- 2-14-2017** **Air-Cooling Greenwash.** I was absolutely amazed to see this today: *"The current Leaf's air-cooling is insufficient for hotter climates."* That's a claim easy to disprove. Why would anyone make such an obvious attempt to mislead? Perhaps he thought readers would take the claim at face-value, not bothering to click the link also provided. If they did, the hope would be the age of the article wouldn't be noticed. It was 5.5 years old! Greenwashing by posting outdated information is quite desperate. But when you are a hard-core GM supporter and the article is about Nissan's next-gen Leaf, doing that still happens. Heck, I got annoyed by how many times facts were voted down just because they didn't like them. So, using facts to mislead comes to be an expectation. Anywho, I didn't hesitate to point out the attempt with: September 22, 2012 isn't remotely *"current"* from any perspective. That article has been called out as greenwashing material for being so outdated. Leaf batteries were upgraded mid-cycle, greatly improving their resilience to heat. We know the batteries will be upgraded again (chemistry & construction improvements) with Leaf gen-2 rollout too. We also already know they will be air-cooled.

- 2-14-2017** **Too Late?** Someone else sounded off with superiority chanting. Ugh. I was dismayed by reading: *"Nissan is late to the new EV party. By the time the new Leaf is available, the Chevy Bolt EV has taken up that market. And I don't believe that a *cheaper* Leaf against the Bolt EV will sell better, because quality and quantity has its price, and true BEV believers (just like Tesla buyers) will pay whatever to get the best EV possible."* Was he really that clueless or close-minded? It was yet another audience problem. Some people just never learn, I guess. Of course, it could just be denial. Being backed into a corner, you really don't see much from that perspective. I decided to deal with the denial in this fashion: Late to what? Which market? The acceptance of EV by ordinary traditional buyers hasn't happened yet. We're still trying to get out of the low-hanging-fruit stage. Reaching beyond early adopters is still just a hope... realistic, but clearly some time in the future still. Once sales occur without any tax-credit subsidies, that milestone will be reached. Until then, it's just enthusiasts helping to prove the technology is worthy for the masses.
- 2-14-2017** **Improvement & Cost.** Attempts to inject constructive points into GM discussions when you own a Prius is usually futile. Many just choose to not listen anymore. That's actually progress. It sure beats those attacks of the past. Denial turning to acceptance is much better. Enthusiasts becoming supporters is a challenging process to usher along. It is working though. The struggle of gen-2 Volt has helped it along. We all can see the potential for Prius Prime. Once production & delivery is finally ramped up, Toyota will take the lead they've always feared. It is no longer a matter of *"IF"*. It is now trying to figure out the *"WHEN"*. My hunch is that will be around Earth Day. Waiting for things to fall in place is quite a challenge though, a test of character through patience. It's well worth it, of course. It teaches you not to burn bridges too. Those still showing some resistance will eventually either vanish or become an ally. So, I keep interjecting some sense into the daily topics. Hopefully, this will be considered helpful... someday: With respect to design, there's the big issue of production cost. For EV to be directly competitive with traditional vehicles, it must have a closer MSRP and no dependence on tax-credit subsidies. Not requiring liquid is a way of cutting cost. It reduces complexity too. That's good for reliability. It's the advantage of going electric. For example, electric power-steering doesn't have liquid. It doesn't have a belt either. That's a clear simplicity improvement, as well as a cost reduction.

- 2-14-2017 Diesel is Dead.** The official "50 MPG" rating is making news today. Ugh. That's the highway rating for the Chevy Cruze diesel. Focus on just highway is rather blatant greenwashing, criticized extensively in the past for drawing attention away from overall efficiency. It was cherry picking, plain & simple. A method of deception, similar to "*clean diesel*" from the perspective of intentionally excluding vital information. The choose what to tell you and totally disregard the rest. For example, how often do you hear mention of urea refills? That's the cleansing agent required for diesel vehicles. It's a liquid that's sprayed into the exhaust system. I'm willing to bet most diesel shoppers never encounter any mention of it. There's the issue of diesel being more expensive per gallon than gas too. Think that is ever brought attention to by diesel promoters? Anywho, I don't like diesel for passenger cars... and expressed that sentiment in response to the news: 37 MPG combined for the manual and 31 MPG combined for the automatic is so bad, it's not possible to take it seriously. No mention whatsoever of emission-rating is the evidence of being severely wounded, especially from all the awareness raised by the cheating scandal. After 15 years of tolerating the claims of being as clean & efficient, it's time to move on. Gen-4 Prius easily surpasses that it both regards. Adding a plug to it to make a Prime buries the coffin. Diesel for passenger cars is dead.
- 2-14-2017 Terrible Timing.** I had a follow-up post to my declaration of death. The ironic nature of attempting to gloat about a diesel efficiency rating right when such a huge efficiency hybrid milestone has been met is poetic. The sweet sound of electric silence. That's so much of a contrast to the clatter of a diesel engine. Ugh. I'm amused and was quite happy to keep any spin attempt at bay with: Toyota just surpassed the 10,000,000 mark for hybrid sales. There have been a total of 34 models offered. Availability has reached 90 different countries. An affordable plug-in model is being rolled out in Japan, the United States, and Europe. The timing is terrible... for diesel.
- 2-16-2017 Totally Inferior.** I was very amused to see the term "*totally inferior*" used in place of "*vastly superior*". That's a level of desperation so blatant, it's almost pointless to respond. That mantra of the past was absurd. The gen-1 Volt enthusiasts just kept chanting that over and over and over again. Its lack of substance ended up driving many away. They didn't want any part of a technology unable to actually compete on merit. Needing to embellish for the sake of retaining attention is a bad sign, and they knew it. That lesson learned is apparently something this new gen-2 audience seems to believe they are immune to. That type of attitude is the very reason history repeats itself. The leaders become complacent... exactly as I witnessed today. I was amazed to see that. They say you cannot fix stupid. Seeing it play out firsthand is troubling. But then again, we're seeing similar on the presidential level. Awareness have never been raised to such an extreme level before. I wonder what kind of long-term effect that will have. The short-term outcome will definitely be painful. Arrogance can be quite expensive, stirring unforeseen costs on an enormous scale. Calling something "*totally inferior*" without evidence to support the claim is usually evidence of trouble to come.

- 2-16-2017** **Hitch.** One month from now, the first receiver-hitch for Prius Prime is supposed to become available. That's well timed. With the dual-wave window in back, I wasn't certain the idea of using my adjustable strap-on carrier for bikes in the meantime was a good one. Though, with the other Prius, the feet on top were for nothing by stability. All the weight was on the lower legs. Not being able to actually measure yet had been a set back. Living surprisingly close to 2 different hitch manufacturers would have made that easy too... if I had my Prime. Delivery is still a month away though... coincidentally, it's the very day the hitch could be delivered. Searching online, I haven't found any information yet. My source was from a friend who pushed for one last year, shortly after the gen-4 was rolled out... since he needed a hitch. He let the use his own Prius for measurements to build the very first one. That worked out well. For me, looks like I'll have to do even less... except be patient.
- 2-16-2017** **Scare Tactics.** A common method of dishonestly discrediting is to claim that your safety is threatened. It's bad enough seeing that in politics. Having to deal with those same scare tactics for Prius is even worse. That's puts you on the defensive. Not taking the bait can be a challenge. They'll just keep posting it. For awhile, the claims about Prime being inadequate came in the form of expressing danger when entering the highway. They'd focus on merging. Yet another attempt happened today: "*The only way to merge safely in a Prius is to hope those cruising in the right lane move to the center or left lane so you have an 'open' channel to merge.*" But rather than follow that line of thinking or trying to get back on topic, I kept the focus on acceleration. They don't expect you to play along. You're suppose to fight back directly, throw a punch to the face. I decided to jab from the side instead. It worked too. I simply gave another example of accelerating, one even more extreme: It's claims like that raise the intrigue. Are you in denial, poorly informed, or just desperate? The safety comment is simply not true. I pass with my Prius PHV from time to time. It's no big deal. Heck, even when going through South Dakota at 80 mph, there's still power available for me to accelerate even faster to get around those I no longer want to follow.
- 2-17-2017** **Wasted.** There are some posts that you know are going to be trouble right from the start: "*As a curious person it makes me angry that they wasted so much... everything. Their continued blindness to the nature of electric mobility is shocking and saddening.*" Was this person totally clueless or focusing entirely on something incorrect? Running into an innocent individual who has been a victim of greenwashing happens from time to time. So, you have to carefully consider how to respond. I try by posing a question, then proceed to point out how the situation is not how they interpret it: What was wasted? Toyota is pushing the affordable approach. They didn't take the easy route by simply rolling out an expensive plug-in, then hope for the best with cost-reduction after the fact. Notice how that didn't turn out so well for GM? Heavy dependency on tax-credits is a terrible idea. Instead, Toyota took the more difficult path, having to tolerate the snickers of doubt & belittling along the way. Now, they are mass producing the needed components at an affordable cost. The regular Prius uses lithium battery cells too. That's a huge economy-of-scale benefit other automakers don't have. Also from Toyota is their very successful first-year debut of RAV4 hybrid. It's a platform that sets them up very well for adding a plug to a SUV, the market that no automaker in the United States has yet to tap. In other words, the spin about waste is without merit.

- 2-17-2017** **Instead.** Another technique to discredit is to sight a situation as polarized, with the hope readers won't realize the choices aren't mutually exclusive. I could see that coming with the newest topic on the EV blog... which recognized the strong potential for Prime sales, it catching on faster than EV choices. Naturally, that brought out the hate for Toyota taking the mass-market approach. In the minds of some, leadership is only represented by pushing extremes. Acceptance by large sums of ordinary people doesn't count as progress. They don't recognize that as any type of accomplishment. In fact, many simply don't care. The word "*mainstream*" only serves as an indicator of obsolescence. That's really sad. But then again, we know that the 99% are often not considered. So, the perspective is no surprise, like this: "*It means they will continue to drag their feet as much as they can instead of going full EV.*" My guess is the reply will be snarky & dismissive: How do you figure? Lithium battery-pack production is being ramped up, used in both the regular Prius and the plug-in model. That economy-of-scale is absolutely essential for selling an affordable EV that doesn't depend upon tax-credits... which is well worth waiting for. In the meantime, they continue to improve electric design. Traction motor production is in full swing and they are delivering (in Prime) the industry's most efficient heat-pump.
- 2-17-2017** **Clueless.** That was the conclusion I came to. The series of posts responding to my lithium information were nothing but a collection of off-topic rants. Some rambling is understandable, since not everyone posts well. Communication skills vary. But when the comprehension is totally absent, not even an attempt to figure out the situation, you can tell they simply don't have a clue. For example: "*What are you talking about with the batteries? You think Toyota has some magic with lithium ion batteries? Their batteries don't mean much in the scheme of things.*" Reading something like that is a good sign of when not to bother. They won't have any idea what you're talking about. So, I just ended it with: Prius Prime offers full EV driving until the battery-pack is depleted. Adding more cells increases EV range. How does that not mean much?

- 2-17-2017** **Next Big Thing.** I found this new spin interesting: "*They have clung to the hybrid for dear life for too long now and the industry has moved to the next big thing...*" That was spoken like a truly believer in only looking forward, never bothering to consider what's on their sides or behind. Being so blinded by the hope of roads filled exclusively by EV choices that they dismiss everything else is a very big problem. Seeing Hyundai, Chrysler, Honda, Ford, and GM rollout new hybrids doesn't happen. They find a scapegoat for their frustration to be vented upon. In this case, it is Toyota. The 25-mile range delivered by Prius Prime is too confusing to deal with. A pure EV driving experienced delivered by a non-EV wasn't a problem when it was just the small & expensive Volt. It was a niche, nothing to worry about. Ordinary consumers wouldn't be interested. That's not the case with Prime though. We can see the potential. We see that opportunity about to be exploited, not squandered as GM had done. Toyota is ramping up for the next big thing... which is not EV. We'll see lots of success from the EV market. But the lack of infrastructure is still a very real problem. Prime can totally recharge overnight with nothing but an ordinary household outlet. Heck, you can even use an extension-cord for the charger. You can be out really late and have to leave early for work the next day without worry. It only takes 5.5 hours. No added expense. No special instructions. Just plug it in. Owning an EV isn't that simple for many. Driving range and recharge convenience present barriers... for the foreseeable future. It will change eventually, but throughout this current generation (the next 5 years) we face challenges. Just education alone could take that entire duration. Major expenses, like a new vehicle purchase, are very difficult to pattern break. It's far too easy to just upgrade to the newer model of what you are already driving. That's why the simplicity of Prime presents a very realistic next step for a large number of consumers. That's the next big thing.
- 2-18-2017** **Called Out.** The fighting has escalated: "*They still haven't realized just how much work needs to be put into the effort to march forward.*" There's been a defiant stance taken, making generalizations without any bother to provide specifics on subsequent posts. In other words, there's a sense of new rhetoric growing in response to the potential some see from Toyota's newest offering. It's the same old downplay from the past; they attempt to misrepresent. Making it seem as though the technology is only an upgrade, rather than at a competitive state, is key. Most everything else with a plug is stuck in the "*too expensive*" stage. So, you can imagine how much animosity is stirred from the base price of Prime. \$27,100 for a MSRP is low enough to derail any argument of affordability... so much so, there isn't even reason to mention the \$4,502 tax-credit that's also available. The potential is obvious. That means focus on stomping out undermining attempts to greenwash about the technology itself are a priority. Adding in a little bit of a personal jab works too, to ensure the message gets to intended: Prius Prime has a top electric-only speed of 84 mph. It offers the industry's most efficient electric cabin warmer, a vapor-injected heat-pump. It also has electric steering and electric A/C. There's no tie to the gas engine. It's there to take over after depletion, providing both propulsion power and the ability to recharge the pack without plugging in. Prius Prime is an EV with a small battery-pack. The next step up for power & size will be taking advantage of the hybrid system in RAV4, adding more battery-capacity for EV driving. All necessary work is already done. That attempt to disparage has been called out. You are clearly in denial of recent advancements.

- 2-18-2017** **Too Bad.** I've been participating a lot on the blogging site for EVs lately. Like with Volt years ago, a few see Prius as a threat. They push the same perspective too... lack of purity. With PHV, that had no merit. It didn't make any sense, since the purpose of the plug was to boost MPG, not to offer an EV driving experience. Comparing the two fundamentally different approaches as if they were the same was rather desperate. That's why I participated there so much... to point that out. Struggling sales is what ended up keeping the posts lively though. Technical arguments did eventually fade. Much of that came from posting video which made it overwhelmingly clear certain individuals were outright lying about how Prius PHV actually worked. I wonder if the same will be needed again, here on the new venue. Here's my effort to find out, directly confronting an individual desperate to mislead about how the new plug-in Prius operates: Prime provides an all-electric drive for the first 25 miles of travel. There's no way to spin it. That is a short-range EV, period. You plug it in and get another 25 miles of EV. You don't, the gas engine will provide power instead. With an entire system totally electric... traction-motor... battery-pack... heater... air-conditioner... inverter... charger... and controllers... there is no merit to claims of falling behind or lacking EV experience. Too bad if you don't like the approach. Refinements to design and improvements to production are several generations along now. Steps to offer a variety of affordable plug-in choices are well underway.
- 2-18-2017** **Battery Density.** At first glance, this gives the impression of being constructive: "*With a continual gain in battery energy density, you can just skip the hybrid.*" It falls apart though, when you look for detail... since there isn't any. Vague comments like that are posted all the time. No timeline. No scale. No target. No audience. Nothing. Heck, even what "*hybrid*" actually refers to is uncertain. In this circumstance, it was reasonable to assume the reference was to the plug-in type. Generalizations are basically worthless. When "*waste*" is highlighted as a concern, that waste of our time is a big deal. What did that phrase actually mean? Anywho, I posted this in return: That makes sense, long-term for many, but that certainly isn't the case for this generation of offerings. The option simply isn't realistic yet. Choices are extremely limited. Supply is almost non-existent. Production cost is too high. And the high-power recharge infrastructure isn't there. The realities of dealer disinterest and not having a plug available at home are very real barriers to overcome too. Battery technology is only a small part of the equation. In other words, being a worthy design is far from enough. The market for traditional guzzlers still holds strong consumer interest. Reaching those ordinary consumers means taking the hybrid approach.

2-18-2017 **Barriers.** Over a decade and a half of dealing with thorns has taught me how to navigate through the briar patch. Being able to avoid attack has been key. From time to time though, I have actually been able to proactively deal with the desperate attempts to bring Prius down. Like when in the briar patch, you need to know what to look for and what path works best for each particular situation. Seeing the same thing happening with this new wider audience on the green website (no more daily blog for Volt), I'm well prepared right from the start. So, I'm pointing out problems, rather than waiting to react...

I'm seeing 2 patterns emerge from discussion topics involving Prius Prime:

- Some truly believe the competition is other plug-in vehicles.
- Some couldn't care less about kWh consumption or production cost.

That first is truly unfortunate. But not seeing the forest is nothing new. They focus on their one tree and forget about everything else. Reality is, we haven't left the early adopter phase left. Those purchasing plug-in vehicles are the low-hanging-fruit, the easy sales. They are enthusiasts taking advantage of the tax-credit opportunity. True, they are helping out, but they don't represent mainstream buyers... the true competition, traditional vehicles.

The second is the ugly reality of blind hope. So much attention is set on proving the technology from an engineering perspective that other important aspects are disregarded. In this case, we see the belief that leadership comes from pushing EV range limits. Efforts to make the technology affordable aren't recognized. In fact, some is even shunned & belittled. The other problem is electricity consumption. Try pointing out KWH/MILE ratings. Watch the anger merge from someone finding out their EV is a guzzler in comparison.

Watch for confirmation of the patterns I have observed. For us to progress to further market penetration, we have to acknowledge our own barriers.

