its delay and the possibility of not being able to collect due to AMT avoided. As for appearance, you know how that gets spun. Lastly, note that size doesn't come into play when comparing vehicles of the same class. Long story short, it's very important to know your audience.
- 1-30-2014** **No Recharging.** With the daily high temperature below 0°F, then need for heat has prevented battery-pack capacity from being used entirely on my daily commute. I haven't been recharging at work as a result. To my delight, that hasn't impacted efficiency as much as I thought it might. After 50 miles of driving, each of those days ended with MPG in the low 50's. The engine runs more to produce that heat, but it's not in the on/off fashion people tend to assume. In actuality, the RPM is just higher at times. That adjustment works well. Producing heat also produces electricity. So, there really isn't as much waste as you would think. The hybrid system still proves quite beneficial, even with such extreme cold driving conditions. I do miss Summer though. The Prius always being dirty and virtually no outdoor activities is a sad. Of course, a warmer Winter would do the trick. There's plenty of recreation possible when the temperature is closer to just under freezing... in other words, 30 to 40 degrees warmer. Waking up to -18°F is just plain nasty. But seeing the temperature still negative when you drive home from work is even worse. Blah!

- 1-31-2014** **Plug-In Rage.** That new topic has had an interesting thread going on the big Prius forum. I added this to it: It's somewhat puzzling to read posts about whether or not employers should provide the ability to plug in when there isn't even a requirement to provide a spot for employees to park their traditional vehicles. No regulation or mandate will make people to be civil with each other either. Good behavior comes from people sharing a common goal, a clear & concise objective that benefits many. That's what we need to find & spread. Waiting for the situations emerging to somehow work themselves out on their own isn't exactly the approach we want. That's attitude is common though, so it's understandable. But being reactive is not how change comes about. We need to proactively seek out solutions. That requires actions like engaging other plug-in owners by holding gatherings... because it obviously isn't effective to have direct confrontations at charging-stations. Anyone remember how effective gatherings were, over a decade ago when hybrids were still new? We're only now reaching the stage where our efforts can even be effective. Getting over the chaos of initial plug-in rollout was rather painful at times. Those first attempts unable to reach the masses resulted in disappointment & resentment... something we don't want to carry over to the charging-stations. Recognizing what the mainstream actually needs has become easier. A big part of that is getting away from the one-size-fits-all mentality. Notice how resulting efficiency varies dramatically from owner to owner even with the same vehicle? That's why what happens at the plug is such a big deal. Each person will have a very different experience from the same recharge opportunity.
- 2-01-2014** **Looks.** This particular quote caught my attention: "*Bought my Prius for what it can do, not what it looks like.*" How can you resist that. I couldn't: It very refreshing to hear that. Think of all the SUV owners who did exactly the opposite... the heavy-duty suspension and high ground-clearance combined with all that power, wasted. Prius got mocked relentlessly for many years due to its practical look. The hatchback screamed convenience that no sedan could possibly compete with. To make matters worse, it was the only midsize hatchback available in this market. They were all compact & sub-compact back then. Add to that the 50 MPG owners were reporting, there was simply no way to avoid all the negative attention the supporters of other automakers could dish out. Mainstream vehicles have a familiar look anyway. That's what makes them common and so easy to consider. With millions of Prius on the road now, other priorities are what compel consumers to take a closer look to see what else it has to offer. Enjoy your Prius. Take advantage of it like I do. Load up the interior with cargo, toss some bikes on back or kayaks on top, then hit the road.
- 2-01-2014** **Winter Driving.** It's always nice to read a new thread posted by a new owner. Today, it was a report of Winter driving. The results were quite pleasing. The excitement was easy to see. In fact, a photo was even included. I welcomed the new forum member with: Slow down from Winter's snow & ice certainly does have its benefits when your driving a Prius. It's quite refreshing seeing MPG go up, rather than down, when there's congestion on the road. Think about how the effect those same conditions have on others. They grow increasingly frustrated. Some of that is the direct result of gas being wasted. We don't have that with the hybrid system. In fact, I bet you may have had a silly grin appear on your face at some point... watching the impact of the drive have a positive effect on efficiency. Enjoy Winter, but also remind yourself what happens with the arrival of Spring.

- 2-01-2014** **Looking Back.** That chaos a week ago was nuts. Volt enthusiasts got so angry. Some were absolutely furious. They lashed out at the only scapegoats they could find. I was quite amused by the senseless reaction. What did that accomplish? Getting accused of being a troll, even though my content posted was totally on-topic, confirmed their responses. There are so many opportunities to do off-topic other times, but I resist. Today provided an excellent example. There was a review of Cadillac ELR. It overwhelmingly confirmed GM's stance on niche vehicles. It was pointed out how Toyota's battery production (enough to deliver 1,000,000 hybrids in 9 months, which they recently did) grossly outweighs GM's effort to achieve cost reduction. The economy-of-scale benefit should be obvious; yet, some argue anyway. Some are dead-set against smaller battery-packs. It's more evidence of how focus on engineering alone has harmed mainstream penetration. Being business realistic isn't exciting. They always wanted a vehicle that was exciting. Failure to recognize that would inevitably lead to the outcome we now all see didn't matter. They kept contributing to their own demise, hoping it wouldn't happen. Looking back, I was drawn by the opportunity to witness such self-deprecation... again. Looking forward, I wonder how that failure to recognize will change. Third time's a charm?
- 2-01-2014** **Favorite Example.** Looking way back over the years of chaos, the reoccurring theme Prius antagonists posted (yes, Volt enthusiasts) was that technology had become "*obsolete*". There was a deep denial to acknowledge it was actually "*mature*". That was a dead giveaway they weren't concerned about mainstream offerings. When pressed about the needs of middle-market, they'd reply with how electric purity will win people over. They sincerely believed ordinary consumers were find a way of justifying the extra expense. That level of differentiation is why there's been luxury brands for decades. The majority of people are unwilling or unable to pay more, regardless of how desirable the drive is. That's the way the real-world works. Not wanting to accept that has resulted in serious disappointment... on their part, anyway. I'm simply pleased that's over and can now reflect back upon their refusal to face facts. What a waste. We shouldn't have had to go through that nonsense. Sadly, the warning signs we got from the Two-Mode failure to sell well should have been enough. It too failed to address the needs of the masses. I'm always amazed by hard the loss of perspective can cause such a mess. Oh well. At least some of us know better.
- 2-02-2014** **Better Understanding.** We're moving away from struggles of the past caused by misconceptions. Some of that comes from no longer having to deal with greenwashing, the intentional misleading certain groups of people spread. Back then, people were innocent victims, unaware they weren't being provided with correct information. Now, it's more a matter of providing clarification. There's enough real-world data at this point to make the greenwashing efforts suspicious. Phew! What a relief. This was the response to one such situation today: "*That's good to know, thanks! Pretty darn clever.*" It came as a results of several Prius PHV owners providing detail about how the battery-pack capacity is managed when the engine starts. Mine was: If you get an aftermarket gauge, you'll be see that RPM is held to 1500 during warm-up. That's done to help reduce emissions. It's achieved by drawing from the battery-pack at a higher rate than in HV mode, hence EV range being burned during that time. We call that EV-BOOST, since you aren't really in HV mode yet. It automatically switches over once warm-up is complete, then works to restore the electricity it consumed during that time.

2-03-2014 **Plug-In Sales.** The month-end results for the auto industry were revealed today. January is always a rough one. Cold weather certainly doesn't promote sales. It's uncomfortable looking in dealer lots and no one wants to have to deal with snow & ice right away. So naturally, the weather was the number one reason for blame of low sales. Most everything was down. The few vehicles doing well were flat. In other words, those results were quite predictable. It's been a challenging Winter so far. Looking at the plug-in market, the three big players stirred online chatter. Leaf managed along just fine. I'd personally say that's extra impressive due to impact the heater makes on range, reducing rather significantly. 1,252 wasn't too bad. Of course, the 2,529 sales from last month (stimulated heavily by end-of-year tax-credit incentives) was obviously better. Volt dipped to 918, making it a larger percentage & numeric drop from last month's 2,392 than Leaf. Both marketing & inventory were to blame for that. I'd say there was more at play, but supporters disagree. Prius PHV, which is still only available in the 15 initial rollout states, dropped from 919 last month to 803 in January. That lack of major change was interesting. I'm not sure what the reason for that was. Perhaps buyers really do understand how well the plug-in Prius copes with the cold. They may know that since the engine has to run anyway, it's much more efficient then when the one in Volt runs. I honestly don't know. But it sure is nice seeing MPG averaging above 50 even in the dead of Winter. Hopefully, February will start steady growth. Expansion into other states sure would be nice too.

2-04-2014 **Growing Pressure.** It looks like the sting of price (more importantly, cost) is becoming apparent. More and more posts are focusing on that now with the topic of plug-in sales. This is what I chimed in about today: *"GM will face more price pressure from more plug-in offerings as well. Hyundai-Kia will be bringing plug-in versions of the Sonata-Optima in 2015. The hybrids are \$25,900. I could see the plug-ins below the magical \$30k number."* Volt supporters are well aware of how that *"nicely under \$30,000"* goal fell short. My way of stating that fact now is: All automakers knew the importance of price and how big of a gamble it was waiting for battery cost to come down, while hoping gas prices would remain relatively low in the meantime. They also knew the true competition was traditional vehicles, not other plug-in vehicles. That's why the PHV model of Prius was designed with cost being a very high priority... so it could be in sold in high-volume for a profit. Toyota worked really hard to squeeze as much as it could out of a battery-pack that would still deliver ample cargo space, hybrid efficiency following depletion efficiency, and hit that magic price-point. The fact that sales for it have remained relatively flat (rather than dropping) and the fact that rollout beyond the initial states hasn't happened yet means there's potential for this generation, no waiting. Pressure will continue to grow. Look at how strong of a hold traditional markets still have on the market. They will keep pushing. It's not other plug-in offerings you should be worried about.

2-05-2014 **Lease Replacements.** Seeing some former foes turn in their Volt after the lease expires and purchasing something else to replace it comes as quite a vindication. Some were down right cruel. Now, they have abandoned the very thing they had so passionately defended. A few have even sighted the same reasons I stated others would find unappealing. Price and legroom in back have overwhelming been the most common. They didn't want to admit mainstream need was such a big deal. They truly believe the performance aspect would justify the shortcomings. Being well-balanced, like Prius, was uninspired & boring... or so they thought. It was a group-think trap they fell into... and surprisingly admitted to the mistake afterward. That's why we can now so solidly declare a new chapter having started. hey now understand the tradeoffs required to appeal to the masses. Being extreme earns trophies. Being seemingly ordinary results in lots of sales and sustained profit. Lease deals designed for short-term gain have consequences... which are quite obvious to see now.

2-06-2014

Success. The inevitable summary came today... It boils down to how success is defined. We saw the problem right from the very beginning with "*vaporware*" arguments. Most of the enthusiasts claimed that simply meant proving the technology, demonstrating it was a viable option. But when pressed for detail, there was an obvious effort to avoid providing any. They didn't see how it mattered and declared the requests for clarification attempts to undermine. That gave GM free reign to do whatever would draw attention. Warnings of the past were not heeded. Lessons from the failure of Two-Mode to appeal to the masses were outright dismissed. The motto of "*no plug, no sale*" emerged, making a bad situation worse. Heavy emphasis was placed on the purity of electric-only driving and series-hybrid operation following depletion. The thought of anything but electricity providing thrust to the wheels was deemed an attack on Volt. Bringing up the issue of needing heat in the winter for both cabin & battery resulted in hostile replies. MPG would be outstanding. Price would be easily justified. They didn't see how there could be any resistance. The thought of actually defining success measured by sales was laughed at. That brought about the "*vastly superior*" claims. It was an indication of history repeating. Enthusiasts just plain didn't care; instead, they mocked & belittled other automaker offerings. They truly believed the technology alone would be enough to stimulate purchases in high-volume. Why would anyone doubt strong demand? Pointing out concerns was assumed to be support for another automaker. Remember how GM told us development would include "*transparency*" of unprecedented level? Yet, whenever there were certain questions from enthusiasts, like CS-mode efficiency, the answer was vague at best. Why didn't those responses raise any red flags? How come no one wanted to state who the target buyers were? What should have been done when well-known contributors became disenchanted? When was it clear that executives leaving the project indicated trouble matching market need? Now, over 3 years after rollout, there are a few still making excuses and defending the failure to understand the business of selling vehicles. We routinely see examples of innovative technology failing in other industries. That's why manufacturers don't bet the farm on a single product and strive to offer diverse choices. GM decided to risk it all on an inflexible design, one requiring a large & affordable battery-pack. That has proven unwise. Sales, even with a generous tax-credit, have been well under expectations and nowhere near mainstream levels. Achieving success isn't as easy as earning engineering trophies. Enthusiasts learned that lesson the hard way. A few still refuse to accept that reality. The business of appealing to ordinary consumers not interested in anything but transportation with a good price is a substantial challenge... like it or not.

- 2-07-2014** **Ugly Mess.** This was my follow-up post on what's left of that daily blog, which features many topics outside of Volt now: Unfortunately, looking back, we see that constructive criticism about GM wasn't welcome either. The topic of non-traditional vehicles had already become a polarized topic by the time Volt was revealed. GM's reputation for "*over promise, under deliver*" had already been freshly reinforced by the struggles with Two-Mode. It fell short on several goals. Volt was the ultimate diversion from that. Tesla's competition made it all better. Having been burned so bad by Toyota, none of that rhetoric was any surprise. Lutz had embarked on a major anti-hybrid campaign and lost. Then he set out to trump hybrids with a superior design and lost again. Third time had to be the charm. So right from the very beginning, we got lots of cheerleading. Pointing out the past wasn't allowed. Questioning claims wasn't allowed. You had to support the effort. Period. Red flags kept popping up. Those warnings were disregarded. Touting the "*vastly superior*" design of Volt served to quiet comparisons to Tesla and served as entertainment for mocking Toyota. Cheerleading turned into hype. The situation degraded as details were learned. Many who had labeled those asking questions as "*trolls*" vanished from discussions. They figured out the promises wouldn't be delivered. Rollout confirmed that. It turned into an ugly mess. 3 years later, we find ourselves wondering what comes next for GM. Tesla has done surprisingly well and other automakers are quietly attempting to emulate Toyota. What does GM hope to achieve?
- 2-09-2014** **Audience Search.** Not being able to agree who the target market is for a vehicle dooms it to fail. The meaning of "*success*" is not shared among all involved. Conflict with a group of enthusiasts should be a red flag, a warning of mixed messages. Sadly, that's been easily overlooked or dismissed. Instead, focus is still being diverted. This quote from yesterday provided a great example: "*There are 3 reasons I see for people buying Prius. 1) Ignorance. 2) Brand Loyalty. 3) Snobbery. There is no possible way that someone who does genuine research of the Hybrid Market in 2014 could come to the Prius.*" That's hardly a ringing endorsement for Volt on a Volt forum on a thread deciding between the choice of a Prius C or Volt. The very fact that the smaller model of Prius could even be compared directly should highlight the internal struggle taking place. We left the previous chapter with a "*niche*" status. This new chapter is off to an interesting start. It's quickly becoming a search for an audience.

2-09-2014 **Short vs. Long.** Far too often, we get narrow perspectives. Today, it was: "*But more competition from higher mileage cars really is eating into prius liftback market.*" Encountering comments like that is quite typical. Hopefully, the reaction to my response will be too. With expectations for Volt having fallen apart, there isn't much arguing anymore. Taking the next step is quite a bit easier now that there's a good sense of direction & speed. The chaos before sure didn't provide that. I'm thinking this new chapter will be much different: Short term, that's a reasonable assessment. Long term, more competition is a win for Prius. Counter intuitively, waiting for the next generation is too. Other automakers pushing the shift away from traditional vehicles is how penetration deeper into the market will happen. It's necessary for expansion. This opportunity for catching up helps all involved. We obviously find the slow pace annoying. That's how the mainstream market works though. The high-end niche can move rapidly. But with the majority in the middle, speed of change is glacial. Paradigm shifts means someone will lose. That means fighting for survival, even though the inevitable cannot be avoided... only delayed. That's why Toyota's effort to offer an affordable plug-in option is so important. They are well aware of how long it takes to refine a design and not incur increase cost as a consequence. Being able to share improvements with the regular model makes competing with the wide variety of competitors, including their own traditional vehicles, is a major benefit. Notice how much of a non-issue the switch to lithium has been so far. Both the 7-seat Prius wagon and the PHV work well with it. Although still expensive compared to NiMH, the new battery type has proven resilient in addition to being more efficient. Increased competition will help drive down the battery cost. Toyota is positioning to take advantage of that.

2-09-2014 **Product Gap.** This topic of Tesla production intentions certainly has stirred up some rhetoric of the past. Remember a decade ago when Lutz launched his "*stop gap*" campaign? It was a clear anti-hybrid effort to promote fuel-cell vehicles, a declaration to end the consumption of gas. That fell apart. He got burned bad by Prius. When Tesla came along, it was a golden opportunity for vindication. That ugly chapter from the past would be forgotten by the way of crushing a bold, new, player with strong potential. Volt would be superior, offering the best of both worlds. Unfortunately, the realities of business crushed those ambitions. Volt created a product-gap instead. Price was too far out of reach for GM's own customer base. It would be competing directly with GM's other offerings. Despite countless warnings that would happen, hype clouded judgment. When sales began, so did the denial. Purchases well under expectations spurred the need for delay, making the product-gap worse and leaving GM with an expensive niche. Meanwhile, Tesla continues to press on... leaving us all wondering who the next Volt will actually target. The spin we now get from certain individuals confirms the lack of clarity. The same market question will need to be asked again. It's quite obvious that will be the source of trouble again too. Watch for it. Those vague answers are a dead giveaway. Ironically, that's what enables Tesla to continue to be a "*disruptive*" company. Each time detail is avoided, it strengthens them. Pressure is growing from many directions. GM must offer something, anything, for the masses in the high-efficiency category.

- 2-10-2014** **Power or Energy, not both.** Upon reading the following quote (from the moderator of what's left of that daily blog for Volt), I knew an explosive reaction was about to occur: *"An important consideration that people without a technical background don't understand is that you can either have a high power or a high energy cell chemistry, but not both. Since the battery pack in a plug-in hybrid like the Volt has to generate the same power as a much larger battery pack in a pure electric vehicle, it has to use a low energy cell chemistry."* That came from Elon Musk back in 2009. He's the person responsible for Tesla, well informed and passionately disliked by Volt supporters. Getting such a comment from him was going to be a problem. It backed my stance. So, they wouldn't like hearing from me at all. Who could resist that? I posted the following: Thanks for digging up that quote. Having a source to refer back to about that fundamental difference would have been handy. It's a factor rarely brought up in the non-tech discussions. Ironically, engine running is often posted. But sadly is used as an insult, rather than an objective comparison. GM chose to design a vehicle which depended heavily on the battery-pack, doing everything it could to avoid starting the engine. Toyota did the opposite, allowing the engine to start for the sake of maximum overall efficiency. In other words, one automaker sacrificed electricity for the sake of purity and the other decided sacrifice purity to avoid some losses. The reason for the approach difference should have been obvious. It was to protect the battery-pack. Why allow heavy draw knowing that accelerates deterioration? What is obvious is the obsession with power. It doesn't make sense carrying around a engine if the point of it is only for use after depletion, especially when supporters want a larger capacity battery-pack to prevent ever having to use it. How many times have we seen "blending" labeled as a shortcoming? That points it out as a strength for vehicles which include both a plug and an engine, who's system is designed to squeeze out the efficiencies of each by using them in conjunction.
- 2-10-2014** **MPG not MPH.** The hate really came out today. I innocently made a comment about diminishing returns, how efficiency gain drops significantly after exceeding 75 MPG. The person who attacked clearly didn't read anything I wrote or even looked at the link provided. Each of the line included in the quote responded to stated "MPG" too, all in upper-case letters. He assumed "MPH" and the dozen who quickly voted positive for his post did too. I was amazed at such a blatant attempt to greenwash and the lack of integrity. Of course, that's why I never got banned. Me being detailed & polite is quite a contrast to the Volt enthusiasts intentionally misleading. I later called that post out too, pointing how the response was completely unrelated to the quote. They didn't care. That's why this new chapter is so easy to see. There's a huge divide between those trying to genuinely support the replacement of traditional vehicles and those who simply thrive on pride & conquest.

- 2-12-2014** **Sighting.** Well, that was quite unexpected. While taking a nice walk with my sweetheart, she suddenly got excited and pointed. Having spotted another Prius PHV before me came as a very nice surprise. With them still not available in Minnesota, it isn't something you'd expect. But being that color unique to the plug-in model, it's difficult not for it to not stand out in the eyes of another Prius owner. Hopefully, when the Winter finally melts away, there really will be a chance of more. Right now though, forget it. Between the cold & snow, it's a miracle to be seeing a solid 60 MPG average. That's half of what I saw during my best month last Summer, but remarkable when compared to other vehicles... even hybrids without a plug. It's lonely still. But with the chaos coming from the first chapter, it has been confirmed a wise decision to wait. In the meantime, the few of us who do actually own one are gathering lots of real-world data. Remember the mess caused by rolling out without? Setting realistic expectations is important. How many people really understand how Prius works in the first place? Adding the plug option confuses matters. Thankfully, there are some of us who know the differences well. Too bad I didn't actually get to meet the owner.
- 2-14-2014** **Showing The Love.** I watched the opposite this week, perfect timing for Valentine's Day. There was a "*recall*" issued for the current generation Prius. It's actually just a software update, providing preventative & longevity improvement. But the stigma of updating is a major image problem for the auto industry. That's really unfortunate. Look how widely accepted that practice is for phones & computers. People think nothing of accepting them and they most definitely don't treat that as a recall. On-Going improvements for vehicles is still thought of as a bad thing though. Why must we deal with that rhetoric? The posts on the big GM forum and the big forum dedicated to Volt were outright cruel. What I got a kick out of was the blatant effort to attack supporters. I was called out by name, even though I haven't posted on the one in well over a year and never on the other. Since I had established myself as a lightning-rod, an owner spokesperson due to having so much real-world data easily accessible, they felt the hostility was justified. They felt I could be blamed for Volt's struggle and wanted Prius to suffer. I thought it was quite amusing how they misrepresented both me and Prius. What was more telling though was how both threads abruptly stopped when it got personal. True supporters of Volt understand the benefit of software improvements. They also see what can be gained by having a well-known hybrid success as an ally rather than an enemy.

2-15-2014 **You'll Know When.** Setting proper expectations is a very big deal. We saw how much of a problem that was for Volt, where hope had wandered far from reality. So naturally, the topic of the next generation Prius is a popular one. There's over 1,850 posts on that particular thread already. This recent comment caught my eye: *"I am beginning to believe that Toyota is experiencing problems meeting the expectations, including fuel efficiency, handling, comfort and cost. The G3 was a wonderful achievement in all of those area, and it may be very difficult to eclipse that success. OTOH, no other manufacturer has been able to, although some are getting closer and closer."* That opened up the opportunity for me to set some expectations, especially having been through this several times already over the past 14 years: Putting developing-market expectations on a maturing-market will inevitably bring disappointment. It's not realistic to think each generation will bring major improvements without something actually changing. You can only squeeze so much out of a design. The engine/battery approach will only take clean & efficient so far. There's nothing left to prove either; real-world results ended all misconceptions. The next step is engine/battery/plug... which Toyota already has a huge industry lead on. No other automaker is working so hard to squeeze out so much out of so little. Dropping in a larger battery-pack is easy. Getting a large return from a capacity of just 4.4 kWh is quite a challenge... but that's exactly what's needed to not compromise on efficiency, handling, comfort, and cost. Thinking people will suddenly embrace high-capacity batteries is futile. They won't, period. Look at the computer & device industry. Large solid-state drives are clearly superior to traditional hard-drives, yet they are still far from standard. People don't care how much more robust, faster, and efficient they are. The cost just plain doesn't justify that. So, the best to hope for high-volume market penetration with much smaller capacity solid-state on common tablets for now... however, that is a sign of maturing. Seeing the plug-in Prius emerge as an affordable choice, an option actually competitive with traditional vehicles is what we should hope for. We'll obviously see design gains from the regular Prius. But those will contribute to mainstream expansion and the reduction of guzzlers. The push into new territory comes from adding a plug. Watch as the term *"hybrid"* fades away. That's when you'll know it happened.

2-16-2014 **Only For Green.** The online fighting has come to an end. We are seeing hypocritical posts and childish parroting now. That's a sure sign nothing is left to say. It further reinforces the reality of a chapter having ended. The audience has moved on and even those extremes aren't drawing attention. I find comments like this interesting: "*But, if you look at Ford sales numbers, Energi isn't exactly selling like hotcakes, so Ford hasn't exactly found the answer either....*" They give the impression of being constructive, until you look at the actual numbers. Being vague is the key to keeping discussions alive. But at this point, even that doesn't work, which is why comments like this emerge: "*You're the person that shows up invited to a party and can't take a hint to leave.*" Making opposing viewpoints feel unwelcome is nothing new. The catch is, the moderator shares the same sentiment. Rather than agreeing with those everyday posters who just want cheerleading, more and more evidence of a new chapter beginning is provided. It's an obvious effort to get the discussions to change. I joined in by providing some insight: There were 1,004 purchases of Ford Energi models last month. Comparing that to 959 sales of Volt & ELR puts GM in the same, if not worse, situation. Taking into account the reality that the GM plug-in hybrids offer \$3,493 more tax-credit incentive makes those Ford purchases even more meaningful. Then when you notice 471 of the total 1,418 C-Max sales were the plug-in model, it really provides some perspective. Volt was available for a full 2 years before the first Energi model too. Seeing the latest Volt advertisement focus on range-anxiety and only the cheerleading comments about it acceptable, tells an unwillingness to address the problem of low gas-prices and high battery-prices. Using a double-standard to distract from the "*too little, too slowly*" concern having been proven correct sends the message of genuine trouble. Avoidance of an issue doesn't make things better. This new chapter in the history of Volt, having the current generation officially declared a niche, makes the next offering even more of a challenge to face. Continued advertising to the EV market rather than ordinary mainstream consumers would otherwise purchase a Malibu or Cruze reinforces the "*only for green*" mindset. The step forward is appealing to the masses. Not wanting to tackle that and just quarreling amongst ourselves doesn't accomplish anything. We already know that production cost must be given high priority and practically cannot be sacrificed. The expectation of high-efficiency (better than traditional) following depletion is being sighted as important now too. Goals must be clear and taken seriously. So far, that hasn't happened.

2-17-2014 **BMW Plug-In.** Some information about the expected plug-in hybrid from BMW was provided. No, not that model which messes up the vague & misleading enthusiast definition of EREV. It's their true plug-in hybrid. You know, a vehicle which blends power-sources for the sake of achieving optimal efficiency rather than forcing electric-only power initially, sacrificing opportunity to use the engine. The detail we got came from BMW. It was the result of some photos having been leaked. Rather than allow hype and false expectations to emerge, they took advantage of the attention that had garnered. We learned it will provide roughly 190 horsepower and will likely use a high-performance 1.5 liter 3-cylinder engine. The key is will look similar to the common hatchback/wagon offerings we see now and the battery-pack will be in the 13-mile range. Not intruding on cargo or passenger space is obviously an important aspect of design... the very thing complained often about with Volt. Sometime the middle of next year is when the availability is planned. That timing should make it quite interesting.

2-18-2014 **Meaningful Technology.** It's nice when someone asks a constructive question: "*What *meaningful* technology lead is that?*" With supporters claiming GM is a technology leader, you have to ask what they are actually leading. I couldn't resist. Joining in was a must: That's the magic question. We've seen many, many efforts to undermine Prius as a result of asking. When all attempts to exploit misconceptions failed, they turned to making "*old*" and "*outdated*" and "*obsolete*" references. When that hope to conceal its maturity failed, they tried to spin the situation by using the "*early adopter*" label for Volt. But after 3 years, still calling it that is too much of a stretch. So, the move has been to ignore the regular model of Prius entirely, focusing on the plug-in model instead. That's a complete reversal of original arguments. The reason why should be obvious too. Toyota clearly stated goals for the regular model next generation. The engine will be more thermally efficient. The hybrid system will be smaller & lighter. The production cost will be reduced. The hope is to switch from NiMH batteries to Lithium as well. Taking all that into account and the fact that United States annual sales of the regular model have remained steady at 145,000 for the past 2 years put supporters of Volt in a difficult position. They certainly didn't want to bring up the compact or wagon models. And the hybrid Camry scares the heck out of them, knowing its traction motor is nearly identical in size to the one in Volt. Toyota also offers an AWD hybrid Highlander with a 3,500-pound towing capacity. Attacking the plug-in model has been their only option available. Our encouragement to get GM to also offer a variety of configurations continues to fall on deaf ears. After all this time, including 3 years of weak sales, some Volt supporters still don't want to acknowledge the need to diversify. It's bizarre how they don't want to see the benefit from offering the choice of a smaller battery or a model without a plug, despite the growing pressure to meet CAFE requirements and the requirement to deliver sustainable profit. Toyota has broken out of the "*only for green*" stage, confirming that technology is meaningful. This new commercial portraying Volt as an electric car with a backup engine leaves us wondering who GM is attempting to appeal to. With the necessity of mainstream interest for high-volume sales, it assumes there's ample demand for plug-in vehicles... despite the recent trend and generous tax-credits. It would be great to see the masses flocking to plug-in vehicles, but that isn't realistic yet. It means the lead must come in the form of companion technologies in the meantime. The approach of battery-advancement and engine-refinement through vehicles without plugs was an aspiration GM shared with Ford, Toyota, and Honda. GM's gamble to leapfrog of abandoning that design backfired and supporters now feel burned. So, some are expressing their hurt & frustration by lashing out rather than championing the next chapter. What a waste.

2-20-2014 **Charger Failure.** I got an email from the Prius, stating recharging had failed. That certainly got my attention. With wet & heavy snow coming down, I wondered what could have happened. I know plugging in at work wasn't out of the ordinary. Nothing stood out in my mind. So, I walked over to investigate. Checking the plug, all looked fine. So, I went into the ramp office to point out their first ever charging issue. They said for me to play around and report what I discovered. Upon ending my efforts, I returned the plug to the charger. It kept asking me to do exactly that, even after doing it and rescanning my card. I went in and told them the unit had become confused, likely needing a software reboot to get it back on track. They said it would be called in. Nothing appeared damaged. So hopefully, the fix is that simple.

2-20-2014 **Industry Disruption.** There are many innovations from the past that we can look back upon with great favor, saying they were an obvious next step for an industry. Each takes a collection of other new technologies combined to make an entirely new product which causes a disruption in the industry. The intent is to cause the end of the current product's production. Digital cameras are a prime example. The use of film by consumers ended as a result. People switched to saving images electronically instead. That was a major boom for those producers who could handle the change. Those who couldn't disappeared. The technologies that didn't achieve change disappeared too. In fact, most of the history and players involved vanish, especially the competition. DIVX is the prime example of that. No, not the compression format we recognize nowadays. The optical-disc. It was competition to DVD, introduced after DVD had established itself as an industry agreed upon replacement for VHS video-tapes. The now bankrupt Circuit City sponsored it, enticing movie studios to offer it as an alternative. They paid a total of 300 Million dollars to those interested to join. They pitched it as a copy-protected format. The optical-disc could only be used when activated via phone-connection and would only work for 48 hours. After that time, people would simply throw away the disc. Back then, the late 90's, that meant a major opportunity to tap into the home-rental market. Many saw it as expensive, complicated, and wasteful. Now with digital downloads, the concept seems absurd... which is why barely anyone even remembers it. Yet, it dramatically slowed down DVD production for nearly 2 years. It was a true disruption which ultimately failed. How is Volt any different? It too is heavily subsidized, uses a convoluted system, and isn't actually as efficient as it would seem. In the meantime, it has slowed the progress of other plug-in hybrids. Look at Toyota, Ford, and Honda's efforts. All use battery-packs notably smaller. Supposedly, bigger is better. But evidence to the contrary is becoming easier to find. Just look at Hyundai and BMW. They intend to offer plug-in hybrids with smaller battery-packs too. GM intends to stick with a larger pack, despite sales being far below expectations and tax-credits expiring. Remember what happened to Kodak from not embracing digital photography?

2-22-2014 **41 MPG.** There was lots of running around yesterday. It was annoyingly cold and I didn't get an opportunity to plug in. Not being able to recharge and frequently having to start up a cold engine wasn't the weekend I had looked forward to. But then again, that's what real-world data-collection is all about. Fortunately, the results weren't too bad. Getting 41 MPG was quite nice. Too bad this terribly long Winter continues to drag on. Snow piles at edges of driveways have climbed as high as the lower branches in the trees. That well above average. It obviously a big safety issue. Having to deal with slippery & bumpy roads is bad enough. Spring sure is going to be nice. Thankfully, I can plug-in most days in the meantime... twice, in fact. That boosts MPG into the 60's. Gotta like that improvement. It's way better than any guzzler could deliver.