2-19-2017 **What Is Your Point?** I climbed up onto the soapbox last night, without any reason to. That surprised & bewildered some. I was asked what the point was of what I had posted. Providing a big-picture summary out of the blue like that is a bit odd to do. But then again, I was attacked for being a petroleum industry supporter for not embracing the purity of electric-only vehicles. Showing favor for a plug-in hybrid is unacceptable for some. Their absolute is all they care about. That's really unfortunate, as well as difficult to deal with. The idea of endorsing battery advancement in the form of smaller packs and lower power recharging doesn't make sense to them? They don't realize most of the world is unwilling to take one massive step all at once. Some are intimidated. Some simply don't have the money. Some don't have anywhere to plug in. Some just don't have that far to drive. In other words, we are back to the "Who?" question... which you've heard countless times now: Understanding audience is vital. If you don't, discussion value is lost. In other words, progress isn't possible.

2-19-2017 **Catching On.** That wasteful "*more is better*" perspective immediately surfaced. It's a terrible precedent to set. The seemingly simplest of things become a problem if you don't think them through. For example, a vehicle that consumes more electricity to travel the same distance will take long to recharge, since it needs more battery. Do you really want to have to wait longer for that? Do you really want to make someone wanting to use the charger after you are done to wait longer too? I expressed the growing lack-of-awareness problem this way:

Notice how some use much less electricity than others to travel the same distance?

35 kWh/100 mi = 97 MPGe = 2017 Ford Fusion Energi
35 kWh/100 mi = 98 MPGe = 2015 Chevy Volt (gen-1)
31 kWh/100 mi = 106 MPGe = 2017 Chevy Volt (gen-2)
30 kWh/100 mi = 114 MPGe = 2016 Nissan Leaf
30 kWh/100 mi = 116 MPGe = 2016 VW e-Golf
29 kWh/100 mi = 111 MPGe = 2017 BMW i3 PHEV
28 kWh/100 mi = 119 MPGe = 2017 Chevy Bolt
27 kWh/100 mi = 124 MPGe = 2017 BMW i3 EV
25 kWh/100 mi = 133 MPGe = 2017 Toyota Prius Prime

Those outcomes are the direct result of design choices. Engineers are typically instructed to favor power over efficiency. Sound familiar?

That same problem in the gas world also exists with electricity consumption. Sadly, virtually no attention is given to the topic though. In fact, a design is often mocked if it doesn't provide lots of power.

Notice how the KWH/MILE measure is almost never discussed?

2-19-2017 **It's Over, Already!** The new attacks are Toyota are quite amusing. It's confirmation of worry about their latest rollout, in this case... Prius Prime. The desperation is quite telling. Sighting extremes and drawing conclusions so early is a dead giveaway. This morning, it was: "*They ceded the EV market.*" How could I resist? Not responding to that is impossible. Resistance is futile. So, I jumped into that mess: Claiming it's all over already, despite still just being in the initial rollout stage (dependency on tax-credit subsidies), doesn't make any sense. Who exactly did the cede to? Who are you trying to convince of this? For that matter, who do you think the EV market is? By the way, I find the constant attempts to discredit Toyota by sighting fuel-cell diversity absolutely hysterical. GM just announced a major effort to invest in updating their fuel-cell technology. Honda & Nissan have been heavy investors for awhile now. Toyota is not alone. Those others also recognize that one solution does not fit all.

- 2-19-2017 Cheap Crap.** It was only a matter of time before the insulting & belittling began. One particular individual responded to several posts on the same thread all with a common theme, attempting to label Prime as: "*cheap crap*". The words of desperation I found most revealing were: "*With that amount of power and that amount of space you can hardly get out of the garage with the driver alone.*" When they don't even try to post something sensible, you know the message has got through. They see weaknesses in their own argument. The response is simply lashing out. Reaching that point is a vindication, a milestone indicating points posted were valid. If they weren't, they'd be addressed. Reverting to childish name-calling says it all. There are always a few who really struggle with the acceptance of change. It's unfortunate we have to deal with that. But then again, this behavior shows us change is happening. Each step forward has included the need to deal with this nonsense. That's part of the process. We are clearly making progress.
- 2-19-2017 Moderator Intervention.** That daily blog for Volt didn't have any. In fact, you weren't even required to register. It was open posting. That's how things became so chaotic. The website I have transferred to is quite different: "*We do not permit direct personal insults, profanity, off-topic posts, gratuitous political commentary, or denial of climate science in our comments.*" That policy isn't taken lightly either. They frequently sweep through discussion threads and enforce those rules. The posts are changed to a notice stating they have been altered by moderators to remove the inappropriate content. Individuals abusing that will get publicly called out too, given this warning: "*If you cannot abide by the rules, please don't comment at all. Repeated violations will get you banned, blacklisted, and reported as an abusive commenter. Thank you in advance for helping us keep comments on our site on topic, civil, respectful, family-friendly, and fact-based.*" The few antagonists who followed me are struggling with this new reality. Their attacks are not tolerated. This website is not filled with enablers. Participants want constructive discussion, not cheerleading. It's quite a wake-up call for those just wanting to stir trouble and express superiority. I'm delighted to see such a reversal of circumstances.
- 2-19-2017 Misleading Titles.** I'm really getting tired of the nonsense. Recently, I've stumbled across several articles where the content didn't actually match the title. If all you do is just read the title and opening paragraph, you wouldn't realize the information to follow doesn't actually support the claim being made. It's a problem we see online routinely with forum posts. That other content confirms whatever point they take the time to make, but isn't what the title suggests. For those simply looking for validation of their feelings, they tend to just gloss over what's published or don't even bother to proceed beyond the introduction. It's really unfortunate such greenwashing exists. I run into articles like that far too often. The hope is that people won't check facts, that they'll accept what's there at face value. Sad.

- 2-19-2017** **Turbocharging.** That's how a number of new vehicles are squeezing out a few more MPG... but with a penalty. There's also some type of tradeoff. Engineering is filled with things like that. For Prius, it was always the penalty of added cost. Fortunately, the simplified transmission offset that. Coming up with that type of balance isn't easy though. Automakers are getting desperate though. So, they add turbocharging. It's not like decades past. Lag is minimized. There is still added cost & complexity. Yet, that is becoming the most desirable upgrade for improved efficiency. Oh well. Someday hybrids will be more common. In the meantime, cheap gas means not bothering to make the serious investment in electrification. It's more of doing the minimum.
- 2-19-2017** **Fuel Cell, part 1.** A software-related recall on Toyota's fuel-cell vehicle is being twisted into a change of plans. How that news got distorted into a turning of favor for plug-in vehicles remains a mystery. But some antagonists have abruptly changed their stance, despite so little substance to support such a move. My guess is they've seen the potential for Prius Prime and didn't have a means of showing their agreement to the approach. Having been in opposition for so long, you look for an outlying excuse to justify the new position. That works, though it's quite a stretch if they expect everyone to overlook such an obvious move. I jumped into the new discussion with: The well informed always knew focus would shift to plug-in offerings following fuel-cell rollout. It simply didn't make sense doing them at the same time, especially since fuel-cell was long-term and the next plug-in Prius was immediate. That's why there were repeated reminders of co-existence and time-frames. It was never an either/or situation. Mirai was low-volume with no intentions of this generation being anything beyond site testing. Toyota selected an isolated area for extended real-world data collection using actual consumers. That's a textbook approach.. not a big deal like the antagonists made it out to be. The next-gen Prius plug-in was always expected to be a major step forward in the advancement of hybrids. We knew all the greenwashing posted about Toyota abandoning EV interest was a just a desperate measure to steal away the spotlight in the meantime. It never ceases to amaze me how often people lose sight of the big picture.

- 2-19-2017** **Fuel Cell, part 2.** Good reception to my previous post keep the discussion lively. A good friend of mine added: "*But sometimes you have to perform the experiment to the bitter end.*" Helping that sense of closing along provided a good feeling for all those involved. I played along, but included a dose of reality too: There was (and still is) the need to be aware of how the oil industry will respond. They are a very powerful entity with a lot to lose and strong ties to regulations. Throwing them a bone with hydrogen production opportunity did buy us time to prove the plug-in robust enough to compete with the big boys. Heck, despite the small pack in Prius PHV, the local plug-in owners group was pleased with my endorsement of lithium batteries. That is vital for both sellers & buyers. Let's not forget that the technology wasn't ever entirely throw-away either. We'll see fuel-cell use emerge in the portable-generator market, a market which Honda has always been a big player in. We'll also see the direct benefit from all the electric components in fuel-cell vehicles carried over to the plug-ins. An affordable, reliable, efficient electric-motor is valuable regardless of electricity source. We get the industry's most efficient heat-pump out of it too. Things like electric A/C, electric steering, and lots of software provide benefit as well. It is interesting to see the hybrid aspect of Prius fade into the background now. It has been so well proven over the past 20 years, that shouldn't be a surprise though. The goal was to make the technology ubiquitous... which essentially makes something you take for granted. After all, how much do you think of touch-screen technology now? 25 years in the making has proven an effort well worth it. The same is what we are beginning to say about hybrid technology.
- 2-20-2017** **17.2 Percent.** Within the next month or so, my Prime will finally be delivered. That has me closely watching final details with my PHV model. Today, it was the observation of warm-up boost. When the EV range is depleted, the engine will start up. To minimize emissions, RPM of the engine is restricted to 1500. Limiting excessive spinning is achieved by using up as much HV capacity as possible. In other words, you can see a discharge from 8 bars to 2 on the battery display. In terms of SOC (state of charge), that's a drop from 23.5 to 17.2 percent. It's a clever way to ensure a long life for the engine, that reduced stress is cleaner anyway. I suspect Prime does something very similar. After all, I clearly remember that happening which each of my previous regular hybrids... especially in Winter. Being so easy on load demand during warm-up worked great then. It was a nice confirmation of a well thought out design... if you are paying attention... since it can be heard when carefully listen. Or you can just do what I did today, watch that activity on a phone-app with lots of gauges and bluetooth connection to a OBD-II reader.

- 2-21-2017** **Consequences.** The result of fake news is beginning to become apparent. There are consequences. First, it's important to recognize human behavior. We're seeing lots of evidence of information avoidance. When a person doesn't want to hear something in particular, they will get drawn to something they prefer. When they find it, they seek out more. That's how the publishing of alternative facts comes to thrive. People feed upon it. That makes it grow. Knowing that, understanding how easily it can get out of control isn't much to ask. Volume normalizing it. Becoming familiar makes the loss of perspective a very real problem. You get so use to that extreme, the unrealistic nature of the claim gets overlooked. How could so many different sources all be wrong? Sadly, they can be. The consequences can be disastrous too. Think about how hard the oil industry has worked to convince you that there's no reason to conserve. You don't give a second thought to driving around a monster-size guzzler. Excuses are abundant. Fake news assures you all will be ok.
- 2-21-2017** **Devil's Tower.** It was a beautiful Winter day... not a cloud in the sky... no wind... warm... where we were. At home over 700 miles away, friends & family were messaging us about the danger on roads back at home. Freezing rain was coming down pretty hard. It made no sense whatsoever traveling there. Our location was just 18 miles from the turn off for the road to go to Devil's Tower. Why not? I hadn't been there for 20 years and never in Winter. Of course, 35°F is hardly Winter by Minnesota standards. So, we headed that direction. Getting there, we discovered the entrance-gate had an "*enjoy the holiday*" sign on it... informing us the national holiday meant no fee to enter. Sweet! To our surprise, only a handful of people visiting too. We almost had the entire place to ourselves. Whoa! That an incredible opportunity. I could park anywhere I wanted to take Prius photos. Hooray! I used the camera here & there, then we went for a hike. What an odd place. It was a beautiful setting out in the middle of nowhere. We did the entire walk around... though lost the trail at one point. That faint path in the snow disappeared. You'd think following it would easy. Turns out, the rough terrain makes things surprisingly difficult. We had a good time though. I took a bunch of photos without the Prius too.
- 2-22-2017** **Clueless.** I keep hearing this now: "*I still have no clue what your point is.*" That's a basic greenwashing tactic not often used... until recently. It has been coming from someone who just plain cannot see beyond the size of the battery-pack. That reality of an owner recharging at work or simply not driving that far for their commute seems to be beyond the grasp of understanding. Heck, my errand running into town is well within the reach of the capacity available for Prius Prime. Just think if I was retired. Bigger would be gross overkill. Why pay for what you don't need? That's a question we aren't even getting to. The simple acknowledgement of electric-efficiency continues to be a problem. Can some people really be that clueless? My effort to find out hasn't been going well: Imagine the same size battery-pack in the same body style. That is the point of EV offerings, for their to be a variety of choices available, right? They won't all use the same amount of electricity to travel the same distance, since efficiency differs. Some use more efficient electric motors. Quality of material and machining matters, so does the controlling software. It is no surprise that most people cannot see beyond the current size of battery-packs. That will become a really big deal at some point. Do you really want some to waste and others conserve? That's an especially important question when considering the "*guzzler*" will need to use a charging station more often or for a longer duration. It also means having a higher ownership cost.

- 2-23-2017** **July Production.** We are finally starting to hear more about Model 3 production. With Bolt still very limited, Leaf pretty much static here (though selling strong in Japan still) and the next-gen unknown, the expectation of Ioniq EV coming soon, and a next-gen eGolf on the way, there's a mix of electric-only stuff going on. So, this news was a welcome change of pace: *"Our Model 3 program is on track to start limited vehicle production in July and to steadily ramp production to exceed 5,000 vehicles per week at some point in the fourth-quarter and 10,000 vehicles per week at some point in 2018."* No one has any idea how things will actually play out in that particular market, but it is very encouraging. In the realm of purchases from the ordinary, the mainstream consumers whom all automakers much eventually reach, we still see a lot of potential for the plug-in hybrids. Being simple & affordable is key. Prius Prime will offer that. There's potential for the PHEV version of Ioniq to do the same. None others have emerged with potential for 2017. We will see Pacifica this year. But like Volt, it's on the pricey side. Being too expensive remains a deterrent for the masses.
- 2-23-2017** **Shame.** The fall of Volt isn't argued about anymore. The standout nature is gone. If faces a very real struggle now, among a market growing more and more competitive. Yet, there's still a sense of superiority. Knowing how much pride gets in the way of logic coming from that perspective, I switched to shame to stir attention. This is why: *"2019 Cadillac XT3 (Equinox-based CUV) is rumored to have a plug-in variant with 30-mi AER. Quoting Mary about lots of vehicles based on Bolt EV, sparked speculation about a full-on EV variant as well!"* It's that blind hope with no aspect of urgency, yet again. I fired back: Still no plug-in SUV after all these years, despite gen-2 Volt rollout completed and Bolt rollout well underway. Remember the Saturn Vue plug-in hybrid GM talked about back in 2006? Waiting 2 more years for a non-Chevy offering confirms they are clearly not interested in changing their primary market. Say what you want about leadership or other automakers. Heck, shoot the messenger too. It won't change that reality though. Some relentlessly fought me about concerns of progress. Yet, their so-called victory now faces expiring tax-credits and a government simply not interested in their cause. Traditional vehicles pose a massive challenge to overcome still. It's time to get serious and stop with the **mine is bigger** nonsense. What a huge waste of time. When will the push for affordable choices that are actually competitive finally begin? Proving the CAFE standards are realistic doesn't come from just waiting and hoping for the best.
- 2-23-2017** **Laughing?** Denial in the form of mocking was no surprise: *"Given GM will be the first manufacturer to run out of tax credits I'm having difficulty seeing your point. They're in first, right? Why not talk about laggards ... like Toyota LOL"* I was quite curious how that was a good thing. Leadership is not just offering technology advancements. Some people still haven't figure that out, as I attempted to convey with some scenarios & questions: Running out prior to having achieved sustainable high-volume sales would be bad. Keeping sales low to avoid running out too soon would be bad. Favoring Bolt at the sacrifice of Volt would be bad. What do we see as good? Remember, the goal is to compete directly with traditional vehicles... head on... no subsidies... and with cheap gas. That's a mighty big barrier to overcome, especially with the cards stacked against plugging in. Sorry, but reality is that Toyota having held off on their tax-credit use could really pay off. Why use them on gen-1 having known gen-2 would be so much better? That's interesting question to look back upon GM with now.

2-24-2017 **Being First.** I expanded upon last night's laughing comment: "*They're in first, right?*" After so many years of sitting back and hoping for the best, you'd think they'd notice the pattern of failure. That goal of sales growth to the level of being business-sustainable, just like popular traditional vehicles, doesn't come from that approach... as I again tried to point out:

Do you need a reminder about the tortoise and the hare? Simply being ahead doesn't mean the race will actually be won. There are tradeoffs from going faster. That story reflects as a fitting analogy. Others could still cross that finish line first. The catch is, it's not just a single race. The competition isn't just other plug-in vehicles either. Each year, traditional vehicles will address the challenges to achieve high-volume profitable sales. We see that the plug-ins have yet to achieve that, even with tax-credit subsidies.

Watching GM squander tax-credits is troubling. Volt will be left mid-cycle without any. A price-tag that's \$7,500 higher will make sales even harder. Introducing a plug-in hybrid SUV under those circumstances is terribly unrealistic.

We've been told plug-in variants based on Bolt are on the way. What does that mean for growth of the plug-in hybrid choices? Will Volt just remain a low-volume offering? We've seen the spotlight move to electric-only vehicles now.

Enthusiasts of Volt worked so hard to promote it as an EV. Have you noticed the negative effect GM's naming decision is having? Calling the electric-only vehicle "*Bolt EV*" pushes Volt out of that supposed shared category. Volt has solidified a label of plug-in hybrid, without a strong selling point. It won't be competitively priced with Prius Prime or Hyundai Ionia PHEV. It won't offer a competitive range with BMW i3. It will stand alone, without a tax-credit.

Sorry, but that is the situation. The consequences of being first are becoming apparent.