2-23-2014 **Not Serious.** Proof that things have changed (we started a new chapter) is becoming very easy to find. In the past, there was so much rhetoric against the plug-in Prius, the assumption was that Volt would naturally do far better. The catch was, the belief only worked if you didn't include the regular model. It couldn't be part of the equation. The enthusiasts of Volt kept claiming Toyota's efforts weren't serious. They didn't understand how change really occurs though. Now, there's a "*disgust*" thread growing. The supporters are sounding off about the observations of GM. It started with a commercial for Cruze Diesel. The original advertisement stated "*best mileage of any non-hybrid*" then later got switched to "*best in-class mileage*". Remember the big question of who the market for Volt was? They now see the competition coming from within, not Toyota. The very thing we warned them about is coming true. As a result, comments like this are getting posted: "*I have said before and I will say it again, GM has no interest in selling volts!*" I find that quite ironic, especially since I don't recall ever having read that. Of course, many never wanted to acknowledge the leadership issue either: "*It got me thinking about whether or not GM will let the Volt wither on the vine... Half of the top people that were responsible for the Volt are no longer with GM.*" My posts pointing that out resulted in hostile responses. They'd keep posting information about promises having been made about upcoming expectations, but wouldn't acknowledge those who were responsible for delivering the improvement were no longer there. Without accountability, it's really easy to abandon particular efforts. Plug-In support (both marketing & financial) won't come from a regular hybrid either, since GM doesn't offer one. There's literally nothing to leverage from. In fact, all there is available is a tax-credit which will expire during the sales period of whatever is offered next. Basically, seeing the current loss of interest, GM will have to start from scratch. That reintroduction of what's called "*Volt*" a few years from now will be a major effort. Think of the competition then. Too bad things got so out of hand. Supporters trusted the right decisions would be made rather than helping GM be better informed. They cheered each step instead of providing constructive criticism. Consequences of that blind hope are abundant. GM wasn't serious. Turns out, the enthusiasts weren't either.

2-25-2014 **Focus Electric.** Looking in the mirror, I saw a familiar but unrecognizable car approaching. It was sunset. That made the LED stylelights really stand out. They were unique, yet something about the vehicle kept nagging at me. As it got close to pass, I could identify the Ford badge and noticed it had a door emblem. I quickly dismissed it as saying "*HYBRID*". So, I kept looking, hoping to confirm it said "*ENERGI*". It didn't though. It said "*ELECTRIC*". That took a moment to register. The car was one of the rare Focus Electrics. With so few on the road, you simply never expect to actually see one. That was cool. It did make me wonder. Why are there so few? Nissan sells far more Leafs. Oh well. Not sure way. But that makes it official. I finally saw one.

- 2-26-2014** **Not Anymore.** It's nice reading this from someone who had for awhile pushed in the other direction: "*This is no longer the happy go lucky community of first adopters. It's back to the real world and it's a dog eat dog one.*" Some obviously pushed harder than others. But it always came down to who each person considered the competition. Overwhelming, owners of Volt considered the other plug-in vehicles. Now they are only a tiny fraction, nothing to actually worry about. In fact, the spirit of cooperation I had sought all those years ago is finally becoming realistic. They now acknowledge the massive threat traditional vehicles pose. It's about dang time! I responded accordingly: The warnings about "*too little, too slowly*" were not understood and were often dismissed with an "*early adopter*" excuse. That isn't happening anymore. I like this new chapter. Seeking out cooperation across automakers is becoming realistic. Those seeking out solutions using electricity now recognize the real threat is traditional vehicles, not other plug-in vehicles. It was rough initially. Back when we were in the "*only for green*" phase, it was easy enough to just argue against plugs using talking points without any merit. But now that 3 years have passed, there's real-world data shaking out the unrealistic from the practical. Some feel threatened, since they see the change coming. They fear the inevitable and lash out. We've seen a plug-in owner get arrested for plugging in using an outlet without explicit permission, even though that's a very common occurrence with cell-phones. Now we see someone has intentionally destroyed a charger-cord. Meanwhile, former quarreling parties are now trying to work out how to handle demand at the plug. Those are all examples of a turning point having been reached. The choice of plugging in isn't anywhere near as simple as had been portrayed. Competition will be much more intense. Look no further than the computer market for a parallel. Remember back in the days when a system's worth could be evaluated primarily upon processor-speed? Now, there are far more configurations available and measuring performance varies dramatically upon need. We're seeing similar emerge with plug-in vehicle choices.
- 2-27-2014** **Honda Insight.** The idea of an ASSIST hybrid never made any sense. It lacked the flexibility needed. Not having a power-split device, instead being directly integrated, meant missing out on efficiency opportunities. It also meant only a tiny electric-motor could be used. There was no possibility of ever supporting a plug either. So, it was doomed from the start. The fact that Honda was able to milk the design for over a decade and provide some amount of competition was amazing. But with so few choices, the challenge wasn't great. Things are different now. Honda has since developed its own FULL hybrid system too. That made today's announcement quite predictable. Insight production for the United States will end. It simply wasn't able to compete here. 280,629 were sold worldwide last year, which is quite good. But only 4,802 of those were purchased by us. That's so small of a number, it's just plain not worth the effort anymore. Honda will focus on other offerings instead.

- 2-28-2014** **Starting Over.** It doesn't take much to see that the first-generation issues for Volt are now just a memory. That attitude of being vastly superiority is long gone. It's as if someone pushed a reset button. Promises of the past have been abandoned. They've started over. Posts are so vague, what to expect next is anyone's guess. That makes sense too. All those years ago, the enthusiasts didn't anticipate the EV would be so successful. The very idea of Tesla & Nissan holding on strong enough to show growth potential at this point was a joke. Taking that possibility serious simply wasn't going to happen. They also thought hybrids would be severely weakened at this point. Seeing Toyota deliver 1,000,000 in just 9 months most definitely wasn't in their plans. So, they have to recalibrate... without sounding hypocritical. They don't want to fall into the hype trap again either. Somewhere in the middle there's a happy balance... the very target Toyota has been aiming at all along. I like the fact that such information doesn't rouse intense emotional outbursts anymore. Recognizing need is progress, long overdue. Better late than never... even if it does mean having to start over.
- 2-28-2014** **Tax Reform Act.** Countless warnings that this could happen weren't taken seriously. Finally, someone heard. Of all people, it was the last Volt holdout who voiced some worry. But when the Ways & Means committee for the House of Representatives brings it up, rather than Prius owners, the reason for concern is much stronger. I responded with the news of the possible end of tax-credits for plug-in vehicles coming this way: When the tax-credit for hybrids was offered in 2006, the expectation was that it would quickly stimulate sales. The amount was \$3,150 per vehicle with a quantity of 60,000 per automaker. In 2010, for plug-in vehicles, more than double the amount (up to \$7,500) and more than triple the quantity (200,000) was offered. Expecting to milk that for 5 years was pushing it. Hearing that it could indeed end after 5 years shouldn't surprise anyone, especially knowing the financial situation our government has been struggling with since 2008. The need to proceed quickly was part of the economic recovery advice provided. We all saw the possibility of incentive funding coming to a end. Cost reduction is vital and you cannot wait until after the tax-credit has ended to deliver it. The expectation has been to increase sales right away, to achieve some lower prices through the benefit of high-volume production. What plug-in vehicles are in the position to deal with that just 10 months from now?

2-28-2014 Business Realities. The topic of profit for automakers has been beaten to death, to the point that even the most stubborn finally acknowledge the problems high-cost cause. Some truly believe the "*if you build it, they will buy it*" model... despite countless examples of that not actually working. In fact, there have been some monumental failures of the past they simply refused to address. Thankfully, that's over now. We can now move on to the other pressing matters. Yet another example of "*too little, too slowly*" is the business reality of is the adoption of charging-stations. Those fighting more practical plug-in hybrids, like Prius PHV, didn't realize they were shooting themselves in the foot. Adoption of the plug by everyday consumers needed to be done quickly; otherwise, issues unique to niches emerge. Lately, that has manifested itself with the quarreling of who is "*entitled*" to plug, rather than finding a way to make it work. As a result, some owners are having charging-stations removed. That's quite a dramatically different outcome from the expectation of installing more. They are tired of dealing with those arguments & complaints and don't see the patronage benefit they had anticipated. Things like this are exactly why the "*vastly superior*" attitude frustrated me so much. With over a decade of hybrid ownership, I knew the rollout wasn't targeting the correct market, which the masses needed to embrace plugging quickly.

2-28-2014 Quick Adoption. Fallout from 2013 will hurt some far more than others. Toyota already has a profitable platform to leverage from. The key to greater market penetration is using PHV to raise the bar. When mainstream buyers see the plug from time to time, they'll look upon the regular model as the new normal. After all, we are well into the 21st Century at this point. Think about how much internet, phone, and television have changed over the past few years. Being able to deliver an affordable plug-in model... quickly and without tax-credit dependency... to reach those consumers is realistic. This is why Toyota worked so hard to squeeze out a significant return from just a modest battery-pack. The 4.4 kWh size was quite deliberate. It was small enough to be thought of as an upgrade option, once the cost of lithium reached a profitable level... which thankfully is right around the corner. The fact that the battery-pack is also small enough to be totally concealed under the false floor without taking away from any of the open cargo area is a nice bonus. The prototype models used a 5.0 kWh size, which did indeed reduce the space for cargo. The change was a smart move, especially now knowing how 2014 looks to play out. Being positioned to take advantage of a paradigm shift is important. Quick adoption of hybrids will catch some automakers completely off guard. Think about those that don't have anything but a loss-leader to offer. They'll be stuck trying to compete with only traditional vehicles.

- 3-01-2014** **Record Winter.** It is still horribly cold. We are on track to setting some records for coldest & longest in 35 years. The situation has been nasty. What a pain. To have to deal with so many days below 0 makes it quite unbearable. Rather than a few cold spells, it has been an endless string. The count will likely be 50 days this season. That makes Winter really annoying. At this point, we should be enjoying signs of Spring. Instead, there's only a glimmer of hope at the end of this next week and snow on each side of my driveway piled taller than me. Blah. Thankfully, the Prius managed just fine. Averaging a little over 60 MPG for the past 2 months is nice. I sure miss the efficiency warmer weather brings though. With temperatures so far under the freezing mark certainly makes that a challenge. There's simply no way to avoid having to turn on the heater right away. That prevents you from taking full advantage of the plug-supplied electricity. Fortunately, you still get a boost from it. But there certainly isn't any opportunity to roll down windows yet. That aspect of Spring has been delayed. Winter is still thriving.
- 3-03-2014** **Long Ago.** That antagonist from way back when Prius was first rolled out still trolls the big forum. It's the same old message from the past. He pushes diesel and defends Honda. That never ceases to amaze me how angry he gets with how all that played out. Diesel has barely been able to maintain the status quo and Honda continues to struggle with older designs. Thankfully, Honda has delivered a new design. It's much better, so much so, the old is being discontinued. That admission of defeat has obviously caused some upset. So naturally, he's lashing out at Toyota. It started with: "*Wow..... discontinued their CRZ and Insight. Now their EV. Who on earth is running Honda these days?*" Then ended with a sludge attack, concluding this way: "*Toyota demonstrated their warranties don't mean anything.*" It makes a person wonder if he'll accept change in any way. Other intentional troublemakers fade away over time. He's firmly held on, unwilling to take the next step. Will this move on Honda's part help? Who knows? I responded with: That was a chapter from long ago, a past already overcome back when Prius was rolled out here. How does it apply to anything now? So much has changed since then, it's just a note in history. We could stir others from other automakers too, but that wouldn't accomplish anything. Heck, for that matter, bringing up stuff from prior to the market fallout doesn't necessarily apply anymore either. What's important are the choices being made now, reaction to how the market has changed. We're seeing that happen. Those decisions to compete with designs actually capable of competing directly with traditional vehicles are vital and should be applauded. Posting dismay & distractions isn't constructive. They are finally taking the situation seriously. It's a move long overdue.

3-03-2014 **EV Button.** I thoroughly enjoyed the latest thread about the EV button leading to this inevitable comment: *"I still kind of wonder why the button is there at all though."* It provided me with the chance to post: The answer to that is quite obvious, once you step back and look at the big picture... especially the history. Well over a decade ago, Toyota delivered a FULL hybrid. That meant it had a PSD (power-split-device) which enabled a wide variety of efficiency options, the flexibility to seek out opportunities. One of the many abilities was that of electric-only propulsion. Back then, the threshold for it was 42 MPH. The redesign many, many years later changed that to 46 MPH... giving us a clue that more had actually happened behind the scenes. Toyota had altered the carriers on the PSD to allow a greater range of operation. They had added another carrier, changed the tooth-count, replaced the reduction gear with another PSD, and increased the RPM range of both the generator & traction motors. We now had an EV button. It worked different than the EV we were familiar with though (often referred to as *"Stealth"* mode). It delivered much more power, but the upper speed threshold was only 25 MPH. Research as to why revealed that it was a factor of battery draw. More electricity meant more power, but it was limited to what the battery could deliver. Then came along PHV, the plug-in model of Prius. It used a more powerful battery-pack. And sure enough, both EV power & speed were increased... without any change to the existing design. Sure, owners of the 2010 model (like myself) were able to find a practical use for the EV button in the regular model, but that wasn't the point. It was simply a nice benefit. Notice how often those desperate to discredit Toyota claim PHV was a scramble to compete? They insist the plug-in delivered is just an afterthought. They refuse to acknowledge it was part of the existing design, that the current generation took into account the ability to support a better battery all along. Toyota understands the market and is well aware of what it takes to counteract undermining, both intentional and what comes about through assumption. The button is proof of that.

3-03-2014 **Disappointed.** There's no other way to describe the situation... which is why the word *"disappointed"* was used a lot today. The numbers speak for themselves: Cruze 21,836; Equinox 21,587; Malibu 17,448; Impala 12,008; Sonic 7,586; Camaro 6,211; Spark 2,576; Corvette 2,438; Volt 1,210. GM's premiere high-efficiency vehicle ranks so low on their car sales chart, there simply no way to spin the results in a positive way. Into the 4th year of sales, seeing less than 1 per dealer per month is not what anyone had hoped for. That's well below expectations for a one-size-fits-all gamble. Without any other high-efficiency vehicle being offered, there's nothing to look forward to either. This year is when the competition overwhelms Volt to such an extreme we aren't likely to hear anything. The rhetoric is dead. Enthusiasts were warned that traditional vehicles were the true enemy. They were told over and over and over again that you couldn't isolate the plug-in market. They didn't care. They belittled Prius, even though it had diversified to take on the challenge high-efficiency vehicles faced. They declared superiority, even though ordinary consumers simply weren't interested in an expensive compact requiring a plug. They dismissed need, even though the requirements of business were made quite clear. The outcome of disappointment was inevitable. How many monthly sales reports had to be given before they finally saw what was actually happening? Today, we got the answer.

- 3-03-2014 Tier-3 Emissions.** The new standard was made official today. The final rule impact analysis was 618 pages. The summary and analysis of comments was 982 pages. The preamble of regulations was 1069 pages. Needless to say, there was quite a bit of detail provided. Long story short, the new level of clean will become a reality in 2017. Those who said what we have now is clean enough are scrambling. Clearly, evidence to the contrary is overwhelming. It sure is nice seeing this happen. Far too often, the purpose of hybrids reducing smog-related emissions is totally disregarded. At best, carbon emissions are mentioned. But they have nothing to do with the quality of the air we breathe. Far too often, carbon is used as a distraction with hope the smog type is overlooked. After all, the days of diesel smoke & soot are gone. The problem now is invisible, easy to forget about. Some of us remember though. In fact, we notice more and more warning days during the Summer, when the elderly & young are told to stay indoors and refrain from activity. Traffic continues to get worse too. The problem won't get better by ignoring it or saying good enough. Vehicles put in service now will continue to pollute for the next decade, making the issue a doomed situation if you wait to react. So, the new Tier-3 Emissions standard is a welcome improvement. It will require cleaner vehicles as well as cleaner fuel.
- 3-04-2014 Change.** It's tournament time now. That meant the possibility of encountering vehicles not normally in the area. Sure enough. Just as I was about to leave the highway, there was Focus-Electric. It was brand new, still with a temporary license in the window. Cool! A few blocks down the road, I parked. Along with the Leaf that I share the chargers with daily, there was a Volt. Cool again! However, it actually parked right next to the Leaf, taking the only cord available on that side... since the other is now officially broken, awaiting a replacement part. That was the first time I ever saw the sharing situation... 2 spots with only 1 charger available. Here in Minnesota, the market is still quite limited. So, my curiosity was peaked. It seemed odd though that the driver simply didn't park on the other side instead, since there are 4 chargers available there. Fortunately, it didn't matter. They were able to share just fine. The Volt finished before the Leaf actually needed to plug in. Cool.
- 3-05-2014 Groupthink.** This turned out to be a nice wrap-up of recent posts, in favor of the status quo, fighting those of us pushing for change: The constant effort to discredit has been reasoned as a "*groupthink*" problem. How ironic. Usually, consensus is the desired outcome. It's futile to believe the needs of the many don't actually have something in common. Look at the ELR commercial. The controversy comes from intended audience. Who? Isn't that the same question asked about Volt for years? Sadly, we did know, but certain individuals didn't like the answer. So, they attempt to discredit those asking. After all, that's what draws attention and stirs participation. It's too bad constructive dialog hasn't been possible. You say something requiring change or compromise, it quickly gets labels as anti-GM or anti-Volt. Every month, the same thing repeats. They know a vehicle for the masses is needed; yet, they allow the opportunity to slip away. We knew from the beginning the trophy-mentality was a challenge to overcome. It's far too easy to fall into that trap. So when GM decided to offer the next Voltec vehicle with a wide array of luxury features rather than simplifying the current to appeal more to mainstream consumers, the outcome was inevitable. But rather than just acknowledge and strive for a better next step, shoot the messenger. Ugh.

- 3-06-2014 Redesign.** To those few still fighting change: How many times does history have to repeat before finally learning from those mistakes? We saw this coming. Though, each instance parallels were pointed out, the messenger was attacked and everyone else was told to just be patient. Over 3 years later, after elsewhere. Those individuals here pushing inaction are losing their audience too. Remember the Volt goals? Remember the ELR expectations? These are some quotes I came across elsewhere today, all comments on a thread about the redesign for 2016, all sharing the message I've been conveying for years: *"It needs to be in different vehicles, including a larger sedan, a luxury sedan and crossovers."* *"It's a compact car so make the next gen Volt the same size. But have a big brother, too."* *"I will never understand why GM has been so slow on expanding the Voltec powertrain to other models."* *"I can't see why Voltec couldn't be used in larger sedans, small and large SUVs and trucks."* *"Seating for at least 5 - needs to be as close to a family car as possible."* *"GM loses money on Volt."* *"The Volt is outsold by every retail offered, GM car/truck/suv except for the SS."* *"My big worry is that GM is treating VOLTEC as they did Two-Mode: Hype the crap out of it, and it when it didn't sell to expectations, give up and then ultimately kill it."*
- 3-07-2014 Plan "B".** Not having one is the problem Volt has struggled with for many, many years. GM was betting the farm on a single effort, risking it all for the opportunity to trump the other automakers. When that failed and sales lagged well below expectations, supporters lashed out. Prius became the target, since it was the most diverse offering. Already complemented by Camry and Highlander, seeing a larger & smaller Prius emerge made the anticipation of a plug-in model too even worse. Far more dynamic than hoped, it was the technology proven to deal with the unpredictable market and wide array of political & economic pressures. That flexibility of design was becoming well proven. The resulting hate was no surprise, especially when Ford ended up following the same success approach as Toyota. So, the past few days have been included close watching of Volt enthusiasts turn from dismissing sales of other GM cars and those traditional offering are just as efficient as hybrids, to again building up hype. Remember when Two-Mode sales became so undeniably bad focus was shifting to the "next" thing? That's how Volt came about. Well, now that Volt has fallen from grace, rumors of a redesign are emerging. There's no detail whatsoever and the only "facts" are those based upon executives who are no longer with GM. The very same rhetoric is emerging again. They honestly think third time is the charm... but not for just being competitive, it's the belief that the competition will be squashed. They never believed mistakes of the past could be repeated. Yet, we witnessed it happen. Now we are watching the cycle start yet again. They basically didn't learn anything. The trophy-mentality continues to cloud judgment. The mainstream vehicles sell in quantities so large, they don't draw much attention. They are so common, they basically go unnoticed. For enthusiasts, that's considered boring & uninteresting. So, they dismiss & disregard them. Why bother with a Plan "B" when your vehicle is a sure winner? Some actually think that. With new plug-in choices entering the market, tax-credits expiring at some unknown point, and both traditional vehicles & regular hybrid pushing up expectations, the risk is increasing. The gamble is even greater this time. Not having something else as a backup isn't wise. Diversity is a fundamental principle of good business. The question now is will those enthusiasts drown out the true supporters, those not fighting change.

- 3-07-2014** **2.75 kWh.** That's the quantity of electricity I should be using to represent each full recharge. It takes both usable capacity of the battery-pack and the extra electricity required (charging loss) into account. Currently, I use 3.0 kWh. None of my recharges at work, using the level-2 connection, have come even remotely close to that all throughout Winter. Most don't even exceed 2.7 kWh. The level-1 recharger I use at home takes more electricity, since slower isn't as efficient. But even then, the value of 3.0 kWh per recharge is still too much. It's an easy number to work with though. I'd much rather overstate than understate anyway. People finding out Prius PHV is actually more efficient is a nice ownership reward. That's what happens with MPG already. After all, you don't want to set expectations too high. People are far more likely to complain than praise. Unfortunately, that's how the internet works. It's in our nature to throw a fit when things don't match hope but not say anything if they do. So, I don't use the 2.75 kWh value, even though I very reasonably could.
- 3-08-2014** **Unsupported Hope.** It lives on. In disbelief, I pointed out: At a loss for positive news about sagging sales, enthusiasts are taking supposed facts from former executives and spreading them. Rumors are emerging. The hype returns. It never ceases to amaze me how "*over promise, under deliver*" keeps coming back. It's great material for blogging... That ELR commercial is an ideal contribution from GM to assist with the distraction effort. The pattern of trying to sell us what they want to produce rather than what they need to should be obvious. Yet, some choose not to see it. If there was any sort of balance, it would be somewhat acceptable. But when they push an expensive compact then follow-up with a luxury compact, what the heck are you suppose to actually purchase? There's nothing practical & affordable offered, nothing resembling their traditional choices. Enthusiasts want you to forget how much anticipation there was about ELR. They strongly believed it would usher in version 1.5 for Voltec, a major system upgrade. Since it was an entirely new vehicle with a higher price anyway, hype easily bolstered that belief. Instead, all they got was comfort & handling improvements you'd get from other Cadillac vehicles. One year later, the situation is a mess. So, the cycle of unsupported hope begins again. Ugh.

- 3-08-2014** **If They Build It.** There's quite a bit of speculation about the next Volt. With both Toyota's and Ford's plans so easy to see, wondering about GM is becoming quite a popular discussion topic. On the big Prius forum, I posted: ELR is a bit of a head scratcher. It's not really certain who GM is actually targeting with the price so close to Tesla. But with the trophy-mentally so prevalent still, intentionally delivering a niche is understandable for the Cadillac model. For Volt, that's entirely different. It was supposed to appeal to mainstream consumers. There was a sincere belief by enthusiasts that the "*if they build it, ordinary people will buy it*" motto would actually work. They figured the electric drive would be so appealing, the higher price countered by lower fuel expenses, would easily justify the purchase. To them, it was an easy sell. The compact rear seating and the low range in Winter were non-issues as far as they were concerned. The low MPG following depletion was too. They were wrong. Even Volt owners complain about that now. Yet, we had to deal with countless claims that wouldn't be a problem. So, we are left asking the same question again, who will the next be marketed to? I suspect the design will be altered so profoundly to finally address the needs of middle-market, it won't resemble the original in many ways. The early promotion of Volt during the design phase significantly limited options going forward. GM backed itself into a corner... over promising. Even though some enthusiasts haven't learned from that mistake, at least the automaker itself seems to have... for the next generation.
- 3-09-2014** **Generation End.** When the new one approaches, what happens? Having witnessed it firsthand, several times, I provided some background and insight: The aging cycle is an interesting one. Some people actually wait for this stage before purchasing. They want to make sure all possible problems have been worked out already. The "low" gas prices are a very real problem though. We've been watching the "*boil a frog*" scenario play out right before our eyes. I still remember when gas first shot up to \$2.25 per gallon. It was a very big deal, since gas was still less than \$1 when I first bought a Prius. It had more than doubled since then. Later on, \$2.99 ended up scaring the heck out of people. Stations kept the price at that as long as possible, eating into profit to prevent having to advertise \$3. Then all of a sudden, we had to deal with \$4. Afterward, back down to around \$3.25 made everyone breath a sign of relief. Now at \$3.59, some people have upgraded to a more efficient vehicle. Automakers have convinced them that 40 MPG highway is plenty good. The fact that combined MPG is mid-30's and city is low-30's isn't considered a problem is reason to worry. They've been led to believe that's good enough. After all, they had to downsize their vehicle quite a bit to achieve that. Traditional vehicles still very much dominate the market... leaving hybrids in a struggle-for-survival role. That obviously puts Prius in a delicate position. Increased choices from other automakers as well as Toyota itself makes it easy for a sale to be lost. But establishing diversity now is priceless in the long run. The debunking of misconceptions and the squashing of greenwashing efforts has contributed to the loss of attention. They are becoming more and more common. Nothing stands out anymore. Flatten purchase-rates aren't the end of the world. In fact, stability can get a good thing. There is hope. We know interest will rise with the release of the next generation. Gas prices will continue to steadily rise too. The water can only get so hot before the frog eventually dies.

3-09-2014 **\$699 Now.** I remember back when level-2 rechargers for your home were priced nearly double that, they started at \$1,199. Seeing them drop so much already is great. Sadly, I still don't have one though. Knowing I will be moving, it didn't make sense running a 220-volt line out to the garage for a first-gen design. That won't even be a selling point. Why not wait for the new location instead, then indulge with a web-enabled recharger? I'll likely need 2 lines in the future too. Having them both wired at the same time would be worthwhile. After all, I couldn't imagine owning a vehicle without a plug anymore.

3-10-2014 **Selective Amnesia.** Each month, it was the same thing. Eventually, that ended. Unfortunately, it's back again. The new chapter is allowing old problems to re-emerge. Fortunately, those are much easier to deal with this time around. The first example today came from a well known antagonist. He enjoys debating. So, regardless of how clearly you state something, he'll re-ask the same question again later, as if the answer had never been provided. It's like a troll with constructive content. In other words, he doesn't want to acknowledge the previous chapter has concluded. If you must reply to that type of behavior, provide only information relevant to the new chapter. In this case, there were questions about GM not having fulfilled the promises about Volt. Everyone knows the situation. The topic has been beaten to death. So, I simply replied with the obvious goal and improvements enthusiasts have been hyping: *"Again... somehow production COST must be reduced, yet some people still think that will happen while also getting a larger chassis, more refined engine, and longer range while also compensating for the loss of the tax-credit."* The response was just a contradiction to earlier posts. Why even bother wasting my time? So, I abandoned the thread and headed over to that daily blog for Volt. Post after post provided vindication. What I had been saying for years was repeated over and over. It was great! Of course, they'd outright deny the idea hadn't come from them. That's how selective amnesia works. You only remember what you want. Anywho, there were a surprising number of suggestions all stating the same thing. GM should offer a choice for Volt, a second model. To think that it took enthusiasts 3 years of struggling sales to finally recognize that shortcoming some of us saw long before rollout. The resulting fallout could have been avoided. Oh well. Their loss. I see the hypocritical nature of their posts. That history is well documented, in extreme detail. Those quotes of the past won't haunt them though, since they choose not to remember. As for the rest of us, we can breath a sigh of relief. That rhetoric is over. They're asking for the same things now that we did many years ago.

- 3-10-2014** **Sales.** With the former chapter having ended long enough ago for others to now notice, old threads are being brought up again. Looking back at them with the new perspective brings interesting comments... and opportunity for me to keep contributing summaries of what happened. After all, knowing how we got to this position helps. I'm happy to oblige too. The mess we had to endure shouldn't be repeated: When people evade goals, you know there's a problem. When they take a goal and change it to an expectation, you can expect failure. I was amazed to see that with Two-Mode. Seeing the same thing play out again with Volt was shocking. Recognizing the pattern emerge for a third time is leaving beside myself. Don't people pay attention? Are they really that naïve? Or is it that some just like to debate? And once speculation is disproved, bringing it up again doesn't accomplish anything. Ugh. Whatever the case, we can see that second generation Volt targets set by the former CEO are now being spun to mean a promise. Certain shortcomings of the design are being flat out denied too. It's barely even worth documenting anymore, especially since there isn't any accountability. We all know sales are the ultimate measure of success anyway. There's a big difference between a trophy and a purchase... which a few still don't understand. The need for sustainable profit will trump efforts to divert attention. No amount of blame or excuses will overcome that essential requirement miss. Consequences of short-term efforts (like cheap leases, large price cuts, and clever markets) will make themselves apparent too. There's simply no way to avoid the reality of not having delivered what was actually needed. This thread turned out to be a good example of how heated & unproductive things get. Many arguments were pointless. Those same mistakes are being made again, but it doesn't matter. It always comes down to the same thing in the end... sales.
- 3-11-2014** **Seamless EV.** Neither one of us was paying attention. We just jumped into the Prius and drove away. Leaving the city, you obviously want to take advantage of electricity (lots of stoplights). So, I did. Upon jumping out on the highway, the engine started... automatically. I hadn't pressed the EV/HV button. That meant the Prius was in EV-BOOST mode, still drawing plug-supplied electricity. So when engine warm-up completed, it shut off and returned back to EV mode... automatically. Only being on a 55 mph highway, one with lots of bumps and cracks and hills, that transition went totally unnoticed. It wasn't until I saw the display change that I realized the last of the electricity had been used up. Oops! That was a waste, considering how efficient highway driving is anyway. Oh well. It was a great firsthand demonstration of how seamless the design is.

- 3-12-2014** **Comments Elsewhere.** It's interesting to read comments posted by those on generic automotive blogs. When a random hybrid or plug-in topic emerges, you never know who will post or what they will say. Today, this caught my attention: *"Plug-in hybrids are simply too expensive. I think hybrids will have a future for sure. But plug-in hybrids won't come into play until gas reaches \$6."* I was intrigued how people would respond to the detail that lacked. So, I provided it: The plug-in Prius uses a 4.4 kWh battery-pack. That size keeps cost within reach of being affordable for the masses. It's quite a bit smaller than the other choices available. So, blanket statements like that (dumping all offerings into a single category) can be misleading. \$6 gas isn't necessary either. 73 MPG is the average from mine (which just turned 2 years old yesterday). That's a big improvement over the 50 MPG average over almost 3 years from the 2010 it replaced. The real-world result, driven in Minnesota (where winter really hits efficiency hard), shows gas prices don't need to go up much for the benefit to be obvious. Toyota's effort to squeeze out so much from a battery-pack concealed under the false floor, which doesn't take away any of the open cargo area from the regular model, is a good approach for growing sales. They could the plug as an option, just like other upgrade packages. There's an obvious gain from short trips and you still get 50 MPG following depletion. It's a best-of-both-worlds design. Being able to recharge entirely in less than 2.5 hours using an ordinary 110-volt household outlet is another size-related perk often overlooked. Larger battery-packs take longer to recharge entirely, unless you invest in a level-2 charging station. That extra expense & uncertainty scares away potential buyers. They kept it simple. Unfortunately, that simplicity makes improvements difficult to notice unless you actually drive one fully charged a few times. As people begin to figure out how it differs from the regular model and realize some of their assumptions may have been incorrect, it should add to sales.
- 3-13-2014** **Spring!** It has finally arrived; well, just a taste of it anyway. The temperature shot up from the 20's to the 50's. It was amazing to feel the warmth of the sun when things are melting rather than frozen solid. Cold weather is far from gone though. But at least the time today was an opportunity for some relief. EV driving was effortless. That hint of what Spring has to bring was fantastic. This Winter was horribly loooooong and cold and snowy. It was just plain nasty. Of course, here in Minnesota, we got more cold than snow. So, in a way, we had it somewhat better than those elsewhere in the country. I always look forward to the transition. That annual cycle so refreshing. Watching MPG climb is exciting too.
- 3-13-2014** **It Never Happened.** That old attitude seems to have vanished. Some would pretend it never happened if there were no posts to that effect on the forum where the discussion was taking place. We're making progress. Things posted elsewhere are finally getting acknowledged. Outright dismissal is rather fruitless at this point anyway, though a few still try: *"I would say its best to avoid fanboi sites if you really want to avoid the hype. Most of us never bought into..."* That particular effort backfired. My reply set the record straight, pointing out what's really important and the consequences: Just because we can see through the hype, that is no reason to turn a blind eye. It will continue to be a major source of misinformation unless someone speaks up. And yes, they resented having to face real-world data and debunking of unsupported claims on a regular basis. Many, many people were sucked into their rhetoric. Mass disenchantment resulted. That hurt both consumers and the market itself. Why allow it to repeat?

- 3-14-2014** **Misrepresentation.** I find it a ringing endorsement for Prius PHV when certain individuals online go way out of their way to misrepresent it. Those blatant greenwashing effort speaks volumes. Rather than actually compete honestly with the comparison of real-world data, we get the same old rhetoric. The best example today was a salesperson from a GM dealer, one who posts frequently about Volt he has in stock. He's still trying to convince people the battery-capacity is only 6 miles. It's a true act of desperation at this point, with so much detail & videos proving the EPA mention is just a testing example. But we know how exploiting a single instance is a golden opportunity for some. Everyone else calls the intentional disregard for other data cherry-picking. He just plain doesn't care. It's more vindication as far as I'm concerned. Some people would rather go down with a fight. Unfortunate for them, I'm not interested. Why bother? Wasting time responding directly is no where near as effective as continuing to capture video of just driving it. More of that will eventually expose his attempts to misrepresent. It helps draw interest for PHV too.
- 3-14-2014** **Change.** Some are joining the team, rather than fighting the very people working hard for change. Remember the goal of delivering something for middle-market? I liked reading this: *"I'm predicting five seater and battery capacity options."* Only being that Volt owner's fourth post on the big Prius forum, it's difficult to know what the response will be. But the effort to reach out was appreciated. Hopefully, my post will be too: That's the same thing some of us have been suggesting for many, many years. Looooong before rollout, the *"too little, too slowly"* advice was repeated over and over. Only now, that idea of offering choice is finally being embraced. Do searches on those other websites for *"second model"*. Even just the mention of one-size-fits-all absolutely enraged enthusiasts. They felt any attempt to alter design to widen appeal should be considered a threat to the purity of Volt, since that would make it too much like a Prius. But now, with the blatant need to lower cost and increase sales, the idea of diversifying is welcomed. They learned that lesson the hard way. Rather than send a message to GM back when it could have really made a difference, they gambled and waited for the sales struggle instead. The very thing warned about... Calling the situation *"better late, than never"* is fine. Leveling the playing field after having to deal with the *"vastly superior"* nonsense is a nice outcome. After all, those enthusiasts were told countless times the goal is to replace traditional vehicles. Achieving that isn't possible if they don't want to recognize what makes those traditional vehicles so appealing. More legroom and a fifth seat in back will most definitely draw interest. A smaller battery-pack to reduce cost is an obvious next step. After all, traditional vehicles have offered the choice of engine size for decades. Why shouldn't a plug-in have some type of power variation option too?

- 3-15-2014** **Misleading Continues.** The effort to greenwash is far from dead. Thankfully, dealing with it takes less effort. It never ceases to amaze me how certain people use deception. But they are well aware that others will innocently fall victim, believing what was posted and unknowingly spread the incorrect information. So, posts like this are needed from time to time: The 6-mile mark in the EPA testing cycle has been a source of misleading for years. It does indeed trigger the engine to start at that point, but that is by no means an indication of the plug-supplied electricity already being used up. That's just when the hard-acceleration test is performed. The engine shuts off shortly afterward. There's still 5 miles worth of electricity remaining. Yet, no matter how much real-world data and driving videos are shared, the claim of 6 miles being the total available continues. I posted this back in September: *"Using Volt's own specification for comparison: 16.5 kWh = 38 miles. That works out to 2.3 miles per kWh of electricity, which means 4.4 kWh = 10.1 miles. Then when you take into consideration Prius PHV weight is 621 pounds less than Volt, it's easy to see where the 11-mile EPA rating came from. The capacity is clearly there."* The math is simple. It takes into account usable capacity from full and compares systems using the same approach too. There is no reason for any more misleading to continue.
- 3-16-2014** **Final Fight.** I keep waiting for a finale. Maybe this was it: *"The distinction you miss is when gas starts being used. What good is my car if it has 100kWh of battery, but it starts using gas after 2 miles?"* We've seen the hypocritical stance being taken routinely. You argue with someone disingenuous long enough, they will eventually contradict themselves. The fact that I got labeled as a *"broken record"* in the past for repeating the same message over and over served as confirmation that I was paying close attention (noticing the tree directly in front) and so were they. So when I read that quote today, it provided reason for excitement. The absolute approach was a clear effort to avoid contradiction. Working so hard to avoid slipping down that path (forgetting to also observe the forest) exposed a weakness. That's what I'm always looking out for... and was rewarded nicely this time. It was a blatant misrepresentation of the plug-in model. He got caught portraying it as Prius delivering either EV (electric drive) or HV (gas drive). Either he didn't want others to know there was more or he simply didn't understand the design himself didn't matter. All that was necessary as a response was to point out there was indeed more. Excluding vital information is greenwashing... and everyone is well aware of that. The implications of a very active poster intentionally doing that was huge. It was checkmate. Whether forfeit or denial, it was irrelevant. I won the fight. That worked out great! I closed the chapter with: After all this time, you still don't know how the system in Prius PHV actually works? Well, that explains a lot. Even when the engine is running, it's still heavily drawing from the battery-pack. That plug-supplied electricity is still being taken advantage of. Take the time to watch the videos and read detailed information. Notice how engine RPM stays extremely low (usually 992) and the resulting MPG is well over 100. Owners call that EV-BOOST.

3-17-2014 **We Knew All Along.** No longer interested in the nonsense being spread on what remains of that daily blog for Volt (which only rarely features Volt anymore), I spend more time following the big Prius forum. Who knew that there were be pot-stirring there too. It was a blatant effort to start up some discussions... provokes to engage in fierce debates. Certain individuals thrive on that. So, they drop bait to entice. If you were an outsider, that would be called trolling. Unfortunately, there's standout term for long-time members who do the same thing. Anywho, it was a claim that Volt was an entirely new design and was in no way related to Two-Mode. Excuses used to justify delay are acts of desperation at this point. Even some Volt owners have changed their tuned, finally supporting what the rest of us knew all along: *"Volt's 4ET50 transmission is a complicated device. It contains a planetary gear set, three clutches and a final gear reduction set. The advantage of the 4ET50 transmission is that it allows the Volt to operate in two modes during extended range mode: pure series and power link. The advantage of power link is that it increases mpg in extended-range mode by mechanically connecting the internal combustion engine (ICE) to the wheels."* I posted that in response to a trolling attempt, followed by this: That's a quote from a strong supporter of Volt, one who cared about being straight forward with what the next-generation design should feature. He wasn't afraid to go into great detail explaining how Volt is indeed a successor to Two-Mode. He also pointed out how Volt doesn't fit the EREV definition coined for it. He didn't waste time feeding rhetoric. That's a stark contrast to the posts here.

3-18-2014 **Double-Lens LED.** When it comes to being "*vastly superior*", there is no argument about which headlight type illuminates the best. Unfortunately, that is one of the many reasons for Prius hate. The advanced-technology models feature double-lenses LED-bulb headlights. That's what I have on mine. It's the ideal combination of light-source and light-projection. Road illumination is clearly the top offering, so much so, it scares me when I notice how poorly some other lights work. Some people literally cannot see the road at all. There's nothing but a bright glow a single car-length in front of the vehicle. Mine is dramatically better... which is why we are starting to see LED headlight with single-lens popping up now. It's hard to believe it took so long. I put a set on with 55-watt halogen single-lens lights on my 1984 Dodge Omni, way back in 1990. Those were called "*projector beams*" back then and were a great aftermarket add-on. The clean height cutoff and even broadcast made them an uncontested leader. Who knew it would take 23 more years for them to catch on. Prius has had single-lens with halogen, even on the base model, since the third-generation rollout in 2009. They are standard on the new Toyota Corolla, with LED. They will be available on the upcoming Ford F-150 too. This market acceptance has stirred Volt discussion, since it comes with lens, but uses halogen bulbs. Stepping up to LED should be a given, considering the market it now appeals to and growing competition. I welcome the change. All the lights in my home were switched to LED back in 2010. They use less electricity. They have proven robust & reliable too. LED bulbs have been used as brake lights in Prius since way back in 2003.

- 3-19-2014** **Gone.** All that rhetoric. All that misleading. All that chest-pounding. It's all gone. The situation now is as it should have been right from the start, Volt is a plug-in hybrid contributing to the effort to help wean us off our oil dependency and reduce emissions. No more "*vastly superior*" nonsense is such a relief. It didn't actually accomplish anything. In fact, there are many who would say it caused a market setback. Whatever the case, the change now is obvious. The blogging & posts have died. Activity has almost completely vanished. Most supporters left long ago. Now, even the enthusiasts are moving on. It's a welcome transition... further proof we are in a new chapter. Unfortunately, talk dominating the big GM forum is all about their 3 new small engines just unveiled. In other words, traditional vehicles will pose an even greater challenge to overcome... a reality most in the past didn't take seriously, hence being identified as "*enthusiasts*" rather than supporters.
- 3-20-2014** **Plug-In Gathering.** There were 40 of us this evening. About 20 of the vehicles in parking lot used plug-supplied electricity in some fashion. Tesla. Leaf. Focus EV. i-MiEV. Volt. C-Max Energi. Prius PHV. That was a great experience. Unfortunately, most of the event took place indoors, away from the cars. It's still Winter here. So, everything was still cold & dirty and the sun was quickly setting. The upcoming gathering in May will be dramatically different. I'm really looking forward to that. The attitude of Volt owners there are dramatically different from encounters online. In person, they are a joy to spend time with. They are true supporters, interested in taking the steps needed to achieve acceptance by from the masses. They desire mainstream penetration and don't share that nasty attitude of enthusiasts. I really enjoyed getting to chat with them. The others were fun too. Seeing several Leaf & Tesla parked them among the others was sweet. It's what I've been looking for to for a very loooooong time. Their understanding of Prius PHV being an affordable option for high-volume middle-market sales was clear. They agreed. There were no arguments or debates. None of the nonsense I had to deal with online ever emerged. We were all on the same team, working together to make recharging at home a simple & ordinary experience. The evening was quite inspiring.
- 3-21-2014** **Failed Because.** We are faced with thought-provoking situations now. Some people are looking back, referring to what happened with a hindsight perspective. The resulting distortion is a very common problem when depicting history afterward. Past decisions are unintentionally misrepresented, seemingly obvious long after the fact. But when in the depth of it, while events are unfolding, those same circumstances appear very different. That's why the Volt enthusiasts disliked Prius supporters with a passion. They worried that some of their observations while previous chapters in history played out would resemble current dealings. I was outright hated by a few, since I had documented that past in great detail. It makes them worry about the potential of repeating the same mistakes again, especially after having been warned about them the first time. Misrepresentation is where it starts. That's where the "*failed because*" problem emerges. More and more, I hear people claim Volt failed was because GM had expected the price of batteries to fall much faster. It's stated as if that was the sole reason. All the others are being forgotten already. That overly simplistic view contributes to assumptions, leading to future trouble.

- 3-22-2014** **Feeding Hype.** It doesn't take much. It feeds off of itself too. A great example from yesterday was a comment posted in response to this information: "*One of the units, most likely the 1.0-liter three-cylinder version, is expected to be utilized for the redesigned 2016 Chevrolet Volt.*" It was a statement in an article that highlighted the upcoming new engines just revealed by GM. It was only speculation, a reasonable guess. Clearly, the commenter didn't understand or didn't want to know that: "*So, it looks the 'downsizing' of the engine in the Volt is real and confirmed.*" Someone else will naturally take that as supporting evidence... totally unaware of its origin. Stuff like that happens all the time. The nature of the original information won't be entirely known or it's taken out of context. One thing leads to another and you end up with a mess. Claims without merit or any type of support take on a life of their own. Those posting clarification get attacked, labeled as trolls, then ultimately banned. We've seen it before. That ended up in disaster. Yet, hype starts again. It's easy to see why too. Hope blinds logic. People wanting it to be true won't question the claim. As a result, they become enablers. They serve as silent approvers. That makes a bad situation worse, contributing to the growth of hype. The cycle continues. Ugh.
- 3-22-2014** **Almost Out.** Within the next 3 weeks, the HOV sticker supply will run out. They allow single-occupant vehicles to drive in the carpool lane on select California highways. Only plug-in vehicles were eligible and that was a compelling reason for many dealing with the dense commute traffic there to purchase one. Their absence soon means uncertainty is coming. No one has any idea how it will affect sales. Years ago, when that was an incentive for Prius, sales continued relatively unchanged after the supply was gone. But back then, there was little competition. Fewer choices is easier to deal with. What will happen this time? If nothing else, the stickers (75,000 total) provide a high resale value, which will stir the used market. Waiting to expand rollout until then makes even more sense now. This unknown is a big deal. Each automaker reacting in a different way could introduce yet another chaotic element to deal with. It's confusing enough with state incentives varying so much. Just imagine what added dealer incentives could do. Remember the inventory pile-up last Summer and the abrupt price reductions?
- 3-24-2014** **Changing Perspective.** Forcing it is called greenwashing. Looking from elsewhere is called spin. In other words, you can't win. So sometimes, you just have to go with it. I found this particular claim amusing: "*If I did my math correctly the Volt is the best deal.*" It came from a well known antagonist attempting to undermine Prius PHV. My approach was to point out the perspective of the rest of us by implicitly asking if our tax making is being spent the "*best*" way it could. I suspect the response will be anger. But shouldn't that question be addressed? Why should only a select few benefit? Just think if there was a specific amount allocated to the automotive market instead. It would encourage competition. The more you rollout, the more you benefit. Right now, there's no speed incentive. Each automaker is independent and they can milk the "*halo*" effect in the meantime. So, I replied with: Isn't the point to encourage & spread plug-in vehicle acceptance? We'd get more bang for our buck if 600,000 people got \$2,500 credits than 200,000 getting \$7,500. The same amount of money would have triple the market impact.

- 3-24-2014** **Plug-In Hybrid, part 1.** I wasn't too thrilled to read this post today on the big Prius forum: *"Another prime reason why I say the PiP is a patched together EV is..."* Curiosity did compel me though, especially when it ended with this: *"When/if you eventually get up to 60 mph or so, it is spinning MG1 at close to its redline RPM and using power to spin it backwards just to keep the stinker from spinning. With the Volt both MG's are working to move the car forward!"* Most pushing the rhetoric were too afraid to actually join the discussions there. But here was a Volt owner doing exactly that. It provided a minor glimmer of hope. Unlike me, he wasn't serving as a lightning-rod, a well known owner facing opposition head-on to keep the fighting off-site. That worked remarkably well for years. But times are different now. It's a new chapter. So, I asked: Why do Volt owners continue to force PiP, a vehicle clearly presented as a PLUG-IN HYBRID, into the category of EV? Notice how no one else does. Notice how they focus on results instead? As PiP owners, we see the efficiencies from blending electricity & gas for power. We see the MPG above 100 while cruising faster than 62 mph.
- 3-24-2014** **Plug-In Hybrid, part 2.** I got a few likes and he got a few posts countering his position. The choice was post operational detail, complete with a video showing battery, engine, and motor information: In the past, which could be coined the "purity" chapter, there was much propaganda coming from Volt enthusiasts. Their efforts to belittle Prius PHV marks a ugly point in plug-in history. Thankfully, most of that is just a memory now. Attitudes are changing. Priorities are being reassessed. I'm thinking this particular comment is about being poorly informed, simply passing along greenwash material without verifying whether or not it is actually true. Watching that video of my commute, first at 70 mph, slowing to 55 mph, and then onto suburb roads, it's easy to see the redline statement is quite incorrect. MG1 is rated for a RPM of 10,000. During that drive, the highest RPM we see is under 6,700. It's not even close to reaching maximum. So what if a little power is used for carrier balance. That's the point of a hybrid. It seeks out efficiency opportunities by taking advantage of the resources it has available. It was designed to operate that way, and does even with the models that don't include a plug. The misrepresentation of Prius PHV needs to be stopped. It would be great having Volt owners as an ally in the effort to replace traditional vehicles. That support would be mutually beneficial. Sadly, gaining it continues to be a challenge. The *"leap"* comment clearly confirms we are not there yet. See the end result of that 16.8 mile commute. Isn't that 128 MPG the point of being able to plug in? That's significantly higher than a Prius without a plug could deliver, especially when the temperature is below freezing like that.

- 3-25-2014** **Plug-In Hybrid, part 3.** He became very angry at the replies. You could tell he was at a lost about what to do at that point. There was quite a bit of evidence confirming his claims were incorrect & misleading. So, what do you think he did? I found this the next day, on the forum dedicated to Volt: *"Well while we're ragging on the PiP, I think of it as a patched hybrid to kind of act like an EV, a 3 season EV, no EV heat. Then when/if you eventually get up to 60 mph or so, it is spinning MG1 at close to its redline RPM and using power to spin it backwards just to keep the stinker from spinning. With the Volt both MG's are working to move the car forward!"* It was a blatant effort to greenwash. The quote was nearly identical to the original on the big Prius forum, but with the EV wording altered. I found that change amusing, since Volt owners often take advantage of engine heat to spare the battery drain. And of course, below 15°F, the engine in Volt must start anyway. He excluded that, as well as the information that the engine shuts off in Prius PHV and continues to provide warmth from the heated coolant while driving in EV. As for his purpose, it was clear. The intent to undermine was obvious. Prius PHV is a plug-in hybrid. Misrepresenting as an EV is bad enough. To be willing to outright lie... It speaks volumes.
- 3-26-2014** **Struck While Parked.** I wasn't too happy, but was in the state of mind to forgive. She drove into her parking spot and kept going. She struck my Prius while it was parked. Since I was on the sidewalk at the time, crossing over to get to the cars only took a moment, too quick for her to figure out what had happened or what to do. When she got out of her car, I stepped to the side, stated *"You hit my car."*, then got into hers saying *"I'm putting your emergency brake on so your car doesn't lurch when I move mine."* Having seen how far a pushed parked cars can bounce in that situation, it was a sensible choice. After all, there was no need to allow further damage or for anyone to get hurt. Thankfully, when I pulled forward, there were only scuff marks. Somehow, the plastic was spared the typical bolt impressions from contact like that. She made up some excuse about a truck rushing her, something I certainly didn't see, then said there didn't appear to be any damage. There was no direct apology. How anyone could hit a hatchback with such an easy to see back end while pulling into a perpendicular parking spot on a beautiful Spring day, is beyond me.
- 3-27-2014** **Plug-In Hybrid, part 4.** Despite warnings from Prius owners about being off-topic & belittling and Volt owners apologizing for his behavior, the trolling continued. It was surprising to witness. He changed his wording again too: *"As said earlier, the PiP is a hybrid that plugs in and can do some EV tricks. Not bad for 90's tech, but tech marches on!!"* Certain people cannot resist a jab. They always try to sneak in a mild insult, then deny it happened, even though it is just a page or two back in the thread. I found this the ultimate response to that: *"Reminder to self: do not read anymore "Volters" negative comments in the inappropriate thread."* He didn't return to that particular discussion either. It seemed enough to get the point across. It's too bad things like that still happen, especially when the topic was for sharing one-year driving statistics. The trophy mentality and perceived engineering advancement is still more important than actual results. That's sad.

- 3-27-2014** **Former Foes.** They have the choice of facing the facts or disappearing entirely. The desire to be part of a winning team compels some to admit the approach failed and move on. That's great. We need diversity in the team of players working to replace traditional vehicles. Giving up bragging rights is tough though. Some still don't understand what the message that "*smug*" episode was meant to convey. Fortunately, some do. I'm thankful for that. It's progress, like this: "*Tomorrow, I am turning in my Volt at the end of lease. I tried to buy it but even the lease company said the loan would be undersecured because the car had lost too much value, go figure. I have instead purchased a Ford C-max Energi.*" I happily posted: Thanks for the update. You are certainly not alone in that situation. I met with about 20 other plug-in owners last week. It was fascinating to see such vehicle variety all in the same lot. None of the rhetoric of the past carried forward. There was no more debate anymore about production cost needing to be the top priority. It was really unfortunate that GM chose the short-term approach, gambling on market embrace strong enough to retain loyalty after leases expired. Even though they contributed to some of the mess we are having to deal with now, at least there are satisfaction reports like your own to help with this new chapter. This week started with 3 of us parking at the work chargers, my Prius PHV, a Leaf, and a Volt. It was a nice sight. Each plug-in serving a different purpose, yet all on the same team. That's what we had hoped for years ago. It's too bad the hype got so out of hand. I sure am glad that's finally over. Enjoy your Energi.
- 3-27-2014** **Website Cards.** It has been a very long time, several years in fact. I use to handout "business" cards all the time. Someone would ask about the Prius and I would provide that in response. A nice photo with some summary information on front and some detail on back worked out really nice. They'd have a little something to follow-up with. It was an effective way to spread the word about Prius and my website. In the past, I did that simply by printing a graphic & text template on card-stock. But nowadays, that actually costs more to do it that way. Online services make it easy & convenient to order your own custom content. So, I gave it a try... and wasn't disappointed. There's a glossy photo on front and statistics on back, featuring my Prius PHV with 2 full years of real-world data. This page shows what I created... [prius website cards 16](#)
- 3-28-2014** **Plug-In Hybrid, part 5.** Concern is growing. We're seeing more and more draw to PHV discussions from outsiders, specifically Volt owners. Now that the former daily blog for Volt is featuring discussion topics about Tesla, the automotive battery industry, and general market interest, they have nothing compelling to participate in anymore. The fact that some recently parted with their Volt adds to it. In other words, the big Prius forum is a welcoming venue. That's quite a extreme from the hostile environment I participated in, where there were screams for banning based upon on-topic information they simply didn't want to fact. That soured the appeal for the long-time posters. They wanted no part of such close-mindedness. The catch is, they aren't ready to deal with the big picture yet. They evade certain topics still. PHV being a plug-in hybrid is difficult enough to accept... especially when realities like diminishing returns are given attention. I simply chimed in with the following this time: Notice how the topic of overall MPG is carefully avoided? That's what attracts to this particular thread. As more PiP owners celebrate anniversaries, it becomes more and more difficult to spread generic hype. Real-World data trumps those claims. It's easy to see the better overall choice for mainstream consumers.

- 3-29-2014 Engineering Advancement.** The belief that advancement is measured in terms of electric range & power is difficult for some to overcome. Even those trying to be constructive fall into that trap. Yesterday, it was this coming from a Volt owner: "*Toyota chose a more conservative path.*" I'm thrilled that we have active dialog on the big Prius forum. But questions like that still fall on deaf ears. He ignored my question asking what that actually meant. I pointed out how delivering a plug-in without liquid cooling took quite a bit of effort and how delivering it on a mainstream platform was risky. I also reminded him how squeezing out more from less is much harder. GM delivered a halo vehicle, later even validating it was only a niche. They could garner kudos for having offered consumers a choice without actually addressing the direct need of traditional competition for an extra 5 years. It was the ultimate compromise, making enthusiasts happy, quieting technology naysayers, and giving the impression all was going well for ordinary consumers. Shutting up the well informed continues to be a problem though. We keep asking questions and not getting answers. We see the challenge still faced for moving advancing niche. It's not measured in terms of range & power.
- 3-29-2014 Not Toyota.** The typical response to constructive feedback from owners of vehicles not a Toyota is that you're just defending Toyota. That instant assumption contributes to a world of trouble. Then when it comes to efficiency technology, comments from a Prius owners are interpreted as Prius related, even if the discussion has nothing to do with Prius. That makes it even worse. The situation is maddening sometimes. The self-inflicted nature of their problems is easy to understand though. Toyota was attacked relentlessly a few years ago. Reputation was everything and some worked relentlessly to tarnish it. Now, the tables have turned. GM is really hurting. 4.2 Million vehicles have been recalled this month and bankruptcy recovery didn't result in a promising outcome. Having only achieved status quo isn't encouraging... especially when you bring other automakers into the mix. Ford frustrates them (deniers) more than any. Watching former Volt owners embrace the C-Max plug-in is a victory lost. They use to celebrate conquest sales. But now when they are out of favor, it hurts. Of course, turning to Chrysler makes it even worse. The 2015 model of the Chrysler 200 will feature a 9-speed automatic transmission. That offers a 5 MPG gain over the current model. 36 MPG highway takes away bragging opportunity. I find the 28 MPG combined disturbing, especially with such a complex & costly system. Give me the simplicity of a hybrid with a power-split device any day. In fact, that's actually the very reason I discovered Prius back in 1999. I was frustrated with 20th Century design... which sadly, continues in 2014. Adding more gears isn't a solution. Taking advantage of motors & batteries is. Toyota draws many sales for their effort, hence the aversion.

- 3-30-2014** **Not Much Anymore.** The difference between ordinary mainstream consumer and enthusiasts should have been obvious. But hype blinded the hopeful. That meant some victims emerged along the way. Afterward, those who were misled or misunderstood said things like this: *"I want to drive as close as possible to 100% electric without range anxiety. And I'm tired of paying attention to the list of conditions that turn the PiP's ICE on, including exceeding 62 mph."* Sadly, that particular quote was from today. I pointed out what supporters are now quite familiar with: Notice how rare comments like that have become? In fact, the only remaining source is from those who purchased a plug-in hybrid but really wanted an EV. It made sense. Years ago, with so little information available, people made lots of assumptions. That spread misconceptions and contributed to greenwashing. Now, people are seeing the variety of offerings available and are researching the differences. That's why asking for goals is so important. There are tradeoffs. Not understanding the differences anymore, well into 2014, is the purchasers loss. The design & approach of each automaker is clear at this point. Change will come. Selling at a loss and depending upon tax-credits can only be short-term and at low-volume. In the meantime, gas prices continue to drop and pressure from traditional vehicles grows. Most people won't care when the engine starts. They'll just want something affordable, practical, reliable, efficient, and clean.
- 3-31-2014** **Standing Ground.** It's not easy. There's a lot of pressure to give in. That's what happens when hype grows. Thankfully, we get some wisdom like this from time to time: *"I am glad Toyota stood their ground and did what they should (reducing emission by increasing efficiency with a balanced design) rather than what they could (add bigger battery to exploit tax credit and greenwash with meaningless big MPG numbers)."* Reminders like that are important. I added: We knew GM was appealing to an enthusiast audience. That's why the *"Who is the market for Volt?"* question kept getting asked over and over again. The response of great EV acceleration was a dead giveaway that the design wasn't balanced. Tradeoffs were being made to retain that electric purity, but they weren't being acknowledged. So, we asked about heat in the Winter. Response to that made it overwhelming clear that it the sacrifice was a problem being avoided. The first generation had been demoted to a proof-of-concept and enthusiasts were celebrating the victory. GM choose to call it a niche. Whatever the case, an appealing vehicle had indeed been delivered. It supported the bragging rights owners had hoped for and delivered a nice driving experience. It was what both wanted, not what was actually needed. Ordinary consumers kept purchasing Malibu, Impala, and Cruze instead. Looking toward the second generation, we see some enthusiasts having become supporters. They now openly address the changes required for Volt to reach a mainstream audience. Rather than being addressed as shortcomings or missed goals, they are instead referred to as upgrades and improvements. That's ok. It's progress. But the delay is really unfortunate. The backlash against Toyota for not having waived from priorities of the masses is disappointing. I'm hoping those who have owned both will help us deal with the issues. GM must align priorities to match what the bulk of their customers will actually purchase. The need for profit from selling lots of low-margin vehicles, without any government assistance, is a bitter pill to swallow. Enthusiasts don't like the idea of being common, but it's exactly what's needed. That means having to give up bragging rights and shift focus. It's their choice. Change or be left behind.

- 4-01-2014** **March Sales.** There wasn't much to say this month. Prius PHV sales were within 26 of Volt, so the rhetoric was moot. Only being available in less than one-third the number of states makes it difficult to argue demand. The big story was the same too. Traditional vehicles are far out-selling Volt. They didn't take the "*too little, too slowly*" warning serious. They dismissed all other options, risking everything on a signal choice. It didn't work. Now, some are actively seeking out an alternative. Yeah! It's unfortunate the fallout had to get so bad. Ford was able to avoid problems just fine. They understood the importance of keeping cost in check and not sacrificing other priorities too much. Tradeoffs are normal, but consumers lose interest quickly. GM has found out the hard way out. The scramble to catch up is underway. Toyota already has a platform delivering great hybrid efficiency and able to grow it as costs allow. In the meantime, we're seeing adequate Prius & Camry hybrid sales. More would be nice. But considering the current price of gas and the sluggish economic recovery, it's reasonable since both are profitable and selling without markdowns. The situation needs to pick up, especially as competition grows for both hybrids with and without plugs. Honda is the automaker to watch at the moment. The hybrid version of Accord has been selling well and supply is low. April should be interesting.
- 4-02-2014** **Arguing Semantics.** A dead giveaway that things aren't going well for the opposition is when they begin arguing semantics. Today, we got a new thread titled: "*Does the Prius have a transmission?*" It was started by a Volt owner on the big Prius forum frustrated by seeing the topic of transmission being brought up so often when debating against Volt. The simple nature of that in Prius is what allows it to be efficient, reliable, and affordable. That edge obviously frustrates. Knowing there's no way to win that argument perspective, the posts inevitable switch over to definitions. As long-time supporters, we know that's a red herring. Whatever label it ends up with makes no difference. But Prius newbies are compelled and Volt enthusiasts crave some kind of victory... hence the thread. I couldn't let it go on without saying anything. So, I responded by posting: The question misses the point of why "*transmission*" comments have been made. Of course there is transmitting of power, but it works more like a differential rather than something actually shifting gears. A quick look at the complexity of other systems is why. It's the simplicity.

4-03-2014 **In A Vacuum.** Month after month. Year after year. It was always the same story. No matter what happened with Volt, it was ok, since it was supposedly the best plug-in available. All they cared about was bragging rights. Everything else came secondary. It was a recipe for disaster. They didn't care though. Operating as if they were in a vacuum, the enthusiasts simply didn't care. In fact, they made fun of the "*too little, too slowly*" concern. They'd twist it around and mock Prius PHV. In their mind, the smaller battery-pack made it a loser. Whether or not it actually failed didn't matter. GM offered more of an EV experience than Toyota, so nothing else made any difference. They were wrong, very wrong... and now they're finding out just how bad neglecting the big picture hurts. Much harm was done by believing an abundance of time was available, that the second generation would be delivered in a few years with major improvements and a much lower price. Somehow, resources to achieve that would magically be available. Other priorities of the automaker were unrelated & unimportant. Reality is crashing down. That isn't how the market actually works. The technological challenges are big in themselves. Pressure from the traditional market is diverting attention & priority. Competition from other sources is growing. The opportunity Volt had is shrinking, rapidly. The theme of "*too late*" is becoming overwhelmingly apparent. Choosing to disregard what else is happening has consequences. Survival in a vacuum isn't possible.

4-03-2014 **Recall Crisis.** All we can say at this point is: "Wow!" The situation with GM is a spectacular disaster. The scope of problem concealment is enormous. The liability is remarkable. Rather the spreading of fear like what happened with Toyota, there are actual deaths and a clear effort to avoid taking responsibility by hiding evidence. I remember executives leaving the Volt program before they could be held accountable for their promises. It was an easy way to dismiss goals not achieved. That seems so small in comparison. With these recall issues, like the ignition switch, excuses or dodging isn't possible. It's a public-relation nightmare on a crisis scale no one has ever seen. Supporters burnt bridges in the past too, making this difficult situation even harder to deal with. What a mess. Barely having emerged from bankruptcy in the form of a massive bailout (money never paid back to the government), the recall count of over 5 million is an unimaginable amount of damage to repair... something money & forgiveness cannot fix. How will GM recover from this? Where will limited resources be invested going forward? What will be their stance on mainstream cars, making pickups guzzle less, and somehow transforming Volt into something profitable?

- 4-04-2014** **Split Personality.** No surprise. Quite predictable. The media from Detroit published an article to inspire & distract. It speculated about the next Volt, using extremely ambiguous information to imply it will split into 2 distinct models... one offering increased capacity and the other less. Needless to say, hypocritical posts quickly emerged. All that talk about the need for a second model and the product gap was totally forgotten. Many acted as though those same suggestions made in past were entirely new now. Ugh. At least there is growing recognition of need. The childish avoidance was such a waste. They kept arguing about superiority, even though sales weren't growing... despite market recovery and a \$5,000 price-drop. That desperation & denial was maddening. I couldn't believe how bad it got. But then again, the behavior on their part was exactly what we needed to conclude that chapter. It's over obvious. Sales were well below need and there wasn't a Plan-B available. The entire farm was bet on a single massive risk. It failed miserably. A proper step will be taken next. The split attention confirms priorities being addressed, providing some hope. Sadly, it will come 5 years later than promised. Better late than never?
- 4-05-2014** **Greenwashing Victims.** Reading comments like this irritate: *"It is a standard Prius in almost every respect, with a small additional all-electric range. The engine turns on for heat, acceleration boost, and speeds over 62 mph. I wish I had understood that it wasn't an EV before I bought it."* Enthusiasts of Volt campaigned intensely, working hard to misrepresent Prius PHV. Over and over and over again they would make direct EV comparisons. No matter how many times we pointed out it was a "Plug-In Hybrid" as stated by the emblem on the car itself, they kept insisting it was a terrible attempt to deliver an EV instead. Some people had no idea that was happening and just assumed the only difference was a smaller battery-pack. Just like the old days with hybrids, we were fighting the efforts to greenwash with *"not the same"* clarification. Sadly, no matter how much we pointed out differences, like what EV-BOOST provides, it got drowned out by rhetoric. Thankfully, there are some Volt owners tired of that nonsense, no longer willing to allow it to continue. Rather than the enabling silence, they are speaking out to against enthusiasts. They are true supporters, those not afraid to face facts, are helping to undo the greenwash damage. I really appreciate that.

4-06-2014 Remembering Propaganda. Since the very beginning, there have been efforts to generalize. Sadly, many were with ill intent. The hope is that dumping vehicles into a simple category, they will be easy to dismiss. Fortunately, uniqueness from Prius has made that a challenge for well over a decade. It never ends though. Here's an example from last year: *"You basically have three choices of electric vehicles today, Hybrid, Plug in Electric only, and Extended Range Electric."* That was the introduction on a webpage setup by, you guessed it, a Volt owner. She was clearly attempting to undermine. Why isn't there any mention of plug-in hybrids? Both Toyota & Ford were selling them. Such a blatant omission is wrong. Whatever. Reading the descriptions to follow said it well: *"Hybrid Electric Vehicles (like the Prius): These are basically gas vehicles using an electric motor to improve the miles per gallons. Although a move in the right direction, you can get clean diesel vehicles (like the Volkswagens) that are more fun to drive and that have as good or better miles per gallon than the best hybrids, so for me today it is only a partial solution."* We know that the better claim isn't true. Yet, the broad dismissal was made anyway. Then came this: *"Extended Range Electric Vehicles (like the Chevrolet Volt): These are 100% electric vehicles, meaning that the wheels are only powered by an electric motor, but you have a small gas engine that can be used as an electric generator to provide electricity to the electric motor when the battery is depleted. The advantage of this solution, is that you (almost) get the best of both worlds."* The misleading was obvious at that point. Not only were Toyota's PHV and Ford Energi choices excluded entirely, the information wasn't even true. At times, the engine does indeed provide power to the wheels. It is not just a source for the generator. All that brings up the question of naivety. Could she be so poorly informed that she didn't know she was spreading greenwash material? That's called propaganda.