2-26-2017 **Weekend Trip.** We took a load of stuff out to my wife's parent over the weekend. The Prius was stuffed silly... not just full, so squished there wasn't even room for a change of clothes. I was amazed. What a remarkable feat. We fit an entire queen-size sleep-number bed inside the Prius, complete with all the plastic pieces for the box-frame and the foam for the outer shell. None if it blocked the field-of-view either. The entire contents fit below the window-line, not impairing the mirror inside at all. We also squeezed in a coffeemaker, 2 pair of boots, and a bag of miscellaneous items. It was quite a testament to the practical nature of having a hatchback. When those seats are dropped, it's quite impressive how much can fit inside. MPG for the drive was impressive. 49 for the 145 miles there and 56 for the 171 miles on the drive back. That was all with just a single charge with temperatures slightly below freezing. I can't wait for the opportunity to do that drive again... in warming weather with the Prime. Running errands aren't so bad when you can do stuff that way.

- 2-27-2017** **Test Drive.** It was a really nice afternoon. I had time available. Called my salesperson. She said stop by the dealer, we can take the demo-model Prime for a spin. So, I did. Then, we did. My choice of where to drive was open. I decided to jump out on the highway into the thick of the fast traffic, then get off on a country road a few miles away. That nice scenic drive brought us to a beautiful park on a lake... where there were 2 charging-stations... which still hadn't been enabled. All through out last year, there was a "*coming soon*" sign. It was disappointing. I took the chance they would finally be activated. Sure enough! It was a great opportunity to show my salesperson how the public chargers worked. I was curious how much faster the Prime would be than the PHV. I saw it ramp up to 3.75 kW, then settle in at 3.6 kW. Nice. That is quite a bit faster than the 2.3 kW from PHV. In the 10 minutes and 53 seconds it was plugged in, 0.608 kWh of electricity was added. We had started the journey without any electricity, so I had put the Prime into charge-mode along the way. Between that and the brief recharge from plugging in, there was about 6.5 miles of EV range available. I took full advantage of that. Pulling out onto the country road was with a rapid acceleration to 60 mph... using only electricity. That was impressive. Clearly, the added power from the new one-way clutch works well. Yeah! It sure was an exciting test-drive experience. There's much to look forward to.
- 2-27-2017** **Delivery Expectations.** According to the information the dealer has, my Prius was produced 10 days ago. In just 3 days, it should arrive in port. 2 weeks later, the expectation is to have it plugged in overnight to recharge... in my garage! We're getting close, so close, it's time to clean out the Prius PHV. Spring has already arrived, making that pretty easy. Back when Winter was nasty, it would have been nice to take delivery... so I could experience the extreme cold right away. Oh well. It gets like that every year. My first drives will be in much more pleasant situations instead. I'll be able to see the new color too. Being dark & dirty during January isn't fun. Having a shiny & clean car for more than just a few minutes will be really nice.

2-28-2017 **Being Affordable.** Having driven a Prius Prime less than 24 hours ago, in the cold no less, all I can say is: *Whoa!* The effortless EV acceleration is great. The cabin is surprisingly quiet. The engine is remarkably smooth. The handling on roundabouts is sweet. So, the attacks have begun. Those reviews with outright lies are starting to emerge. Until now, it was just exaggerations we had to deal with. This morning's article marked a turn for the worse. I didn't like the tone of it right from the start. Then, I read this: *"Just don't turn on the heat/AC, radio, windshield wipers, try to accelerate to fast or – get this – try to regen too much electricity going down a hill. All of these things turn the ICE engine on and keep it on for 5-10 minutes regardless of how much battery you have and what roads you are on."* I know that is just plain not true. Of course, with the silly radio & wiper reference, you'd think that was just another exaggeration example... until reaching that 5 to 10 minute part. Warming up from a cold in the cold only takes 3 minutes while driving. That's it. The 10 made me very suspicious. That was following by this conclusion: *"...it is a retrofit of the hybrid Prius design with a slightly bigger battery/motor and not much else. A hack."* At that point, it was quite clear the writer didn't actually have a clue how Prime actually worked. All the other articles with any type of credibility mention the new clutch which allows the second motor (usually used as a generator) to join in to contribute additional power. This didn't. Having a battery 9 times larger isn't by any perspective slight either. The final comment is what really made the intent clear: *"However, the patch job that Toyota did to make this Prime version an *EV* isn't worthy of your pocketbook. If you are looking for a similar plug-in petrol/EV hybrid, I'd check out the Chevy Volt, Hyundai Ioniq, BMW i3 w/REx or similar options."* No price was ever mentioned. How can you refer to a person's pocketbook without ever referring to cost of any sort? Of course, why the heck was the Ioniq mentioned? We already know the plug-in model coming late this year will have a smaller seating area in back and they electric side will deliver less horsepower. Most importantly though, price hasn't been revealed yet. Prius Prime is all about being affordable. Toyota strived to deliver that... and was very successful. Yet, this article avoided any detail to that affect. I sure will be glad when I get mine in a few weeks. Then I can start filming some drives. Fortunately, in this case, the writer did too. Watching it, we discovered he was in "EV Auto" mode... not "EV" as he had claimed... which negates much of what he said. Unfortunately, most people won't notice that though. That auto feature tells the system to take advantage of the engine when the opportunity arises. Clearly, he didn't study the vehicle before taking it for a drive.

2-28-2017 **New Attacks, Old Rhetoric.** A new thread about Toyota on an open-audience green automotive website stirred the pot. It rapidly fell apart with an effort to undermine by distraction. I was annoyed by the obvious attack on Prime, but kept my response brief and to the point: It truly amazes me how some attempt to distract from the effort to deliver a plug-in choice that delivers both outstanding hybrid efficiency and outstanding electric-only efficiency that's actually affordable by using a hydrogen red-herring.

- 2-28-2017 The Right Way.** I was quite intrigued to find out more about what this actually meant: "*But for them to hack the Plugin onto the HSD is not the right way to do it, imo. They have not moved on...*" What was his opinion? I had no idea what that could even be in reference too. It was well beyond the usual vague. So, I asked: What does "*the right away*" actually mean? Toyota delivered an outstanding plug-in hybrid. They added a one-way clutch to allow the second motor (which is usually used for generating electricity) to provide additional horsepower for propulsion. That modification allows the system to act as an EV without sacrificing any of the hybrid efficiency. Attempting to give the label of "*hack*" a negative stigma doesn't work without any explanation of your claim that they need to move on. What should they move to?
- 2-28-2017 It Got Weird.** The response to that "*the right way*" question was an answer claiming that was a response what the author of the article had written. What? Having used "*imo*" (in mind opinion) clearly confirmed that was not the case. There was nothing of that sort in the article. I couldn't find anything of that nature. So, in return, I posted: Yes, we have an insistence upon calling a "*Plug-In Hybrid*" something it is not, in this case "*EV*". I suppose that should have been given the most attention in reply. That absolute of never warming up the engine sends us astray. It only takes around 3 minute while driving, then the on/off is nearly instant. The engine shuts off so fast after a hard acceleration, you sometimes don't even notice. This makes the EV-Auto mode very handy. I'm about 3 weeks from getting my Prime, but owning an Prius PHV for 5 years, I expect the on/off to become a trivial matter. It's a plug-in hybrid, taking advantage of the engine when an efficiency opportunity presents itself.

2-28-2017 **Ill Intent.** It was obvious the article we were all posting about was an attack on Prime. Reading for detail wasn't even necessary to see that. A simple compare of the cargo photo posted for Prime verses the one for Volt makes that very clear. One was stuffed with boxes and bags haphazardly. The other had a single small item. Ugh. Quite annoyed, I summed up the ill intent this way:

Reading the article for a bigger picture, rather than getting hung up on obvious misrepresentation attempts, it simply looks like that writer didn't understand the purpose of a plug-in hybrid and has carried buyer's remorse for a very long time. This was the clue: "*The local Toyota dealership sold me on the Plug-in version of the Prius getting 12 miles of range before the ICE motor kicked in.*" Regret from having believed an incorrect salesperson can really sting... resulting in clouded judgment later.

Purpose of the augmentation was to deliver a MPG boost. Having a larger battery replenished with plug-supplied electricity allows the gas-engine to work less. Operating at lower RPM and off more frequently was a very straight-forward way of achieving that goal. There was never any absolute declared for EV driving. That's why Prius PHV was called a plug-in hybrid.

Same is the case for Prius Prime. True, you get more battery-capacity, more electric-only power, electric-only heating, and electric battery-warming. But it's still called a plug-in hybrid. In extremes, like driving in temperatures below 15°F, why not take advantage of the gas engine? It shuts off as soon as the coolant is warmed. The engine then stays off until all the heat from that coolant is depleted.

Not studying before a purchase is quite common. People make assumptions. People make mistakes. People stumble across incorrect information. That's no excuse to spread it though. Seeing a follow-up article with detail filling in what the initial review missed would be very nice.

3-01-2017 **Passing Along.** Sadly, I still encounter stuff like this on a regular basis: "*They have not moved on and left the HSD, which was GREAT in its time, behind them. Like others have said they lost an almost 20 year head start (first prius Dec. 1997).*" Lack of information is often the problem; assumptions and drawing quick conclusions are the result. Hoping to not have to deal with that pointless claim, I posted: Are you aware that is passing along of rhetoric spin? GM knew way back in 2006 that there was no possible way to compete with Toyota hybrid technology. Two-Mode design shortcomings made that overwhelmingly clear. That's why the next-gen design of Two-Mode, now referred to as Voltec, had a heavy dependency on a large battery-pack. In fact, that is why all the efforts from supporters about delivering a more affordable version called "*Volt lite*" always fell apart. In fact, that is also why GM's newest hybrid with a plug doesn't offer a smaller pack either. In other words, the others didn't move on back then. Instead, they recognized there was simply no way to match that level hybrid efficiency and devoted resources to alternative approaches. Honda got close many years later, but the system turned out to be very expensive. Hyundai thinks it can, with this year's rollout of Ioniq. Nissan is trying. GM no. Ford no. FCA no. VW no. BMW no. Mitsubishi no. Subaru no. Put another way, it depends upon your perspective. They moved on because they had no choice. That's not good in a time when gas is cheap and regulations are being rolled back.

3-01-2017 **Compelling & Affordable.** Those adjectives are often carelessly thrown about: "*I think the author wishes Toyota would had a compelling and affordable Range Extended EV in its program.*" It's easy to reveal the lack of objectivity with such claims. All you have to do is request detail. Avoidance of any type of quantifiable measure reveals ill intent. I deal with this instance by replying:

The weight increase from the battery turns out to be advantageous for handling. On both my test drives, I hit the tight round-about aggressively. The lack of body roll from the new suspension-system combined with that weight showed a clear improvement upon the previous generation. That is compelling.

Toyota's approach to raise the floor rather than keep it flat sets them up for being cost-competitive immediately, without dependency on tax-credits. That gives them a huge advantage over the more costly plug-in hybrids. It also sets them up for a potential capacity increase mid-cycle.

Very few who participate in online discussions represent mainstream buyers, those ordinary customers would just replace their traditional car with another traditional car. Those here are the ones who step up to the plate and proudly become early adopters. That's not who Toyota is targeted. Going after those more difficult sales is vital... and they are the ones who don't seek out compelling.

Think about how "*exciting*" the high-volume sellers are, those profit-sustaining vehicles. For Toyota, it's Camry, Corolla, and RAV4. Notice how well the RAV4 hybrid is selling? Notice how easy it would be to offer a Prime version? Look at the new hybrid on the way C-HR. Think about who it targets and why.

3-01-2017 **Spreading Misinformation.** That ill intent article was referred to by another. Those hoping to undermine use a misleading source to spread their own misinformation. It builds the appearance of credibility, as if all they are doing is sharing something well endorsed. It got horribly vague right away: "*A certain Toyota Prius Prime owner revealed that his vehicle lacked the promised mileage when it is set to electric vehicle mode.*" Then throughout the article, we got descriptions claiming "*another defect*" and "*sub-par*" and "*disadvantages*". Rather than providing details for you to evaluate, they make the decision for you. It's quite annoying. We've been dealing with that nonsense for decades too. My favorite part of this one was the opening: "*The 2017 Prius Prime doesn't deserve coverage on...*" That immediately set a dismal tone. I wondered who that was. You never know what searches will reveal. Turns out, the source was extremely biased. It was quite obvious. Just scrolling through recent other published articles on the front page made that easy to see.

- 3-02-2017** **Compliance Claim.** The worldwide rollout of Prime all within a few months, starting with the coasts in the United States, has contributed to greenwashing. Today, from a really nasty antagonist came: *"That didn't stop people from making the same claim against the 2016 Volt..."* He just plain doesn't care and has made that clear repeatedly. Now, he's attempting to claim the rollout is only for compliance. I wonder what his undermining efforts will shift to when Midwest deliveries begin. For now, I went with this as a response: Leaving out the part about having a MSRP so high it stands no chance of competing with traditional vehicles once the tax-credit expires isn't constructive. Prime is designed to overcome that very real obstacle of production cost & profit.
- 3-02-2017** **Reality.** It's crashing down, coincidentally, on the eve of deliveries for Prius Prime to the interior of the country. All the excuses for Volt have been used up. The long-time barrier GM created that... just like we worried ...would stifle the market, did indeed. It's history repeating itself yet again. They created a similar mess with diesel decades ago. It caused chaos within the efficiency market. Ugh. Oh well. Sadly, some more history is about to be repeated: *"The tax credits haven't expired yet. The Bolt isn't priced with their expiration in mind. When the credits go away the price will almost certainly come down."* Remember how supporters of Volt genuinely thought battery-cost would drop enough to allow gen-1 Volt to compete? It was yet another *"over promise, under deliver"* situation we could see coming years in advance. Guess what, it's happening yet again. I tried to express a sense of reality with: That won't be anywhere near enough. Simple math using a quick & generous cost drop from \$145/kWh to \$100/kWh for the 60 kWh battery-pack would only provide a \$2,700 reduction. That would only make Bolt competitive with Model 3, a highly desired EV with a nearly identical price almost 2 years sooner. It also leave Volt in a very difficult position. GM won't want to sell 2 plug-in vehicles in high-volume with razor-thin profit margins. That sets the stage for a very unwelcoming dealer & salesperson situation. It also crushes the hope of growth by spreading the tech to other vehicles. Reality is, traditional vehicles pose a monumental competitive challenge. And if you don't believe that, consider how much promotion for diesel GM has been doing lately.

3-03-2017 **Moving On, competition.** We're almost there. This month, deliveries to the center of the country will finally begin. Yeah! That will bring about fresh perspective. In the meantime, it's the same old problem. Focus continues to be limited to only plug-in choices. There's an intense refusal to look at the market as a whole still. Moving on remains a challenge. I keep trying with that stubborn group, who is not ready to consider GM choices. Oh well. Change will come soon. In the meantime, provided a dose of reality to their celebrating, with the hopes of preparing them for what's to come... Except when compared to the true competition: TRADITIONAL VEHICLES. 22,464 - Equinox; 15,367 - Cruze; 12,406 - Malibu; 7,165 - Impala; 6,606 - Trax; 4,658 - Camaro; 2,140 - Sonic; 2,139 - Spark; 2,081 - Corvette; 1,820 - Volt; 952 - Bolt. Sorry to be the voice of reality, but GM is a for-profit automaker. Plug-In sales must grow quite a bit very quickly to survive loss of the tax-credit. When that \$7,500 subsidy begins phaseout, the technology must already be showing obvious signs of being self-sufficient. We are most definitely not seeing that yet. Notice how GM is investing in 10 new diesel choices for their customers? Notice the cylinder-deactivation project underway? What about their recent investment in fuel-cell development? Do you really think dealers will be interested in selling low-profit, low-volume vehicles? It's time to focus on the bigger picture. Look at those other counts for February. Plug-In choices have a long way to go still... and that progress must happen in a very short amount of time.

3-03-2017 **Moving On, competition.** We're almost there. This month, deliveries to the center of the country will finally begin. Yeah! That will bring about fresh perspective. In the meantime, it's the same old problem. Focus continues to be limited to only plug-in choices. There's an intense refusal to look at the market as a whole still. Moving on remains a challenge. I keep trying with that stubborn group, who is not ready to consider GM choices. Oh well. Change will come soon. In the meantime, provided a dose of reality to their celebrating, with the hopes of preparing them for what's to come... Except when compared to the true competition: TRADITIONAL VEHICLES. 22,464 - Equinox; 15,367 - Cruze; 12,406 - Malibu; 7,165 - Impala; 6,606 - Trax; 4,658 - Camaro; 2,140 - Sonic; 2,139 - Spark; 2,081 - Corvette; 1,820 - Volt; 952 - Bolt. Sorry to be the voice of reality, but GM is a for-profit automaker. Plug-In sales must grow quite a bit very quickly to survive loss of the tax-credit. When that \$7,500 subsidy begins phaseout, the technology must already be showing obvious signs of being self-sufficient. We are most definitely not seeing that yet. Do you really think dealers will be interested in selling low-profit, low-volume vehicles? It's time to focus on the bigger picture. Look at those other counts for February. Plug-In choices have a long way to go still... and that progress must happen in a very short amount of time.

3-03-2017 **Moving On, history.** The personal attacks started right away... immediately followed by a newbie asking why. I was comparing GM to GM. It was constructive. It wasn't what they wanted to read though. Having deal with that rhetoric extensively over the years, I choose to reflect upon their version of history with this summary, reusing their own "*long, sad history*" claim: There's a history. A long, sad history. Over promise, under deliver. Too little, too slowly. One size fits all. There is indeed a long, sad history. Trying to steer posts to be constructive discuss has been a huge effort. My active participation in the local plug-in owners group is what keeps focus on the true competition. Celebrating a "*best*" month requires a serious look at overall sales, not just a focus only a plug-in vehicles. The push has been to get GM to diversify, to offer a choice of Voltec options. Ironically, the argument often used against Toyota has been to claim they are resting on their laurels. Now, the shoe is on the other foot. The effort to get a "*lite*" model of Volt fell apart. So, focus has shifted to get a model of Equinox or Trax fitted with the Voltec system. In other words, the goal is and always has been to get something that can compete directly with traditional vehicles... and we are still waiting... long, sad history.