4-06-2014 Continuing Propaganda. It is quite redeeming to see Volt owners on a Volt forum argue with each other to stop the spread of misinformation. You can't help but to feel fulfilled that little bits of the truth have snuck through, that there is a desire to be honest & constructive. Things like the videos have really paid off. With so much detail available, people can watch & decide for themselves. It's unfortunate that things like cherry-picking continue to be a problem. But at least progress is being made. Those old problems, such as focus solely on the short-term gain, are becoming less and less of an issue. Some barriers really are going away. Sadly, we do still have some propaganda to deal with. The key is, some Volt owners really do want that next generation to be competitive. They are sick & tired of lies being spread and bragging taking precedence. That sure is a relief. I bet some of the underlying cause is watching 3-year leases expire and those drivers becoming owners of plug-in vehicles from other automakers. Conquest sales in the other direction certainly can be humbling. Hype won't repair that damage. There is hope for a genuine progress. After all, you can only deny that the true competition is traditional vehicles for so long.

- 4-06-2014** **Good Business.** The approach with Prius was to deliver a vehicle for the masses. That irritated enthusiasts to no end. An ordinary mainstream vehicle should not draw attention like that. So over the years, we've seen sports-car enthusiasts publications half-heartedly embrace the idea. It generated lots of traffic to their websites. So, it wasn't all bad. But then came along the Volt enthusiasts. They didn't care about high-volume sales. Their interest was bragging rights. That's why supporters of Volt have distanced themselves, not wanting to be part of a group not interested in the long-term well being. That's how we end up with comments like this: "*Toyota still refuses to sell the PiP nationwide.*" It gives the impression of missed opportunity, but doesn't take into account anything other than initial sales. I tried to inject a dose of reality: With so much effort being taken to undermine the plug-in model by misrepresenting & misleading about it, that continues to confirm itself as a wise choice. The resulting confusion & assumptions is something we are constantly having to deal with. The market isn't ready anyway. Even without the anti-plug rhetoric, there are still challenges to overcome. Look at the struggles with charging-stations. Their variety of issues make them a mess. Cost is obviously another big problem. Batteries are still too expensive to be competitive. We'd like wider availability. But focus on increasing demand in established areas makes more sense. There shouldn't be any argument that figuring out how to grow sales there, rather than just spreading inventory, is the better move. The need is to actually penetrate deeper into the market, to overcome initial interest. Look at what GM did with Volt. Drawing in sales from consumers other than early adopters has proven to be much harder than expected. Now, they are stuck without a next step available. What incentive is there for a dealer to offer more and for a salesperson to show more? The market is already saturated. Like it or not, Toyota's response is a good business decision.
- 4-07-2014** **Nothing New.** Staying out of the spotlight is not a strength of GM. This particular moment in time is a turning-point too, so it's been especially difficult. Over the past few months, we've watch a chapter end with Volt. That has left the industry wondering what comes next, especially with Ford having done so well with the introduction of their next-generation pickup. Focus on mainstream cars isn't exactly the excitement GM thrives on. But that's all they've had until recently. The flood of over 5 million recalls, which includes a cover-up concealing the deaths of 13 people and crashes of 32 vehicles. That has left them quite desperate for some other type of attention. So, in the usual GM fashion, they announced an upcoming announcement. It will happen tomorrow. We'll finally find out what's next. In the meantime, there's nothing new. But a look on the internet blogs & forums sure don't give that impression. We're seeing the same hype pattern emerge again. Heck, some of the posts are nearly word-for-word repeats. Hope without merit is feeding what very well could turn into another frenzy. It's like nothing was learned by some. Remember what happened before?

- 4-08-2014** **Waste Of Time.** All automakers invest in their future. GM is the only one to make a big deal out of it though. Notice how none of the other automakers make announcements like they do? Anywho, the information we got today simply stated tooling, equipment, and plant upgrades would be taking place in preparation for the next generation Volt and other vehicle electrification efforts. Naturally, the worst of the antagonist posted this in celebration: *"What's truly dead is hybrids like the Prius. That technology is at the end of its life. Toyota has so indicated by creating the PIP."* And followed with: *"The biggest thing holding back electrics is range and charging time."* Don't you love how conclusions can be drawn with nothing but a vague announcement? It's quite amusing, especially since there is obviously a place in the market for hybrids without plugs. But what I got a kick out of the most was the blatant disregard for the topic of cost, which is clearly the biggest holdback. That's what Toyota has been saying for many, many years now. If the vehicle isn't affordable, it won't be adopted by the masses. Heck, that is the very reason why the tax-credit amount is tied directly to battery capacity. Needless to say, I wasn't about to take his bait. It would only be a waste of time rehashing the same old arguments again.
- 4-09-2014** **Not A Peep.** I've refrained from posting anything, even though quotes like this make it tempting: *"Much to my surprise almost all responses were positive to the idea."* Learning to deal with deception is one thing, but actually getting agreement is another. Of course, most readers have no clue the idea is old. They basically assume it's a new twist which just emerged, a next step that just naturally happened. In other words, the long overdue necessity of a Volt for the masses is finally being addressed. Remember all those *"second model"* arguments? I couldn't believe how they feared that idea. They truly thought that would result in the end of Volt, that the effort was to kill it off entirely. No matter many times the *"one size fits all"* reference was made, they just plain didn't want to acknowledge the possibility of two. Even the *"lite"* term was coined to make it easy to dismiss. Enthusiasts wanted no part of a Volt with reduced battery-capacity. Even though that would deliver better depleted efficiency, increased interior room, and a lower cost, it was far too much of a compromise for them... until now. Many are embracing the idea. Pointing out that it's what some of us have been fighting to get for a very long time is pointless. So, there hasn't been a peep from me. Achieving the objective is all that counts... even though the *"too little, too slowly"* has played out right before our eyes.
- 4-09-2014** **DVD Discovery.** It really surprised me. I thought playing video was only possible from the navigation system's drive, which is a separate slot on some. On mine, there isn't one. The data is stored on a hard-drive instead. So, I never even considered the possibility. Accidently inserting a DVD from a 2-disc package rather than a CD quickly set me straight. Audio was playing, but there was a blue window on the audio screen. And sure enough, when I stopped and pressed the emergency brake... ta-da! There was video playing on the screen, complete with menu features to select. It's an interesting feature if you ever hopelessly get stuck somewhere or end up waiting for someone. I now keep a few episodes of M*A*S*H in my car, just in case. You never know when that could come in handy. Listening to the audio track of some movies is while I drive is quite realistic too. You'd be surprised how the video part isn't necessary. Many musicals and animated features have stories easy to follow without seeing anything.

- 4-10-2014** **Sometimes.** Patience is important, but ask what sacrifices are made in the meantime. We really don't want to keep putting countless traditional vehicles on the road. They'll remain in service for the next decade. So, we have to consider comments like this carefully: "*Sometime it just takes much longer than we want it to!*" That's very reason we need to keep carefully focused. Anywho, this was my post in response: Sometimes? With the automotive industry, when hasn't it? Seriously. They always rollout in slow motion. Each new advance is loooong awaited by the time we actually get it. You complain about slow expansion with the plug-in Prius, yet don't mention the very same thing happening twice in the past. We didn't get the Gen-0 model (Dec. 1997) at all. Instead, we got the upgrade 2.5 years later and called it Gen-1 (Aug. 2000). Then that rollout was internet-order-only for 2.5 years (until May 2002). When Volt enthusiasts were making bold claims about mainstream sales by the end of year-2, some of us were shaking our heads in dismay. What made it especially interesting was the outright dismal of anything related to Two-Mode, which was GM's own recent attempt to capitalize on their much stronger market... trucks. We all knew the car market would heat up. Pressure from traditional vehicles has been growing as the price of gas climbs and the efficient requirements rise. That meant anything attempting to appeal to those same consumers absolutely must match their purchase priorities. Toyota has remained true to that with Prius and has remained competitive. GM decided to risk offering something at a higher cost while sacrificing interior space and is paying the consequences as a result. So, we look ahead to what will be delivered for 2016. Reading the blogs & forums for Volt, I find it ironic how many of the "*second model*" comments are exactly what many of us labeled as "*trolls*" were saying years ago. They are now endorsing those very suggestions they had once despised. The fear that our attempts to help progress along was really an effort to kill Volt. Turns out, we had studied the market and understood it better. It had nothing to do with the engineering. It came down to basic economics. Automakers are a business. They cannot just build what they want, no matter how much hype that desire stirs. It's all about high-volume profitable sales.
- 4-10-2014** **Dishonesty.** GM's frequent mention of the next-generation Volt encourages speculation. That's perfectly fine. There's nothing wrong with exploring options. Hope without merit isn't constructive though. When it leads to hype, the situation creates reason for concern. When it results in dishonesty, problems arise. We're seeing it already. This new chapter ushered it back in. Ugh. There's one person flat out denying past discussions ever happened, even though the exact phrases recited were from many posts with him, over and over again. For the same topic to be addressed repeatedly and now conveniently forgotten, you have to carefully choose how to respond. My choice is abandonment. The effort simply isn't worth it... especially since it would only serve to confirm his hypocritical stance. His claim is dishonest, but that can be accepted. That change was the goal anyway. With another, the problem isn't so easy to deal with. He continues to outright lie about how Prius operates. Now, he's claiming the videos he watched validates the misinformation. Upon reading that, I was stunned. How could anyone be so desperate to undermine still? Making statements so easily proven false is a good sign though. It serves as indication that Prius is seen as a true threat... so much for finding an ally to help replace traditional vehicles. I'm choosing to ignore him too. With so much real-world data now available, we'll just focus on that instead.

- 4-10-2014** **Encouragement.** Those working against the effort to reach the mainstream with hybrids & plugs are disappearing. The ones left are quite amusing. One website still working hard misleads for the sake of promoting diesel. This month's attempt was to misrepresent by posting the total sales for hybrids and for diesel. It seemed innocent enough... until you realized the hybrids were exclusively passenger vehicles and the diesel included commercial trucks. How is that even the slightest bit honest? Whatever. We're just looking for signs of encouragement asking how things have changed. The most intriguing is the shift of former Prius owners replacing their aged vehicles with hybrids from other automakers. That appears like a loss. But stepping back to look at the big picture, it's really an industry plus. Those owners are now pushing their expectations elsewhere... encouraging market growth overall. Yeah! It's one of those situations like negative publicity, where it ultimately has a positive effect. The circumstances are counter-intuitive. Conflict at the plug can be that way too. Owners are figuring out what works best on their own, rather than being forced to conform to a standard established by group unfamiliar with we actually encounter. There is a spirit of cooperation growing in the forums. Defeat tends to encourage finding a compromise. New hope is growing.
- 4-11-2014** **Non-Hybrid Use.** Some of the engine technology only used in the Toyota hybrids will be carried over to the Toyota traditional vehicles. It's part of that on-going process often referred to as the "*moving target*" we are always concerned about. There's a constant cycle of improvement which is an endless source of market pressure. It can be good, but you need to take a reality check from time to time. Expanding production & distribution reduces cost. That's a win-win situation, especially since it means continued investment. The most obvious change is switching from the Otto piston pumping to Atkinson. The longer strokes provide more output for each act of combustion, resulting in higher efficiency. While driving at a steady speed, that's great. However, the tradeoff is reduced power. Of course, not much power is needed while cruising anyway. There are also refinement approaches, learned such as exhaust-gas recirculation, variable-valve timing, and air-intake ports, which can all be used in non-hybrids. They increase the engine's thermal efficiency, resulting in higher MPG output. It's an interesting situation. Makes you wonder if the typical consumer has any clue what actually happens under the hood as they drive.
- 4-12-2014** **Smart-Entry / Smart-Start.** That's how it was first named, abbreviated as SE/SS. The reason for that was the more popular name now used wasn't specific enough. Smart-Key-System (SKS) implies you can both unlock & start the vehicle with a wireless transmitter... which wasn't the case originally. Some only allowed entry, but you still had to use a physical key afterward. Anywho, I made a surprise discovery that it was smarter than I had thought. My girlfriend had one of the transmitters in her purse, still inside the Prius. When we walked away from it, I pressed the lock button on my transmitter. The Prius doors locked. Later when we returned, I discovered the doors weren't unlocking by just passing my hand through the handle like usual. After several attempts and worry something was actually wrong, I pushed the button on the transmitter. It unlocked. All was well. It took a minute for me to put together what had just occurred. The system had automatically disabled the proximity feature, since it detected a transmitter was locked inside... forcing me to physically touch my own outside for entry. Had it not done that, anyone could have got in the vehicle and driven away. Sweet!

- 4-13-2014** **Lessons Learned.** An article summarizing the situation this way said it well: "*In an effort to boost sales and find a wider appeal, a lower-priced, shorter range version of the Chevy Volt is reportedly planned.*" That pokes at goals, indirectly highlighting how Toyota had it correct with Prius from the very beginning by holding price an extremely high priority. As sensible as it seems to deliver a vehicle that's faster and more powerful, it doesn't actually mean that will result in more sales. Those who support Volt have learned that lesson the hard way... and some, more so than others. Quotes like this highlight the circumstances now: "*I'm glad that I didn't buy my Chevy Volt. Just 3 years lease.*" and "*I'd gladly sell the Volt, only GM has destroyed my resale value...*" Think about the damage that \$5,000 price drop has done. Think about what will happen when the \$7,500 tax-credit expires. Think about what happens in a few weeks when the HOV-sticker supply runs out. What about making a profit? When and how will that be achieved? With so much marketing emphasis still being placed on the having a 40-mile range, the introduction of a reduced model clashes with what we've been told is important. Remember, reduced capacity can also mean reduced speed & power. Whatever the case, it ultimate must reach more consumers... an audience well beyond that of the first attempt.
- 4-13-2014** **Bottom Line.** The academic arguments are annoying. People think they're being constructive, but don't realize excluding real-world is a major oversight. They assume people make logical choices. To make matters worse, they believe the best option is what offers the most of something. So naturally, agreement is elusive. Then there's the blame game, especially when it comes to Volt. That means when we shift focus back to goals, the response is typically one of anger. But that's how this works, resulting in: "*Who cares about "he said, she said". The truth is the bottom line: final sales numbers at the end of the year. Enuf said.*" Who is GM anyway? Hype was allowed to take on a life of it's own. Whenever something was said, it was always intentionally ambiguous. There hasn't been any accountability. Anyone of responsibility left the project. Enthusiasts were enabled. Look at what's happening was the next generation, the same nonsense is repeating. We all know the what's required. That shouldn't need to be said. Success will always be defined by sales. The business requires high-volume profitable sales. Being green cannot be achieved without those sales.

- 4-14-2014** **The Past.** It's nice having an open & constructive dialog now. Things have definitely changed. I pointed today's observations out with: It is unfortunate most people are unaware of the past. To those of you who have openly stated not having followed Volt until later in the process, THANK YOU for stating that. It's far better than back when we pointed out the parallel to Two-Mode development and having been accused of trying to promote Prius rather than getting any type of constructive acknowledgement. That's what the nonsense emerged from. Having witnessed the entire process twice already and seeing the pattern start for a third, it's a very real issue finding an effective way to convey that information. Items get argued down simply due to lack of detail... the very content I documented to the extreme back when those previous events happens, as they were unfolding. Even the act of looking back afterward presents a perspective different from that of not knowing yet. Long story short, I expect quite a bit of criticism from the resulting over-simplification. Not addressing all the reasons why is a problem we've already seen repeat. Then, of course, we have the problem of some people not having the background. Unless you've studied economics, accounting, and engineering, there are aspects of discussions being missed. The biggest problem, though, is not having goals or even an audience clearly identified. Failure is inevitable when particulars are not provided for the measure of success.
- 4-14-2014** **Rumors.** It's nice when we get a reminder how not-so-obvious a situation can be: *"Well, we're coming up on the two year anniversary of this thread. Still, I have no idea how these rumors get started."* That's a very realistic comment to make; yet, few ever actually make it. The online forum isn't a venue for that. There's no way to follow the activity of all threads at the same time other than at that very moment. It's impossible to know what things were like at any particular point in time. You're stuck with a today-only perspective. Fortunately, the blogs do capture thoughts as they are happening. Mine is among the sources readily available for hybrids. So, I responded with: I do. There are countless quotes in my hundred of pages of blogs pointing out the emergence of false beliefs. With Volt in particular, there were some rather intense fights which came about from those of us who questioned sources and pointed out claims without merit. Sadly, there are also greenwashing efforts. My all time favorite is how Toyota clearly stated in a presentation how lithium-based batteries were still too expensive to be used profitably and people would intentionally misled by making the claim that those batteries could never be used. It was a blatant disregard for what was actually said. They didn't care. Then when Volt rolled out, there was a huge effort to undermine PIP by making people believe the plug-supplied electricity wouldn't be used at all once the engine started or you exceed 62 mph. No matter how many times the correction information was provided, the same people would keep posting greenwash material. So, simple things like rumors, are easy to see how they get out of hand. Consider the reality of most people taking what they read at face value, never bothering to confirm facts or follow up. It's really disappointing to learn how common that is.

- 4-14-2014** **Greenwashing Efforts.** There are more and more Volt owners attempting to squash efforts to greenwash, no longer willing to be enablers by not speaking up. They don't like when misinformation is spread, especially when it is about other plug-in vehicles to make Volt appear better. Their desire to honestly gain people's acceptance is triumphing over the superiority approach. Substance over attitude, gotta love it. Anywho, it's stuff like this we are currently seeing: *"You and PiP owners talk about how anytime you want full power you just step down and the engine comes on and gives XX HP. That sounds like a horrible way to wake up an engine first thing, especially when it's -10°.* The Volt never does that to its engine." Volt never does because the engine fires up at temperatures under 15°F. The same is true for the plug-in Prius, but he intentionally left out that vital fact... hoping you'd assume it was different. Also, notice how he was ambiguous by not being specific with temperature? On the Celsius scale, -10°C is actually 14°F. So technically, it's accurate, but could easily mislead. Lastly, the inclusion of adjectives, like *"horrible"*, draw the conclusion for you rather than just providing information. Not being allowed to decide for yourself is yet another way to greenwash. Lastly, watch for words like *"never"*. Sighting absolutes by focusing on extremes, rather than ordinary circumstances, adds to disingenuous portrayal too. It's sad, but true.
- 4-15-2014** **Lunar Eclipse.** It was 2:00 in the morning. We were in Northern Minnesota, looking up into an icy cold clear sky void of any city lights. The moon had just turned red. The lunar eclipse was in progress. We were already freezing. Another 45 minutes was too much. I suggested taking advantage of the Prius. We jumped in and drove down to a location where we could park in the road without any possible traffic interference. Our breath raised a new problem. It instantly froze to the glass. Oops! Without the Prius running, we were comfortable... but the windows wouldn't remain clear for long. Sitting back did the trick. That was nice. Neither one of us cared for the idea of having the engine heat coolant for our warmth for that long. Why waste gas and have to deal with the engine & blower noise when we were already comfortably dressed? So, we sat there and watched, in as natural of a setting as possible. I enjoyed every moment of that experience. It was quite humorous afterward too. Our breathing frosted over all but the two side-windows we were viewing out of. There was a hysterical amount on the front windshield. The drive back to our place was only a 1/4 mile. Starting the engine would have been counter-productive. So, I scrapped... no realizing my breathing would frost it back up 10 seconds later. The angle of the glass, rather than being vertical like the sides, made keeping it clear nearly impossible. But out there in such a rural area at 3:00 AM with powerfully bright LED lights, made crawling along at a snails pace using only electricity and scraping the entire time was no big deal. In fact, that added to the memory. We had a very unique time, just the two of us watching a rare astronomical event... with a plug-in hybrid.

- 4-16-2014** **Traditional Competition.** Downsizing to a small SUV has been the solution for many of those who had been driving monster-size guzzlers. That's obviously an improvement. But still, the resulting efficiency is well under anything actually competitive with a hybrid like Prius... which ironically, offerings larger seating & cargo capacity in some cases. Later this year, that most definitely will be true. GM is introducing their subcompact SUV known as Trax to our market. It has been available in Canada & Mexico since 2012. It will continue to be produced in South Korea & Mexico. Sales potential seem pretty good, considering the 26 City and 34 Highway ratings. After all, most consumers have been greenwashed to believe that is efficient MPG. The idea of traditional vehicles delivering efficiency in the 40's has long since been abandoned. That's why Prius hasn't seen much growth. We've lowered our standards. That's sad. But just like the automakers perversely predicted, vehicle size would get smaller. It's an absurd reality, since some had become so large they no longer fit in garages and were quite difficult to squeeze into parking spots. Needless to say, it will be quite interesting to see what happens later with sales when gas prices rise again.
- 4-17-2014** **Outdated.** The discrediting continues. Fortunately, each attempt appears more and more desperate. I sounded off to one today with: Ironically, the antagonist position is to claim Prius was cobbled together in haste, a direct response from Toyota as a result of Volt. In reality, it was the opposite. Toyota already offered a refined hybrid system and was able to augment it with a plug by basically just swapping out the battery-pack and adding a charger & plug. The platform already supported that next step forward into the mainstream. GM was scrambling to keep from being left behind, so they squeezed in as much battery as possible, connecting it to an upgrade of the Two-Mode system. That's why the topic of "*transmission*" is brought up so often. We all know GM didn't start from scratch. That wouldn't make sense. Trouble was, the expertise they had acquired was from an expensive system which didn't deliver as high efficiency as needed. But in the short term, adding enough battery-capacity to compensate for that could hold them over in the meantime. Problem was, it trapped them into a non-competitive design. Every time the idea of a reduced-capacity model came up, there were highly emotional (and sometimes hostile) responses... since depleted efficiency and reduced power were such obvious shortcomings. To make matters worse, there was little doubt Toyota's plug-in design was profitable. Though priced a little out of reach for the target market, the cost-reduction was achievable within the current generation. For GM, there was no chance of reaching profit until the next... which is how the "*old*" claims came about. The effort to portray Toyota's design as "*outdated*" rather than acknowledge it had matured for the masses was rather desperate, but quite common. The idea of getting any type of recognition that Prius offers a nice balance of priorities is still too much to bare. Watch the type of reply we get to this. Avoiding the topic of business need for the sake of winning an argument is pretty much inevitable... here anyway. Elsewhere, we do see some GM supporters in favor of a competitive model turning on some current Volt owners.

- 4-18-2014** **Progress.** Now that there's a message of support for a model of Volt actually affordable & profitable, the divide is growing. We're seeing a group embracing the idea, thrilled something from GM not serving just a niche. Nothing available for the mainstream after all this time was making them feel let down. They're a stark contrast from the other group, those who continue to make "*still no competition*" proclamations and are quite insulting when pointing that out. It's the typical enthusiast stereotypical response we've come to expect. I don't see them as much of a concern. Attitude like that doesn't earn any respect. The other is what stirs interest. They're saying exactly what some of us who were labeled as "*trolls*" said years ago. It's quite hypocritical, but that's progress nonetheless. The realities of highway-travel and winter-warming have overcome the blindness those chanting for EV purity have caused. Toyota delivered the design needed, through blending of power. Admitting that won't happen, but supporting the efficiency outcome doesn't require a sacrifice of pride. That was the reason for stating goals all along. Too bad so much chest-pounding prevented the progress we are only now seeing. Oh well. It sure feels good having supported what was truly needed. The assumption that switching from electricity to mechanical was better than balancing the too sounds so absurd now. Yet, there were a few who passionately believed it.
- 4-19-2014** **Enjoying Outdoor Recreation.** We tried. Unfortunately, our timing was off. Heading up north with the bikes seemed a sensible escape. After all, all the snow was gone. Sadly, the only nice day for temperature was really windy. Then, it snowed. On the way back, there was a fierce headwind, temp was in the 40's, the Prius was packed inside, and we had 2 bikes on back. I knew that 175-mile trip with lots of highway travel at 65 & 70 mph wasn't going to be ideal. 38 MPG was a pretty good outcome in those circumstances. How many other cars could accomplish the same thing? That's the only way to look at it. The efficiency penalty for enjoying outdoor recreation is well worth it. Sometimes, you do get lucky. I've taken my kayaks that distance too. Surprisingly, they don't impact MPG much more than carrying the bikes. Still, upper 30's is quite a bit below the usual commute MPG from a fully recharged battery-pack. Oh well. With the warm season so short and nice days when you have time free, it's best to try to take advantage when you can. Being able to use the Prius to do that is nice, really nice.
- 4-20-2014** **Spring!** We hit the 70's for the first time in what seems like forever. Temperatures that warm seemed like a distant memory for those of us up here in Minnesota. Thankfully, they returned today. It made for a fantastic Easter Sunday. You could tell, the highways were filled with everyone else taking the opportunity to drive somewhere too. Next week it will be colder and the replenishing rains will arrive. That's a welcome situation. It will help open up the lakes, melting away the final layer of ice. I'm getting anxious to kayak again. The rack for the roof of the Prius is ready to go. It will be just a matter of waiting for the water to warm up. Perhaps I need to finally get a wetsuit. In the meantime, I'm watching the green grass emerge. That usually means photo opportunities. Hopefully, I'll find a new location to take advantage of the improving weather.

- 4-21-2014** **More Progress.** Evidence of this new chapter is becoming easier and easier to find: *"The amount of disinformation and FUD I constantly see here regarding the Prius is incredible. Why is there such an inferiority complex and a constant need to bash the Toyota by a tiny but vocal minority of Volt owners?"* That particular quote came from a forum dedicated to Volt, one in which I do not participate. Being just a lurker there has provided a great opportunity to observe without influence, watching how enthusiasts & supporters interact with each other. Lately, it hasn't been pretty. Spreading of FUD (that's Fear, Uncertainty, and Doubt) combined with some outright lies has become a liability. The reputation of their forum is threatened by loss of credibility from such activity. The very same thing happened on the big GM forum. Eventually, the moderators had to take action. Allowing it to continue wasn't worth it, even when that meant having to ban some of their own most popular long-time posters. They're the real troublemakers, thriving on any chance to exclaim superiority. That idea of partnering for a common cause is unacceptable and the thought of a "*Volt lite*" is bringing out the worst. They wouldn't go to such extremes if the idea didn't have substance. It's a good sign though, a sign of progress.
- 4-22-2014** **Rerated MPG.** Remember the public outcry and legal action late last Summer about Ford? Those not distracted by the chaos caused by Volt do. The hybrid model of C-Max has really been struggling, and that's what ended up being the big news for Earth Day today. That's not the kind of attention desired. Unless of course, you're GM. There is a sense of relief for Toyota too. The advertisements praising C-Max efficiency over Prius V was quite intense. We saw countless television commercials. It really got annoying, since things didn't seem to add up. Eventually, that claim of 47 MPG was revealed to be false. The efficiency numbers were rerated, reducing the 47/47/47 rating officially to 40 City, 45 Highway, and 43 Combined. That stirred emotion from owners and scared off many potential buyers. In fact, if it wasn't for the Energi (plug-in) model of C-Max, it would have been looked upon as a market failure like Insight. The reputation was tarnished and continues to be. That's a real problem without any good solution available. How do you recover from that... especially with a next-generation Prius on the way?

4-23-2014 **Discouraged.** The reality of traditional vehicles being the actual competition is finally becoming apparent. To think that it would take this many years to get recognition of the true problem... it's mind boggling. What it took was a change of perspective and the information coming from a different source. Volt enthusiasts don't want to hear that from a Prius owner. In fact, some will go to extremes to avoid acknowledgement. Sadly, that meant having to deal with misleading and dishonest posts online. Fortunately, we are finally getting past some of that rhetoric... but not in the best way. This statement from Consumer Reports is what contributed to the change of attitude: "*In our own tests, we found the Prius Plug-in offered a scant mileage advantage over the standard Prius at a huge additional cost.*" Taken at face value, that could be used as material against Prius PHV. But when you give it some thought, the statement doesn't actually tell you much. What does "*scant*" indicate? What about the meaning of "*huge*"? They are both vague, void of any detail. For that matter, who is the "*additional cost*" referring to? The price some consumers pay is nearly identical right now when you take federal & state credits into account. Toyota's cost is more, but they don't make that clear. And since when is comparing to another model appropriate without including a baseline? After all, the point is to look at the big picture. Why no mention in comparison to other Toyota vehicles? Of course, there's no way to summarize in a single sentence anyway. Prius PHV offers a major advantage over the regular model for short trips, hardly a "*scant*" aspect about that. The warm-up process is greatly improved for longer trips too. We have lots of real-world data clearly showing that. The reality is, plug-in supply is limited and profit for the dealer very small. It's far more lucrative to sell traditional vehicles, so that's what they do. Articles about discouraging practices at dealers should be no surprise.

4-24-2014 **Dealing With Change.** It's hard to believe a former Prius owner who leased a Volt, then replaced both with Teslas would claim the "*vastly superior*" period of history never happened. I have hundreds of pages of blogs documenting the belittling of Leaf and Prius PHV coming from the voices of Volt. Those die-hard enthusiasts caused all kinds of trouble. Pretending that wasn't the case contributes to the barriers we are still trying to overcome. So, I had quite a bit to say when it was denied: I'm enjoying the change which has taken place since the end of last year. A spirit of cooperation has emerged now that everyone is in agreement about who the competition actually is. It's about dang time. My participation on the Volt blogs came about shortly after the initial reveal. There was an intense campaign to mislead about Prius, and posts to provide correct information were looked with suspicion. They believed that was really an effort to undermine Volt. It got really bad. My own blogs are loaded with their quotes, documenting the rhetoric we had to deal with. Then, it got worse. When Prius owners started asking constructive questions about range reduction from heater use, depleted efficiency from series operation, cost from battery-capacity & system-complexity, the response was routinely hostile. They were brutal. Then, reality hit. Many of those individuals abandoned the blogs, knowing they'd have to confront their own posts from the past... showing them to be dismissive, hypocritical, and just plain wrong. That's made moving on much easier. Phew! Now, it gets interesting. Recent posts from Volt owners are revealing frustration with a handful of Volt owners. Rather than FUD, those few are outright lying about Prius PHV. That desire to restore integrity is quite encouraging. They are taking it upon themselves to ensure reputation isn't tarnished by the intentional spreading of incorrect information. Gotta like that. For me, it's rewarding to interact with other plug-in owners. I park with a Leaf everyday at work. This weekend, I'll be at an Earth Day event showing off the PHV with others. There's a plug-in owners group here in Minnesota now. All the automakers are represented. It's fascinating to interact so directly with Volt owners there. What a difference. Seeing the Tesla, Energi, Leaf, iMiEV, and Prius all mixed together sure is exciting... with each owner doing their part to support choices for the masses. It's unfortunate there are a few bad fish in the pond. I really hope people will eventually read my blogs in dismay, not believing it ever could have been that bad. Right now though, we have a strange mix of support... especially owners of Volt who purchase something else when their lease expires. There is obviously the desire for greater capacity from a Toyota offering. But those who move on from Prius take along with them other purchase priorities, more than just efficiency. That's a win-win. They understand the pressure traditional vehicles pose. They continue to help even as former Prius owners. So, whether you own one still or not, the advancement forward helps. As long as they don't revert back to a guzzler or spread FUD, it's good.

- 4-27-2014 Bonding.** Attacks coming from the desperate are contributing to that bond we've been striving to achieve for a very, very long time. Volt & Prius supporters are working together to squash their greenwashing. The biggest effort is to end their lie being spread about PHV only delivering 6 miles of plug-in capacity. It goes way beyond misleading at this point, and that's stirring anger. Intentional deception is just plain wrong. So, the shared endeavor to end that is much appreciated. The other bonding aspect comes from the acknowledgement of the need for business-sustaining profit and the consequences of being dependent on government subsidies. Concern for overall well-being is redeeming. It's long overdue and very welcome in any form we can get it. The fact that it's coming as a result of a small number of Volt enthusiasts determined to portray other plug-in offerings as inferior is rather ironic. They had accused the effort to seek out cooperation an act of undermining. I found it funny that no matter what you said, all they'd hear is "*Prius*" even if Prius was never mentioned. That's what happens when you get desperate. Who knew it would contribute to bonding too?
- 4-27-2014 Real Issues.** It's nice to finally see some constructive dialog. The new discussion started was about younger buyers, discussing the pattern we've observed. I contributed with: The thing I run into with some older buyers is how their assumptions cloud judgment. They believe they have all the information needed to make a decision. Being unaware of what's actually available is a very big challenge to overcome still. Today at the barber shop was a great example. The barber's mom-in-law was there chatting with the people waiting to get their hair cut. The topic started with flat tires (it's pothole season, after all), then became a discussion about cargo you could carry inside, since spares aren't always included anymore. I mentioned mine didn't; instead, there was a battery-pack. The woman immediately chimed in about "*not being comfortable in one of those cars*". That got my attention. I asked for clarification. She said she had looked at "*one of those*" and didn't want any part of them. Baffled by her lack of clarity, I asked about seating space. She made some obscure reference about being small... which made no sense, since I knew her vehicle was a PT Cruiser... not a large vehicle which she had inferred owning. Then, the topic was abruptly changed. She had made up her mind, believing her stance was based on complete up-to-date facts. She was wrong, but not having an effective way to point that out without embarrassment or disrespect is a very real problem. Younger buyers don't have an extensive past to leverage upon and have grown up in an age where improvement was continuous & often. So, most automatically seek out information. That's a big difference with older buyers. Assumption issues are a barrier to accepting high-efficiency vehicle choices. How do we deal with that?
- 4-27-2014 Broken Charger.** On a cold, rainy day, what do you do? Go to the mall. Joining in that chaos wasn't the ideal choice. Everyone else had the same thought. But having a plug-in vehicle, at least parking would be too bad. Of course, getting to the spot itself was a challenge. It took awhile for us to reach the chargers. Thankfully, there was room available. That was a relief, considering how few spots are actually there. Believe it or not, only 4 are offered at the Mall Of America. That's a massive shopping destination. With 2 huge parking ramps, that's beyond disappointing... especially since the recent efficiency upgrade. All the lighting was switched over to LED. Anywho, it got worse. The charger I pulled up to was broken. The L2 cable wouldn't release. Only the L1 was operational. That was a let down. Hopefully, it will be fixed soon. The broken charger at work took over a month to get repaired. Oh well.