3-04-2017 **Moving On, realistic.** Knowing this will all be coming to an end soon, I went all out responding to a KMA comment:

Again, you are supposed to be realistic. Celebrating a lead is fine; it's the fierce resistance to looking at the big picture that's a problem. We don't want to watch more opportunity slip away, especially with time running out. Think about why the market is moving so slow. The barrier to wide acceptance is not the technology, it's the cost.

Battery reliability has reached the point where talk of replacement due to failure has vanished. Even those with little information about plugging in focus on range concerns now... and that's only with EV choices. When discussing plug-in hybrids, it always comes down to how much they will have to pay.

That consideration of price is the challenge to deal with. Yet, no one here wants to.

GM made the decision to diversify. Great! We want choice for consumers. We want to see a commitment to growing the market. There's a tradeoff though... only enough full tax-credits remaining to last through roughly the end of next year. That means an already prohibitive MSRP will become unpalatable.

For years, we heard about cost-reduction efforts that would make gen-2 of Volt competitive with traditional vehicles. That didn't end happening; instead, we saw a shift from anti-EV to pro-EV. The very problem Volt was supposed to overcome... range anxiety ...was solved without the need for a gas-engine. That has left Volt with no marketing advantage. It has fallen into a niche. The time to be realistic is long overdue.

GM needs something to stop losses on the showroom floor. That market is still not being addressed.

At least with Toyota... since you love to bring up those comparisons ...we see an undeniable effort to align Prime with mainstream buyers. The very appealing MSRP and comfortable seating make it competitive. The fact that it is a hatchback allows it to carry larger/more cargo than the sedans. Plugging in only requires 5.5 hours from an ordinary household outlet.

Already having a competitive MSRP means, when the tax-credit phaseout begins for Toyota, they have choices available. No need for a price adjustment then will provide the opportunity for a battery upgrade. There will be a choice between physically reducing the size of the pack to offer more cargo room or keeping the size but increasing energy-density to offer more EV range.

The point is, that's realistic. Watching opportunity continue to be missed is not.

3-04-2017 **An Evening Out.** We had tickets to a performance unlike anything we had ever seen. I had no idea that would lead to a night of discovery. We decided to run some errands on the far end of the cities, since we'd ultimately end up downtown anyway. That led to a search for a new restaurant, something we could potentially take advantage of later someday when out with a group of friends. That's exactly what we found too. It was a great experience. Leaving there meant taking an entirely new route from highway to urban jungle. The dizzy array of one-way streets & construction detour made us short on time. Upon finally getting close, we decided to park in a ramp further away than expected. Walking was a good way to avoid potential traffic congestion. It was a nice night for a walk anyway. To our surprise upon entry, there were 8 empty spots for plugging in. Gasp! No need to go up several levels with the hopes of scoring a place to park. There they were, right next to the skyway entrance too. Simple parking and a full recharge. Sweet!

3-05-2017 **Moving On, goals.** The upcoming end is bringing us back to the beginning, yet again: *"And in case it isn't obvious to you, we all want the fastest growth possible. That requires all automakers to get on board."* Fortunately, things about about to change. In the meantime:

Fastest requires concise identification of goals, then placing heavy emphasis on them to achieve that speed. Rather than doing that, we've witnessed GM continue to move goal posts. The resulting outcome has been much slower than expected.

They started with the best of intent. Their plug-in hybrid goals were clearly stated: 40-mile EV range, 50 MPG depleted efficiency, base price of \$30,000 MSRP, by the end of 2010. That was a moonshot, but based upon lessons learned from Two-Mode. Unfortunately, those goals were not met upon rollout. So, a new delivery date was changed to gen-2 rollout.

Fine. We could reluctantly accept the revised timeline. When gen-2 was revealed though, the EV range was raised to 53 miles, depleted efficiency was only 42 MPG, and it started with a MSRP of \$33,220. Why had the goals been disregarded?

The overall goal to address *"range anxiety"* seems to have been all but abandoned too. There simply isn't any news anymore about improving Volt to become the EV alternative it had been marketed to be. Attention has shifted over to Bolt instead.

Other automakers are now getting on board, moving to fill in that gap GM is leaving behind. Kia appears to be the first with a plug-in hybrid SUV. Niro is now expected around October or November. Hyundai & Toyota are moving in to provide plug-in hybrid hatchbacks with Ioniq & Prime. Then, there's Chrysler with their plug-in hybrid minivan, Pacifica. We also we Nissan preparing for the potential plug-in version of Rogue hybrid and Toyota with the same for their RAV4 and C-HR hybrids. Let's not forget about Mitsubishi with the Outlander plug-in hybrid selling well in Europe either.

In other words, we want to know what the heck GM has planned for plug-in hybrids. We have the impression GM is getting off board, since plug-in hybrid activity as slowed so much. What are the goals now?

- 3-05-2017** **Fighting Back.** I'm on the offensive again, playing that position like many years ago: At the grocery store this morning, 1 of the 2 available chargers got ICE'd. My wife said "*Hi*" to that person in the spot with his traditional vehicle and pointed out that it is only for plug-in vehicles. He replied back with "*I know*", then arrogantly walked away without a care. Making excuses to try to justify the expensive nature of your plug-in vehicle enables him, with his old beat up guzzler, to not give a crap. Providing him no reason to ever believe he'll have an opportunity to plug in allows him to justify blocking the charger. You aren't taking the situation seriously, so why should he? You are the one holding back progress by blowing off the importance of cost. You are the one slowing advancement by saying diversification is fast enough. You have become part of the problem, no longer contributing to the solution.
- 3-05-2017** **Wrong!** How would you react when someone responds to all of your comments with just "*Wrong. BS.*" That's denial on such an extreme level, there isn't anything to say. Not even bothering to be constructive means nothing will make an difference. The decision to outright dismiss is quite clear. After quite awhile of mulling thoughts, I ended up with: That equivalent of yelling FAKE NEWS is pointless. Voting down to hide what you don't want to see is like sticking your head in the sand to make a problem go away... which doesn't accomplish anything either. Reality is, growth remains a huge challenge and there's an obvious effort to avoid dealing with it. Sales hovered between 1,600 and 1,700 each month for years for gen-1, back when the automotive market was smaller. Now that it's bigger, we're seeing roughly between 1,800 and 2,000 for gen-2. In other words, sales have remained flat. Knowing the \$7,500 tax-credit is limited and some of that is being used up by Bolt, it simply makes no sense just hoping for the best with Volt. You want GM to expand Voltec beyond niche use, you actually have to do something about it. Remember how & why this website got started?

3-06-2017 **Affordability.** The craziness from this paradigm shift about to come led to this summary, dealing with a rather extreme case of denial:

Sounds like your frustration with the outcome has manifested itself into a misrepresentation of me. I was interested in EV1, all those years ago. Not being able to purchase one locally, my interest shifted to Ranger EV, since production was just down the road from here. Unfortunately, the 1999 model wasn't made available here. My support for plugging in remained though, as did my support for electric propulsion... which is how Prius support came about. In fact, I helped to coin "*stealth mode*" back in 2000, from a comment about my test-drive while trying to patiently wait for delivery.

When gen-2 of Prius rolled out, renewed interest for plugging in emerged. It was still far too expensive to be feasible for the masses; however, the technology for it was evolving. The ability to travel up to 100 km/h using only electricity was already part of the Prius design. That push for affordability was well underway by automakers. Owners experimenting with augmentation had begun too, adding battery-packs in parallel to exploit the inherent part of the design.

Volt emerged as a result of a disastrous implementation of Two-Mode, its predecessor. Being well aware of the lessons learned from it and the fundamental shortcomings to overcome, enthusiasts weren't happy with me from the start. I was always trying to be practical, not allowing blind hope to setup unrealistic expectations. My endorsement for a "*lite*" version following the gen-1 sales struggle is what stirred trouble though. Some panicked, assuming that was really an effort to undermine GM's work. Sound familiar?

It was a push for affordability. I never lost sight of what was truly important. The system was simply too expensive to reach beyond interest of enthusiasts. That was overwhelmingly proven the problem by gen-2 rollout. To make matters worse, the price of gas was dropping, resulting in a growing renewed interest in guzzlers.

Being correct about affordability is how we now have the problem with Prius. The regular model uses lithium batteries, an outcome directly from the plug-in model... which I've owned for 5 years. The next-gen model I will be replacing it with next week solidifies that endorsement for the affordability approach. That irritates some Volt supporters intensely, apparently clouding their memory as a result.

Too expensive to reach the masses remains a critical issue. Overcoming that requires letting go of Volt itself, but not the technology. It just needs to be reconfigured for mainstream appeal. The need for a "*lite*" version should be obvious. Look at how many automakers are all targeting around 30 miles for EV range. It's practical & affordable approach. It even ushers in the opportunity for a SUV model. Continuing to sacrifice cost and depleted efficiency for the sake of range & power makes no sense.

Squander more time by shooting the messenger. It makes no difference to me. You know I won't go away and the message is still conveyed. One way or another, that essential aspect of affordability will come through. In the meantime, the reality of flat sales will emerge with each month's posted results.

- 3-07-2017** **No More.** The sale of GM's division in Europe brought things to a close yesterday. It's over. Change has come. I put it this way: GM is pulling out of a market unfavorable to Trucks & SUVs, investing in fuel-cell research, and rolling out 10 new diesels. Making matters worse, GM has not expressed interest toward the offering of a popular vehicle with a high-efficiency choice. Notice how poorly Malibu hybrid is selling, despite all the excitement about it 2 years ago? It's an ugly situation with little to gamble hope upon. There has been a lot of animosity toward me for pushing the "*too little, too slowly*" concern expressed by the bankruptcy recovery task-force. I worried that GM would allow opportunity to slip by... then witnessed it happening. They had their chance to capitalize on the efficiency market, back when gas was very expensive and Volt basically had the market to itself. Instead, supporters of GM praised the conquest sales and showed no concern for loyal customers showing no interest. Now, we are watching the deck getting reshuffled... with the cards stacked against support of plug-in vehicles. It's time to get serious about competing directly with traditional choices. Too bad if you hate Prius Prime for being the first affordable offering, beating Volt at its own game. As you know, my concern is for the masses, those mainstream buyers who won't have a tax-credit available. We need to look beyond that 200,000 vehicle limit for each automaker. Far more are needed right away. The ship is sinking. Efficiency requirements and emission regulations are being reduced. Time is quickly running out. No more excuses. No more distractions. No more shooting the messenger.
- 3-07-2017** **No Brainer.** That really was the end. There was no retaliation for what I posted. No more. Yeah! The endless rhetoric was awful. Seeing things through to a nice end was an unexpectedly pleasant surprise. This is what came about: "*It's a no brainer. Losing money for so long was not a smart thing.*" I kept the discussion going with: Cutting losses has been a fundamental very difficult to overcome. Some don't want to acknowledge change is required. Volt gen-2 clearly has not been able to achieve market growth needed to sustain itself. So what? Move the technology over to a platform more appealing to GM customers. They want SUVs, not small cars. Offering an Equinox or Trax with a plug should be a no brainer.
- 3-08-2017** **No Choice.** For years, I complained about the lack of choice. With the relentless attacks on Toyota, we kept hearing GM would do so much better... offering more choices, better & faster. Enthusiasts were wrong, very wrong. Their blind hope led them astray. When I'd point out the lack of supporting evidence, they'll just start waving the flag and belittling Prius any way they could think of. It was embarrassing to see such brainless behavior coming from those who supposedly were fighting for the same cause. Needless to say, that is over. The silence confirms it. They've given up. I was actually somewhat surprised. But then again, a flurry of recent announcements from other automakers puts them in a very defensive position... hence me now playing offense. To make the message of trouble to come overwhelmingly clear, I pointed out how the lack of consumer choice has now shifted to the lack of business choice: The Osborne effect is a term referring to the unintended consequences of a company announcing a future product, unaware of the risks involved or when the timing is misjudged, which ends up having a negative impact on the sales of the current product. Think of what a plug-in SUV announcement would do to both traditional SUV and Volt sales. GM is stuck.

- 3-08-2017** **Clarity Plug-In.** Remember announcements from Honda on Earth Day last year? Most people don't. In fact, I barely had any recollection. They made a statement about the intent to deliver EV and plug-in hybrid choices. Both would share the same body as their current fuel-cell vehicle. Today, 10 months later, that intent was confirmed. Details will be revealed during this year's New York auto show, which is during Earth Day. Nothing was said beyond what we already knew. The interior would be large like Accord, offering seating bigger than any other choice currently on the market here for plug-in hybrids, and range would be around 40 miles. That's really nice for people hoping for more. Price is a concern though. Honda makes a very efficient hybrid system, but it has been expensive. A capacity of that size obviously bumps the sticker up too. Nonetheless, it's a new choice to broaden reach to consumers. It's writing on the wall so obvious, those vastly superior antagonists had yet another reason to keep quiet... even more opportunity missed. I sure am glad so much time was spent on all their terrible activity. Having to deal with their nonsense was bad, but served a purpose. It was to point out the ignorance and help progress along... progress just like what Honda is striving to deliver.
- 3-08-2017** **Review Shortcomings.** This was the parting thought on a lengthy article about Prius Prime published yesterday: *"Take the tax credit and you're looking at a final cost of about \$25,000 for a vehicle averaging 55 mpg."* It spelled out in detail the packages available, then listed destination-fee, tax-credit, and base price of the regular Prius. That made it easy to understand where the final cost came from. It was well done. A long-time automotive correspondent knows how to properly convey that type information. But when it comes to plugging in, he didn't have a clue. That vehicle average simply makes no sense. What the heck was he referring to? Looking back at his EV references, there was a comment about the 25-mile capacity and notes of ranging from 21 to 24.6 miles electric-only range. Reading more, I got the impression the stated values were only the charging-estimate and that he didn't observe how many actual EV miles were delivered. Looking at the photos, it was obviously not warm. The leafless hardwood trees with browned foliage on the ground was a clear indicate of cold Spring weather. My impression was temperatures were in the 40's at the time of the review and 4 recharges he did. That meant EV range was reduced as a result of heater use. It's too bad the writer didn't take the Prime for a drive in nicer conditions. Of course, reporting overall MPG rather than only hybrid efficiency would have been even better. I suspect readers won't notice that omission. Oh well. It was still a nice article.

3-09-2017 **Misleading & Purpose.** New audiences means same old problems come back. Today, the past was stirred by an article highlighting the flood of new luxury plug-in hybrids coming... all with small capacity batteries. That puts Prius PHV front & center for real-world comparison material. Sadly, that also means fake news re-emerges too. Of course, back then, it wasn't called that. We simply referred to it as greenwashing... a term now that isn't clear, to this new audience. So, I have to reiterate some points before we can look forward: Greenwashing was intense. There was a major effort to misrepresent Prius PHV. The purpose of the plug was to augment the hybrid system, for a significant MPG boost... not to be short-range EV. Even to this day, that spin has taken hold so well, unintentional misleading lives on from unknowingly passing along greenwash material. For example: *"And it couldn't complete even 11 miles on electric power under the gentle EPA test cycles; it had to switch on its engine after 6 miles."* That statement is wrong, on 2 counts. The EPA cycle is not gentle. At the 6-mile mark, there's a hard acceleration. That triggered the engine to run briefly, then it shut off. So after, there was still quite a bit of electricity remaining. In other words, 11 miles of EV from ordinary suburb was a realistic measure. At 90,778 miles, the average with mine is 71 MPG. That's from driving for 5 years in Minnesota, dealing with harsh winters and a number of highway trips without the opportunity to recharge. Prius PHV clearly fulfilled its purpose. As for the luxury vehicles also with a small capacity, what is their purpose? Will people really be driving long distances with them or just short jaunts into town? Think about how those luxury buyers usage compared to the abundant much less expensive vehicles.

3-09-2017 **Remembering Two-Mode.** This first attempt to deliver a hybrid competitive with Prius isn't remembered, since most people don't even know about it. In fact, when Volt first rolled out, there were intense fights claiming it was a first-generation design and we needed to show patience for GM to figure things out. That was a load of garbage, an obvious & desperate attempt to buy time. Later, when gen-1 Volt struggles became obvious, they acknowledged that history. But rather than admitting Volt was a failed second attempt, they spun it as a way of expressing maturity. In other words, the "first" portrayal turned from a fresh new approach perspective into a negative stigma. Now that gen-2 Volt is also struggling to achieve growth and the end of the tax-credit advancing faster, hope has turned elsewhere. It's actually rather remarkable to see how many enthusiasts say there will not be a gen-3 Volt. That's a dramatically different attitude than in the past. Perhaps they finally see the pattern I recognized and warned about years ago... Two-Mode was too expensive and too inefficient, GM will repeat that mistake with Volt. Proof of that came before gen-1 rollout even began... hence the hate for Prius. Remember how Two-Mode was going to provide so much better MPG on the highway than Prius? That wasn't delivered for Volt either. So, hope shifted to gen-2. The same mistake was repeated again. Though third time, you're out. This current Volt just plain cannot compete. Toyota rolled out an affordable plug-in that more efficient in terms of both gas & electricity use. Hyundai is about to do the same thing. Kia will share that honor, with a SUV rather than hatchback. Now, we hear of Honda jumping in with their own offering... one unquestionably more efficient and most likely less expensive. The problem of "*vastly superior*" rhetoric has finally come to an end. Who knew the stubborn nature of some enthusiasts would cloud sensible decisions for so long.