- 4-27-2014** **Impressive Charger.** Today's other charger encounter, the best charging-station I have ever seen, offered a nice balance. It's at a remarkably beautiful nature preserve, which just happens to be within EV distance of my home. The station offers 2 high-speed cords, both on those fancy retractable mounts. No messing around with still or tangled cords. The readout is an actual screen too, not a simple digital readout like all the others I've ever seen. There's no charge to recharge either. It's a great setup! The location is absolutely ideal for a gathering as well. There's lots of parking and room to hang out. Sadly, it is rather out of the way for non-locals. But that's life. The best zoo in the state is nearby and people don't have any problem getting to it. So, I've got a great opportunity to now exploit. That impressive charger will help draw in a variety of efficiency supporters. I can't wait for the weather to finally get nice!
- 4-28-2014** **New Discussions.** It's nice seeing new discussions emerge. This one especially perked my interest. *"Why isn't there any discussion here about the PiP vs. the Ford Fusion Energi Plug-In?"* I jumped in with: That's a reasonable question with a stirring answer. In the past, there was a tremendous amount of chest-pounding. Enthusiasts of Volt declared it *"vastly superior"* and celebrated GM having *"leap frogged"* the competition. Then reality set in. Although Volt was an appealing vehicle and did indeed achieve some notable engineering milestones, it did not meet business or consumer need. That's what caused so much attention to be drawn to it, pushing out pretty much all other mentions... except Prius. Since then, GM itself has officially declared this generation and moved on. They acknowledged goals not having been met. That chapter ended. Many people aren't aware of the detail of that history. And as much as some still want to discuss it, I have no interest. I too would like to hear more about the other offerings, especially both Ford choices. C-Max is what we've seen a number of former Volt drivers switch to when their lease expired. Fusion isn't as practical, but it offers ample seating room. Battery-Capacity is the obvious Energi advantage over Prius PHV. That increased kWh provides higher kW draw opportunity, translating to more electric-only power. Depleted efficiency isn't as good though, especially with C-Max. Of course, comparisons are limited to the current situation. We know that Toyota would like to increase capacity as cost drops, keeping it competitive with the real competition: traditional vehicles. Knowing the engine in Prius will become even more efficient, it will continue to retain its hybrid advantage too. Ford's direction isn't as obvious. Capacity is already at a "maxed" threshold, with respect to both cost and physical space. We haven't heard anything about engine efficiency either. In fact, the MPG down-rating has really soured C-Max expectations. Fusion, as a hybrid, is rather competitive already. It rates notably higher than Camry, and matches Accord for combined. Fusion, as a plug-in, has a tiny trunk. Being that limited for cargo space will deter buyers. Being practical has been a strong selling-point for Prius, including the plug-in model. Like it or not, we're still in the early stages. Things will get interesting as tax-credit expiration nears. In the meantime, charging-stations are evolving. There are more locations and the equipment itself is improving considerably.

- 4-29-2014** **Heavy Rain.** This weekend, we had a mini gathering. It was supposed to be an Earth Day event, but the heavy rain left us quite lonely... 6 plug-in vehicles... a Tesla, a Leaf, 3 Volt, and my Prius PHV. Instead, it was a washout. So, we hung out and talked for awhile. The topic of "*sales pitch*" eventually came up. We all recognize that you've got 20 seconds at most to say your piece. After that, you typically lose the person to misconceptions & assumptions. That makes subjects like "blending" nearly impossible to address. There isn't an awareness of tradeoffs. In this case, the belief is more electricity is better. How do you illustrate to them that higher overall efficiency is possible from allowing the engine to run when the mindset is to use no gas until you run out of electricity? To make matters worse, they think when the engine runs the battery is no longer used. Then, there's the reality that much of our electricity is derived from dirty sources. Conveying so much information in just a brief few sentences is basically pointless. We were in agreement that the best way to convince the poorly informed is to encourage firsthand research. After all, it was the test-drive experience that won over countless doubters years ago. Why not with plug-in vehicles now?
- 4-30-2014** **Blending, stigma.** It's been given a stigma. The purity of electric-only drive continues to get praise, regardless of the sacrifices required to achieve it. There's a very active thread on the big Prius forum addressing it. I added more to it today with: Today's travel... mostly highway, in really wet snow, blah ...was 96 miles total. I recharged early in the morning, mid-afternoon, and squeezed in a partial (60%) late in the evening. The result was 62 MPG. Blending is the new "*caught off guard*" situation. People look back and give Toyota credit for being way ahead of the rest of the industry for hybrids, implying the other automakers are now rapidly catching up. They believe the race is over, that a lead no longer exists. Big mistake. People assume the next big step forward is just increasing battery-capacity for further EV driving. That's an easy trap to fall into. It makes sense... unless you really take the time to consider all the factors involved. Sadly, few ever do. Most are greenwashed into thinking more is always better. Engineers know differently. They see how complicated it is to achieve a balance, how challenging it is to deliver an optimal solution. They are well aware of tradeoffs. They understand higher capacity and more power may not actually be an improvement. It will take years for the typical consumer to figure that out. Then, they'll look back and wonder why the others didn't just follow the same path Toyota took. It will seem so obvious to them, at that point. But right now, there's lots of disbelief that blending is better.

- 4-30-2014** **Blending, tradeoffs.** The benefit is far from obvious. Most people aren't even aware of the fact that more of something often means less of something else. When it comes to propulsion, that especially a problem. The assumption is simply increasing the size of the engine, motor, or battery will improve the vehicle's overall performance. That most definitely isn't the case. Ford's plug-in hybrid approach has provided a great example of that. First thing we see with Prius PHV is the warm-up process. It takes full advantage of blending. That 1500 RPM hold limit not only allows the engine to warm-up gracefully, that also contributes heavily to the warm-up speed of the catalytic-converter. Most people forget about the emission system. Rapid warm-up of it is just as important as the engine. It requires 400°F for thorough cleansing. What does Ford do? We know that low RPM following warm-up is a key to Toyota's success. That requires a gear-ratio optimization... which means a tradeoff of a slower maximum electric-only speed. Ford's desire for higher speed in EV mode meant trading engine efficiency. That gear-ratio isn't as well suited for blending as a result, taking advantage of boost from the battery-pack at any speed. That's why neither the highway nor city MPG is as high as Prius PHV. In fact, even that trading can be seen with the other Prius models. To deliver greater power for Prius V, since it is larger & heavier, the final drive uses a lower gear-ratio. That reduces MPG compared to the regular Prius, which shares the same engine, motor, and battery. This is why blending is such a big deal. Focusing on electric-only purity requires sacrifices.
- 4-30-2014** **Getting Old.** Attacks on the plug-in Prius continue. This particular person simply doesn't care either. Quite a number of people on the big Prius forum have called him how, frustrated with his blatant trolling. Every chance he gets, he takes the opportunity to belittle and downplay. As a Volt owner, other Volt owners are not happy about his behavior. Misconceptions debunked long ago are repeating brought back up. Today, it was: *"Still, 'the PiP can accelerate and merge into hywy traffic'? And around here 62 MPH would be a traffic obstacle. My point is when doing this with a stone cold engine, that is not the best thing for engine life."* I'm taken aback by his tenacity. Being proven over and over again to be spreading FUD doesn't deter. He just keeps it up anyway. To make my point, not wanting to have to post rebuttals to the same nonsense again and again, I took a creative approach. I made the post really stick out. But rather than the ALL-CAPS shouting type response, I chose to make each sentence a different color... taking the response of being *"colorful"* in literal form, rather than the usual metaphor. Hopefully, it will really stand out: Since that point has already been debunked on several threads, it is time for a colorful response... Prius PHV is a PLUG-IN HYBRID, which means it takes advantage of having both an electric-motor and a gas-engine. When power beyond the electric-only threshold requested, the engine will start but is not allowed to exceed 1500 RPM. That RPM limitation enables the engine to warm up gracefully, preventing wear a cold engine would otherwise experience. Full draw from the battery-pack continues during the warm-up, which is how engine RPM can be limited yet still deliver power to merge onto a highway. Remember this colorful response, so we don't have to answer the same question anymore. Seeing it repeat is really getting old.

- 5-01-2014** **Bailout Cost.** The final tally was released today. This sentence says it all: "*The U.S. Treasury's bailout fund lost \$11.2 billion on the rescue of General Motors Co. (GM) with the government's exit of the largest U.S. automaker.*" We knew the realities of business would stifle innovation with respect to achieving sustainable profit. That's why the auto task-force issued this concern as part of the bankruptcy-recovery plan: "*too little, too slowly*". That meant efforts to compete would require actions above & beyond. Fulfillment could not come from being reactionary, which is exactly what ended up happening. The result was heavy investment in traditional cars & trucks. Volt was doomed to be a niche. Enthusiasts absolutely refused to acknowledge that reality. Supporters did, abandoning the hope of mainstream until well after the introduction of the next-generation design. No care was given to the product-gap, leaving GM without anything in the high-efficiency category. Neither Two-Mode nor the second-generation of BAS (known as eAssist) could deliver. Both died in response to terribly low sales. Volt is fading. ELR was dead on arrival. Both require a plug. What a mess. The bailout did soften the impact. But to those who absolutely insisted the government assistance would be repaid back entirely, they were very, very wrong. We are left without an expectation for the future too. How will the product-line change? The remaining federal help, the tax-credits for all plug-in vehicles, will expire. Then what? Pressure from upcoming CAFE regulations (minimum MPG requirements) and the inevitable gas-price increases mean status quo isn't enough. The other automakers are striving to provide better offerings too. Progress marches on... with or without GM. Perhaps the recent flood of recalls will encourage faster change.
- 5-02-2014** **Perspective.** Results from April presented a major wake-up call... so much so, there isn't much to do beyond just present the numbers for perspective... which is exactly what I did. To add some perspective, Chevy April sales here of cars: 21,752 Cruze; 19,944 Malibu; 13,915 Impala; 9,043 Camaro; 7,655 Sonic; 3,873 Spark; 3,514 Corvette. Then there's Equinox at 20,315 and Silverado at 42,755. Volt's 1,548 barely even gets noticed among those top-sellers. When you take into account the month total here of 254,076 for GM, there should be genuine concern... especially since those other GM vehicles aren't aided by a \$7,500 tax-credit. They don't qualify for HOV stickers either. Reality is, the market presents great challenges still. GM's own product-line is the competition.

5-03-2014 **Given Up.** It's an interesting situation. Volt enthusiasts have lowered their expectations so much, debates are pointless. Their vehicle of praise was to take the market by storm, to put Prius to shame and make electric-only vehicles look silly. That didn't happen. In fact, things have went so poorly, they have allied with the electric-only vehicles. The theme in today's April sales discussions has been that we need to be patient. Progress been so slow, it's pointless to even bother to argue. They've given up. Embracing the much longer adoption path is now the plan. Those who had exclaimed superiority and celebrated conquests are dismissed as rhetoric of the past, never having had any credibility or influence. In other words, that effort to point out reality worked well. They believed without supporting evidence and hoped for victory. As technical detail was revealed, shortcomings with associated to goals were abandoned. It's been a disaster... repeating the very same mistakes we saw with Two-Mode. That's remarkable to have witnessed. *"Those who do not learn from the past are doomed to repeat it."* was a warning not heeded. Advice was simply disregarded. Assumptions were made. Preventable mistakes happened. What a mess. Fortunately, the attitude now makes taking the next step easier. Unfortunately, the *"too little, too slowly"* concern has been overwhelmingly confirmed. Volt was supposed to be a major player at this point, dominating the efficiency market and competing directly with traditional vehicles. That didn't happen... not in any respect.

5-05-2014 **Making vs. Selling.** Twists like this are always fun to reply to: *"Yep, making the best products is good news for stockholders."* It was more spin from that really smug Volt owner who thinks all vehicles using gas, including Prius, are guzzlers. The 50 MPG following depletion really irritates the heck out of him. So, the attitude is really an annoyance to deal with. Oh well. Reality seems to be rather effective at times: Nope, selling the best products is good news for stockholders... 21,752 Cruze; 19,944 Malibu; 13,915 Impala. Those are the money-makers for GM, returning dividends to stockholders. Selling small quantities of a vehicle dependent upon a tax-credit wasn't the expectation. Remember how enthusiasts here shunned any reference to Two-Mode? Pointing out parallels to it with Volt made some furious and resulted in ardent responses. Now looking back, we get excuses & dismissals, even though it did indeed play out as predicted. Having a costly vehicle which couldn't stir many sales was an outcome no one wanted to address. So, goals were pushed back, delaying those expectations to the next generation instead. The result sounds reasonable, but it requires agreeing with those who said that would happen all along. We see how the *"range anxiety"* campaigning fell apart, that the effort to disparage electric-only vehicles turned into a partnership to recover from an incorrect market belief. It's quite hypocritical. But what makes it worse it to pretend that hasn't happened by attempting to conceal it with rhetoric about the plug-in hybrid which remained true to consumer need right from the very start. Keep saying what you want each time month-end results are published. That won't change them. Stockholders see the outcome. They don't care who supposedly won a debate online. Sales speak for themselves.

5-05-2014 **Big Picture.** More twisting. Anything that can be done to distract from the reality of Volt sales is to be expected following month-end results. Today, it was: "*What is Toyota's response to the abysmal sales of the PiP? Do I need to post the #'s for all the Tacomas, Corollas, Camrys that are sold, and have that debate again?*" The desperation to protect reputation is quite astounding sometimes. But without any alternative available for sale, what else can be done? I replied with: It's quite amusing how cherry-picking is used to derive forgiveness for GM. We all know that Prius PHV isn't the only high-efficiency offering from Toyota... quite unlike GM. The plug-in model Prius shares the same platform (including engine, power-split-device, and both motors) with the regular model, which is profitable and selling at twice the mainstream minimum rate here. In Japan, has been in the top-5 national selling list for many years now. In fact, selling even better there than the regular model is the smaller model. There, the larger model features a lithium battery too. We know the next generation will provide an engine with higher thermal efficiency. The will boost blended MPG even higher, without adding anything to the cost of the plug-in model. There will be refinements to the electrical system as well. It's what you'd expect from a next-generation offering reaching out to capture a larger audience. Volt requires more than just refinements. Complaints about legroom and the desire for more seating in back are abundant. Cost needs to be reduced considerably more too. With a tax-credit being triple that of Prius PHV, that's nothing to take lightly. As for calling sales "*abysmal*" even though it isn't available nationwide and numbers are similar to Volt which is, that's rather sad... especially considering the much higher government incentive for Volt. Say what you want about the competitors. The rest of us will continue to watch the bigger picture.

5-06-2014 **Adaptation.** Being well prepared means also having to deal with: "*So you admit that Toyota misread the market for plug in hybrids with the PPI? That they are just in a holding pattern until the next generation becomes available.*" It never ceases to amaze me how the spin will emerge. Sadly though, not only won't people be able to recognize any of this nonsense even happened, they'll actually argue that encounters like this weren't even possible. They'll look back and say the preparation was obvious, since the actions taken matched need so well. That's unfortunate, but no surprise. Being able to adapt is vital. Those who cannot are simply forgotten. This was my response: That's an absolutely fantastic example of not seeing the whole picture. Thanks! The either/or mindset is a common problem, especially when it comes to plug-in vehicles. People assume if it wasn't this, it must have been that. They don't consider other choices or outcomes, mainly because they aren't even aware of them... hence not having all the information. In this case, Toyota had addressed a variety of different outcomes and planned a strategy for each. This is a very, very common practice in the software industry. You just plain don't know how customers will respond. That means having to accommodate by building in flexibility. So, no matter what the outcome ends, you were already prepared for it. The rhetoric emerges from those who spin that proactive approach as reactive. Those of us who studied the plan are well aware of the flexibility long ahead of time. Those who didn't join in until later, typically when some type of undermining effort catches their attention, lack detail to correct assess what's happening. In other words, since Toyota planned for several different scenarios. Focus on just one provides a distorted interpretation of what actually happened. Put another way, knew all of their bets wouldn't win and allowed for adaption along the way.

5-06-2014 **More Information.** Sometimes, you have to wonder if arguments come about due to lack of information. Not having all the facts causes people to draw incorrect conclusions. So, it should go without saying that their decisions along the way will be misled too. When you bring that point up, some people take notice, others dismiss. I'm curious if this will stir any type of constructive reaction: Neither Toyota nor Ford bet the farm on plugging in. The portrayal of "*not getting it right*" is getting old. They both offer a viable hybrid platform with much opportunity. Nissan took the chance on a single offering, but made great strides for it to be affordable. GM risked it all, gambling that an expensive choice would somehow be competitive. That didn't work, which is why we have had to deal with such a massive amount of rhetoric. We all knew how incredibly difficult the market would be to penetrate. But since Toyota successfully diversified Prius, expanding into smaller & larger models, it became a target. We see how little there is to gain from expanding PHV rollout. We also see the benefit of figuring out how to penetrate deeper into existing markets, rather than spreading limited inventory thinner. Remember how effective it was limiting inventory with the Classic model? Most people don't. In fact, they believe demand was low... since those hoping to undermine never mention the limited supply. It's easy to foresee the same thing playing out again with the next generation PHV... especially with so many damage-control efforts at play with a certain plug-in which took the one-size-fits-all approach. Having participated in the hybrid market for over 14 years, it's easy to see the big picture. For those who don't realize far more is at play than just the information provided in current threads, I don't have a good suggestion, other than just asking them to share what they see. There's no way to know what part of the picture they are missing. The past has taught me that their misunderstanding will clear up as they stumble across more information.

5-06-2014 **Suggestions.** It turned out to be worthwhile. The discussion did take a turn in the right direction. I wonder how long it will last though. Patience is far from a virtue with this crowd. Understanding the value of waiting is not in their interest. Things are still thought of as now or never, one extreme or the other with nothing in between. I find that ironic. Since so much of the Volt rhetoric comes from us being told to be patient, the same comment for Prius falls on deaf ears. Some call that hypocritical. I take it as not having the proper background to interpret the market. So, my post went as follows: I'll certainly agree with that. They most definitely would benefit. But yet again, this isn't an either/or issue. It's not a matter of if, it is when. Waiting will provide a much higher payoff. Look at how limited-market research has provided a massive payoff in the past. Most people have no clue that there were 20 of the 1999 Prius (Gen-0, commonly referred to as the "*Original*" model) provided to ordinary consumers an entire year before the rollout of the upgrade we got in the United States. The feedback they provided was priceless. Some of their suggestions were implemented right away... in what we now call the "*Classic*" model. Prior to the rollout of PHV, the same thing happened. There were a total of 300 circulated around the world for consumer feedback. Toyota took those suggestions and implemented them right away too. We got the upgrade, not the first. Seeing how crazy the plug-in market is, especially having witnessed so much fallout with Volt, the decision to stay within the initial 15 states is proving to be a wise one. What's your next question? I'm really enjoying this discussion.

5-06-2014 **Rush Gamble.** The immediate payoff failed miserably with Volt. You'd think that experience would be observed & applied elsewhere. Not with this crowd. Instead, we still get some of this: "*People can't buy what ain't available.*" Even with good intent, the knowledge of good business is elusive. So much focus on engineering in past has left many without that perspective. In other words, they think it's ok to take the next step without having to plan any further ahead. They assume it will just naturally work out if the vehicle design was well thought out. Disregard for the market (not understanding their audience) comes with great penalty. Yet, that isn't even addressed. The need to have several plans in play to lay down ground work (a solid foundation for whatever may happen) isn't important to them. They see no need to establish many options to build upon. It so disappointing. Upset is inevitable. Yet, some don't even see the risk being taken when not having anything else available to respond with. Oh well. It's not like they weren't warned: Toyota offers other choices. They diversified, allowing the ability to react to the market. Consumers still have something to buy. With the next generation, Toyota will simply just pick up where they left off. Consumers who were aware of the previous will see the improvements. Consumers who will see a plug-in Prius for the first time will be impressed with how well it matches their purchase priorities. GM did not take that same approach. They bet the farm on a single offering, hence such bad fallout with and so much backpedaling. There is nothing for consumers to purchase in the meantime and Volt will undergo a number of modifications, both design & operational. Effort to re-educate will be required having a model so different from the previous. It's a messy situation Toyota was able to avoid. Think about the business. On-Going profit is needed. Having alternatives is a very big deal. There's only so much risk an automaker can take. Is the rush gamble worth it?

5-07-2014 **Rumors.** I find it remarkable how some people simply dismiss. They'll see something, label it as a rumor, then move on. No importance is given to the supposed facts being spread. They don't consider them to have any influence. They couldn't be more wrong. Whether something is correct or not doesn't mean it won't have an impact. People react to misinformation all the time in other venues. Why is it so easy to ignore that reality online? Whatever the case, I watch the situation play out routinely. You can point out the problem and the consequences without anyone caring. They let it happen anyway. That's baffling. But denial like that shouldn't be surprising, since it is so abundant. Oh well. All you can do is point that out: It's GM playing the game. They work the internet, taking advantage of the hype which emerges from their ambiguous releases. It allows them their flexibility. Whether the information is accurate or not doesn't matter, the idea becomes real when there is an endorsement for it. That all feeds upon it self, having a direct impact on other automakers. In other words, asking me to stop is just shooting the messenger. You can avoid participation elsewhere and just dismiss content lacking credibility, but that won't prevent the activity itself from continuing. Rumors have a very strong influence, especially when it comes to spreading greenwash material. Do we really want to just sit back and let it happen... or worse, not even bother to address it?

- 5-08-2014** **Lithium.** The absurd arguments certain enthusiasts continue to make about the cost of Volt's battery pack makes you wonder why it is even worth the bother to respond... until you see their influence elsewhere. The claim has been that the entire purchase price is now down to \$2,700. That conclusion was drawn by looking up parts information from a supplier. The diagram shows the entire assembly for the pack, so they've been assuming battery cells are included. There's nothing whatever to confirm that. In fact, it's pretty easy to see that's it just the outer case... hence this being absurd. Yet, they are absolutely convinced. Pointing out the price of lithium batteries per kilowatt (currently \$650) and the 16.5 kilowatt capacity should be enough to show their conclusion is quite incorrect. Yet, they don't budge. It's bizarre how they choose to only see what they want. The cost of the lithium component alone is somewhere around \$10,000. Add to that the assembly components, you've got the price we've been discussing since rollout. Drastic reductions have not happened, no matter how hard they hope for it. This is why Toyota's design isn't anywhere near as dependence on batteries. They figured out how to squeeze out higher efficiency with a much smaller pack... knowing cost would remain a major issue for years to come. A bit angry by having to deal with such nonsense, my post was: \$650/kWh speaks for itself. Toyota worked extremely hard to deliver something cost-competitive. By sharing their already profitable platform, they are well prepared to take advantage of lithium prices dropping.
- 5-09-2014** **Greenwashing.** It still happens. Some of it is quite intentional. Some of it comes from people unknowingly spreading misinformation. All you can do is address it directly when it emerges, like today: Let's not overlook the greenwashing campaign which PiP is having to deal with. A small group of individuals are working hard to make people not see the differences between the plug-in and regular model. They're doing it by misleading about how "*blending*" actually works. For the regular Prius, it means combining gas & electricity in an optimized way. The end result is higher MPG, even without ever plugging in. For the plug-in Prius, it also means combining gas & electricity in an optimized way. It result is also higher MPG. The catch is, plug-supplied electricity is taken advantage of. Those attempting to greenwash hope you won't seek out any detail, wanting you to assume it works exactly like the regular model. It doesn't. What actually happens is the battery provides much more electricity. Since people assume that means greater distance in EV, it's easy to get them to think there's no benefit when not in EV-mode. In other words, the hope is people will believe the plug-in only delivers 49 MPG on the highway. It doesn't. That "*more electricity*" is really a greater draw-rate. In other words, the electric-motor works more and the engine works less in the plug-in model while on the highway. That's easy to confirm too. At 65 mph, which requires the engine to run, you'll see the system maintaining 100 MPG... a value clearly much higher than what the regular model delivers. So what if that "*blending*" means less electric-only driving. It still means more MPG, by reducing the impact of engine warm-up and increasing efficiency at high-speeds.

- 5-10-2014** **More Greenwashing.** It continues. No surprise. All we can do is confront it when it happens: The other active greenwashing effort is to mislead about electric power by downplaying it. That same small group of individuals are hoping their random belittle comments will be accepted as genuine. After all, most people don't have a means of verifying those statements. As a result, people get the impression the plug-in Prius is an after-thought for Toyota, something cobbled together in response to GM. Some of us are aware that isn't true, that the traction-motor is underutilized, limited by the amount of power available. The bigger battery provide that extra power. The hope is an assumption that this model of Prius works the same way as the one without a plug, that the bigger battery simply allows it to operate that way for a longer duration. It doesn't. As owners, we know that acceleration from a stop in the suburbs and hill climbing in EV-mode isn't a big deal. Greenwashers want you to believe that isn't possible. Ironically, that desire to undermine serves as an endorsement. There wouldn't be any reason to post false information if the system wasn't able to compete.
- 5-10-2014** **Even More.** The posting goes on: In addition to posting false information, there's also an on-going undermine effort. The desired outcome is to mislead about the size of the battery-pack by getting others to express a need for it to be larger. That way, it appears as though the current offering isn't enough. It give the impression of a shortcoming, a feeling of not enough. It's a technique which plays upon "more" marketing. Given a choice, people will basically always desire more. Ask them about MPG. Who wouldn't have a preference for a higher number? That's human nature. It's a weakness we routinely succumb to. The key is leaving out important detail, like the sacrifice of interior space and being affordable. They don't address that. Avoidance is a dead giveaway the "discussion" isn't constructive. That type of manipulation happens on a regular basis. It's quite annoying, but not unexpected. Any technology providing a true advance forward (change of the status quo) will come with resistance. Think about current Prius owners. Their purchase was based upon the practical nature of the vehicle and it being reasonably priced. Why would their next be any different? Having the engine stay off longer and getting more electric power is what they'd like, but they aren't going to consider that a high priority. That means the plug-in battery-pack should be on the smaller side. More isn't necessarily better.
- 5-10-2014** **Batteries.** Finally, the decision changed to batteries, with: *"There is no way you could get the variety of types of EVs on the market if they all had to use the same batteries. Why not tell all car companies they have to use the same size engine?"* I wasn't expecting someone fairly well informed to make such a comment. You'd think he was well aware of how modules & cells make up a battery-pack. There's a lot of flexibility within not be addressed. I wasn't sure what he was thinking. So, I said: That's a bit overly simplistic. There's no reason battery cells cannot be standardized. Having a small variety of them available, as we do now for other batteries, would still allow for the flexibility each automaker desires. Internal arrangement and charging approach would still be at the discretion of the automaker. After all, that's what an automaker will want anyway. That's how cost will be kept down and risk reduced. They'll spread those cells in different configurations across their fleet. Battery suppliers will want some type of "same" as well. The manufacturing process thrives on producing high-volumes of similar product.

5-11-2014 **Mother's Day.** It was an awkward situation. On the street outside my sister's home was a Camry-Hybrid with people inside and standing outside it. They were checking out Mom's brand new car. Seeing us standing by my Prius, her mother wandered over. Telling us about her daughter's purchase, it became obvious she knew little about how hybrids actually worked. I answered questions she asked about mine, but refrained from mentioning the plug. My own mother, not aware of that lack of background like me, just blurted out a comment about plugging in. That got an interesting reaction. The woman who had excitedly come over to tell us about the hybrid she knew of suddenly found herself shockingly uninformed. It was the deer-in-the-headlights stare, abruptly silent and clueless. Changing the subject quickly remedied that. Some people on the big Prius forum make comments about how hybrids have become mainstream, now that Prius has been sustaining sales at twice the minimum for so long. Reality is, that type of acceptance is just the beginning. Far more needs to be achieved still for that to become the top consideration when researching the purchase of a new vehicle. Sadly, we are far from that. Many people still outright dismiss hybrids, making some comment based upon an incorrect assumption. That makes the idea of a plug well out of reach. It's the very reason the 73.5 MPG average stated on my website card gets such a reaction each time I share it. That's also why I put so much pressure on the Volt enthusiasts. They didn't understand the importance of the "Who?" question. They didn't know their audience. The encounter certainly made an interesting Mother's Day memory.

5-12-2014 **Elaborate.** I knew he was just stirring the pot. He does that quite a bit, just for the sake of keeping discussions going. Some people simply like to debate. They seek out activity on the forum and contribute with informative comments. The catch is, they aren't constructive. Since the goal is to prevent conclusions from being drawn to keep the posts coming, some comments are intentionally vague. This was such a case: *"...I hope toyota will take what it has learned and put out a much improved prius phv. IMHO they have plenty of engineering talent to do it."* And sure enough, he didn't provide any detail after I asked: Care to elaborate? What does *"much improved"* signify? Look at how a few Volt owners turned the *"6 mile"* nonsense into a brainless game of misleading, just because they viewed EV purity as vastly superior. Their success depends upon people not actually taking the time to consider detail or goals. The *"0.2 gal/100 mi"* listed on the window-sticker means the 11 miles of blended driving would consume 0.022 gallons of gas. That's a drastic reduction of gas usage compared to a vehicle averaging 35 MPG, which would consume 0.314 gallons for the same 11 miles. Isn't reduction the point? If not, how does electricity usage apply? It has to come from some type of fuel. In most cases, it's no renewable or even clean. Neither coal nor natural gas offer the purity they portray. Also, let's not overlook how much effort Toyota made to keep cost in check. They adhered to that important \$30,000 price-point, rather than sacrificing affordability for the sake of delivering more range & power. In other words, we're back to asking the question of what mainstream consumers will actually purchase. That's a big difference to what they say they want at auto shows.

- 5-14-2014 Federal Gas Tax.** We've been hearing a lot about the upcoming shortage. Not enough money from gas tax is being collected to support the federal funding our roads need. Projects like bridge replacement are in serious jeopardy. There's simply no way to pay for them. Naturally, plug-in cars and hybrids are considered the primary source of the problem. But in reality, it's the fact that people have switched from guzzlers to more efficient traditional vehicles. That has a much greater impact on gas consumption, which means less tax being paid. Unfortunately, the tax itself hasn't been adjusted for inflation. It hasn't been increased for higher expenses either. In other words, our funding system is a mess and the politicians responsible for fixing that are afraid to raise taxes. So, the problem has been progressively growing worse and worse. The deadline is rapidly approaching. The time when not being able to pay bills becomes a genuine problem is August. Then what? With gas prices so low right now (\$3.55 per gallon here), it's the perfect time to increase them... especially with the big effort being made to keep them from rising. How many years can the bucket be kicked down the road? Someone must finally do what needs to be done.
- 5-15-2014 We Had A Blast.** Try to envision roughly 50 plug-in vehicles parked in the lot. It was the Spring gathering of the local plug-in organization. We had the opportunity to play with each other's vehicles on a closed track. I was curious how the Fusion Energi drove. Naturally, I jumped in a Volt too. The biggest surprise was having a BYD there. That's a brand from a Chinese automaker. They try to deliver lower cost vehicles. You could tell. That EV was nowhere near as refined. It was rough & noisy, a rather dramatic difference from the Prius. It was quite a reality check. There was a Smart EV there too. Driving around such a small EV certainly was interesting. The Tesla was obviously impressive as heck, especially being the top-of-the-line model too. What really caught my attention was the RAV4 EV. Being supplied with parts from Tesla, it performed surprisingly well. Unfortunately, there wasn't a Leaf available for driving. That certainly would have been nice. Oh well. Unexpectedly, there was a VW hybrid. It seemed to lack the "fun to drive" aspect commonly attributed to the brand. I wonder why. Hmm? After the outdoor activity ended, we all wandered inside for a presentation and sharing stories. My stance was one which had others curious. What could a plug-in hybrid owner have in common with those who depend exclusively upon electricity? The answer was simple and all got their attention: Lithium. When I mentioned my effort was to provide an endorsement for that type of battery use by the masses, they were quite pleased. Prius has been successfully paving the way for mainstream acceptance for a long time now. Why not help out with EV progress too? Having an engine, that aspect is easy to overlook. But that battery is the key. Without proof it works on the grand scale (high-volume presence), the odds of purchasing a vehicle without an engine are quite low. The general market poses a major challenge. Being able to coax that along is great.