- 3-09-2017** **Political Parallels.** Notice how this administration says everything is fine, despite an abundance of evidence to the contrary? That's a very familiar problem. How many times were we assured production-cost would dropped and demand would rise? If supporters of GM ever want Voltec spread to other vehicles, they have to be honest about the flat sales and the heavy dependence on tax-credits. Pretending all is well undermines progress. It's a self-inflicted wound. Ironically, the opposite happened with Toyota for Prius PHV. Not only was the mid-cycle limited-market rollout recognized as unable to compete (with the true competition: traditional vehicles), production was actually halted 1.5 years prior to a successor being delivered. There was no denial. There were no excuses. There sure was a lot of greenwashing from others though. Admitting more was needed isn't what they had expected or knew how to deal with. So, they choose to deceive & mislead about the outcome instead. Remember how they claimed Toyota had abandoned plugging in entirely, rather than acknowledge that halt could be the result of a much improved design on the way and the obvious benefits of not confusing customers & salespeople by rolling out the older generation any further. In other words, they said what they wanted people to believe, disregarding the information they don't like. That's exactly what we are seeing now in the political arena. It has become like theater, where they hope to draw your interest based on what their performance, not what you see in the world around you.
- 3-10-2017** **Rollout Delay.** I knew this spin would stir discussion: "*We sometimes forget that Volt went from concept to production in a short four years!*" Disregarding for the plug-in hybrid technology itself, by substituting the Volt identifier, is very misleading. It's a matter of semantics. Do you argue the idea or take everything literally? My point is that we continue to wait for that plug-in hybrid SUV promised all those years ago. Why the continued delay? I presented the situation this way, in a topic thread about upcoming technology: GM had been working on plug-in hybrid tech long before that. In fact, they revealed a pre-production Two-Mode plug-in Saturn Vue back in 2008. Being able to deliver the engineering does not mean the business will be able to embrace it though. The cost to produce that tech can keep it out of reach. Watch for parts of the tech to emerge on existing vehicles as standard. When they become common like that, then the business can move on to delivering on the next part. For example, we are starting to see that with safety packages.
- 3-10-2017** **It Gets Complicated.** A smaller battery-pack, offering greater cargo area in return, can face tradeoffs. Offering the same capacity with less physical volume would mean more dense of a build... which could lead to it being heavier. That tradeoff thought rarely crosses the minds of those simply looking at what a tape-measure reveals. Another common oversight is cooling. Increased density (through different chemistry or tighter manufacturing method) could result in a tradeoff influencing the ability to cool. Thermal limitations could impact the electric draw. You ever consider that? Of course, there's protection of the battery-pack itself to consider too. Keeping the design simple to produce & install is a decision factor for both engineering & business. In a discussion with a focus of "*trunk space*", I pointed out that there's more than meets the eye by drawing attention to the power aspect: Tradeoffs are a reality with any type of engineering. Let's not forget about EV power... 68 kW (91 hp) for Prius Prime... 45 kW (60 hp) for Ioniq PHEV. Ask yourself why. It gets complicated. There are many factors of influence.

- 3-10-2017** **Preference.** Reading this, I knew the pot was about to be vigorously stirred: "*Does anyone else notice that whenever there are "Cars of the Future", they are almost always these tiny little electric, self-driving pod-things.*" Concept vehicles rarely resemble the production model that's rolled out many years later. Futuristic renderings of what could be generations from now are basically pointless. Yet, we see them on a regular basis. It stimulates imagination and builds excitement. Of course, that did backfire with flying cars. The oldest generation came to expect something resembling that level of sophistication by now. True, we are starting to see aspects of that emerging with safety features. But we are still over a decade away from anything even eligible for the masses in terms of daily driving. Anywho, I poked back with: That is the very reason I asked the SUV question. Trying to be realistic about what people will actually buy, we need to relate it to their purchase preferences. That is why Volt & Bolt are head-scratchers. Compact hatchbacks & wagons are clearly not what GM customers favor.
- 3-11-2017** **Carbon Fiber.** This got me worked up this morning: "*German car companies have done very little beyond making minimum-range PHEVs so far.*" It was on an EV website discussing the topic of Bolt, sighting how it would have never existed without Volt. Naturally, everyone was putting their own spin on who should get credit. Never once, in any of the comments, was the word "*Prius*" uttered. With all the posts over the years, expressing intense hate for Toyota's achieve, it's undeniable there was an influence. You don't highlight something of no significance. That's why Volt got so much attention here. It was validation of Toyota being right all along, that holding true to mainstream consumer need was more important than appealing to enthusiasts. Anywho, I was happy to point out BMW's contribution. Delivering a system using a motorcycle engine with a tiny gas tank took guts. That's the type of risk GM was unwilling to take; yet, BMW gets ridicule instead of praise. The bigger step forward, which continues to be ignored, is their effort with carbon fiber. That material is 20 times more expensive than steel. The improvement to strength and obvious weight reduction is remarkable... well worth the effort to achieve cost-reduction. This is why Toyota traded some hybrid technology for the sharing of manufacturing expertise. The rear hatch in Prius Prime is carbon fiber. That's a large, complex piece of the vehicle that will have to endure impact routinely was chosen as Toyota's first step toward mass rollout. Knowing that, it should be easy to understand my response to "*very little*" claim: BMW delivered i3, the vehicle Volt was meant to be... a true range-extender, rather than a plug-in hybrid. Range of i3's first year offering was over double that of Volt too. BMW's use of carbon-fiber has been impressive, so well implemented, most people don't even realize that huge step forward in weight reduction even took place.

- 3-11-2017 Back to Basics.** The level of frustration coming from former Volt enthusiasts who have turned to support Bolt is growing. Attempts to distance themselves from that ugly history of desperate misleading for a configuration with obvious shortcomings isn't going well. You can't just ignore mistakes of the past. That's how they get repeated. The pattern is starting to get recognized. Staying true to goals is vital. With Prius, it was a careful tradeoff to achieve balance. Toyota didn't care about power only be average, since it meant keeping cost contained. GM didn't care. That priced Volt well out of reach for ordinary consumers, forcing it into a niche. Enthusiasts hated me for pointing that out on a regular basis, since I kept warning the same mistake could happen with gen-2. It was too. Why? Simple. GM obsesses with power. Heck, that was one of the reasons Two-Mode didn't appeal to GM's own SUV customers. They wanted more towing capacity. Power was inadequate... due to the relentless marketing push from GM that more is necessary. Ugh. I provided a bit of common sense... which is fall on deaf ears. Nonetheless, I posted it anyway: Replace the "*no compromise*" requirement with "*practical & affordable*", then it becomes realistic. That's the classic NEED verses WANT problem, a difference enthusiasts have a very difficult time understanding. Mainstream buyers know. Their purchase preferences are regarded as boring though. This is why Prius has rubbed Volt supporters the wrong way for so many years. Prius addresses need. Volt focuses on want.
- 3-12-2017 Charger Fundamentals.** There are problems. Lack of consistency says is all. How much you pay varies tremendously. How you access them goes beyond randomness. How fast of a recharge speed they provide is anyone's guesses. You just plain don't know. This is a big part of "*too little, too slowly*" the Volt enthusiasts did everything they could to undermine. They were likely oblivious to the problem. It was their obsession with belittling Prius PHV to make Volt appear better that prevented actual constructive discussion. The penalty that caused with gen-2 Volt is undeniable now. Having focused so heavily on EV range, simple matters like charging speed was neglected. That group of antagonists did so much damage to their own cause, they likely will never come to realize the true scope of the problem. An option available in Japan for Prime Prime is CHAdeMO charging. That's those high-speed DC rechargers Nissan Leaf takes advantage of. You'd think Volt would, especially since Leaf was supposedly since it was GM's biggest conventional competitor. (Tesla has the even faster superchargers.) Now, Toyota does too. Heck, Toyota's system offers delivery of electricity in the other direction too. In Japan, you can also get a 1500-watt inverter option. That's the ability to plug in high-power household electric appliances into your battery-pack... supplying enough power to actually run a portable A/C unit. Anywho, even the fundamental of home recharging was disregarded. Think of how many gen-1 Volt owners who end up buying a Bolt, then discover their 240-Volt charger is low-amp. Having only purchase a 20, not realizing that a 40 should have been invested in is a major oversight. Taking twice as long to replenish the battery-pack is a big deal. Needless to say, they messed up. Consequences of that are now becoming apparent.

- 3-13-2017** **800-Mile Trip.** The first Bolt owner long-distance trip published with details for others to critic didn't go well. The expense (time & money) made it clear GM should have invested in some infrastructure. The charging network is still quite limited. After 150 miles of high-speed travel, the hunt for somewhere to plug in becomes a critical concern. Chargers aren't always available. The ones that are have limitations. Some restrict use to 30 minutes per session. Others deliver a slow recharge rate. It's not as simple as using a Tesla supercharger. Bolt's charging speed isn't as fast either. As we know though, GM is terrible at balance. They focus on a strong trait and let other aspects of importance slide. With Volt, it was power & range. With Bolt, it was range & price. As useful as those purchase priorities can be to some, you don't sacrifice others... without some type of penalty. Dealer interest was a major negative consequence from Volt's obvious trade-offs... now inarguable sacrifices. It was intended to overcome the same problem as Bolt, to alleviate range-anxiety. Clearly, there is some still when taking an 800-mile trip. Oops!
- 3-13-2017** **Blatant Denial.** We've been seeing more and more of this lately: "*We are not familiar with any scientific institution with relevant subject matter expertise that has reached a different conclusion.*" That goes well beyond the usual greenwashing tactic of raising doubt. This is just a flat out lie, pretending there is no evidence whatsoever to formulate even an alternate perspective with. In this case, it was about climate change. So much proof is now available and so many scientific experts have confirmed our need to reduce carbon emissions, there is literally nothing remaining to debate. That puts them in the position of either admitting defeat or attempting to push their own agenda by ignoring everyone else. They chose the latter. This reminds me of the tobacco industry decades ago, doing everything possible to avoid their inevitable downfall. Basically, they are now just fighting for delay... but the damage they'll cause in the meantime could be enormous... especially since this is coming from the new administration. Driven by greed, money, and power, some will do anything they can to impede change. Sad.

3-14-2017 **MPG Concerns, next steps.** This new administration is working hard to undo legacy of the previous. There's an intense need to erase anything credible from the past, paving the way for change... in the wrong direction. Eliminating efficiency improvement regulations is getting a lot of attention. This is yet another consequence of "*too little, too slowly*". The naive nature of Volt enthusiasts prevented them from coming to the realization that engineering alone wouldn't be enough to overcome potential future obstacles. They foolishly expected gas prices to rise and battery costs to fall enough to overcome shortcomings with the vehicle itself. They were wrong, very wrong. Now, those same concerns are even more of a problem to overcome. Ugh. Oh well, this is how I put the situation:

All those years ago, in the early stages of Volt development, there was a statement made about price. Specifically, it was a target for delivery was set at: "*nicely under \$30,000*". When the literal interpretation of that was not fulfilled, we saw a wide variety explanations attempting to justify having missed it. The spirit of such a goal remained though... to offer something competitively affordable.

Today's topic makes the reason for that overwhelmingly clear. Worth of hybrids was always measured based upon purchase price, with efficiency gain the means of offsetting the upfront premium paid for the better technology. Worth of plug-in vehicles will be measured the same way. 15 years of history taught us that. It also taught us how difficult diminishing returns based upon MPG increase would be to show.

This is why concern for the heavy dependence on tax-credit subsidies has been a forefront issue. It's proving an extreme challenge to grow the market, even with that \$7,500 discount. Watching it be phased out, then disappear prior to the current product-cycle of Volt ended, is a major problem in the making.... which brings us back to initial price.

I am not sorry to point out that Prius Prime achieved target, since I saw this coming years ago and pushed for a second model of Volt to deliver the same. Instead, there was an intense effort to silence that concern. Now, I ask what should be done.

What next step do we expect GM to take?

3-14-2017 **MPG Concerns, attacks.** It got personal immediate, attacking me rather than even bothering to acknowledge the actual problem: "*Yet another vague rollup of straw arguments, half remembered history and meaningless queries. Meanwhile, GenII Volt easily out-performs GenII PiP in all but extreme edge driving scenarios.*" It was the same old disregard of any concern; instead, that childish "better" rhetoric was repeated. Ugh, again. Oh well, again: That attempt to downplay & evade doesn't change the intent of the "*nicely under \$30,000*" target. As for performance, that claim is a clear indication of misunderstanding purchase priorities for ordinary consumers... which is a big reason why Volt isn't competitive with traditional choices. The claim of "*all but extreme*" just plain isn't true either. Prius Prime is more efficient with both electricity (kWh/mi) and gas (MPG). Those are very important performance measures for everyday driving. Again, the question of next step for GM... What should it be?

3-14-2017 **MPG Concerns, superiority.** After a series of senseless attacks, I decided to fight back against that same comment: *"Yet another vague rollup of straw arguments, half remembered history and meaningless queries. Meanwhile, GenII Volt easily out-performs GenII PiP in all but extreme edge driving scenarios."* Re-quoting it again, but this time blatantly pointing out the advantages of Prime Prime... rather than sticking to the usual regiment of GM only discussion... was well earned:

Hope was the situation would finally be taken seriously. Cards about being stacked against plug-in vehicles. But rather than consider the market as a whole, it was just more of the same old *"vastly superior"* nonsense. I remember that history quite well... and really enjoyed your ironically vague reply today.

In what categories does it easily out-perform?

Volt = 0-60 acceleration

Prime = electric efficiency

Prime = hybrid efficiency

Prime = heater efficiency

Prime = emission rating

Prime = safety rating

Prime = turning radius

Prime = recharge rate

Keep in mind that 25 miles covers more than 50% of commuters, so calling it an extreme would be a bit of a stretch. There will be some, like me, who can recharge at work too.

3-15-2017 **MPG Concerns, goals.** The big problem with GM's struggle has been a disregard for goals. They'd ambiguously state the intent to reach some milestone, then never mention it again when it was missed. With Volt, we heard the 60,000 annual goal repeated on a regular basis. Reaching that sales rate (5,000 per month) would be strived for by the end of the second year of sales. There were attempts to retarget along the way, like the claim that count was really 45,000 for this market and 15,000 for Europe. But when neither of those were met, talk of sales got ugly. Attempts to discuss the much touted 120,000 annual production capacity which has been a popular justification point of the past turned to claims from Volt enthusiasts of Prius owners attempting to undermine & mislead. That's why turning on them by pointing out *"vastly superior"* aspects of Prius Prime is long overdue. They need a wake-up call, to finally accept what needs to be done. The concerns about MPG regulations being rolled back is a good reason to give them the kick in the butt they've deserved. It's not like Voltec is a loss. It's just poorly configured to actually compete with traditional vehicles. The upcoming expiration of tax-credit subsidies will be such a wasted opportunity too. Time is now to do something to prevent that. Addressing goals is how.

3-15-2017 **MPG Concerns, avoidance.** To my surprise, the most intense of the antagonists avoided discussion yesterday. He didn't post any type of rebuttal today either. I knew he was active online, since the new topic had several new posts from him. Normally, he'd lash out afterward to get the last word in. This time though, I obviously drove the point home... Volt has serious shortcoming, so obvious that consumers are not interested. It's really unfortunate a second model configured for mainstream buyers was never rolled out. Oh well. This is how I brought the senseless bickering to an end:

See the reason for MPG regulations?

Investment in battery production and charging infrastructure is a whole lot easier when you know the entire industry is working toward delivery of efficiency improvements.

GM's rollout of Bolt is surprisingly slow. By the time nationwide availability is reached, Tesla will be in a position to shoot past. The hope was that being early meant opportunity would be capitalized upon. We're not seeing that. We're not seeing anything in terms of high-speed charger availability from GM either.

This brings up back to asking about Volt. More of the same is clearly not going to achieve needed growth. Not hearing anything whatsoever about next steps leaves us only with that, which is really unfortunate... and give good reason to push.

Watching GM turn to diesel for higher MPG, because their plug-in sales growth continues to remain a challenge and unsold inventory of traditional cars builds up, is not what anyone hoped for. There's definitely reason for concern at this point.

3-16-2017 **Many Sightings.** I'm seeing a lot of gen-4 Prius now. The first-year glut doesn't appear to be reflective of the second. Seeing quite a number of older drivers (those who look like they've been retired for awhile) has made me wonder. Could it be that the radical look... to them... is the futuristic vehicle they had always dreamed of owning someday? What an interesting perspective. From their point of view, the design does indeed resemble what had been marketed to them long, long ago. After all, we are well into the second decade of the 21st Century. That's beyond what many ever expected to ever live. Imagine being able to fulfill a childhood desire like that. Cool! The new Prius really stands out. It handles remarkably well. Technology is gushing out. That approach really is something they thought they'd never had. What in the world does that send for a message to their grandchildren? For me, I remember inspiration of new-tech coming from my grandpa. Remember how the Mercury Sable had headlights that wrapped across the entire front of the car?

- 3-17-2017 Refill Distance?** I could have reached 1,000 miles for a single tank with my Prius PHV. It was the right combination of weather and driving circumstances. Unfortunately, I ran out of time. The next day was July 4th and plans were to travel. Opportunity lost. Oh well. That should be much easier with the Prius Prime. The longer distances between refills should allow me to collect sizeable discounts from the local grocery store too. Normally, I only have a few cents accumulated. But soon, I'll be making various purchases many more times in between visits to the pump. That should make things interesting... even more saving, beyond plugging in while shopping there. Anywho, these are the numbers from my over the past 5 years: After 91,355 miles and 172 refills, the real-world average tank distance with my Prius PHV is 513 miles. That's as real as it gets. There's a wide mix of short drives, long trips, and top-offs. The variety represents the randomness encountered from everyday need, where you don't plan when. You just do when needed. With the Prius Prime, I'll be able to drive the entire commute with just electricity. There will be a lot of errand running with EV only too. The tank is larger as well. So, it wouldn't be much of a stretch to routinely expect +1,000 mile tanks.
- 3-18-2017 Environment Attack.** It's getting ugly. All we hear is rhetoric. Unwillingness to consider any detail of any sort is a warning sign of major problems to come. Federal funding reduction is being planned on an enormous scale. The belief is that the approach to clean air & water will come from state choices instead, that they will provide the regulations, enforcement, and funding. Problem is, jurisdiction beyond state lines is a major obstacle. Litigation is costly too. Dirty emissions from burning coal or river pollution from manufacturing or construction from neighboring states is a very real dilemma. Who's going to oversee those issues and ensure everyone is treated fairly? The disastrous outcomes can be very, very expensive to resolve... and that's not even taking into account the MPG issue. Even with guzzler sales remaining in place, there are many other concerns the EPA must address still. Preventing that by cutting funds is dangerous for everyone. This administration is so short-sighted. What a terrible situation we are now having to deal with. They don't show concern for climate or the environment. Seemingly benign budgetary cuts, can have huge consequences.