5-16-2014 **Interesting Perspectives.** This post obviously caught my attention: *"I test drove a Chevrolet Volt while my 2012 Prius was in the shop for 25,000 mile maintenance. I'm tempted to trade my Prius for the Volt. BUT I love my Prius - it's been 100% reliable. The Volt would allow me to electric commute, 25 miles one-way, and re-charge at work. The Volt feels like a quality car, with lots of torque, and very quiet. I'd appreciate your input. I need a reality check."* Having just spent last night with a bunch of Volt owners, it was quite refreshing to read that. The nonsense online basically doesn't exist in person. When you get to interact, seeing the problems engineering faces in the world of business, perspectives get interesting. We see a sense of bonding, all in favor of finally ending the reign of traditional vehicles. The rhetoric coming from brand & reputation is very easy to overcome face-to-face... an aspect lacking greatly on forums. Anywho, I posted this and got several likes from it as a result: Yesterday, I was on a closed track.... chasing a Tesla P85+ with a Volt. It was quite amusing. There's no contest that Volt delivers more EV power and better handling, an upgrade to Prius without debate, but it doesn't hold a candle to the Tesla. Audience has always been the primary issue. Toyota aimed squarely at middle-market, those buyers who were looking for something reliable, affordable, practical, and comfortable. GM didn't; instead, their target was enthusiasts. There would be nothing at all wrong with that if there was also a choice offered for their everyday customers. So, we ended up with an unbalanced choice which fits some people really well. Just not something for the masses. The tax-credit makes Volt a bargain right now. If the tradeoff is a nice fit for you, go for it. Remember, some purchase decisions carry emotional weight. So, choosing doesn't have to totally be a factor of looking good on paper. There are of course considerations like resale value to keep in mind, since the market for plug-in vehicles is rapidly evolving. Some regret may come in a year or so when the next generation is revealed. These are definitely interesting times.

5-18-2014 **Final Fling.** Feeling pressure from both Prius & Volt supporters fed up with the misrepresentation, his greenwashing effort moved to comments posted on random hybrid & plug-in articles. Today, I found this: "*The PIP has an all electric range of 6 miles. Look closely at the EPA sticker. The 11 mile rating involves using gas unless you keep it under regular highway speeds and off hills....*" It was the same nonsense from the same person. He was seeking out a new audience. So, I took advantage of the opportunity by refining my response: Only pointing out the parts of the EPA sticker you want people to notice is called cherry-picking. Looking at the rest of the EPA sticker information, we see that the gas consumption rate is 0.2 gal/100 miles. That means over those 11 miles of travel, only 0.022 gallons of gas will actually be consumed. A car delivering 35 MPG would consume 0.260 gallons over the same distance. In other words, PIP is using less than 1/10th the amount of gas when combined with electricity. That's a dramatic reduction, which is the point of a plug-in hybrid. The other bit of information on the EPA sticker is the electricity consumption rate of 29 kWh/100 miles. That means 3.19 kWh is required to travel 11 miles. Knowing that PIP utilizes 67% of the capacity available from its 4.4 kWh battery-pack, we can easily account for 10 miles. Then when you acknowledge that gas engine always directs 28% of its energy to the generator for combined (blending) optimization, we see more electricity being available... even without considering energy recovered from brake regeneration. As for the "*highway speeds*" and "*hills*" references, we know those were intentionally vague. No matter how many times detail has been provided, you avoid it anyway. Well guess what, I'm pointing that out and mentioning that hill climbing at 55 mph in EV mode is quite realistic. I routinely do it with my PIP on the commute home from work. Again, since PIP is a plug-in hybrid, avoiding use of the engine under all conditions doesn't make sense. The system still draws plug-supplied electricity even when the engine runs. The result is MPG well above what any non-plug hybrid can deliver, which is the reason for increasing capacity and adding a plug.

5-20-2014 **Semi-Conductor Improvements.** Efficiency improvement is more often focused on the battery's density. The more energy you can fit into the pack without physically increasing its size, the further you can travel using electricity... which is an obvious benefit for plug-in hybrids. There are some refinements to the traction-motor itself, but that is minor in comparison to what things like improved battery-chemistry has to offer. An aspect pretty much overlooked entirely is the circuitry. There are losses caused by the transmission & utilization of the electricity itself. With computers, we see efficiency improvement in the way of smaller & faster processors. Toyota is working toward that with future versions of their hybrids too. But even more of a problem, primarily due to the larger quantity of electricity, is loss in the form of heat. That comes from the design of the power semiconductors. Today, we got a mini-presentation showing their pursuit of silicon carbide, which could dramatically reduce component size to reduce energy loss. It's something to look forward too. But like with all new technologies, even once proven viable, it still takes many years to actually implement. In other words, don't expect it with the next generation of Prius. Even so, it still provides hope in an avenue pretty much entirely unknown. Pursuing that type of improvement opportunity is great.

- 5-21-2014** **Change.** The rhetoric has virtually vanished. Volt is what stirred the pot, boasting it would be a "*game changer*". When that hope fell apart to an extreme, we had to deal with the fallout. Many of the troublemakers leased, rather than purchasing. As those leases expire, they are finding no affordable option other than to just move on to something else. Expecting to consider Volt again, later on when the next generation becomes available, it's easy enough to silently disappear. So, they are. GM over-promised and under-delivered. They didn't believe it could happen. Toyota did. That's why they approached the market that way. Those of use who participated online and owned Prius many years ago recognized the pattern too. This effort was repeating the Two-Mode was a disaster. More and more are seeing that now. There's no need to place blame or feel sorry either. It is what it is. True, much of that could have been prevented. But there's nothing to do about that past now. It (thankfully) is over. Change has come. What a relief. Phew!
- 5-22-2014** **70-100 Category.** With every plug-in argument imaginable coming from Volt enthusiasts having been beaten to death countless times already, it's no surprise that something entirely new emerged. After all, so many have chosen to ignore the rhetoric, it was pointless rehashing any of it... though they certainly tried to stir up no interest on those disproven topics. Anywho, we got the claim that the "*70 to 100 mile*" category is what Volt was designed to compete with, that all along buyers of that range EV were the target. Spin of that nature certainly wasn't expected. But then again, that was way the "*Who?*" question was asked so frequently. Of course, it came from someone who hadn't participated in anything related to Volt until after rollout began. So, anytime history is brought up, it's his interpretation of the past looking back rather than an account of having actually witnessed it. That's prone to distortion. In this case, it was the belief that such a category existed all along. He can have credit for coming up with something original, but that certainly isn't what actually happened. Awareness of heater impact didn't take hold until well after sales began. Awareness of cost certainly wasn't a factor of capacity until shortly before sales began. There wasn't anything delivering 200 miles either, until Tesla came along well afterward. To claim that such a grouping of EV range existed way back in 2007 achieves what? Why are there even any attempts to change history at this point? Needless to say, I'm not going for that bait. What does it matter anyway? Sales are what measures success in the end, not categories.
- 5-22-2014** **eAssist Abandoned.** This second-generation design of BAS didn't work out either. It was supposed to be a low-cost mild hybrid. The catch was, the cost ended up too high and the benefit only minor. All that hype ended up being a complete waste. GM has decided to just deliver start-stop now instead... the very technology automakers boasted about being superior to Prius 13 years ago. It's nothing but an system that turns the engine off, then back on, when you're stuck in stop & slow traffic. So if you're driving along at a steady pace, there's no efficiency improvement. No mention has been made about the impact to emissions. It's quite unlikely that the system spins the engine up to idle speeds, then waits until oil-pressure is established prior to introducing fuel & spark. Neither the starter-motor nor the battery could be big enough for that. There isn't a traction-motor to provide propulsion power in the meantime either. But it's still better to abandon eAssist, rather than further deploy a technology with no potential for improvement. At least start-stop is cheap, easy to deploy across the fleet, and will save some fuel for those in lines at drive-thrus and waiting on highway ramps.

5-23-2014 **Summing It Up.** The only audience left for Volt at this point seems to be the big Prius forum. The news has dried up. We really are moving on. Hooray! The catch is, a few still don't get it. They still believe heavy dependency on EV without concern for the electricity consumption itself or cost of the battery-pack is perfectly fine. The rest of us see it this way: *"Volt transaxle is a step backward. It reduces both gas and electricity efficiency in attempt to increase EV ratio. The big non-sense MPG displayed in-car got people greenwashed, creating an illusion that it is more efficient due to higher MPG and using less gas."* The intent never has been to do anything other than point out priorities. But you know how it is when there are a few who would rather go down fighting than admit having to reconsider choices. Oh well. To that, I say: The selling points for Volt have been *"EV at all speeds"* and MPG that's *"vastly superior"*. So, it's rather ironic that those are actually both gas & electric efficiency sacrifices. The mindset of faster & higher being better is a marketing problem we'll likely have to deal with for many years to come. People don't recognize the benefits of blending. They see MPGe values and simply dismiss them due to lack of understanding what they actually represent. Greenwashing has been a very effective tool in the past. People pass along and contribute to the misleading without even realizing what they took part in. The effort feeds upon itself, leading us down a path we assume is better without taking the time to verify whether it actually is. That step backward will eventually reveal itself as a shortcoming. The cost aspect of it is already starting to become apparent. In the meantime, we have to find a way of dealing with the illusion.

5-26-2014 **Backward.** However the market should be considered or what people have to say, time marches on. The hostile attacks are long gone. The seemingly endless debates over. Sales have revealed the true nature of emission & efficiency efforts. Traditional vehicles continue to mount a massive offensive. What's done is done. Those who are comfortable embracing the past far outnumber those hoping for progress forward. It's a sad reality. Fortunately, the technology employing batteries & motors continues to improve. So whether or not there's wide acceptance yet, at least the solution itself becomes more and more competitive. Those days of Volt propaganda draw lots of attention from ordinary consumers. That backfired though, since not much became of it. They saw the price and the compact size, then dismissed it the same way enthusiasts had dismissed Prius. It's a cruel irony. The outcome is a step backward too. Now traditional vehicles have an even stronger foothold. It's that *"too little, too slowly"* which never goes away... returning us to the backward design. Sacrifices were made with the hope of rapid advancement. That didn't happen. Not wanting to get sucked into that mess becomes increasingly clear each time the same old talking points are repeated. So, what's next?

- 5-22-2014** **70-100 Category.** With every plug-in argument imaginable coming from Volt enthusiasts having been beaten to death countless times already, it's no surprise that something entirely new emerged. So, what's next?

5-30-2014 Soapbox. The fall of Volt has provided lots of opportunity on the soapbox. It's quite remarkable how the audience changes with hype turns into reality shock. Most of those who didn't heed the warnings vanish, leaving the few stubborn ones left rather desperate. I posted this on that thread where the trolling has been quite active lately: Some people take failing to meet goals harder than others. Watching the movement of goal-posts for Volt over the past few years has been quite intriguing. The shortcomings we pointed out back then have since been confirmed. Ending the reign of traditional vehicles took much more than they wanted to recognize. We all know Toyota stayed true to that need to deliver a clean high-efficiency vehicle for the masses. That has always meant it must be reliable, practical, and affordable. GM did a fairly decent job of addressing that first requirement but neglected the two in the process. So, we've had to deal with the fallout and delay until the next generation. In the meantime, Toyota continues to refine Prius, which continues to sell at mainstream volume. We know the next generation will get an engine with improved thermal efficiency, retaining its advantage over their non-hybrid offerings. We also know a great deal of effort is being expended to deliver better batteries. The hybrid system itself will get upgrades as well. So what if they are also pursuing fuel-cell technology at the same time or not investing heavily in EV-only vehicles. The point is to keep delivering choices people will actually purchase in large quantity today, since that's what really changes the market... not something that will eventually become competitive. Think about the millions upon millions of cells being produced for battery-packs from those hybrids. That's what really makes a difference. The plug-in model won't need to wait until a next generation either. When demand for plugging increases, they already a well-established vehicle to leverage advantage from. It's basically just a package upgrade with easy to understand benefits. Those of us already driving them are providing reliability data too. I'm thankful most of the rhetoric, but will be glad when all of it is just a memory. Some people take longer. At least there's plenty of evidence showing what needs are not being met. Watch the reaction to sales results of the month concluding today. The harsh reality of goals not being met will be quite clear.

6-01-2014 When To Charge? I'm really enjoying the PHV discussion lately. I joined in with: Allowing the battery to rest (known as a "*cold soak*") prior to recharging is helpful. Since evening electricity rates are lower anyway, that's a win-win situation. The timer makes that quite convenient too. Just hit the button and plug in before you leave the car for the evening. As for running it down to "*empty*", the system prevents the battery-pack from hitting the common lows you see in portable devices. The assumption that 0% is fully depleted is quite common. What actually happens is the engine fires up, switching from EV to HV mode automatically, when the charge-level drops to 23.5%. That helps with longevity. Another approach to slow the aging process is never fully recharging. The system automatically stops at 85%. Staying well away from 100% capacity is known to be quite beneficial, something we don't take a second thought about with other rechargeable devices. Not allowing that with Prius is how the design avoids ever needing battery replacement. With respect to system "*switching back & forth*", that type of HV energy activity is just shallow touching of the battery-pack. Being just a tiny fraction of the electricity transfer during plug-in recharging and sustained EV draw, you can still have a big influence. You can choose when to recharge and push the EV/HV button. Thanks for starting this thread. It's nice to see some back-to-the-basic questions being asked.

- 6-01-2014** **Full Charge.** What a change. The fallout of "*more EV*" is getting interesting. When the belief was that Volt had more to offer, attention to detail about Prius was difficult to maintain. The enthusiasts simply drown out man of the discussions. But as they quiet, we finally get an opportunity. Today, there was a new thread about the "*full*" indicator for PHV. Some new owners totally overlook the difference between full EV and full HV. They assume there's only just one representation for battery-capacity. I was happy to provide samples of each. It's nice having a collection of photos readily available to share online. This is what I included as a description for them: Even though the bottom one appears to displaying a high charge-level, it really isn't. In fact, there's less electricity available. Notice the horizontal lines and the lack of an EV mile estimate? If Toyota hadn't done that, the battery gauge would be worthless during HV driving, since it would appear totally empty. The original plug-in model did exactly that. It was overwhelmingly suggested to provide a multi-appearance design like this instead. That way, you know when both EV and HV modes are high & low for their respective capacities.
- 6-02-2014** **Carbon Emissions.** It's about time. We got federal weigh in on the long fought against need to reduce carbon emissions. Like with rhetoric in the past, fear continues to be spread that jobs will be lost as a result of need standards & regulations. In reality, new jobs will be created. But past examples of that being true are simply ignored. I personally found the timing amusing. Yesterday was the 5-year anniversary of GM having officially declared bankruptcy. Executives claimed it would not be a bailout, that no money would be lost as a result of the restructure. Not only was that far from what actually happened, it also ended up revealing a troubling past which carried over to the new GM. They again are facing uncertainty with the future. But now, many industries are impacted, not just automotive. Our dependency on non-renewable fuel that's polluting our air with both breathing-related and climate-altering problems for our children to deal with isn't comforting. Think about how long of a delay there will be between intent and actual implementation. We'll be generating electricity with dirty coal and producing traditional guzzlers for many years to come. It's quite disturbing, especially when people resist change simply from the fear of it. Thank goodness we have a large fleet of Prius helping to prove change isn't that big of a deal.

6-03-2014 **May Sales.** It has been a waste of time pointing out that Volt sales have been flat for a very long time. Even the \$5,000 price drop didn't make any difference. There was an initial spike for the intended inventory reduction, then it went right back to the 1,600 to 1,700 per month level it had been selling at prior to that. No growth is real the problem... a point which last month's sales made especially clear. Everyone assumed PHV would plummet due to the HOV stickers no longer being available; instead, they skyrocketed. 2,692 for the plug-in model Prius was so many more than Volt's 1,684 that it wasn't worth the effort to discuss. The thought is that Toyota offered generous incentives, which make sense when trying to proactively avoid model-year inventory surplus. That begs the question of what will happen with ELR. Only 52 were purchased and production continued as scheduled anyway. The supply estimate now puts it at 903 days. Falling well short of the anticipated 200 per month hurts. But to make matters even worse, roughly 80% of the purchases came from Volt owners. The situation is nuts. Thankfully, the regular model Prius is maintaining a rate of triple that of the mainstream minimum. 15,944 is a solid number. The smaller C model is creeping up. Sales were 4,590. Achieving the 5,000 per-month mark is becoming quite realistic. V is climbing too, but lower at 3,567 for the month. It was nice to see Camry-Hybrid at 5,199 and Fusion-Hybrid at 4,641. Considering the strong growth in the overall market, that's important. Traditional cars continue to mount quite an offensive... something the Volt enthusiasts shrugged off as a non-issue, an effort to undermine. Clearly, they were wrong... very wrong. Providing hope though was Leaf sales, at an impressive at 3,117. Realistically though, the market isn't ready for plugging. Far too many misconceptions combined with cost barriers keep impair progress. That's why the one-size-fits-all GM strategy was always such a concern. The gamble was a risk that failed to deliver. Now the consequences are evident. Next year certainly will be interesting. In the meantime, I'm looking forward to answering questions and collecting data for those curious about PHV. The endorsement it provides for mainstream acceptance of lithium batteries and plug simplicity is great.

6-03-2014 **Cargo Capacity.** It was quite amusing to exploit the large interior of the Prius today. We ordered an 11-foot offset umbrella for the backyard. It came in a box, 75 pounds and just a little over 9 feet long. I was prepared to do my first ever drive with the hatch open. That would have been interesting, especially on such a pleasant evening. I haven't done that since the early 90's, back when I owned a '84 Dodge Omni. That old car taught me the value of having a hatch. It was very handy, especially in college. But that design then was rather a pain. It didn't having a flat floor. You had to lower & lift cargo in over a ledge. That limited what you could carry, since the interior wasn't flush with the seats. Coincidentally, that's the way Volt is configured. Talking about an outdated approach. Anywho, the flat in Prius made loading the large box a breeze. It just slid right in... so deep, I could almost shut the hatch. Hmm? Curious, I lifted the box's edge onto the front dashboard. Sure enough, the Prius swallowed it up entirely. Cool. I was thrilled how convenient it turned out to be. Both long & heavy isn't a combination many cars could actually handle. For that matter, I wonder what the heck you'd do to transport it a bigger vehicle. Lowering the front seat like I did in the Prius, to match up with the cargo area isn't possible. That wouldn't work with a SUV either. Interesting, eh?

6-04-2014 Battery Temperature Data. The warm weather has stirred interest in battery temperature data. Not having it has left an opening for undermining attacks. A rather blatant troll has been claiming during both recharging and driving, Prius will suffer... since it only using air for cooling, rather than liquid like his Volt. To us, that clearly isn't a problem or even an exposure. Toyota took that need to keep battery temperature in check all throughout the design process. Nothing was ever sacrificed. But since Leaf has been dealing with extreme examples (Arizona heat) and it only uses air to cool, supposedly the situation is the same. It clearly isn't. Prius obviously has an engine available to supplement & protect. But those few remaining Volt enthusiasts are quite desperate to impede success. This particular attack shouldn't last long. I'm well equipped for sharing this type of data. All I really need is some cooperative weather. As I play, my "what to look for" information will be refined. But the initial collection has already been quite helpful. This is what I posted today, along with the raw data I captured using the app on my phone and a bluetooth OBDII adaptor: I'll have a chance at some point to generate some graphs from the data. It should go a long way toward ending the FUD being spread due to lack of real-world data and such a wide variety of chemistry types available. In the meantime, I'll keep gathering. The other day on the drive home, it was 76°F out. I did hill climbing and a bit of 55 mph along the way, staying in EV for the entire capacity. The battery-pack temperature stayed just below the 100°F mark. I believe that is the normal operating expectation for continuous discharge of the type in Prius. We'll see what happens when it gets hotter out. But since most people simply use their A/C and the engine is there to protect the battery-pack, it's hardly a concern the rhetoric would lead us to believe.

6-04-2014 Real-World Data. Having it readily available is power. There's no way to stop the nonsense. The greenwashers will do everything they can to keep you from drawing conclusions. And without that real-world data, there isn't really much you can do. They'll just keep spinning whatever you post, twisting to the point of confusion. That's why I'm taking advantage of the weather finally turning nice to collect. Here's the latest contribution to the on-going effort: It's quickly becoming obvious that the claims of liquid-cooling is necessary for battery longevity were acts of desperation to undermine. Today it was 79°F on the drive home. The 12 consecutive miles of EV driving I did never pushed battery temperature above 100°F, without anything but open windows to provide cooling. The electric A/C is available and will be used when it gets hotter out while driving. That will make the air available for cooling even cooler. So, there's nothing they can argue. The A/C could even run as part of the recharging process. Toyota didn't find that necessary though. The chemistry chosen is proving worthy without the need for liquid. By the way, I can turn it on remotely from my phone now using Entune. It does a very nice job of cooling the interior. 10 minutes of running consumes roughly 0.2 kWh of electricity.

- 6-06-2014** **More Data Collected.** Continuing to post observations will go a long way toward keeping the rhetoric we are doing now from getting so out of hand ever again. Others will chime in with their own data, once they have an idea of what to look for... which is surprisingly easy with a Bluetooth adaptor and a Android phone. Too bad we weren't so well armed years ago. Oh well. We did what we could and have built upon it. Being part of such an effort is rewarding too. Newbies find the inner workings fascinating with that type of visual helping to explain the design. Anywho: I plugged in this afternoon at work. The Prius was already warm from having taken it for lunch, with the windows open to enjoy the fresh air. It sat windows shut in the parking lot as the surface-temperature climbed to 90°F while recharging. That was quite a bit warmer than my previous data collecting. I was excited about the opportunity that presented. The air-temperature was 86°F, just at the tolerable limit for driving without A/C use. I lowered all the windows and headed home. The temperature of the battery-pack stayed within the comfort-zone, despite being warmer outside. It peaked for EV at 100.2°F, which was right as the plug-supplied capacity ran out. While warming up in HV, the Prius was required to climb a hill at 55 mph. That pushed it to 101.5°F before dropping back down and staying down. I'd consider that a worthwhile sample for warm-weather driving. Any hotter and most of us would simply turn on the A/C instead, which drops the temperature of the intake-air quite a bit.
- 6-06-2014** **Joining the Debate.** Seeing issues as either/or is a big problem. That's why blending has been such a difficult approach to get some to embrace. Debates of substance are difficult under those conditions. Conclusions get draw quickly without considering all the possibilities. I finally joined in today. Some feel Toyota has abandoned the idea of plugging in, based upon the recent Lexus promotions. Relating television commercials and printed advertisements for selling current inventory to overall corporate strategy is stretch. Yet, that's what some are doing. They also see the situation now as never changing. Either it is this or it is not. Ugh. Oh well. Maybe my contribution to it will shed some light: "*Plug Not Required*" has been the message from Toyota for well over a decade. It sounds like those who claim "*plug-in bashing*" still aren't acknowledging the difference between a hybrid and a battery-only vehicle... which is no surprise, since we've already had to deal with quite a bit of intentional misrepresentation for Prius PHV. They go well out of their way to force EV comparisons on a vehicle designed to take advantage of having more than a single power source available. Ask yourself this... How is this any different than pointing out limitations of engine-only vehicles? The over-reaction has been quite a surprise. Some think Toyota has abandoned the idea of plugging in all together, just because they adjusted their schedule in accordance to the initial market reaction. Taking the time to refine the plug-in model while at the same time continue to push market penetration of hybrids should be recognized as logical step forward; instead, some see it as a failure. I look around and see almost no support for plugging in. The idea gets shot down within seconds, effortlessly dismissed. It's sad and quite disappointing, but at least Toyota has an approach designed to easily take advantage of increased electricity use... without dependency. People can bash that approach. But reality is, that's required to retain profitable high-volume sales. It's a business after all.

- 6-07-2014** **Change.** The recent discussion on the big Prius forum sure has been interesting lately. This what I interjected into it today: The so-called "*hate*" for Volt came about in large part due to misdirection. If you stated anything about the need for diversification or cost-reduction or not meeting their own sales goals, it was interpreted as an endorsement for Prius. Look up the old threads on forums & blogs other than here. The ones devoted to GM products were overwhelmingly anti-Prius. A thread would get created and discussion about Volt would ensue. When civil and constructive, very little interest stirred. Someone would inevitably interject some comment about Prius to ignite it. That increased posts dramatically. Hosts thrived on that kind of attention. It was unfortunate. I'd watch it happen time and time again, staying silent until the fire built up to an intolerable level. Then when I finally chimed in, I'd get blamed as a Prius owner for starting the mess, though it was easy to confirm I hadn't. And even when I didn't actually say anything about Prius, they would imply that's what I meant. Watching the denial was remarkable. Volt was suffering as a result of competition from within, yet enthusiasts would direct focus on Prius instead. They didn't care that GM's own production was squeezing the life out of Volt. The care was on bragging rights... which is why attempting to have a constructive discussion comparing the regular Prius to the plug-in model is so inviting to Volt enthusiasts. Fortunately, we have recently seen some Volt supporters turn on the enthusiasts. They see the business need is not being fulfilled by engineering praise. They want the next generation to actually be competitive. Are they also included in the hate? I've tried to point out the difference and the change with mixed reception. Change is difficult. This thread clearly shows it.
- 6-08-2014** **Shortest Drive.** I drove the Prius out of the garage to provide an area for setting up the bikes. When done, I drove it back in. A single car length is the shortest distance I've ever driven in one day. That's not enough to log. Our journey on the bikes was though. It was a beautiful Sunday afternoon. We rode just shy of 30 miles. Spring is in full swing now. It won't be long before the comfort will turn into cooking sun. Then, it will be kayaking... which require the use of a Prius. I'm looking forward to take. It sure is nice being able to throw kayaks on top or head out to a distant trail with bikes on back. But for today, that didn't happen. Travel was entirely human-powered... which I really enjoyed... though, I cannot recharge with electricity. For me, it requires pizza.
- 6-09-2014** **Senseless Waste.** I had some painting to do outside. It was a beautiful sunny day, there was only a calm breeze and the temperature was 70°F. That made the activity of my neighbor (actually 2 houses down), truly bizarre. Why in the world was she sitting in her idling diesel car talking on the phone? The clatter of the engine was annoying to me, all that distance away. I couldn't imagine what that sounded like over the phone. Already in her driveway, why the heck not shut off the engine? For that matter, why stay in the car on such a spectacular day? I was truly baffled... initially. 25 minutes later, I was well beyond annoyed. What a senseless waste! Who in their right mind would ever do such a thing? Diesel is currently \$3.89 per gallon here. Why consume it when you don't need to? Why intentionally pollute like that? It was very disappointing. That totally explains why her son would let his truck warm-up for 30 minutes (and sometimes longer) during the cold season. What a terrible influence on the younger generation. Now, I feel disgusted recalling the event. When the conversation ended, she hung up the phone, shut off the car, then went inside her house. Why would anyone do that?

6-09-2014 **Launch Spin.** Try as we might, information like this continues to fall on deaf ears: "*PiP was supposed to launch with Gen3...*" What do you do though? Those wanting to undermine will keep making up their own version of history. We keep trying to share what actually happened. Hopefully, some lurkers will be compelled to find out more: That information has been provided a number of times now. It hasn't done any good. The history just keeps getting spun and the belittlingly continues. Like I said, at least that serves as a gauge. Away from that nonsense, I'm enjoying my PiP. Today, it was a round-trip through the heart of rush-hour congestion territory. It was 19.5 miles each way. We escaped the meeting just prior to afternoon rush kicking it. Since I wasn't alone, I took advantage of the carpool lane. Rarely ever having reason to be in that area of the cities during that day of the time, why not try it? Long story short, there was a little bit of stop & slow followed by a nice highway cruise. Having started the trip with only 1.3 miles of EV available, it was almost entirely hybrid operation. I was delighted with the results... 60 MPG on the way there and 61 MPG on the way back. So for those who sincerely aren't aware of the potential the system offers, that's a nice real-world sample of what's possible even with very little plug-supplied electricity available. For those who continue to spin, mislead, and downplay, they can kiss my gas. As for the delay of PiP rollout, it should be clear why. The battery-cost & greenwashing should make that quite obvious. There are other barriers too. People simply have no background or basis of comparison available for making the purchase decision. That education takes time. Just look at how many assumptions continue to come out of the initial rollout states. To make matters more difficult, we even have some EV supporters working against acceptance, despite the fact that Prius can have a major influence on the advancement of plug-in batteries. Toyota really did their homework to deliver a system able to reach the masses. So what if we have to deal with a few sour grapes. Owners are pleased with their choice. They didn't have to sacrifice seating or room for large cargo. They still get fantastic efficiency even when the battery is depleted. They purchased a reliable hybrid with a plug. It's a winning formula for high-volume profitable sales. That upsets a few individuals, which is why we have to deal with their on-going banter.

6-09-2014 **Losing Market Share.** Always be suspicious when a published article doesn't actually include any numbers. All the one today provided was a vague graph, a claim that hybrid cars were losing market share, and this as the closing sentence: "*But the systems are expensive because of their complexity and costly batteries, and their highest costs are often passed on to buyers.*" The article was brief. The intent was to mislead & undermine. That was easy to prove too. All I needed to do was verify the supposed facts. I looked up the actual numbers. The scope of the article was overall sales for the United States over the past few years. For 2010, 2011, 2012, and 2013, the counts were: 11,588,783; 12,734,356; 14,439,684; 15,531,609. The upward trend of those totals is easy to see. The same is (for the most part) the case for hybrids: 274,763; 268,807; 434,498; 495,685. That's undeniable growth. Even if there was some misleading through statistics, that's a difficult argument no matter how you spin things. But it turns out, even the percentages themselves disproved the claim. 2.4%, 2.1%, 3.0%, 3.2%. So no matter how you look at it, hybrids clearly aren't losing market share. There's a clear gain... and that's with even bothering to add in the hybrids with plugs, which have been growing too. The desperation of some continues to be easy to stumble across. No matter how slow change comes, there will always be some who deny & resist.

- 6-11-2014** **Interesting Times.** With Volt fading away into memory, an unfortunate chapter in history supporters want everyone to forget, we see forum & blog activity changing. We're all quite curious what happens next. Volt had stirred so much interest and resulted in so much disappointment, it's hard to imagine what 2015 will bring. Consumer reaction is very difficult to predict. Purchases are even more of a challenge. Basically, there's just plain no way to know. That's why sticking to principle is so important. That's boring though. Toyota gets ridiculed on a regular basis for holding true to keeping Prius practical & affordable. Enthusiasts find that far too much of a sacrifice, since they thrive on power & handling beyond what's actually needed. Mainstream consumers don't notice the effort, since there's little to draw attention. Fortunately, the masses place being practical & affordable high on their purchase priority list. The catch is, the vehicle must also be well proven. Being reliable is vital. The importance of that cannot be stressed enough. That's why Volt is now in such an awkward position. The next generation will hold little in resemblance. People will see the changes as an improved approach, cancelling out credibility of the current. After all, the forum & blog activity is making an effort quite evident to distance old & new. The first Volt had so many shortcomings, the less it can be related to the next plug-in hybrid the better... which is why these are interesting times. Remember Two-Mode? Most people don't.
- 6-12-2014** **Naive & Undermining, part 1.** There are times when patience & tolerance really pay off. Over the past few days, on the big Prius forum, we've been dealing with a blatant Volt troll. He has no audience anymore. The daily blog is dead and the big GM forum couldn't care less anymore. So, we end up with some of that fallout. The situation isn't always understood though. This was the conclusion expressed from one active participant: *"I had higher hopes for this forum than for some threads to degenerate into name-calling sessions."* He got sucked in, a victim without any awareness of the problem. I was intrigued. He took a fierce stance at one point, arguing intensely with me about how Prius worked. He was just plain wrong, not even close. But it was easy to see how his assumptions came about. Providing a video of the gauges showing operation as I drove along with an explanation of the components involved quickly changed his tuned. He happily retracted his erroneous claim. It was a nice, productive exchange... a wonderful result considering how heated it had become. Experiencing that, it's no surprise he was a bit baffled how that degeneration followed.

6-12-2014 Naive & Undermining, part 2. This was my response: When someone wanting to undermine gets caught and there are no more unknowing enablers available, posts turn to shooting the messenger. We've seen it countless times before. Those who didn't realize they were contributing to making the discussion counter-productive end up in a flood of mixed emotion. They had no idea what was happening as it was playing out. It all seemed so innocent. The rise was subtle. Later, they look back and realize it was an good example of being naive. There's an effort to stir the pot, to sour the thread, causing participants to go elsewhere... because that thread had taken such a turn. It becomes obvious if you follow forum activity as a whole over time. You can see the push-out pattern after awhile. But in that particular discussion, motive goes essentially unnoticed. Direct confrontation becomes a necessity at some point. Bringing up goals is an effective way of flushing out purpose, exposing intent. They evade by changing the topic, often in the form of an empty compliment. We saw that here when bringing up big picture strategy. Toyota has one, it's diverse & profitable. GM is still grabbing at straws, leaving us clueless what comes next. That's an uncomfortable position to be in. There is some good that comes out of these exchanges. You were unaware of how Prius operated, acknowledged the misunderstanding, then moved on. It worked out well. Lurkers likely really appreciated the detail that it took for that to happen too. We ended up with a gain, despite the effort to undermine. Participate on some other forums. They get downright hostile at times and will outright lie to protect their interests. It's really sad. We tend to be quite civil here in comparison.