3-19-2017 **Ioniq Reviews.** They are starting to trickle in. Competing directly with Prius won't be easy, especially with the misleading precedents established by Volt enthusiasts... the very thing I fought for many years, foreseeing impeded market growth as the result of such narrow-minded views. Anywho, the initial impressions of Hyundai's approach are looking good. This is what I posted as a comment for an article comparing Ioniq to Prius:

3 months of 2016 sales were lost to slow rollout of that next-generation model and the stop caused by the parking-brake recall. You simply cannot buy what isn't available. Some customers shifted interest from Prius to the new RAV4 hybrid too. There was also a wait-and-see delay from the introduction of Prius Prime.

Judging demand of the newest Prius is easier in 2017. Looking around, you'll spot them on the road much more frequently. Like with the previous generations, that "*polarizing*" demand is what draws new buyers after the first year. For those who prefer to blend into the crowd, there's the new Camry hybrid coming this fall and the RAV4 hybrid.

Looking beyond the visual appear, sticker price, and efficiency numbers, people will discover Prius comes loaded with safety features standard. Things like dynamic radar cruise, pre-collision braking, lane departure with assist, and automatic high-beams are all new and unfamiliar, so most people currently are not including them in the purchase decision. Those are part of the base for Prius, included in all models. Hyundai offers some in upgrade packages for Ioniq.

As for Hyundai itself, they seem to have done an excellent job of delivering a well-balanced high-efficiency choice of design to appeal to the masses. Ioniq should have a very positive effect on the hybrid market. The big influence will come from the 2 plug-in models though, not the regular hybrid.

3-19-2017 **Safety Coup.** The clever move on Toyota's part to offer a collection of safety features standard looks to become a coup. Automakers weren't expecting that. Hybrids have always focused on efficiency, with the expectation of other options being upgrade packages. In fact, most comparisons were mismatches as a results. That constant misrepresentation of writing a review comparing a fully loaded Prius to a base model of something else was just plain wrong. Stuff like that is how the "*greenwashing*" term cam about. Now, we're seeing comment sections pointing out how the effort to avoid bias by comparing base models of both is misleading... since even the lowest priced Prius comes better loaded. Safety features are a strong selling point too. In other words, Toyota stacked the deck and no one noticed. Having such a nice advantage is really a wise decision in this time of oil over-supply. Gas is cheap and there's no end to that expected for many years. This added appeal makes choosing much easier. Sweet!

- 3-20-2017** **Midwest Deliveries.** They have finally begun... or at least Prius Prime offerings are now listed. I haven't confirmed any are actually at local dealers yet. Searches show some though. So, we can at least say "soon" is realistic. Mine is supposedly getting closer. The end of next week is a possibility. If not then, it should be by the early part of the following. Whatever the case, it will no longer be Winter. I was able to place an order for a hitch. My effort to call ahead, prior to websites being updated, allowed for that opportunity. I was the first to get notified. That's nice, just in time for biking season to begin. I already have floormats in the garage... waiting. Meanwhile, I do know of a delivering in Nebraska. He's been anxiously hoping. That worked out nice. This reminds me so much of the first deliveries of the Classic model back in 2000. Similar rollout reports and restless wannabes were keeping the forums lively. Exactly as anticipated, we're seeing rollout ramp up just before Earth Day. This is getting really exciting!
- 3-21-2017** **Growing Demand.** We are already seeing a shift of discussions to Prius Prime. The strange discounts for Bolt and the flat sales of Volt are making that easy. It's nice actually having constructive posts to respond to. What a change. This is how I joined into the flurry of replies: Dealer interest is a major factor, one often disregarded as important in the past. Now, it's finally getting proper attention. They'll contribute heavily to demand growth. Being easy to sell is key. People see Prime, notice the plug and the sticker-price, then go for a test drive. The Prius reputation for being green, efficient, and reliable is already well known. Nothing else to tell the customer. That's it. Sold. The salesperson could matter-of-fact mention plugging in overnight to an ordinary outlet. There literally isn't anything else needing attention. Toyota nailed the KISS approach.
- 3-21-2017** **Tough Decisions.** Slow sales for Bolt and dealer discounts ranging from \$2,000 to \$5,000 has supporters wondering what's going on. This particular comment about the situation really stood out: *"Perhaps GM is suffering from the 'big truck and SUV company' image from EV buyers?"* As you could imagine, I didn't hesitate for a moment to post: Asking *"Who is the market for Volt?"* scores of times eventually resulted in that same thought. It should have been obvious right from the start. Knowing your audience is a fundamental not to be taken lightly. Enthusiasts did though. Consequences of that neglect are reflected in sales struggle for gen-2. This is why the push for spreading of Voltec to Equinox should have happened years ago. Unfortunately, the Osborne effect has become double-edged as a result of the delay. Any announcement now would have a negative impact on both Volt and Bolt sales. To make matters worse, the excitement for Tesla is growing as GM's rollout progresses far slower than anyone had hoped. The first Model 3 sales to regular customers will begin the same time Bolt finally becomes available to a large portion of the country. On the plug-in hybrid side, we are seeing both Toyota & Hyundai pushing low-priced choices, putting Volt in an uncompetitive position. Negative vote this dose of reality. You know it won't do any good. GM faces tough decisions. Are they going after conquest sales or trying to attract their own showroom shoppers? Who?

- 3-21-2017** **Missing the Point.** Some people completely lose perspective, forgetting what the original effort was trying to achieve: "*Why race towards losing the tax credit by hawking Volt as if it were a Cruze or Corolla?*" How can the intent to replace traditional vehicles with affordable high-efficiency choices be overlooked so easily? That comes from making excuses for shortcomings. Volt was plagued with a listed of goals not achieved upon gen-1 rollout. The upgrade was supposed to address them, fulfilling expectations later than hoped, but nonetheless achieved. That clearly didn't happen with gen-2 either... which is why it is mentioned so often in these blogs. Making sure those same mistakes are repeated is vital. So far, we're seeing excellent recognition of need from Toyota. It's too bad they don't. Oh well. I can only restate requirements so much. Fortunately, I can also add some perspective: That is the point of the tax credit. Its purpose is to help draw mainstream buyers to the technology. Only rewarding enthusiasts is a sign of trouble, a reason for concern. Automakers need to build up momentum so the loss of subsidies won't matter. Establishing popularity among the masses prior to reaching the 200,000 limit is how to do that. Remember, there is a phaseout period. That is limited to time, not quantity. An automaker could capitalize on the opportunity... if demand has already been created.
- 3-22-2017** **Delivery Preparation.** There isn't much I can actually do beyond wait. I ordered aftermarket floor mats and a receiver-hitch. One arrived, the other will soon. I'll be ready for a bike trip as soon as the weather warms here (Minnesota). I'll be among the first in the country to do that too. I managed to get an order request in prior to the manufacturer even revealing availability. It's nice being able to work with providers directly. They are quite receptive to those wanting to help get word out about their new product. That means even more initial photos than anticipated. Of course, I've been preparing for delivery for a very long time now. I'm definitely good to go. Keep those opportunities coming! I have a beautiful new location scoped out. It's some land just outside the extremes of the suburbs, a massive new park created to retain the wild setting yet be readily accessible. Development will surround it decades from now, making it a premiere location to escape to. It already offers an impressive pavilion just off of a large spread out parking area... with 2 charging-stations. Paths are not paved yet. The trails going around the lake and through the country are only dirt so far, but you can see the effort to make them become nice paths for walking & biking. The private road that twists through hills will be a great setting to play with the new Prime. I really lucked out with this, prepped beyond expectations. Who would of thought something so nice would emerge just before getting my new plug-in... and it only be 6.9 miles from home!

- 3-23-2017** **Video: Coffee After Dinner.** Having just upgraded to a better OBD-II reader in preparation for getting my Prius Prime, one last recording with the Prius PHV was needed. I could tell the evening would bring a nice sunset. So I saved the last third of the capacity, then plugged in upon getting home from work. That left just enough time to fully recharge while eating dinner. My drive would be to the new coffee shop and back. The engine would be partially warmed. It would reflect exactly what I encounter while running errands at night. I'd had enough electricity to get there, then switch over to the hybrid system during the return trip. That's exactly what happened too. You can see both what I see on the dashboard while driving, as well as detailed information from gauges that aren't usually available. Using that aftermarket device, I was able to capture values, then later convert them to frames of video which could be added to the camera footage. 15.3 miles for the entire drive. 9.9 miles of EV (electric-only), despite the temperature being very close to freezing. 154 MPG was the average for the drive. Looking at the dashboard, you can also see my overall average for the day... [Coffee After Dinner](#)
- 3-24-2017** **Diesel Fallout.** What a mess. As anticipated, the required updates to those VW diesels violating emission requirements are causing problems for some owners. It should have been obvious that vehicle variances would mean the proposed fixed wouldn't behave well in all conditions for all owners. Think about how different each driver's needs are, how different road conditions, speeds, and distances can be. It's hard to know how many are actually having trouble, especially since the internet tends to exaggerate problems. However, there is some merit to claims of burn-offs happening more often. This is when the revs high to produce an excess level of heat so the emissions held in the trap can be released. They need to be burned before purging. The event had been extremely rare, in the past. Now, it seems to happen on a very regular basis. Did VW plan that, but not inform owners? There are reports of stalls and rough idling now too. The expectation of the system now being sluggish & underpowered has been confirmed too. Are you ready to be following one of those TDI vehicles, waiting for a puff of smoke out of the tailpipe? Think about the MPG penalty from those updates. Even if there are not any operational issues for some, there is still that to deal with.

- 3-25-2017** **Looking Back.** Much like the the current administration, boasting doesn't match reality. Attempts to spin struggling sales for both Volt & Bolt went nowhere this week. Enthusiasts had nothing solid to work with. All the low-hanging fruit has been picked & eaten. Thank goodness that nonsense is over. GM's effort to win customers based on nothing but engineering proved a terrible plan. All we're hearing now is the same old chant: "*Give it a chance.*" Neglect of what happens on the showroom floor has significant consequences. That sounds just like the problem with all those empty political promises. Lack of substance is a dead giveaway there will be problems to come. Yet, some people blindly hope for the best anyway. I look upon the failure of gen-2 Volt to achieve the large market growth promised as undeniable evidence of struggle... and a pattern. We were told the same thing about gen-1 Volt. We were told the same thing about Volt's predecessor (Two-Mode). We are being told about Volt's successor (Bolt). How much waiting is required? With so much hype, why aren't the claimed potential buyers stepping up? The answer is simple... there's far more to a plug-in than just engineering. Important business requirements were dismissed greenwashing attempts to distract & discredit. Those who were so naive are now paying the price. We can finally move on to constructive efforts. Yeah! I'm so glad that's over.
- 3-25-2017** **Midwest Rollout.** Looking up inventory online, I see 9 Prime listed for sale locally. Finally! That doesn't mean any have actually been delivered though. It simply indicates at some point that particular VIN will be offered for purchase. None are the Blue Magnetism that I have been patiently waiting for. No one has mentioned any sightings either. I suspect mine will be among the first. It's scheduled for next Friday through the following Tuesday. So... potentially... a week from now, I could be driving a new plug-in. Unlike the excuses still coming from some GM enthusiasts, I expect Toyota demand to be obvious in just a few months. We see that growth in the limited states currently with supply to sell. Spread across the country is all it will take for the spark to turn into fire. There are supporters waiting for people like me to enable them to take the next steps. Some on-going detailed driving reports along with a small collection of videos should do the trick. They'll be able to join in to that mix in the months that follow. Prius Prime is priced for that market potential to be realistic. That horrible "*vastly superior*" attitude won't be part of this. There's simply no need. Toyota designed an affordable choice providing both electric & hybrid efficiency which speaks for itself. Now, it's just a matter deliveries beginning.

- 3-26-2017** **No Agreement.** Collapse of the effort to repeal the Affordable-Care-Act came about from the same fundamental problem Volt suffered. You wouldn't expect such basic mistakes to be made. Yet, that's exactly what happened... they couldn't agree on goals. Replace with what? How many times did I ask that of the enthusiasts. They just kept saying "*vastly superior*" over and over again. It was so idiotic. All they cared about was some aspect being indisputably better. Whether or not the vehicle as a whole stood any chance of actually competing simply didn't matter. They just wanted a victory to declare. Pride blinded them. The same thing happened with our new administration. Not delivering something helpful to the masses wasn't a concern... and they got called out on it. We're seeing the same thing play out with Volt now. The technology isn't progressing. Not having a clear direction on next steps has been the problem and continues to be. What the heck should GM be trying to accomplish? Notice how enthusiasts & supporters have virtually nothing in common? They cannot agree on goals. Heck, they don't even have a clear overall purpose. Mixed messages of the past got worse. They didn't try for any type of unity. It's a chaotic mess now. Oops!
- 3-27-2017** **Better?** I know I won't get an answer to the question. Coming from a website dedicated to early-adopters of plug-in vehicles, there's a bias so deep for more EV range, no one there considers less a good thing. It's always more, more, more. I suspect that will change relatively soon. But with only first-generation vehicle owners participating, that's a tough obstacle to overcome. With the feeling range-anxiety creates such daunting barriers to widespread acceptance, the issue of affordability simply doesn't get attention. Brushing cost-reduction off as an issue to deal with later continues to be the theme. That's why leadership from Toyota in that regard is shrugged off as unimportant. They cannot see far enough ahead to realize the lack of balance is sending them off course. If it cannot even draw high-volume sales with generous tax-credits, how in the world will it compete with traditional vehicles? The disregard for mainstream priorities is a very real problem... and early adopters continue to be unwilling to deal with it. Oh well. That's where I come in. Less EV range isn't exciting for them, but when you see the reaction of ordinary consumers, that demands a rethink. 25 miles is a lot to them. For a minimal cost, they get to plug in too... and still get to enjoy EV driving, as well as outstanding overall efficiency. This is how I asked that group: What does "*better*" mean? GM's low priority to eventually deliver something directly competitive with traditional vehicles is difficult to deny. Yet, that's exactly what Toyota has already rolled out. Again, what will happen when the tax-credits run out? That will happen in this product-cycle. The MSRP for Prime can withstand that loss. That's not realistic for Volt with its much higher price. Remember, the goal is significant sales growth.
- 3-27-2017** **New Photos.** While I wait for my Prime, there's some website stuff to wrap up. A few miscellaneous photos could be shared... before I lose track of them. The expectation is a flood of new opportunity will come with Prime ownership in the first few weeks and I'll be extremely busy trying to document all the little tidbits learned along the way. That initial experience is difficult. There's so much to keep track of that you want to remember for documenting later. Using the camera to save as much as possible is an effective means of leaving notes to myself. Unfortunately, it means sorting through literally thousands of files afterward. Oh well. Bring it on. I certainly do enjoy that work. It's a very rewarding discovery process. In the meantime, enjoy the final few new photos before they become old... [photo album 204](#)

- 3-28-2017 Fake News.** The article was off to an abrasive start with this opening snippet: "...*found it to be competent at maximizing MPG, but not much else.*" I wondered what driving data would be actually provided. Turns out, there was none. They just said it was "*boring*" and "*terrible*" and "*disappointed*". Nothing related to observed fuel-efficiency was mentioned. For that matter, nothing was about electric-only driving either. Their wasn't even any indication it was ever plugged in. In fact, this mention seemed to confirm it: "...*can be charged through a plug port located on the driver's side fender of the car*". That's wrong. The port is on the passenger side. What really got me though was: "*MSRP as tested: \$36,305*". How could that be? The highest priced model is \$33,100. It was yet another source of fake news I had stumbled across. Grrr!
- 3-28-2017 Climate Attack.** Contrary to actual data, we're hearing a lot of claims that green regulations are killing jobs. It doesn't make any sense. Improvements to the coal & oil industry extraction & refining process have been eliminating jobs for years. Sounds more like blame is being placed as a scapegoat. We know for a fact there has been a huge increase in solar & wind product production and installation from increased demand. That creates jobs. Both are renewable resources too, so there's much more potential for on-going employment than the finite amount of fossil fuels available. The renewable industry is only in the early stages too, nothing like the market saturation already causing a growth dilemma for fossil fuels. That's what makes the measures being taken now to rollback regulations such a historic event. You don't even have to take impact to the climate into account. The job aspect alone doesn't make any sense. Why would you just abandon such technological steps forward, allowing other nations to capitalize on the opportunity? It's a losing situation no matter how you look at it, a financial screw up for both short & long term. The only people seemingly pleased about the rollback promises are uninformed voters. Ugh.
- 3-28-2017 Failure.** Acceptance is a very difficult stage. Coming from an enthusiast source, this helps: "*They spent 7 years saying no. Then given a chance to do something they flopped....and they have no one to blame but themselves.*" But it doesn't really address the problem... since that was actually a comment about the Republicans in Congress, not Volt enthusiasts. The realization of the same situation applying to them hasn't sunk in yet. I did find that comment from their daily blog encouraging though. This is how I responded: Will pointing out the irony result in anything constructive? How long did we hear Voltec could be the "*game changer*", that we only need wait for gen-2 for the technology to take off? The unfortunate reality of painfully slow growth and obvious dependency on tax-credit subsidies must finally be dealt with. That attempt failed. Do you try another or pretend all is fine? It happened. Time to move on. Seeing that Prius Prime and Ioniq PHEV poised to take on the mainstream market means the suggestion for GM to introduce a competitively affordable configuration of Voltec for Equinox couldn't be more urgent. That supposed leadership is slipping away as missed opportunity. Who cares what the EV market is doing. That's a different audience anyway. Though, sales of Bolt are eating away at the limited amount of tax-credits available to GM. Something significant must happen this year. On the way is a plug-in hybrid SUV from Nissan, Kia, and Mitsubishi. We could end up seeing the debut of a CH-R or RAV4 plug-in hybrid from Toyota next year too. Shoot the messenger if you want. That isn't who to blame though.