6-12-2014 MPG Revisions. That look back at the big picture helps. Focusing exclusively on a specific vehicle is far too easy of a trap to fall into. It makes people defensive, since they tend to filter out considerations that would otherwise be a necessary consideration... like the need for profit. Engineering praise is great, but it doesn't pay the bills. That's why not drawing too much attention can be a good thing at times. Toyota gets grief for that. But staying out of the spotlight can be a very good thing at times. Ford's latest "oops" a perfect example. They heavily promoted (more like advertised to death) their outstanding MPG ratings. Turns out though, they weren't accurate. We know that well with C-Max. It hurt to find out efficiency wasn't as good as hoped. Today, we found out the Fusion & MKZ hybrids were also misrepresented. Those were inaccurate too. That means a revision to their official MPG estimates, including Energi (the plug-in model). Turns out, 4 models of Fiesta were overstated as well. Seeing that many MPG values go down after-the-fact is sad. Fusion hybrid got hit the hardest, watching the combined estimate go from 47 to 42. Both of the Energi offering now rate at 38 MPG combined. That's far from the hope of being hybrid following depletion. But then again, the 40 & 42 MPG combined ratings for C-Max & Fusion (respectively) aren't exactly competitive anyway. In fact, the 42 MPG combined from Prius V gives a whole new perspective on Ford's advertising campaign. They misled thousands of people, stating their hybrid delivered better efficiency. Turns out, it doesn't. Toyota was in the right all along. Now, Ford is having to apologize. Just imagine the potential discourse that could cause in online forums.

6-12-2014 *The Right Decision.* Seeing Ford take a big reputation hit for having embraced erroneous MPG figures rather than investigating why real-world results were so different makes you wonder. If anything, lack of clarity is misleading. They should have dug deeper into the problem far sooner. Know, it's much too late. They are trapped into a damage-control stance now. How will they recover? Comments like this are emerging: *"We are seeing Toyota made the right decision to make a plugin that they **should** instead of what they **could**. More EV miles does not mean better. A balanced design that gets the most out of both fuel is better, never mind when or not the gas engine fire up. There is a very good reason why looking at the results."* That's not a result Ford will like from any perspective. The values for C-Max Energi are now: 40 city, 36 highway, 38 combined. That's quite a bit lower than Prius PHV: 51 city, 49 highway, 50 combined. To make matters worse, the MPGe value dropped to 88. That's quite a bit lower than the 95 MPGe from Toyota's plug-in hybrid. And for those who doesn't understand the MPGe value, representing the overall energy consumption, there's the EV range. It got reduced from 21 to 19 miles. When we were discussing Toyota's wisdom of delay to avoid fallout, who knew it would be more than just from GM.

6-12-2014 *Fallout.* To no surprise, the problem with MPG for Ford stirred the pot: *"My Volt is rated at 38 mpg. I normally get 40 mpg or higher. The only time my mileage drops to 38 mpg is when I'm driving faster than 75 mph. I'm very pleasantly surprised. Ford could learn from GM's example of under promise, over deliver."* I remember the craziness that emerged from the original "230 MPG" campaign. People were all over the place with that. The well informed knew that was horribly misleading. The naive believed it was the long-awaited efficiency miracle the industry had been waiting for. But that was back in 2009, shortly after bankruptcy had been declared. There was much hope without any substance. Reality eventually set in. That's how the 50 MPG expectation came about. It became the realistic prospect. People believed it too... until the "Freedom Drive". Remember that 1776-mile trip ending on July 4, 2010? It was incredibly suspicious. GM said ordinary consumers could ask anything they wanted while the event was taking place. It was supposedly an educational opportunity, telling people all about how their upcoming plug-in vehicle could run on gas after electricity ran out. More and more kept asking the same question: What is the MPG at that point? GM absolutely refused to provide an answer. Why would they have led us to believe 50 MPG was being delivered, then not confirm it with such an event? It was the perfect endorsement opportunity, lost. Nonetheless, the die-hard supporters kept the dream alive anyway. Things didn't add up. Then the EPA results were revealed, just a few weeks prior to rollout. Seeing 37 MPG for that first-year model was horribly disappointing. There was an incredible feeling of disenchantment expressed online... which no one seemed to remember anymore. In fact, that quote expresses being pleased with an improved 38 MPG rating for the newer model, despite it still falling well short. That number didn't seem correct either. So, I looked it up. It's actually 37 MPG. I wonder why he'd claim 38. Strange. Anywho, the promise of 50 MPG never happened as far as supporters are concerned. In fact, hope of hybrid efficiency following depletion is flat-out denied. Don't you love how history changes as shortcomings are exposed? They spin things to appear positive, regardless of how bad the fallout become. Ugh.

6-13-2014 **More Is Better?** The assumption is getting questioned more and more. It reminds me of the "*not enough*" arguments when Prius first rolled out. Some claimed 50 MPG simply was not enough for anyone to care. Now, we're seeing the same with that magic 75 MPG from plugging in. The reality of diminishing returns has been so easily dismissed in the past. Antagonists insisted the capacity PHV offers is not enough. The claim more is better... even though the data doesn't actually support it. So naturally, there's a lot of discussion about what the next generation will bring. I added this to the online chatting: Toyota established the approach, keeping physical size small enough to prevent a large cargo-carrying capacity sacrifice while at the same time keeping it affordable. Lithium chemistry will improve, as will the software controlling usage & longevity. The result will be in a bump up range. It will fit Prius PHV well. That's how it will be able to penetrate deep into the mainstream. Whether or not Toyota will also offer some type of higher capacity choice is another topic. Successfully achieving high-volume sales with Prius PHV opens the door for that opportunity. Remember, we've seen that priority has been given to delivering a solution for the masses, rather than catering to a niche audience as with other automakers. Notice how important production-cost has been? There's no reason to believe that intent has changed. In fact, things like pursuing wireless recharging helps to confirm ordinary consumers are being targeted. My 73 MPG average is double the efficiency an equal-sized traditional automatic gas vehicle could deliver and quite a bit cleaner. How much more is really needed to achieve high-volume sales?

6-13-2014 **Prius Numbers.** On an automotive blog about the Ford MPG mess, a comment was posted that Toyota should now fix their numbers for Prius. I was a bit annoyed, since it was so horribly vague and provided no suggestion or detail whatsoever. Generic complaints without data doesn't help anyone. So, my response provided lots of data: I owned a 2010 and drove it for almost 3 years before replacing it with the 2012 PHV. That's 55,835 miles in Minnesota, the land of harsh winters. Despite that, the overall average delivered was exactly 50.0 MPG. Now at 42,356 miles with the plug-in model, I'm watching my overall average climb above 73 MPG. When I drive with the plug-supplied electricity totally depleted this time of year, I easily see 60 MPG for the trip. So, I'm not seeing any reason for an adjustment. And yes, the display shows an optimistic value. But all my numbers are from detailed spreadsheets, using calculations based on measurements taken at the pump & plug. Not including my current tank, these are my totals for the PHV: 40,971 miles, 563.149 gallons, 3,712.8 kWh. (Note that 3 kWh is the value used to represent a full-recharge, which includes both the usable capacity replenished as well as the losses incurred while charging.)

6-14-2014 **Balance.** That discussion continues. Getting people to look beyond just the efficiency of electric-drive is really difficult. Sadly, not considering infrastructure is part of our culture. A great example is with trash. Many think throwing it away is all that's necessary. They have no clue what actually happens to it later or how much waste that really amounts to. It being "away" is all they understand. So when it comes to electricity, the "*clean*" aspect is all they understand... since the consumption aspect is all they've ever considered. How that electricity is derived is often disregarded entirely. I added: The belief that "*more electricity is better*" will continue to be a challenge to deal with for years to come. People just assume that's true and don't give it another thought. They have no idea what emissions come from electricity creation or transmission. Some who do recognize smog-related emission simply state they've been reduced dramatically over the past few decades, thinking all is well now. Many still don't believe carbon emissions are any type of problem either. It's a greenwashed mess. Oddly, it is rather fortunate that traditional vehicles continue to advance. That engine-efficiency technology will pay off later. We're seeing that from Toyota already. Being able to take advantage of the engine by being able to run it briefly and at highly optimized rates makes the balance with electricity is what makes it better. The idea of sacrificing electricity for the sake of never starting the engine is a mindset that's counter-productive. It doesn't actually help us overcome all the problems we face. It only looks better when you choose not to consider the big picture. Balance is very important.

6-14-2014 **EPA Advertised MPG.** How many people still don't understand the numbers? It continues. I posted: People seem to forget that the so-called advertised MPG is not a promise, of any sort. The measurement was originally created to provide a standardized basis of comparison. It's actually just a number for rating, not an expectation. Reading the information provided on the window-sticker, you'll see there's a range stated, that the big number is really just an average. So, things like short trips are not necessarily accounted for. Efficiency will be much lower if driving just within the warm-up time. It will be lower in extreme temperatures and at very high-speeds too. There are also circumstances when efficiency is much higher, like suburb driving with few stops. To complicate matters, many new Prius owners have no idea what their previous vehicle actually delivered. There was no MPG display available, so the ups & downs were never known. Things like that contributed heavily to the slow growth of hybrids. Then EPA made adjustments to their measurement process, taking better into account the circumstances not originally considered when the standards were first established. Now, we're finding out the values themselves aren't being properly reported. Ugh.

- 6-14-2014 Super-Capacitors.** The idea of adding a super-capacitor to the hybrid system is getting attention again. This time it was from the Le Mans prototype Toyota is racing this year. The benefit is easy to understand: it provides power, a lot of it very fast. That's something batteries don't. They deliver power better than an engine, but at no where near the level possible with a super-capacitor. That gives reason for pause when considering the plug-in Prius. Having the engine fire up for brief high-demand events, like merging into fast traffic, wouldn't be necessary with a device able to supply that power. Those arguments about the small battery-pack would finally come to an end too. It was irritating having to deal with the lies about the engine being required for hill climbing, when that certainly isn't true. I routinely drive up out of the river valley at 55 mph without ever requiring any power other than that from the battery-pack. It's long and fairly steep. So, that need is clearly covered. A hard acceleration into a busy road will fire up the engine though. But then again, that's an excellent use of the power-sources currently available. Adding a super-capacitor into the system changes the equation... a design approach few have considered up to this point. It could be less expensive than adding more battery-capacity too. Due to its solid-state design, it's much more robust option. So, there's potential to explore... which is exactly what this prototype being raced is doing.
- 6-15-2014 Outstanding Efficiency.** 57 MPG. 123 miles. 0 kWh. That was the result of running around today, many Father's Day destinations and no opportunity to plug in. HV efficiency is outstanding. You can unmatched hybrid performance when the battery-pack is depleted. What else can be said. The system delivers regardless of how you use it. Sweet!
- 6-16-2014 Speculation.** There is a very, very, very long thread on the big Prius forum discussing people's thoughts on what the next generation of Prius will bring, and when. Realistically, we have no real idea of what to expect... since the market is always changing. Fortunately, most of the chance is for the better. The latest to stir the post was that mention of super-capacitor use. There's potential some are quite curious about. I know Toyota will deliver a nice upgrade, even if our guesses aren't correct. At least what we do know is they'll stay true to goals. That important of reducing emissions & consumption without compromise to other purchase-priorities has been the ultimate goal since the very beginning. Planning ahead has been too. I pointed that out with: That brief high-discharge [from a super-capacitor] ability would allow PIP gain the ability to exploit the unused capacity of the traction motor. It's rated at 60 kW. The current battery-pack delivers 38 kW. In other words, there would be increased opportunity to take advantage of the electric system already in place. You could get more power without starting up the engine. That would raise the bar for what the plug-in model delivers.

- 6-17-2014** **Desperation.** I still remember a post from well over a decade ago. You simply cannot ever forget one titled: *"Die Hybrid Die"*. The moderator quickly took it down. But in that brief time it was up, the poster was ranting about some senseless pointless babble that didn't actually mean anything. He was just plain angry and wanted to vent. That's what I feel is happening again here. But now with internet etiquette, there's an effort to at least appear to be civil: *"But when you get into PHEV's, such as the PiP, those numbers ignore electric costs and are therefore BO GUS. You can not compare "Blending" numbers on Fuelly. It doesn't track blending amounts."* His loathe for Prius is quite obvious. A mix of electricity & gas isn't suppose to deliver such competitive results. The plug-in Prius defies what he was taught to believe. So, he's taking out his feeling on us. It's coming out as desperation. I'm growing very curious how it will play out too. In fact, the time has probably come to take action. For the moment, I'm posting this: The numbers are genuine. You cannot just dismiss what you don't like. True, they don't represent cost-per-mile, since electricity isn't included. But when people simply want to know what a large quantity of owners have been seeing for gas consumption, the numbers are quite real. The purpose of Prius PHV is to reduce gas consumption. That's exactly what it does, in a clean manner without compromising affordability or practicality.
- 6-17-2014** **Playing Offense, time.** It finally arrived. When the troll gets so bad nothing else can be done, there is still an option. That belief of ignoring is the best choice really isn't at that point. He or she will continue to drop bait and sucker some innocent lurker to participate. In the meantime, their influence continue. Others will read the posts have no idea their intent is to undermine. You know when to make the move. It's when they outright taunt you in clear disregard of being exposed as a troll. They crave the endless debates. It gives them a thrill and provides interactive entertainment. I've dealt with that in the past. The well known is the *"up to the chore"* thread. It lasted 2.5 years. There were a number of us fighting to prove hybrids were. But rather than the expected outcome, we went for a stalemate. It forced the moderator to eventually declare hybrids were... then hide the thread. Removing access to it was the ultimate win. All that senseless rhetoric achieved nothing for traditional vehicles but provided a valuable opportunity to shake out argument points. Each time they tried something new, we found evidence to prove the claim was false. That worked great. This situation with *"another prius vs prius plug in thread but i badly need your advice"* appears to be coming to the very same end. We gleaned a bunch of points from an absolute desperate Volt owner... yup, the same one who months ago started by outright lying about how Prius operated with *"redline"* claims. Reading his posts on the forum dedicated to Volt made intent obvious. It even upset some of the Volt supporters, who ended up fighting back. But there on the big Prius forum, those allies weren't able to deal with it. Some of that simply came from lack of data... a resource I have in abundance. So, I stated my intention. Rather than being forced into a position to defend, I was about to launch an offensive.

6-17-2014 **Playing Offense, armed.** I hit hard, well armed with data to support whatever he had to counter, responding directly to this taunt: "*Are you still fuming about the directions this thread as coursed through? Enlighten us, please!*" The gloves were off. But little did he know or even try to understand, my goal was never to disprove Volt superiority. No matter how often I pointed out business need and having no interest in trophies, he was too pig-headed to recognize that. It was a weakness of most enthusiasts I was going to exploit. They assume your goal is to prove Prius PHV is superior. I couldn't care less, since no mainstream car has ever really aspired for that. Balance is quite different. Anywho, this was my response: Fuming from blatant undermining? Such obvious trolling isn't worth much to respond. You've may a valiant effort to belittle & insult the plug-in Prius and still have no victory to show for it. There's nothing to defend. The system works quite well. The need is fulfilled. However, this nonsense is an invitation to play offense. So, I will. We've been through this many times in the past. Over the years, it's been intriguing to see the lengths some would go to. A few got very desperate. But in the end, they gave up. They didn't want to acknowledge requirements or even state goals. Finally coming to realize the true competition is traditional vehicles can is a humbling experience. The most recent attack on PHV has been to claim liquid cooling is necessary. No evidence was provided. Heck, we didn't even get any data. It was just an empty statement. I got to do some more testing, in hotter weather pushing the EV system further. The temperature of the battery-pack remained the same, right at the comfort level of 100°F. There's nothing that has been presented to show concern about being able to keep it operating cool with just air. It's a scare attempt falling on deaf ears. Then there's the other superiority claim of electricity usage. Even though there's data showing PHV is more efficient than others, the obscure reference to needing some electricity to hold the sun (MG1) power carrier in place keeps getting brought up. So what? The tiny amount of electricity needed is accounted for in the total consumption stated, which is still lower. Yet, with another plug-in, there's never any mention of the complexity used instead, having to utilize a clutch to allow the system to carry around a gas engine it goes out of it's way to avoid using. What about that waste? There's no reason to have to deal with the obvious rants of a few anymore. The plug-in Prius is proving it's design & approach is capable of taking on the true competition. It would be great if others could do the same. But that's no reason for continuing to put it on the defensive without supporting data. It's pointless baiting. Give it up.

6-18-2014 **Playing Offense, panic.** It took until the next morning to get a reply back. But rather than be a rebuttal, he changed argument points entirely. Obviously, nothing he already tried was working. It was a clear sign of panic. My preparation was undeniable. With so many Prius owners contributing value information and sharing their observations, my summary of the situation hurt. That stance change made it unambiguously known that I wasn't going to take it any more. With so much real-world data collected to back all that had been said by so many already, he didn't stand a chance. Hooray! Wasting so much time & effort on a person who continued to put taunts at the end of his posts challenging his claims just plain wasn't worth it. The tables were turned. I struck with this: The push now is Cost-per-Mile, but the value used for the calculation is price paid rather than the actual cost to produce. That business model is unsustainable. A vehicle must be able to make a profit without dependency on tax-credit aid. Then there's the blatant disregard for actual consumption. Stating a range of 6-11 miles is a obvious dodge to avoid acknowledgement of the capacity available. The electricity is still taken full advantage of, even when the engine runs. Prius PHV clearly can hold its own in the competitive world of traditional vehicle sales.

6-18-2014 **Playing Offense, victory.** The conclusion came dramatically quick. Within an hour, the thread was gone. That hoped for "*it's over*" had become a reality. He lost his soapbox. His posts well off-topic would no longer have to be tolerated. None of the past would either. In an instant, all that nonsense vanished from readers. The content was removed. Yeah! There were over 50 pages spanning over a month. The original poster had left long ago. It turned into a place for undermining Prius. The moderators saw the revolt (pun intended) taking place and wanted it to quickly end. Trolls will always be a problem. But when matters are escalated to what would inevitably become a slaughter, the final step must be taken. In other words, he outed himself. Basically, the switch from us having to defend to choosing to play offense forced him to confront directly... something he hadn't anticipated and unmistakably wasn't prepared for. Seeing that his purpose was not innocent, that he really was attempting to greenwash, made the decision to end easy. That attention combined with the absence of the ill-intended posts can actually have a positive outcome. It presents an opportunity to change without getting kicked off the forum or even having to apologize. It's a second chance. That is usually quite effective. Many take it as a lesson-learned and move on. I can name a number of individuals who changed after recognizing their understanding was based on incorrect beliefs. True, it rarely ever comes to this extreme. But at least there's hope. You really wouldn't want an enemy forever. After all, the technology advances over time anyway. That gives everyone a prospect for a better future. It's just those few who don't take defeat well that we have to deal with in the meantime. They don't want to accept failure... even though that has no indication of whether or not the next attempt will be a success. Toyota understood their audience and recognized need. Goals were set accordingly. GM did a terrible job of identifying who and embarrassed the business with struggling sales... which explains why certain individuals had such a resentment for Prius.

6-18-2014 **Playing Offense, fallout.** Looking back, it's easy to see how some people won't believe any of this ever actually happened. We've seen it before. Two-Mode continues to be a great example too. It was long hyped as being far superior. But then when it was finally rolled out, the "*over promise, under deliver*" problem became all too real. It was quite apparent right away there were a number of shortcomings, many significant. It wasn't a matter of refinements to come, like with Prius. The next generation would have to be a major redesign. So naturally, the choice by a few was to belittle the hybrid that continued to persevere rather than address the problem and set goals accordingly. Fortunately, the choice by the majority was to simply move on. That makes introduction of what comes easier, since there's nothing related to the fallout of the past. Unfortunately, that disassociation means pretty much starting all over again with respect to product marketing. At least that turning point is no longer just a pattern change recognized by those paying close attention. Penetration of plug-in vehicles into the mainstream will proceed. It will be slow going. But the closer the match to consumer purchase priorities, the better chance the vehicle has of becoming common... which is the point... not a trophy. It was rather satisfying to see it come to a close so dramatically. With all the agonizing torment of misleading that never seemed to end, suddenly we find ourselves with a moment of relief. The persistence with a big push to finish worked out really well. Yeah!

6-18-2014 **More Data.** It had been specifically asked for me to observe temperatures of the battery while recharging was taking place. That was an attack point we hadn't been prepared for. Now that the attack is over and the thread dead, it's providing a great opportunity to present & discuss. Hopefully, I get more collection chances soon. But with the crazy rainy weather we've been dealing with, hot & clear days have been rare. Fortunately, today was one. So, I took full advantage of it. That's exciting. Few owners have actually made those observations firsthand. It's so new to us and there's lots to discover & analyze still. I'm getting my nerd on! Here's more: I got that data today. The Prius sat out in the parking lot from morning through lunch, with the hatch facing the sun. The surface temperature was 81°F. The air-intake was 90.7°F. The bank temperatures for the battery-pack started at 90.9°F, 91.7°F, 90.3°F. 1 hour 10 seconds later, 2.235 kWh of power had been used for recharging and the current rate was 2.257 kW. At that moment, the air-intake was 98.7°F and the bank temperatures for the battery-pack were 94.6°F, 94.8°F, 94.8°F.

- 6-19-2014** **Charts.** Several were provided in response to my data. I pointed out: I always park facing the sun, having the front windshield taking the brunt of the hot shine. I also always leave the shade in the cargo area extended to fully cover the hatch area. I leave the Prius in the shade until right before plugging in too. The sun here in Minnesota is less direct than in Arizona as well. So basically, solar exposure in back can be minimized... a point often not taken into account. Yesterday's data collection was an intentional act of leaving the Prius out in the sun and parking with the hatch facing the sun, though the cargo shade was extended. The high temperature during recharging was only 35°C (95°F), a value low on the charts provided. How many owners will recharge during the hottest time of the day anyway? And I do take issue with those charts. That supposed "*significant impact*" glosses over the reality that temperatures are not hot year-round. In fact, here, we only see the potential for temperatures above 25°C (77°F) just 4 months out of the year. That means the battery stays very comfortable for the other 8 months. There's also the fact of SOC level not being addressed. Those charts, from 2006 & 2008, don't make any mention of that. Back then, 100% capacity was the norm. The battery was always recharged entirely. That was years ago. We've learned since then that avoiding 100% is a good practice for battery longevity. Prius stops at 85% for that very reason.
- 6-19-2014** **Significant Impact.** When pushed for clarification & detail, those overly-dramatic naysayers tend to back down. It usually takes more effort to achieve that outcome though. This time, it was surprisingly easy. We got this later in the day: "*I'm just saying that cabin temperatures that feel hot to humans are likely contributing to somewhat faster battery aging in the PiP battery and should be minimized or avoided when it's not too much effort. Just basic common sense.*" Getting several posts from others all finding shortcomings in the charts provided and nothing to explain where most of the numbers came from, not to mention the obvious generalizations, he chose wisely. After seeing the recent all-out assault, being ready for online battle was likely still quite fresh on his mind. I find it very amusing. We went from one extreme to another within just a single day. Gotta like that.
- 6-21-2014** **GM Disaster.** Things did not work out well for Volt. We know all about that mess. But when the trouble spreads, then what? ELR is getting attention from lack of sales. Seeing an article in a popular national publication with this title, "*Cadillac Bombs on ELR Plug-In Luxury Coupe Sales*", there's not much to say. There certainly wasn't any surprise on the big GM forum. So far, the count for that one recall alone is 2.9 million. As of the end of last week, there were only 199,457 vehicles actually serviced. The time & expense is mind-boggling. It's a disaster on a scale unimaginable. How does reputation get repaired after something like this? What will they focus on? There must be some type of "*look forward*" campaign to move beyond the present. But with an automaker not offering anything but traditional vehicles and plug-in heavily dependent upon tax-credits, who's going to be interested? It's that audience problem again. To think of how much anti-advancement crap we had to deal with. The push-button start was routinely mocked. Ironically, eliminating the traditional key start is exactly what's needed. Though hypocritical, that would be a good next step. Status quo is most definitely not acceptable anymore.

6-24-2014 **Brisk Acceleration.** We've been having a problem lately with a Prius PHV owner. He has absolutely no idea how the hybrid system actually works, yet argues with people attempting to correct his assumptions. That push away from facts is troubling. Some people believe he knows what he's talking about. It's unintentional greenwashing. Odds are he got some of what he thinks that way. Misinformation is easy to spread too. His particular comment today about needing to accelerate slow enough to upset the people behind him got me upset. That assumption of slower being more efficient is a common one. It's relatively easy to rebut too... with a regular Prius. Having the plug-in model makes that observation more difficult... and he refuses to purchase an aftermarket gauge to see what we're been saying. This was my attempt to deal with that: Brisk is easy to explain. Owner commonly make the assumption that using the gas engine means an efficiency penalty. They are unaware that it runs in an optimized manner, taking advantage of having a power-split-device interacting to 2 electric motors and a battery. Accelerating with generous pedal will often result in a lot of electricity being generated on-the-fly, the result of the gas engine settling in on a RPM with minimal waste. Some of that electricity is consumed immediately for propulsion power and some goes to recharging the battery. The operation is quite dynamic. In other words, the overall MPG is what to consider, not the acceleration itself. Far too often, owners see the power-bar spike and believe that is a bad thing. The design reveals it typically is not.

6-24-2014 **Back On Track.** It's been a heck of a struggle finding a way to capture & share a large quantity of video data. Seeing the system in action is a powerful learning tool. Conveying so much information without misunderstanding is quite a challenge any other way. But attempting to film a smart-phone while driving doesn't work so well, even under the best of circumstances. To complicate matters, more data than what can be fit on a single screen is needed now. In other words, filming the action live just plain won't work for anything beyond the basics. Improving the look is a plus too. So, for the past year I've been struggling to find a way... hoping something could be derived using the raw data instead. Thankfully, I finally came up with a viable solution. It gets a bit involved, but the outcome should be a high-quality overlay with driving video. This is what I've been experimenting with: 1) Save the data log from the Torque App. 2) Convert the CSV file to Excel format. 3) Import that Excel file into Word using Mail-Merge. 4) Save that Word document in PDF format. 5) Convert the PDF to PNG images of each page. 6) Import those image files as an album into PowerPoint. 7) Export the PowerPoint presentation as MP4 video. 8) Combine that data video with the driving footage. It's many steps, but they're just jobs you submit and wait for... letting the computer do all the work. The trade off is it will make the filming process itself quite a bit easier. The numbers presented will be much nicer on the end-product. No more vibration from having to actually use a camera for the data. Obviously, the raw values themselves will be available for further analysis too. Long story short, we'll eventually have more info to help squash the FUD. It's very exciting to see the process take shape. Yeah!

- 6-25-2014** **\$70,000 FCV.** Diversification is a topic not well accepted in online discussions. After all, looking at the big picture often leads to disappointment. Heck, even in this case it could. That price for Toyota's first fuel-cell vehicle took some people off guard. Of course, it could be that wrecks their arguments. Recently, the spin has been that Toyota will be abandoning hybrids in favor of fuel-cells. That made no sense what so ever. Offering a variety of choices and not risking everything on a single approach has never been a wise business risk. After all, look at how hard of a lesson to learn that has been for GM. Anywho, the price will be \$70,000. That makes it overwhelming clear there won't be a consumer clash of any sort. The audience will be quite different. It's a good way to build reputation and gather lots of real-world experience. Prius will continue to evolve in the meantime. It's a platform with much to offer still. Some of the motor/electric technology will overlap too, providing a mutual benefit. FCV (fuel cell vehicle) is in the very early stages for consumers. It's over 150 years old for the scientific community and has traveled to the moon and back. But being affordable and able to deal with the craziness of our commutes is an entirely different matter. That's why a single offering isn't realistic. Diversifying is a must. Early next year, Japanese consumers will see the first. Europe and the United States will come later in the Summer. The timing will be interesting... since a new Prius will be on the way too.
- 6-26-2014** **Publishing Greenwash.** Reading this today was quite frustrating: *"Hybrids are great at that kind of driving, which is why they get great mileage ratings from EPA tests. But in the real world, they have to keep up with contemporary traffic, which tends to burn more gas. Hybrids are particularly handicapped on highways, where high speeds require their gas engines to kick in and, proportionally, do more work than standard vehicles."* Sadly, things like that are emerging as a result of Ford having to lower MPG ratings on their hybrids. It's fallout which could have been avoided. But since the advertising was so intense on unverified numbers, that is now too late. Other hybrids like Prius will have to deal with false claims. Reluctantly, I contributed some insight about the situation: Using the problem from Ford as anti-hybrid fodder is no surprise. It will likely linger on for quite awhile too, despite no substance with respect to Prius. Heck, having credibility hasn't even mattered in the past. I don't see how this will be any different. Fortunately, the improved internet resources nowadays does at least help us deal with the rhetoric. The nonsense will never end though. Some will fight change to the bitter end.
- 6-27-2014** **Battle of the Uninformed.** One is a well know troll, uninterested in real-world data. The other simply doesn't understand how the hybrid system works. Watching the two of them attack each other on the big Prius forum is something I've never seen before. After so many years, it's quite an eye-opener to actually encounter something genuinely new. I was somewhat blown away. The arguments were senseless, neither interested in learning anything. They were holding to their assumptions and refused to consider the possibility of being incorrect. One has been a troublemaker since the very beginning... a die-hard diesel supporter and a fierce backer of Honda. So, his stance remains clear. As for the other, he's actually... believe it or not... a plug-in Prius owner. Several times now, I've challenged his claims. For some reason, there's no effort to find out why. He simply ignores the information provided. It's a bizarre situation to watch play out. Neither will give in. They'll likely end up escalating the banter. I suspect the insults will grow to the hostile level, much like I encountered when posting on the big GM forum and they didn't like me pointing out certain realities. Who knew something like this could happen?

- 6-27-2014** **More Recalls!** The total is now at 48 this year for GM. Whoa! That affects over 20 million vehicles. What a disaster. The struggle to rebuild both reputation and profitability is growing more and more of a challenge. How in the world does an automaker deal with problems on such a large scale? It's confusing as heck too. Earlier this week, Cruze sales had to be halted due to the recall affecting their airbags. Yesterday, it was their new Pickups and SUVs needing an update to fix a software glitch with the transmission. There has also been some obscure recalls, like faulty windshield-wiper modules and an insufficient weld allowing a shock-absorber to fracture. The variety of issues and knowing what years of what vehicles are included is a mess. The situation is quite confusing right now, as it's all fresh in everyone's mind. Just imagine what things will be looking back a year from now. Misinformation will be abundant. There's simply no way to effectively deal with the magnitude. It makes the recall for Toyota a few years back little tiny in comparison. The mess continues to get worse too. Ugh.
- 6-28-2014** **On The Offensive.** I waited a few days, allowing others the opportunity to chime in before I pounced. This GM salesperson has been pushing Volt by belittling Prius for years. It continues, despite the protests of his own forum companions posting frustrated messages in response to his. The recent belittle attempt was listing the variety of plug-in hybrids available, with this at the bottom: "*7) Toyota Prius Plug-In: EPA All Electric Range- 0 – 6 Miles*". That frustrated me, but at the same time was amusing. He intentionally excluded BMW i3 since it was supposed just a city car and had too small of a gas tank. The reality that it offers a 72-mile EV range from its 22 kWh battery-pack obviously irritates the heck out of him. But we'll address that at some other time, if necessary. Today, it was all about calling out his behavior toward Prius: I'm pleased to be the one to point out that there have been a some Volt owners complaining about your continued misrepresentation of Prius PHV. It looks quite desperate to blatantly disregard total capacity by posting only part of the information available from the EPA. That omission is clearly an attempt to undermine. There's no excuse. Volt delivers 38 miles of EV from the 16.5 kWh battery-pack. Owners often post about exceeding that EPA rating. Looking at capacity the same way, the 4.4 kWh battery-pack in Prius delivers 10.1 miles. That clearly isn't 6, not even close. The fact that Prius weighs less and has a more efficient electrical system is how the EPA rating of 11-mile value comes into play. But you never mention any of that. Tired of your on-going greenwash effort, I've come up with an simple way of capturing both video and a stream of data while I drive. Combine all that with some photos & comments, I've got a handy tool for pointing out Prius PHV performs far better than you care to admit. Remember, the point is to find allies in support of affordable solutions using electricity. Prius PHV does a fantastic job of endorsing lithium batteries for plugging in. This morning's filming was an 18-mile course, a round-trip I filmed many times in the past with my 2010 Prius. It's a mix of suburb roads, rolling hills on a 55 mph country highway, along with some city street. The route is actually what I do when I go to the coffeeshop to hangout while blogging. So, it is what I normally drive anyway. The result was an overall average of 146 MPG... with 13 of those miles EV... double your repeated misrepresentation of just 6 miles... all of which I now have video of to share. Failing to include capacity information will reveal how desperate the claims of just 6 really are. Stop doing it. This nonsense has gone on for far too long.

- 6-28-2014 Replacement Pack.** There was a press release from Nissan for Leaf today. That announced battery replacement details, complete with the price. I sounded off on the thread started to discuss that with: I get the impression the Nissan battery-pack replacement is future-priced, selling it now at a price that will eventually become profitable. After all, how many owners would actually purchase one right away anyway? Cost is likely higher than price currently reflects, but there's no harm from that. In fact, there won't be any need to price adjust later or deal with any of the online nonsense we routinely see with changes being forgotten, overlooked, or intentionally omitted. Subsidizing a little is just another form of warranty. Being able to upgrade with replacement is an interesting (and much hoped for) twist. Support of older vehicles from on-going improvement with battery chemistry is great. It adds a new dimension to automotive practices. We may come to expect mid-cycle upgrades at some point. At the moment, that's just thought of as a bonus. Everyone is used to having to wait until the next generation. This will likely raise resell value too. If nothing else, it's nice knowing with this level of certainty. That unknown was always an opportunity to undermine & mislead in the past. Having such a specific expectation will help prevent some FUD nonsense.
- 6-29-2014 Climate Change.** The cost of inaction certainly has been making the news lately. Sadly, there isn't really that much to say or anything new to look forward too. We can see symptoms of the bigger problem now. Some people just plain don't care though. Why change anything when it hasn't been proven beyond a doubt? I grew up with that nonsense about smoking. There was flat out denial about the health consequences, even though evidence confirming it was all around. An excuse to dismiss each and every circumstance would be offered... until they grew tired of defending. Then they just quietly went about their bad habit. How is guzzling & polluting any different? We know oil is obtained from sources we shouldn't be funding and by means we shouldn't support. Yet, we do anyway. We know the emissions are contributing to breathing-related problems too. So even without the added consequence of climate-change, the reasons to change are quite strong. Seeing the increase in frequency & magnitude of storms just gets ignored. Shortages of water in some places and flooding in others is becoming so common, it doesn't stir much attention anymore. The situation is disappointing. Then when you read about the fights to prevent EPA & CARB regulations, it makes you feel sick. Propaganda has clouded people's judgment. Talking points make the situation easy to dismiss. Not wanting to take action is a sign of trouble to come. Bummer.