- 3-29-2017** **Tomorrow.** What strange timing. I found out my Prius Prime delivery window has shifted sooner by a day. I could potential hear about it being on the dealer's lot tomorrow. As that anticipation plays out, I'm hearing the president exclaim he's bringing about the end to the war on coal. How ironic. You get the impression that will be an effort to bring back jobs by dropping regulations. Even if environmental concerns about the impact to air & water were abandoned, that won't change the risk to works lives & health. The fossil-fuel industry has moved on. The bulk of our energy from the non-renewable sources is split between petroleum and natural-gas. The demand for them as led to such a precipitous drop in coal interest that there will be very little to gain. Then if you look at the massive employment boom there has been from the wind & solar industries, it simply makes no sense bothering with coal. Think about how wasteful it is simply to transport all that coal. Sending renewable electricity through power lines is profoundly better. Anywho, as that all continues to dominate the news, I rather impatiently await delivery. Just think of how my real-world data will stir interest. Owners have already contributed a great deal. I join in, with 5 years of detailed data to leverage. There's a lot to share. It will be very exciting to do that too. The catch is, I have to wait until tomorrow to begin.
- 3-30-2017** **Charger Charges.** How much do you get charged to charge? There is no standard fee. It varies quite a bit. The property owner can set a fee by time, by consumption, per use, a combination, or free. That's what I tell people who ask about price. There are lots of unknowns and it's hard to tell what the person is actually asking about. In fact, the vague question of "how much" can often be misunderstood as being a reference to time or distance, not what you pay. For that matter, how to pay is usually a mystery to people. That will obviously become a section in the new user-guide I'll be writing. This is very much like back in 2001, when I discovered the large number of unknowns being asked about needed to be compiled into a resource to provide easy answers. Back then, that start helped move along the promotion of hybrids. This time around, it's for plug-in hybrids. Too bad so much time was squandered by Volt enthusiasts. None really stepped up to be supporters, providing assistance just like that. You'd think the success would have inspired. Oh well. Their loss. Now, it's prime time! I'll point out how you can request an access card or setup an account on your phone. Using the app or card will all you to unlock a charger. It's needed, even for the free ones. But the process is simple. You can check status while the charging is taking place, then look at statistics afterward. It's very informative. You can find charging-stations and check to see if they are available. Prices are listed too. It's very handy. So handy, you will likely desire a Wi-Fi enable charger at home to get some of those same data features. Mainstream consumers will have many questions. Most answers are very simple. Finding an effective means of sharing that information is very important.

3-31-2017 **Concluding Thoughts.** It's over. I'll be taking delivery of my Prius Prime soon. That brings the absurd situation with GM to a close. My concluding thoughts on that bring us back to the beginning. GM customers prefer SUVs. That's what they buy. That's what is profitable. That's why GM pursued hybrid technology for them. Abandoning the effort in favor of Volt didn't result in a game-changer vehicle. How could a compact hatchback compete? It never made any sense. The rollout confirmed that too. Volt wasn't able to achieve high-volume sales, even with a enormous subsidy. That massive tax-credit should have propelled Volt into the leadership position, as countless enthusiasts ferociously claimed it would. Finally recognizing audience is long overdue. Of course, this came about as a result: "*Wouldn't you say ALL LEGACY ICE AUTOMAKERS' challenge is the same?*" Ugh. Not recognizing the problem specific to GM seems to be root of most of the trouble. All along, that has been a fundamental barrier... some still to this day don't recognize. Oh well. It's not like I didn't try to point that out. Here goes... one last time: No, since some automakers still do quite well with car sales. It's the imbalance with GM that has been the concern since the first reveal of Volt a decade ago. Prior to that, focus was on making SUVs more efficient... hence Two-Mode. For many years, the argument was those large vehicle were much more important. We heard technology should be developed for them, since cars were already efficient. Abrupt change of focus and hypocritical stance on diminishing returns is what brought about the immediate conflict for Volt. The task-force overseeing GM's bankruptcy recovery accepted the new focus, recognizing that potential Volt had to offered... not realizing GM wouldn't actually capitalize on the opportunity. How many complaints over the years have we heard about GM not promoting Volt? With gen-2 rollout falling well short of expectations, clearly not resulting in a choice able to compete with GM's own traditional car offerings, it's time to finally get serious about SUV offerings. People shopping GM showroom floors clearly don't show a preference for cars.

3-31-2017 **Pre-Delivery Photos.** What a surreal day. My wait is over... well, kind of. I got the call. My Prius Prime was delivered to the dealer, but I won't be able to pick it up until tomorrow. My salesperson is very busy with deliveries and the dealership needs time to prep. Hopefully, they'll recharge it. But if not, at least I know it's getting close. The ultimate emotional stir didn't come from that news though. It was the revelation that my wife could have tortured me... with a golden opportunity. Unfortunately, she didn't think of it until I got home from work. She was working from home. That meant there was time to sneak out to the dealer to see the car before I did. The thought of her sending a photo of my Prime before I had a chance to get out there would have been a prank of epic proportions. Heck, tomorrow is April Fool's Day too. I haven't ever actually seen the Blue Magnetism in person. My salesperson (Kathy, a wonderful person to purchase a vehicle from, btw) said the color looks amazing in person. My wife could have. That was the ultimate gotcha... missed! Sigh. Oh well. We stopped by the dealer on the way out to dinner in the evening. This is what we saw... [photo album 204](#)

4-01-2017 **Historical Footnote.** As the years went by, an on online ally became a friend. We even got to meet in person years later. In this case, it was the guy who stepped up to help provide proof that Prius was indeed up to the chore. It was an on-going discussion thread about the Classic model Prius, back when it was brand new and the only other hybrids available were the original 2 from Honda... which were both the "assist" type. The only "full" type was from Toyota. That was ground-breaking, a new technology with potential very few understood. It was yet to be seen if the mainstream would even be interested. At that point, Prius was still an order-only vehicle. It wasn't even available on dealer's lots until nearly 2 years after I had placed my order on the internet. Anywho, we know how popular Prius ended up becoming... and that was all without any tax-credit help! That next generation to follow achieved sales of over 100,000 annual here on it's own. The subsidies to follow were to provide a push further into the mainstream, not to serve as a initial financial support as we see with the introduction of plug-in vehicles. This generation was quite significant. That friend of mine (Dennis) got the honor of naming it. The group of 50 who had been invited to Detroit for the next generation reveal were trying to come up a label which could be as well accepted as "*Classic*", so our references to the past wouldn't be misidentified. He suggested "*Iconic*". What a great idea! I was proud to support that. The identifier caught on surprisingly quick too. We heard Toyota executives using it almost immediately. My suggestion wasn't fitting... or so I thought. Little did I know that the seemingly insignificant day back November 30, 2008 would become a footnote in history. Looking forward, rather than back, brought about some clarity to what I had done... all those years ago... that I would contribute to the name of a new Prius. This is what I posted: After searching and searching through the thesaurus. It just hit me, like a ton of bricks! Since the current model is the one that was adopted by the mainstream, I followed logic of words like "*established*", "*common*", and "*widespread*". The word "*mature*" has been used countless times in response to greenwashing attempts. All those took the mindset beyond "*historic*" and "*founding*". It was the "*familiar*" feel I was looking for, a sense "*base*" that was heavily "*celebrated*" among typical consumers, even "*renowned*" by some. Being "*well-known*" by a "*broad*" spectrum of people gives it reason to have the spotlight... and will continue to, even as the new model takes hold. See where I'm going with this? I suggest we call the 04-09 model: Prius PRIME

- 4-01-2017** **Prime Time!** It's hard to believe, over a full year of waiting, delivery actually happened. The wait to place my order seemed to take forever. There's was a lot of uncertainty about how the process would take place. Interestingly though, we had enough thorough reviews to satisfy the anticipation. It was quite clear any delay would be well worth it. Taking advantage of the new pre-conditioning, electric-heating, battery-warming features was something I had looked forward to. But the idea of driving a brand new car through the craziness Winter roads here wasn't something to want right away. The heavy traffic and instant dirty is a pain. This way, Spring had already arrived. The day was upon us. My wife and I drove to the dealer to reveal our salesperson. It was to be an emotional release for all of us. What a surreal moment to remember too. So much to do all at once. The workers at the dealer had their first Prime to prep. I was rather let down that they hadn't plugged it in. The car was parked just 4 feet from an outlet too, inside their delivery room. Ugh. There was plenty of time to get a decent recharge. Oh well. All the paperwork went fine, even transfer of the vanity-plates. No big deal. After all, this was my 5th Prius purchase... making me the only person in the United States to own all 5 models. That means lots of new photos & video to add to the collection, over time. For immediate future, I have much to learn. There's lots of little details to study before the major sharing of information can begin. Let the driving begin. It's Prime Time!
- 4-02-2017** **Bike Hitch.** The desire to install a receiver hitch for carrying bikes was intense. Biking season has begun and the time to take about the car to connect the hardware was limited, especially if you want to sacrifice nice weather for the effort. I did. That beautiful Spring day was begging for it. The was, I only had about a few hours available. It was already mid-afternoon. Have you ever taken apart a new-to-everyone vehicle just moments after driving it off the dealer's lot? This was to install a hitch only made available for the first time the week before. There was a lot of complex fascia to remove before even getting access to the bumper, which I also had to remove. The hitch nestles in behind the bumper. So, you could imagine how much of the back of the Prime got removed. Blah. I was basically having another "*where no one has gone before*" experience. Sweet... or so I thought. This is how I reported my doings to the big Prius forum afterward: OMG! They weren't kidding when the install difficulty was listed as 10. It turned out nice, but that's not a recommendation I can give to anyone unwilling to really get involved. The steps are tedious & numerous. It took me 6 hours. Of course, you could always have an installer put it on. Stay tuned for photos.

- 4-02-2017** **Bike Hitch Photos.** That was quite an experience. I didn't realize taking apart the Prime right away to install a receiver hitch for carrying bikes would get so involved. Thankfully, I won't ever need to do that again. Though, it would be much easier process now that I've been through it and know what to look for. I also took the time to document what I did with a few key photos. In one, you can see the factory bumper and 4 big pieces of fascia that had to be removed to squeeze in the aftermarket equipment. Such a snug fit made the work a challenge... as well as a learning process. All those sensors and wires had me concerned. What was the proper process for accessing an area never intended to be accessed? All the connectors are that one-way type, designed to be pushed in then snap for a tight fit. The idea of breaking one or accidentally pulling too hard on a wire could be breaking the sensor-array I wasn't familiar with. Eek! The pressure to get it all done that night for our road trip the next day would have been overwhelming without such an understanding. I really love her. Good thing she trusts me with such an expensive endeavor. She sat outside for awhile to chat with me as my effort progressed. Then she went inside to make my favorite dinner... a celebration for when I finally finished... which I eventually did. The hitch turned out nice. It's well concealed and will likely need an extender. But not sticking out like the previous did on my Prius PHV is a nice improvement. Using an extender will push the bike-rack out a few inches too. That will guarantee the hatch won't ever bump on handlebars. So, we're pretty happy with my crazy decision to take the Prime apart for that. Take a look at the situation I faced during the install... [photo album 205](#)
- 4-03-2017** **Road Trip!** The very next day, it was road trip time. My wife had hoped to surprise me with this trip during "prime" timing. Unfortunately, that had been missed by 2 weeks. Delivery was later than expected. We were to travel to the river valley to witness bald eagle migration. That got missed entirely. Fortunately, there is still a population of bald eagles which nest in the area year-round. So, we still saw a few dozen... but not the hundreds possible, had it been earlier. Oh well. That was still a lot of fun. I got "prime" parking too, the spot directly in front of the entrance to the National Eagle Center. What an experience, discovering a brand new generation of hybrid technology just hours after having taken the back end apart to install a hitch. Our drive totaled 163 miles. The average came to 69 MPG, despite the cold temperature. It was a great experience, lots of opportunity to try out a number of features. Photos on the way.
- 4-03-2017** **Road Trip Photos.** We went on our first road trip with the new plug-in hybrid. With so much anticipation, you could imagine how eager I was to take photos. It was an especially big deal due to the particular color of my Prime. When looking online for samples, you quickly find the true look is very difficult to confirm. Photos vary by quite a bit. Heck, my own phone shows it as a deep blue. That's really strange. What is that palette doing to the sensors? The differences are really surprising. How can that happen? My guess is accuracy was never a big priority. I rarely ever take photos I intend to publish using my phone. It's pretty much always with my camera. The only exception is if I don't have the camera handy, since the phone is always readily available. Anywho, these are the first few photos I have available to share... [photo album 204](#)

- 4-04-2017** **First Commute.** What an amazing experience! Thankfully, it would be fairly routine... not the crazy fog-related accident debris mess I had drive through with the Classic on its first commute. This was a beautiful morning. The 19 mile drive was a delight. Travel was entirely using only electricity, with the heater on. I still had 9 miles of EV remaining when I got to work. Last weekend, I passed someone on the highway at 75 mph, all in EV mode. What is GM waiting for? What's taking so long for GM to compete? Where is the affordable choice for loyal GM shoppers? This is the mass-appeal vehicle everyone has been anticipating. Toyota delivered it. Yeah!
- 4-05-2017** **March Sales.** This was very easy to predict: *"I would bet dollars to doughnuts that the minute the credit gets cut in half, the price of most of the top 10 BEVs/EREVs will drop by a nearly identical amount. GM, Nissan and Ford are milking the system to get as much profit, as early as possible."* Of course, half doesn't account for everything. Dropping \$7,500 doesn't seem realistic in any respect. How could those automakers be making so much from such a demanding design. It doesn't make sense. For that matter, just half of the tax-credit is more of a margin than people can reasonably account for. And that's just to retain the status quo! Growing the market requires an even greater drop. I responded with: That's when Prius Prime will really begin to shine. With a starting MSRP of \$27,100 that includes a nice collection of safety features, it stands a chance of holding its own. The tax-credit dependency is much less. For that matter, the tax-credit is only 60% compared to others anyway. Current sales are still in the ramp-up stage, with multiple markets being supplied all at once. For here in the United States, that means supply in the Midwest is basically nonexistent. There are many still waiting to finally just see one in person. I got mine on April 1st, after being willing to put a deposit down and waiting 6 months... long before anyone really knew how Prime truly worked. Now that they are finding out the to-the-floor EV acceleration and 84 mph top-speed EV really does deliver, interest will grow. The efficiency while in HV mode is remarkable too; seeing over 60 MPG is routine. In short, there's quite a bit of potential the other automakers don't have.
- 4-05-2017** **Prime Sunset.** I went out for a ride with a friend. We drove by a lake as the sun was setting, quite by accident. The timing or location wasn't in any way planned. It just happened to be the route to get from where we ate to back home. I saw the colors and a parking area along the lake. I also noticed a boat launch. So, I took full advantage of the situation. Interestingly, there were others doing the same. I actually had to very quickly take my turn. I parked strategically, then popped out of the Prime with my camera and snapped a few photos. It sure is nice being able to do that handheld now. The old days of setting up a tripod are gone. Phew! Good thing too. Time was up. Getting even more lucky was being able to sneak in with the Prime facing the other direction. Since others weren't including their vehicle in their photos, that worked out well. It was a beautiful day with a great sunset. The reflection of colored light off the lake is what really made the scene. What stands out though are the leaf-less trees. Having open water and nothing but silhouetted trees with lots of branches isn't common. There's only a short span of time in the year that happens. The ice melted early this year though. Check out what I was fortunate enough to capture... [photo album 205](#)

- 4-06-2017** **Nope.** I've heard this over and over again: *"I'm telling you, if you put a Toyota emblem on the Volt, John would be it's biggest supporter."* It's a great indicator that the person doesn't actually read what I post. If they did, they'd avoid giving me yet another opportunity to repeat a certain goal. The simplicity of understanding how GM missed the mark is remarkable; yet, enthusiasts believe a compelling argument will justify paying a huge premium. That's why so many believe Volt's failure is primarily the result of GM not advertising it. They truly believe faster & further will triumph over affordability. I responded to that rhetoric with: Nope, and you know why... NICELY UNDER \$30,000. GM's goal was to deliver a plug-in hybrid with a MSRP price able to compete directly with their own traditional vehicles. That meant a decent EV capacity combined with great HV efficiency. GM still hasn't. Toyota just did. Attempt to distort history all you want; it won't change the goal... or the need.
- 4-07-2017** **Unwilling.** This reply to the stubbornness I routinely encounter speaks for itself: First mention of the *"trophy mentality"* problem was a decade ago, shortly after Volt was first revealed. That became the *"vastly superior"* attitude which pushed Volt further into a niche... where it has remained ever since. Appeal to the masses is vital; yet, that point still isn't taken seriously. There continues to be a focus on going faster & further, rather than shifting attention to what mainstream buyers actually want. Look at how many SUV purchases there are still. Do you really think a large battery-pack will draw sales? A configuration to be affordable is a better choice, something GM has been unwilling to try. Ask yourself why.
- 4-07-2017** **Trophy.** This falls into the category of reading what was posted, but not actually comprehending its intent: *"Nothing about trophies was mentioned in the article, or by anyone else except you."* Ugh. After a decade of a tainted perspective, some people simply don't have the desire to figure out if they are viewing the situation from a bias. It's shocking how each of us, including myself, will fall for that trap from time to time. Only difference here is, they've been informed that it's happening. You'd think after someone points it out, you'd check to see if that was actually the case. Nope. Still can't see it. Sad. Oh well. It's not like I don't keep trying: Repeatedly through the comments posted, acceleration speed and electric range were both touted as superior. That is an implicit trophy claim... which only enthusiasts care about and enjoy rubbing it in with inferior declarations. None of that helps sales. Ordinary consumers don't hold either as a priority. They are nice and often get praised, but there is clearly no ambition to spend the extra required to have that. In other words, you are a victim of the autoshow effect. It's a common loss of perspective. Enthusiasts attempt to normalize it too... but usually fail, as we've seen with the confirmation of painfully slow sales growth.
- 4-07-2017** **Who?** Gotta like this: *"Thanks for helping us fall more in love with our Volts with every post."* Again, oh well: You are an enthusiast, not a mainstream consumer. That's been the problem from day one. Put on your *"could I get mom to buy a plug-in"* glasses. You're in for a surprise. Reality is, most ordinary consumers couldn't care less. So whether it goes faster or farther doesn't mean anything to them. They simply aren't interested in paying such a high premium. Another reality is that Prime has a base price \$6,000 less than Volt's base and it's better loaded.