- 6-30-2014** **Charge Time.** It's a complicated topic... with an endless source of individuals wanting to simplify, like: "*Your PIP will full charge in 1.5hrs vs 3hrs on stock 120v charging.*" So many factors are left out. That makes even the seemingly straight-forward decision of whether or not to upgrade your home charging a challenge. All I could do was respond with this and hope it somehow helped: That's not enough information required to make a proper decision about upgrading. 1.5 hours will provide roughly 75% capacity recharge from the standard 120-volt connection. Knowing that it recharges faster (high kWh rate) at first, then slows down later is important to know. 2.3 hours has been the 100% capacity recharge time for me over the past 2 years. That 3-hour rating is only for locations with sub-standard electrical systems or recharging in extreme heat. So, I really haven't found the need. Also, I've also been waiting for the 240-volt system prices to come down (which they have quite a bit recently) and offer smart options. Lastly, the ability for 2 rechargers to utilize a single 240-volt line will be available for consumer use; currently at some point, we're seeing them become common for the commercial rechargers now. That's an obvious expense saver for the family with two plug-in vehicles.
- 6-30-2014** **Delay.** That's a popular topic of discussion now... from Toyota just having announced a 6-month delay, pushing the release of the next generation Prius to the end of next year. I summed up my observation of the situation and the big picture posting: This time next year seemed a bit on the optimistic side, considering all the other things happening in the market now and expected to unfold by then. Early Fall was realistic. So, end of year isn't too far off. As for not getting the plug-in model right away... that's good news from my perspective... though watching others upgrade to the new regular model in the meantime will certainly be a test of patience. Getting it right for the masses is absolutely essential for rollout at this stage. We've already seen how much of a mess GM is dealing with from Volt not being targeted correctly. Ford hasn't exactly had hit the bull's-eye either. Toyota has come closest with being able to deliver something capable of reaching a very wide audience. Mainstream acceptance is essential with the next generation. That means high-volume purchases, able to compete directly with traditional vehicles, and no dependency on tax-credits. The regular model of Prius is already positioned for that. The plug-in model is demonstrating the potential. Waiting that plug-in means not getting sucked into fallout from other automakers and having the extra time to refine the new design. We know that lithium battery chemistry continues to improve and the addition of super-capacitors has been experimented with. Those are worth the wait. Cost reduction is obviously too. Then there's the convenience wireless charging has to offer. Also overlooked is the opportunity lost from current PHV owners. Upgrading so soon isn't an option for many households. An extra year could make all the difference. Many would have had theirs for around 3 years at that point. It will still have retained decent resale value and not be too old to just be better off keeping. That's a good time to capitalize on those seeking the latest & greatest. Like with my 2001 upgrade to the 2004, then the 2010, then the 2012 plug-in, each was totally worth it. This won't be any different. The wait will seem like forever, but the benefit from balance of purchase priorities will be worth it.

- 6-30-2014** **8.2 Million More.** The recalls from GM continue to grow. It's a truly bizarre situation. How many more will there be? Does it make any difference at this point? What are the nature of the changes required? In the end, who will be paying for it? Cost of having to do such a large number of part replacements will be incredible. The problem is difficult to even grasp. Most people believed a car purchase was just like any other product... you buy it, then change oil and rotate tires. The idea of a fundamental component having to be updated or replaced was given the stigma of failure. So, it makes sense that automakers have avoided addressing change on that scale. After the initial sale, nothing more was expected from either party. That's finally changing. After all, how many times does the software on your phone get updated? Shouldn't it be an expectation to get updates for your vehicle too? Some have wondered if aftermarket type hardware improvements would ever be offered from an automaker. Perhaps this is the start of that. Having some post-purchase offerings available by choice could make the mandatory type easier to accept. We'll see how this round of recalls plays out. Hopefully, it will stimulate change.
- 7-01-2014** **Diversity.** Certain on-going arguments get quite tiring. When you know the person simply isn't interested in more than just serving enthusiasts and doesn't care that an automaker is ultimately required to seek sustainable profit, it's difficult to respond. They aren't interested in economics. That desire to push engineering achievement and to place reputation above actual sales prevents much of any type of construction discussion. That made reading this a challenge: *"So Toyota is later to market, and you comment how the earlier estimates were optimistic. GM is delayed and it is evidence of their total incompetence??"* Yet again, it comes down to the refusal to recognize audience. But that is what you get coming from an early adopter of Volt in many cases. The expectation from early purchasers was strong sales from that one particular configuration. Even the suggestion of offering a second model was considered an attempt to undermine and promote Prius. It was quite absurd back then. That group truly thought the available production capacity of 120,000 annually would actually be needed by the third year. Reality wasn't so kind. Of course, they didn't have an understanding of who sales would need to come from. So, all I could really do was respond with this: LACK OF DIVERSITY has been the complaint all along for the target audience of mainstream consumers. GM's bet-the-farm approach has proven a terrible risk. Toyota didn't do that. Toyota chose to offer a variety of hybrids instead: Prius, Prius PHV, Prius c, Prius v, Camry hybrid, Avalon hybrid, Highlander hybrid. Don't be defending GM about their lack of choice for mainstream consumers or the consequences they now face. Don't forget about the Lexus models, including a large RWD sedan, plus the AWD minivan in Japan from Toyota either. Who's making an effort to reach middle-market right now?

7-01-2014 Delay Discussion. At one point, the word "sucky" was used to describe the situation. That's quite understandable. Taking a look at the bigger picture does change the attitude though. Of course, it won't necessarily help those with expectations for sooner, but what are you going to do? It is a for-profit business after all. I interjected saying: Another nice part about the sucky wait... [silly smile] ...is that there will be less to rhetoric to have to deal with. The amount of FUD (fear, uncertainty, doubt) we've been dealing with about the plug-in model is a real problem. The more data we gather with the current model, the less opportunity for those intentionally trying to undermine. It's sad, especially when it comes from supporters of other plug-in vehicles, but that's the reality we face. In a twisted kind of way, it is actually a beneficial... since designs incapable of appealing to the mainstream will reveal themselves. Hiding behind false claims only goes so far. Then of course, there are those who are just plain not interested in change. Their denial is easy to overcome when sightings become frequent. To think that some people will still see hybrids as "*too complex*" as the 2nd generation complete their lifecycle with great success is perplexing. But then again, there's has been fallout in the automotive market lately. The re-rating of MPG estimates along with an overwhelming number of recalls does give reason for pause. So, it does make sense for there to be a delay. Think about how well established the C and V models will be at that point too. Toyota gets the opportunity to work on improving them in the meantime. People are obviously going to be expecting them to get upgrades quickly after the regular model. It will work out fine. But for those who were looking forward to the chance to upgrade sooner, it will be a test of patience.

7-02-2014 Lots Of Data - Video. It took a very, very long time to finally figure out how to present all the data I had been collecting from my plug-in Prius. I was able to capture video of a few gauges while driving, but more simply wasn't realistic. The road vibration made mounting a camera steady for more data (smaller images) impossible. After lots of trial & error, I eventually figured out a way to utilize the numbers themselves instead of depending filming. By converting log file provided by the ODB-II reader application and using a Bluetooth adapter, the video could be created with some formatting software. Then, all I can to do was combine it with the scenery footage. Since data is transmitted wirelessly from a device accessing the vehicle's computer live while driving and a cell-phone running an app is frantically trying to translate & record, the result isn't perfect. There will be an odd number (unusually high or just zero) from time to time. But overall the purpose is well served. You'll see what happens, starting with a battery-pack close to the fully recharged (85%) and driving all the way to the depletion point (23.5%). The gas engine will turn on at times, then shut off again when not needed. Much of the 18-mile drive (to my favorite coffee-shop and back) is using only electricity, specifically 13 miles of EV. The rest is hybrid driving, known as HV. Overall efficiency from that drive ended up being 146 MPG, as photos of the display screens at the completion of the video show. The full-charge of the battery-pack uses varies from 2.6 to 3.0 kWh of electricity, including losses from charging. Here's a link to the video... [Prius PHV - Lots Of Data](#)

- 7-03-2014** **Chiming In.** It's difficult to know when to finally post a response. You know certain individuals will spin whatever it is, regardless of content. Some just like to debate. Others simply don't see the big picture. Their reaction is quite predictable. We'll see what this does: I've been waiting for the *if-it-does-not-plug-in-it-does-not-count* people to say their piece before chiming back in. Their refusal to look at the entire market is not helpful... The goal for the past 14 years is to replace traditional vehicles with a choice that's cleaner and more efficient. Remember Toyota's milestone set for 2020? That means competing directly with all the other vehicles currently available. Growth is necessary, which is what makes the 4th generation such a big deal. Gas prices as well as their associated taxes will inevitably go up. People won't be driving non-hybrids forever. For those hoping to upgrade/replace sooner, you'll end up stuck with a vehicle which should hold out in the meantime and has a proven record of retaining resale value even when the next generation rolls out. Not getting to trade-up when a lease expires is an interesting situation, since we've dealt with long delivery waits in the past anyway. Hopefully, that will work out. It makes sense that Toyota is stating intent so directly. For those sitting on the fence, you can now firm up your own plans... especially now that we see how the competition is with hybrids. They won't even be able to compete directly with the current Prius hybrid system. Toyota's improvements to next will be nice. As for the plug-in model, there is a decent opportunity to finally expand beyond the initial 15 states. Yeah! Education about its purpose and how it actually works is going fairly well. We've seen a clear improvement based on the questions here and the reduction of rhetoric elsewhere. Sales didn't plunge when HOV sticker availability ended either. That was good news. Retaining sales at the current level will be even better. That, combined with advertising and ample supply, will make full rollout nationwide realistic. Remember, it's not just consumers that need convincing, it's the dealers too.
- 7-04-2014** **50 MPG.** 111 miles, against the wind, with 2 bikes on back. Trying to use as little electricity as possible, so I'd have it available when we arrived at our destination, that was the result. HV efficiency (the MPG when there's no EV or EV-BOOST) is quite impressive. What other hybrid could accomplish that, even without those aerodynamic compromises? We had the interior packed with lots of stuff too. Being a holiday, enjoying the long weekend was key. Not having to sacrifice in terms of travel is fantastic. It sure is nice being able to load up the Prius like that to escape the everyday pressures of work. Now, the only thing I have to worry about is getting sun burnt... and perhaps eating too much.

7-07-2014 Lesson Learned? Sadly, the answer to that question is no. This today reiterated the problem: *"It looks like a real opportunity for "conquest sales", if other manufacturers are able to produce affordable all electric or PHEV vehicles with "adequate" all electric range and performance."* It's hard to believe how pigheaded certain individuals will continue to be. They choose to selectively look at the market, dismissing anything without a plug. That's called cherry-picking. It's handy when you want to win a battle but couldn't care less about the war. Disregard for overall goals and just having a purpose of short-term gain is a very real problem we still have to deal with. Why? You'd think that lesson would have been learned after having faced such a terrible economic collapse. Not wanting to go through all that nonsense again, I avoided rehashing history by focusing on what's been important all along: KNOW YOUR AUDIENCE. That's absolutely vital. Yet, some still only see current buyers. The 4th generation Prius will be taking on traditional vehicles. Those are the conquest sales being sought, not that from the tiny-slice of the market for plugging in. It's mainstream consumers be directly targeted, those would otherwise purchase an ordinary engine-only car. That's cannot be stressed enough. Taking on the traditional market directly is the focus for this next release. It's not early adopter time anymore.

7-08-2014 PiP Education. This suggestion left me without an effective reply: *"Make the cars available to people."* That's all I got when the topic of education for the plug-in model of Prius was brought up. To him, the design is so simple, there's no reason to bother teaching... which he stated by saying: *"There is very little to learn with the PiP."* Despite there still being misconceptions about Prius itself and the frequency of incorrect claims about PHV at nearly an overwhelming level sometimes, he still believes mainstream consumers only need the vehicle itself to understand it. I wonder how he thinks the correct information will be conveyed. With the media routinely publishing reports that are incorrect, misleading, and from time to time contain an outright lie, that's certainly not realistic. And for the chance that anyone beyond the well studied will have the ability to sift through forums to find necessary detail, that's wild fantasy. After over a decade of dealing with the rhetoric, the poorly informed, and the greenwashing, the reality is rather disheartening. Heck, even the Volt supporters agree with me on this one. Time after time, we keep hearing them beg GM for more educational advertising. Anywho, this is how I responded: Simply making more available was a disappointing response. The purpose of achieving permanent growth cannot be fulfilled by just offering more. That alone isn't enough to result in higher sustained sales. There must be education too. That requires the clever part of marketing. Most often, it's in the form of television commercials with something that stands out to catch consumer attention. Coincidentally, Toyota is doing exactly that starting next week. We were told: *"The goal is to help educate people about the benefits of Prius PHV in a fun and interesting way."* Remember how I stated that the best next step was to expand within the currently established markets? Toyota's effort to learn how to appeal to a wider audience there is priceless information to know prior to expanding to the larger market.

7-08-2014 **In Other Words.** The hope is this newest round of rhetoric will end quickly. Each time seems to be shorter and shorter. Nonetheless, it is still annoying. The trouble and source of the backlash is well known. Unfortunately, those new to the forum don't know that. They have no idea why such behavior would even take place. I suspect only a few of even the frequent posters actually go to other forums, making a true representative of the big picture limited to only a handful. Reading posts from the same individuals in a different venue sure is enlightening. The different audience causes them reveal other bits of info we don't get on the big Prius forum. It's especially informative with the websites not friendly to Prius. That certainly can be eye-opening. Doesn't really matter though. No amount of online spin will make a big impression on someone who doesn't participate online anyway. That's why so much of what goes on in posts fails to make any difference. Too bad that real-world mentality is so hard to come by. Oh well. At least some insight can still be shared and some question still be asked: In other words, successful sales increase which can be maintained afterward is the sign that expanding beyond the initial 15 states is realistic. Otherwise, why would dealers be interested in stocking a vehicle that would only attract a short-term gain? A brief boom from "*early adopters*" is not what you want to risk inventory on. Unless a strong case for them is presented, dealers in the other 35 states won't embrace the supposed opportunity. The market must be well established first.

7-08-2014 **Expect the Worse.** Anticipating a series of unpleasant responses when pointing out someone was incorrect is good advice. Some type of negative response is inevitable. That certainly was spot-on today. Whoa! Looking at those posts from a distance, it's easy to see the outright dismissal. Today, the word "*nonsense*" was used quite frequently. Taking a step closer, it was the usual misrepresentation. Your words are twisted to imply something else. More often than not, they take context from other people's posts (since the words themselves are easy to remember) and state them as if you had actually said that. After all, remember who is difficult. Next comes vague spin. They pretend the topic hasn't ever been addressed in full and accuse you of leaving out detail accordingly. Today, it was ironic that there was an attempt to restart debate by being vague and making it sound as if I had with my reference to that conclusion from elsewhere. This type of behavior is quite typical. It's no surprise. Any time a next step forward is taken, particular individuals will go out of their way to stir the pot... hoping new bait will bring back active discussion which will result in a different conclusion. It all boils down to the same thing: they so strongly believe something, there don't recognize any alternative outcome. It's that "*all or none*" mentality... the classic oversimplification. That clashes with the balance approach and leaves no opportunity to staging. So, the reality that Toyota allowed for flexibility in their approach is beyond their perception. There is only one or the other, nothing in between. It's an easy barrier to encounter when you attempt to have a constructive look at the economies of business with someone who has no actual exposure to the industry. That's why there was so much fallout with Volt. We had well educated engineers not understanding why consumer interest and dealer support was so low. If you don't know how those complex and counter-intuitive the situation is, you're not likely to have a strong positive outcome any. So, the idea of adaption isn't even a possibility. Adding to that it being of an accounting & marketing nature instead, it's a mess. You basically say your piece and move on. Expecting some type of closure isn't realistic. They will be angry for you having been correct... which makes you wonder how much that same situation will repeat. I've seen it so many times, there's no way to count them. Each advancement comes with someone being left behind. That's what sales are all about. That's why a hybrid like Prius continues to progress.

7-08-2014 **Happy & Sad.** It sure felt good reading that post from Toyota Marketing on the big Prius forum confirming they would indeed be doing what I had predicted the next step would be. With so much studying of what should be done, that is rather obvious. Sad part is though, most people don't pay close enough attention to notice. Even more sad is that some choose to now see. Thankfully, there is a happier side. We will see 2 television commercials and get an online video soon. They will kick-off their education/advertising campaign for Prius PHV. Based on the response to that, it's easy to see some expansion begin. Why's those few individuals arguing with me can't see that is baffling. I suspect trying "win" a debate is more important. After all, accepting compromise has been given a stigma of acknowledging defeat. We'll be intrigued as ever going forward. Rollout to other states, like Florida & Texas, seems quite realistic with the 2015 model. By then, we should have seen growth in the currently available states. Happy for them. Sad for us up in the north though. Winter is a nasty time to rollout a new Prius. The key is setting realistic expectations... which still isn't the norm for the regular model. Why would it be any different for the plug-in? Whatever the case, some of us were well aware of the backlash. Sadly, it's the same few people each time too. Happily, it doesn't last long. Really sad is that newbies aren't aware of this and commonly find the rhetoric frustrating and don't realize the attitude will shift relatively quick as the antagonists exhaust their new found argument points. Anywho, the tide change is coming.

7-08-2014 **Facts & Data.** They can be painful to accept, which is how all the spin comes about. The cold hard reality of what the competition is and who the audience is has become an endless source of rhetoric. Scope is arbitrarily just cherry-picked. Basic principles of business are just swept aside too. It never ceases to amaze me how things like affordability are so easily dismissed. Fortunately, it's easy enough to see past all that... once you start seeking out the facts & data. Interestingly, we're seeing a pattern now. Toyota waits for the competition to complete their rollout before making a move. It avoids getting caught up in any fallout. And this particular stage, what a payoff! They were able to stay clear of the many troubles with Volt and the rating problems with Ford. There's a fresh canvas now for them to paint a picture of what a well-balanced plug-in hybrid has to offer.

7-09-2014 **Commute Home (Deplete EV) - Video.** This is my commute home, taking the scenic route along the river via the high-bridge to the bluff. It's a very pleasant drive through the park and on roads with lots of trees. I used that Bluetooth device again to capture OBD-II data while I drove. Unfortunately, it got hung up for almost a mile, leaving a gap in the recording. Fortunately, it picked up and synced nicely with the video afterward. It's still, by far, the best way to record lots of data for presentation later. I started with a full charge. That's a battery-level of 85%. Not charging to 100% is what most automakers are doing to ensure longevity of the pack. The other technique used is to not discharge entirely. For Prius PHV, which has a 4.4 kWh total capacity, that means ending EV travel at 23.5% and HV at 18%. Having an engine makes that easy. You can see that happen in the video too. Watch for it 12.4 miles into the trip. The hybrid system has an engine and 2 electric motors. The RPM values for all 3 are shown in the video. They are connected via a planetary-split-device (similar to a differential) to combine and direct power. Coolant temperature is important to be aware of... not so much in the summer, more in the winter. The engine will run until demand for emission-cleansing and/or heater-warming is fulfilled. Running will stop when specific temperature thresholds are reached. Battery intake & bank temperatures are becoming more and more of a discussion topic. Heat accelerates aging. Keeping the pack cool is important. Showing the effectiveness of the system goes a long way toward greenwash prevention. You can clearly see how well it works. My 17.4 miles of driving home from work yielded fantastic results. 190 MPG overall. You can see the video here... [Prius PHV - Commute Home \(Deplete EV\)](#)

7-11-2014 **Half Million.** This was the title of an article published today: "*There are now more than 500,000 EVs on the planet.*" Right away, there was a comment posted asking for the definition of EV. Turns out, the writing was about a press release, which clearly said "*Plug-In Vehicles*". That's not electric-only, as the article implied. Misrepresentation like that makes some of us nuts. It confuses consumers. Calling anything with a plug will cause the same problem we had a decade ago. Writers figured anything with a battery was a "*hybrid*" vehicle. That led to quite a bit of online fighting and a number of purchase disappointments. People assumed they were all the same. We ended up arguing "*not the same*" so many times, it still stirs anger all these years later. Needless to say, I wasn't happy. Greenwashing starts with being vague. This was a contribution to that... rather than the celebration it was intended to be.

7-13-2014 **Not Posted.** I refrained from posting this. There was simply no benefit from stirring the pot. So, here in my blogs, those thought will be exclusively shared: Yesterday, a bunch of EV owners got together for a meeting. That was quite enjoyable. There were 5 Leafs, along with 1 soon-to-be-owner. 3 I-MiEV. 2 C-Max Energi. 2 Prius PHV. 1 Focus EV. 1 Tesla Model S. By far, the biggest market complaint was dealer disinterest. They had some very disheartening stories to share. The majority of salespeople simply don't have a clue and have no desire to even learn about the vehicles. So even when an excited consumer comes in to look, they end up leaving disappointed. Imagine what it's like trying to get help and finding out you know far more than they do. To make matters worse, the cars generally aren't even charged up. So when you want to take a drive, it's either really short or just with an engine. What a mess. There is a very real problem still. Those here still claiming just the act of making more available is enough to overcome the education barrier really need to talk to more owners. I stand stronger than ever behind the impression that Toyota is learning all they can in the established markets before moving on to the others. Spreading thinner by not addressing shortcomings with dealers first simply doesn't make any sense. Hopefully, it won't take too long. And since we know there is roughly 2 years until the plug-in Prius upgrade arrives, building up dealer confidence & support in the meantime is realistic. The new advertising campaign is should stimulate a sales increase in the established markets. It would be a good indication that expanding to new markets would reach more than just early adopters; otherwise, we end up waiting.

7-16-2014 **New Attack, good riddance.** How would you respond to seeing this: "*To the Prius Plug In, I say good riddance anyhow, because its such inferior engineering (I'm a Volt owner, though I still love my old '08 Prius for what it does as a reliable and efficient "old" car).*" That was only his third post on the big Prius forum. The other two were today too and both were as abrasive. I was rather surprised to see anything like that anymore. With Volt's struggle and the slow-but-steady growth of PHV, sounding off like that doesn't make sense. What could it possibly accomplish at this point? All those disenchanted had already go it out of their system... or so I thought. Maybe it was just a simple lashing out before giving up. Who knows. I chose to address the new attack with: There have been a small number of Volt owners who flaunted "*vastly superior*" and were happy to belittle & insult Prius PHV. Their attitude stemmed from seeing what Toyota did well, especially when they clashed directly with unmet expectations from GM. It was quite interesting to watch the fallout back in late 2010 and early 2011. All these years later, we're seeing how claims of being "*inferior*" don't actually hold up when detail is revealed.

- 7-16-2014** **New Attack, wake up.** There was a second quote in his post I responded to as well: *"More customers will wake up like me and trade in their last Toyota."* That made me wonder if some of what we were seeing had to do with automaker fallout, rather than just Volt. After all, GM recall trouble continues to increase. The situation is quite remarkable. How it will or even can be properly addressed is anyone's guess. What is clear though is Toyota's stance is much stronger. Being closer to goals for the upcoming market and be much more diversified puts them in a far better position. That obviously feeds the frustration. Keeping objective, my post to that was: Not understanding audience continues to be the biggest challenge. Goals of cost-reduction and depleted-efficiency were easy enough to get agreement on. But as for that question of who, the claimed lost customers continues to remain a mystery. Toyota is focusing their hybrid technology squarely on the masses. It's a replacement for traditional vehicles. That means it must match up with mainstream purchase priorities... a reality some Volt owners don't want to acknowledge. In other words, it's the outcome that matters. Whether or not the system stays in EV mode or it accomplishes that efficiency through blending isn't of any interest. They just plain do not care... as they do now with transmissions. They don't care how an automatic works, they just want it to work well, be reliable, and be affordable.
- 7-18-2014** **New Attack, resentment.** The trolling attempt was so obvious, it abruptly ended. The matter was likely either not realizing he'd get called out so quickly or not realizing how intense the resistance would be. Whatever the case, it looks like the attack is over already. Remember the days when those baseless posts would go on and on and on? Now, we've got so much good quality data, there is little available for trolls to exploit. Gotta like that. It sure was a nightmare in the past. Certain members and their reputations still send quivers down some of our spines. We'd have to deal with their blatant lies of desperation. Undermining Prius at all costs was their intent. Now, especially with this particular individual, it's hard to know. As Volt leases expires, those former owners are finding themselves at a loss for what to replace it with. They didn't expect the plug-in market to be so fickle or anywhere near the money-loser. They didn't recognize the importance of the *Who?* question. They didn't understand how long or complicated the process to change would be. Prius owners did. So, naturally, there is some resentment.
- 7-18-2014** **Moderator Intervention, removed.** There hasn't been anything even remotely *"troll worthy"* published as a daily topic on that daily blog for Volt in ages. All they get now is just a repeat of what's shared on the generic hybrid sight. Interestingly though, there was news about Prius PHV. So when that made it to there (usually a day or two lag), the reaction was something I was quite curious to witness. A record was set with it on a track in Germany. The Volt enthusiasts started posting responses with zeal. That's understandable. Most were fairly objective & respectable. One though... whoa... was an outright attack. It was from that same Chevy salesperson who's been doing everything he can to mislead about EV capacity. It's embarrassing to the supporters of Volt. Not competing honestly is something they just plain don't want to be part of. The moderator obviously feels the same way. The post only remained visible for about an hour. Then, it vanished. I was happy to see that happen. It was a rather blatant trolling attempt and he didn't want anyone to take the bait. Cool! That type of intervention to keep discussions constructive sure is a welcome improvement.

7-19-2014 Moderator Intervention, posted again. Not willing to accept the disappearance of his original post, he posted the same thing again. This time, I decided to respond, specifically to this: *"The Feds tell us that 74% of commuters drive less than 34 miles a day. Driving a Prius PI in EV Mode more than 34 miles with blended gas and electric fuel would require me to plug in over 5 times a day, and still be using gas! If gasoline is at \$4 a gallon I can go 50 miles in a Toyota Prius Plug-In for \$4 dollars."* The obvious exclusion of non-commute miles should be a dead giveaway about intent. It's rather blatant cherry-picking. You cannot just exclude the rest of the miles people drive. Going back & forth to work is not what people actually do in the real-world. That "5 times" claim is rather bizarre. Is he really that clueless about how PHV works? My guess is he actually believes that 6 miles is all the system delivers... even though it has been pointed out countless times that it doesn't. Heck, even video has been provided showing that's not the case. My choice of how to reply was as follows: I find such dedication a sign of desperation. Misrepresenting the plug-in Prius by continuing to imply that "6 mile" rating is the entire plug-in capacity available is just plain wrong. Or look at it another way, misleading about the plug-in Prius is a terrible way to promote Volt. It's been pointed out many, many times that the EPA's testing course triggers the engine briefly at the 6-mile mark. It's a simply on, then back off again, point during the drive. That causes it to get a "blended" rating of 11 miles total rather than the entire battery-capacity available being labeled as EV. Yet, we see on-going exploitation of people's misunderstanding of what that number actually means. In other words, it's greenwashing. You don't want to be any part of that by associating with those contributions.

7-19-2014 Moderator Intervention, facts. Refusing to accept reality is nothing new... but how deep in denial can someone actually be? We've known of individuals who made an assumption and never bothered to do any research. They continue to dismiss facts presented as clarifications to their error for quite awhile. But in this case, especially since the person is a Volt salesperson, there isn't much how of an epiphany. I keep trying though. At least others reading the posts will see his mistake and wonder what's wrong. Hopefully, this at least helped a little: 4.4 kWh is the battery-pack capacity. Avoiding that reality by hiding behind the EPA testing course is intentional misleading. The engine briefly runs at 6-mile mark, then shuts back off for the remaining 5. That's a total of 11 miles using electricity, not just 6. On my daily commute, that amount of electricity takes me an average of 12 miles before the engine starts.... because I don't have a spot where hard-acceleration is required and the traffic tends to flow along with very few stops. On really nice summer mornings, I can go 15 miles... all EV... all consecutive. Continuing to post "electric only" numbers by leaving out vital information is misrepresentation. There's no excuse for that. Then there's the misleading about blending by never including any numbers. It's just given a stigma and the message of inadequacy is conveyed, doing everything possible to avoid ever actually mentioning the resulting MPG.

- 7-19-2014 Moderator Intervention, definitions.** The refusal to acknowledge Volt was a hybrid led to heightened promotion of EREV, even though the other plug-in hybrids contradicted the very definition they embraced. It's screwy. But then again, arguing semantics is never straight forward. In fact, most of the time, it's pointless to even bother. In this case though, I at least wanted to highlight the confusion he contributed to with: "*11 miles Elec + Gas. All Elec: 0-6 mi <———— This is NOT a PHEV!*" That didn't make any sense. Is Volt now a PHEV and this was an effort to disassociate? HV, EV, and blending is an expectation from PHEV. That's what the acronym represents. I found no reason to reply. It would just be a waste of time. Though, it is worth drawing attention to the obsession with EV purity clouding judgment. Any gas usage whatsoever is considered bad... even though Volt has an engine for use after depletion and for battery & cabin warming during the winter. It's so hypocritical. That's why posts are vague and requests for detail result in shooting of the messenger. It's rather annoying to have to deal with too; however, these incidents are so few and far between now that it isn't a big deal anymore. Yeah!
- 7-20-2014 Fuel Price.** It's \$3.29 per gallon here for gas and \$3.89 for diesel. Such a large difference explains why we are seeing more greenwashing they usual from diesel supporters lately. They've been pushing statistics using the percentage technique. It's when you only show sales gain through the use of relative measure. By doing that, it gives the impression of more. But in reality, exclusion of detail (the actual count), it can actually be much less. They hope people assume more though. Not checking facts is important when misleading... and they are quite the pushers of that particular approach. It's sad to know that honest competition doesn't happen. That's why the "*self regulate*" mindset is such a problem. You are only fed the facts they want you to know. Sadly, comments posted about the article can be just as bad. We see the same old talking-points again and again. The most common is that diesel thrives on the highway and there's no benefit from hybrids at those same high speeds. The avoid posting actual MPG as much as possible and simply never explain how they came to the conclusion of no benefit. They also try to keep focus on highway, so the poor city performance isn't ever mentioned. They flaunt the "*clean*" label to prevent addressing actual emission ratings. Again, that's a relative measure. It's annoying to see this same nonsense so often. Fortunately, the much higher price per gallon keeps the situation in check. That's extra expense makes it a difficult sale. It makes you wonder how the loss of some truck space and extra expense is explained away for the diesel vehicles which spray urea into the exhaust system for emission cleansing. Hybrids like Prius are even cleaner, without even using special liquid & equipment.

- 7-20-2014** **53 MPG.** Well, today certainly was exciting. I took a stand-up-paddleboard class with my girlfriend. We had a blast, though I did get a bit sun burnt. That certainly is an interesting way to travel on the water. It's quite remarkable how stable they are, even when you are moving around on top in a standing position. Anywho, since we were going to the lake anyway, I brought along the kayaks. The round-trip was 37 miles, not far enough to bother covering the cockpits. That increases aerodynamic drag even more... as if a 12-foot and 14-foot object carried on the roof of the Prius wasn't enough. On the way home, it was particularly noisy too. With so much air being pushed through and around, that's no surprise. What did surprise me was the efficiency performance. I really wasn't expecting MPG to be so high, even when taking advantage of a full battery-pack. Most of the driving was at suburb speeds, though there was a few miles out on the open highway too. Knowing that my trip up north with the kayaks years ago with the regular Prius resulted in a 36 MPG average (lots of high-speed travel then), I was figuring somewhere in the mid-40's with the plug-in model. After all, efficiency flattens out after awhile. But with shorter travel and that extra electricity, perhaps upper-40's was realistic. Seeing a final result of 53 MPG was quite a delight. I had no idea that expectation could be set for that distance. Sweet!
- 7-21-2014** **Commute Work (Deplete EV) - Video.** Driving to work, rather than the way home, was the next thing to film. The video & data capture went remarkably well. Conditions were near ideal for driving in EV until depletion, which made it great as a measure comparison for battery degradation. There still isn't any after over 2 years of plugging & driving. That's the period when the largest drop supposedly takes place too. Not seeing any at all is proof that Toyota really studied the need and the chemistry well. There are so many conditions to take into account. And with the extreme lows here in Minnesota, that isn't something to be taken lightly... as with the extreme highs in the southern most regions of the country. Staying between the 23.5% depleted and 85% full levels is a key to that. Avoiding too much stress on either side of the total capacity available for the pack is a major contributor to the longevity. And now I have another detailed video illustrating exactly that. I was particularly thrilled with the results too. It's not everyday I get to see results that nice. Traffic & Temperature variations impact the outcome, but causing lower efficiency... though, still quite noteworthy. Anywho, here's the short & sweets comments I included and a link for the video itself: Taking the scenic route to work, along the river, the performance on this beautiful summer morning was outstanding. 418 MPG for the 17.2 mile drive. [Prius PHV - Commute Work \(Deplete EV\)](#)