4-08-2017 **Along The River.** As we were approaching a little town on our road trip, we noticed a park with a road leading down to the river. That would allow me to park close to the water and take some unusual photos. The large trees filled with bare branches up against a gloomy gray sky would really make the color of the Prime pop out. I was really excited to find such a unique location. The location looked very old, something established ages ago, a nice oasis for travelers to just take a break at. Getting close, we could see where boats were launched and were a lot of fish remains had been dumped. With all the bald eagles in that area, I bet a number of people stopped just for the sake of watching them fish rather than going out to fish themselves. That area known for extremely high concentration of bald eagles during migration. So, keeping it in mind for a future visit would be a good idea. We hadn't originally planned to drive how on that side of the river. That made this an especially rewarding find. Anywho, this is what we saw... [photo album 206](#)

4-08-2017 **Final Attacks.** There is a handful of Volt enthusiasts who have chosen to attack Prius Prime, rather than deal with the *"too little, too slowly"* issue. It has been a legitimate concern for years. It wasn't taken seriously though. It was an endless stream *"vastly superior"* nonsense posts to deal with. That has transformed to an effort to mislead. The greenwashing of Prime is well underway. That was expected. Too bad it couldn't be avoided. Unfortunately, it was inevitable. Those who point it out get attacked too: *"An inability to let something go can be a sign of serious psychological malady, and you should really see a therapist."* That was how a post attempting to distort timelines ended. I was amused. Personal responses are a dead giveaway the person has become desperate to change the topic. I simply bounced this back:

Staying true to goals. Keeping focus on audience. Ignoring all the rhetoric. That's bad?

Reality is, Volt promises were renewed for gen-2 and the results aren't looking good halfway through the second year. But rather than actually address that, the choice is to continue to look at the situation through rose-colored glasses. Pretending all is well, that all that's needed is to patiently wait some more, is nuts.

That tradeoff of affordability, for the sake of being able to drive faster & further, has not proven a successful means of achieving market growth. The slow rate at which sales are increasing for gen-2 clearly confirm that. Yet, enthusiasts of Volt refuse to let it go. Claiming I have a problem for pointing that out is crazy.

Dealers won't be interested in selling a vehicle, already a challenge to sell, when the \$7,500 tax-credit is no longer available. Meanwhile, we see other automakers striving to reach mainstream consumers with new plug-in choices. Saying it's best to just let it go and do nothing is idiotic.

- 4-09-2017** **Change, now.** We hit that point today, that undeniable day in history where change can no longer be evaded. I expect an explosion of trapped-in-a-corner responses to result. When an enthusiasts runs out of a excuses, all they can do is lash out to go down with a fight. That's what makes this moment so decisive. It's happening right now, this very moment. The final words in the chapter are being written. I'm actually rather intrigued how it will play out. Looking back, I vividly remember that collapse on the big GM forum. It's happening now on what's left of that broken Volt blog. Change could only be delayed for so long. Some will face denial. Some will be clueless. Some will just accept it. We'll find out soon enough.
- 4-09-2017** **Change, sacrifice.** It started with a repeat of goals, to highlight the sacrifice made: Targeting mainstream consumers was always an effort to deliver something affordability competitive with traditional vehicles. Volt production cost of gen-1 was far out of the reach of that goal. That's why it failed to draw any audience beyond enthusiasts. Ordinary consumers just plain were not interested. No amount of "*faster & further*" made any difference. Even with a \$7,500 tax-credit, the price was too high. GM's struggle was avoided by Toyota when the decision to keep their mid-cycle rollout of Prius PHV limited to just the initial market. They could continue to learn about meeting purchase priorities to achieve high-volume profitable sales, without having to deal with any legacy issues. So, rather than follow an upgrade path, they could start fresh with Prius Prime... and they did. Spin from that decision was remarkable, especially from those setting expectations for Volt gen-2. We now see they were wrong. The "*faster & further*" approach failed to result in the hoped for sales growth. Consumers simply haven't been interested. Too much. It's overkill. Ironically, that is proving the opposite for Prius Prime. Toyota made their next plug-in go faster & further... which fulfills the very criteria suggested for a "*lite*" model of Volt ...and it is showing strong initial demand. GM should not have sacrificed affordability for the sake of increasing power and increasing range. What gen-1 offered was enough already.
- 4-09-2017** **Change, strategy.** Next came an effort to deal with the change by setting the focus forward as a positive outlook: It would be quite interesting to find out that GM has been working on the delivery of a "*lite*" model of Volt after all, something addressing tax-credit expiration. Imagine a Cruze hatchback with the Voltec system using a 9 kWh battery. That would be a winning scenario for GM. Volt could remain a niche, marketed as a premiere plug-in hybrid offering. Cruze would be the choice for everyday users, ordinary consumers who weren't interested in Volt. The situation would save the reputation of enthusiasts while at the same time vindicate those who had argued for a second model all along. Sounds like a win-win.

- 4-11-2017** **Change, hybrids.** I found this especially exciting to read: *"This 'hybrid' movement is a mistake. We can't afford the time to take this 'temporary' answer to the climate problem. The Auto companies are promoting them to slow the transition from ICE to EV. Ignore them, avoid them, make them go away or we will be sorry."* That attempt to dismiss absolutely everything is denial to the extreme. That certainly is one way of resisting change, though futile. I responded with: Generalizations are not constructive. Spreading fear isn't either. The commute today in my 'hybrid' was entirely with electricity, even though it had a gas engine. Promoting them accelerates the transition, by forcing a competitive return immediately. That means the battery, motor, inverter, heater, etc all must be affordable right away. Those same components can be used again later when cost of larger battery-packs comes down.
- 4-12-2017** **Change, weak.** Lasting out at Prius Prime was inevitable. Attack the obvious source of the growing sense of failure: *"The PP is weak as an EV."* It came from an antagonist attempting to defend Volt on a blogging sight not receptive to that type of posting. Sure enough, it fell on deaf ears. Knowing that would be the outcome, I posted this anyway, seeing the exposition opportunity: I've got 640 miles on mine now and all my commuting has been entirely in EV. No gas engine for highway merging, passing, or cruising. It's all electric, with power to spare. The vapor-injected heat-pump is the industry's most efficient electric heater. The electric A/C is a top-notch offering too. I'm also seeing averages around 4.5 miles/kWh. What part is supposedly weak?
- 4-12-2017** **Change, audience.** I was waiting for the enthusiast perspective: *"Many reviewer said that they would rather pay more for the Volt due to FAR SUPERIOR driving dynamic."* It's amazing to confirm how naive some can be. They think their excitement is shared by ordinary consumers. I know mine certainly isn't. If I can draw any interest from my mom, who couldn't care less about a vehicle other than it being comfortable, practical, and reliable, it means I'm on the right track. That means anything related to how the vehicle operations is of no value. That simply isn't a priority for her, as is with most middle-market people. This is how I stated the situation, to hopefully give some perspective: Wrong audience. Ordinary consumers couldn't care less. Those mainstream buyers are looking for a good all-around value. They are unwilling to pay a premium for more, no matter how much enthusiasts provide praise. People declare bias, not realizing they themselves are not representation of those shopping showroom floors, nor having anything in common with them. Volt began as a niche and continues to be. That's fine. We all like faster & further. But that simply is not what middle-market is looking for.
- 4-12-2017** **Change, more.** It's not better. Ugh. You'd think they'd finally come to terms with that, even at this final hour. Nope: *"...don't twist the fate that Prime EV mode is relatively weak."* I find it truly amazing how they think their point-of-view is shared by everyone else. Some people simply aren't interested. That's just the way things are. Different people have different draws. Not everyone likes the same thing. That's why no matter how many times they tell you that the higher price is worth it, some simply won't be willing to pay more. Oh well. All you can do is hope the message eventually sinks in: Face reality. Faster & Further isn't worth a premium for most people. That's why Camry & Corolla are so popular. They target that same market, the middle. Being *"strong"* loses to being well-balanced.

- 4-12-2017** **Change, EV.** Nope, it didn't make any difference. There's still hope that somehow the early reviewers really did interpret their observations correctly: *"I hope they get to test drive the Volt at some point later after having the prius for a while and realize that the gas engine does not have to come on for reasonable acceleration..."* At this point, I've watched quite a few reviewers where the buttons were incorrectly explained. They were clearly mistaken about what each actually did with respect to engine-use and battery-draw. It's rather disheartening to find out how few actually take the time to verify their assumptions. Oh well. Eventually, I'll have videos of my own to refer to, confirming they were wrong. For now: Just switch to EV mode instead. No surprises. There are many reports from people not realizing they are actually in EV-Auto mode, completely unaware that it allows the engine to start at time of high demand. Looking at the button layout, it's easy to see how that mistake could be made. There isn't actually a button labeled EV. You have to look carefully at the dashboard to see the change from pushing them. We've seen people make an incorrect assumption. It's no big deal once you've owned the car for a little bit. Many reviewers simply have no idea what's even available. So, the mistake happens. Owners take the time to push all the buttons. There isn't a rush to write a review and return the car.
- 4-12-2017** **Change, purpose.** Don't you love how some people draw conclusions based on nothing but assumption: *"Most people buying this are gas first, EV second, the opposite of Volt drivers..."* How could that possibly be known about Prius Prime already? I rebutted back with: I don't believe that for a second and I can't imagine you being able to produce data to confirm such a claim. The comments I have encountered overwhelming speak of excitement to use the 25-mile capacity to the fullest, prior to purchase. After purchase, ownership reports of by how much they exceed that EV rating distance are plentiful. Of course, what difference does it make? They aren't the target market anyway. Volt is an enthusiast vehicle. It's nice, but simply priced too expensive for mainstream buyers. More capacity isn't necessary. Faster acceleration isn't necessary. GM doesn't offer something to compete directly with their own vehicles on their own showroom floor. Toyota has just begun. Prime is clearly configured to entice Corolla, Camry, and Prius shoppers. Even without a tax-credit, it can compete directly. The test-drive experience seals the deal. No need to mention MPG. No gas necessary. That EV acceleration, dropping the pedal all the way to the floor without the engine starting, speaks for itself.
- 4-13-2017** **Change, buttons.** The level of desperation has spread. This came out of nowhere: *"I'm also a sucker for physical buttons."* People look at the large screen available for Prime and attack it with claims just like that. There's a full compliment of interface buttons, they just aren't next to the screen. That would make any sense. If you are reaching for the screen, just touch it to make selections. If you don't want to reach, just push with your thumb. Everything you need to interact with the screen is right there... a redundant interface the antagonist hopes you won't mention. They want people to focus only on the screen and assume that's the only way to adjust the sound system or change climate settings. Ugh. I kept my response to that brief: Like all the buttons on the steering wheel? I'm finding that most people look at the screen and never notice all the physical buttons still available.

- 4-13-2017** **Change, price.** The effort to obscure business purpose by focusing entirely on the now from a consumer's perspective was greenwashing years ago. Now, it's nothing but an act of desperation. Yet, a few keep trying: *"Anyway, count in the tax credit, I don't see any point that can make PP win in pricing."* Attempts to misrepresent the problem by confusing cost & price is what I have to deal with most. They pretend they are the same, that it's just an arbitrary label with no different meaning. My guess is the problem originates from people without any type of business background. Never having taken an accounting, marketing, or economics class, I could see how certain concepts could easily be overlooked. Overlooking basics is far more common than most people are aware. That really messes up online discussions. It still try to point out that not-so-obvious problem though: COST not PRICE. Sure, a consumer can snag a good deal right now, but that is very temporary. GM's business model is heavily dependent on the tax-credit. Toyota's is not.
- 4-13-2017** **Change, cost.** Sure enough, I got exactly the response I had anticipated: *"Cost or price doesn't matter as it's just terminology."* That figures. Such a lack of basic understanding means nothing to follow will be of any value. They'll just dismiss what you say as an attempt to twist facts. They pretty much never take the time to actually comprehend what is actually posted. That's the way these final few think... or don't. I'm sure glad there are far more supporters who did. They've become much valued allies for the plug-in effort going forward. Unfortunately, they don't try to help with the cost issue. I suspect some of that comes from price uncertainty. What will GM do when Bolt accelerates the phaseout trigger for Volt? How will a low-volume offering stay relevant in a rapidly growing market? Anywho, I kept the reply short: There's a profound difference, a fundamental relation between business & customer clearly not understood. $COST = \text{how much } \$\$ \$ \text{ it takes to build a vehicle. } PRICE = Cost + Profit - TaxCredit.$
- 4-13-2017** **Change, goals.** Spoken like a true enthusiast of Volt: *"About Toyota, they have been losing the PHEV since the first gen of PHEV Prius, this is their effort trying to get back on track. I have to agree that it's quite a good car but clearly not impressive."* All I could do was recite the same old big picture, which some still refuse to accept... despite the obvious sign of change now upon us: Assuming goals were the same, it's easy to draw that conclusion. They were not though. Toyota rolled out Prius PHV as a mid-cycle update to just 15 states. It started out as an effort to gather a massive amount of real-world data... and continued to be as they witnessed the problems GM was having with the market. That kept rollout confined to those markets, where they could more deeply collection information about what ordinary consumers actually want & need. That has put them way ahead of GM, who has clearly stumbled with gen-2 of Volt... having delivered another enthusiast-oriented vehicle, rather than something for the masses. Say whatever you want about it not being impressive. That will just fall on deaf ears. Those shopping the showroom floor couldn't care less. They don't participate in online discussions. They don't want to pay a premium for performance. Heck, they aren't even interested in statistics. They just want something affordable, reliable, and practical. Toyota has not lost their customer base. The target audience of Corolla, Camry, and Prius shoppers is still there, waiting for Prime. None of them care that GM temporarily gained some conquest sales. Toyota was never off track. They patiently waited and didn't squander tax-credits in the meantime. That resulted in a well-balanced design with a variety of refinements capable of competing with the true competition... traditional vehicles.

- 4-13-2017** **Change, sales.** I wonder what next month will bring. This was my continuation on this history now coming to a close: Reading the same old rhetoric repeated again is a sign of sales growth concern. That continuation of complete disregard for business cost, focusing solely on price paid by the consumer, tells a story of short-sightedness. Attempting to draw as much attention as possible to speed & handling is confirmation. That nonsense solidifies shortcomings. What I find most revealing though is the lack of understanding for audience. Look around. Notice what people actually buy? Ask around. Notice how people actually shop? Middle-Market is what provides business-sustaining profit. That's high-volume production, resulting in sales far greater than the tiny fraction celebrated each month for plug-in vehicles. In other words, the spin here shows that situation still isn't being taken seriously.
- 4-14-2017** **Honda Clarity.** The is currently a fuel-cell vehicle. For the 2018 model year, it will also be offering as an EV and a plug-in hybrid. What I'm most interested in is the later, which is what Honda is too. The other models will be built in very, very limited quantity. The impression given for the EV is just 1,000 per year. So, it's short range really isn't any reason for concern. Honda is simply experimenting with diversification of that platform. Knowing the bulk of those Clarity produced will be the PHEV type is a big deal. The battery-pack will be 17 kWh, which should deliver roughly 42 miles of EV range. The EPA rating expected is 105 MPGe. Being a larger vehicle than Prime, that's not too bad. Electric power is somewhat overkill though. Delivering 181 horsepower isn't really necessary. It's likely a by-product of the battery-pack's capacity. Being larger may offer more amps to pull all at once. That's rather disproportionate to the included 1.5 liter gas engine. It seems rather small, especially when compared to the 1.8 liter in Prius. Of course, it may be setup for an ordinary Otto cycle... which provides more power, with a tradeoff of being less efficiency than Atkinson-Miller. The expected MPG rating was not included in the press release. So, that does seem likely. Recharging only takes 2.5 hours. That's clearly faster than what Prime offers. Having a larger pack, that makes sense. It will be interesting to learn more about this new market entry. Honda most likely learned quite a bit from their limited offering of the plug-in hybrid Accord. That seemed an effective way to collect lots of real-world data, similar to what Toyota did with Prius PHV. We got a nice upgrade as a result. I'm really enjoying the improvements this next-generation provides. Prime is great. Hopefully, the same we'll be able to same about Clarity too. Expanding the market by getting decent choices from other automakers is vital for overall growth.
- 4-15-2017** **What?** The superiority posting continued. It's all about being faster and going farther. That's all this group cares about. To hell with cost. Without bragging rights, you've got nothing... is their mindset. 10 years ago, I said that trophy-mentality would be their downfall. Now, we are watching the change reveal those consequences. They never figured out that their own hopes would have such an influence. It was the same "more" attitude without end. Reading this today summed it up well: *"Toyota is falling behind on this front, considering they practically invented this segment 20 years ago."* I asked: What front? They are pushing diversity by spreading the new design to Camry, RAV4, and C-HR. They are pushing lower cost by not depending upon a large-capacity battery or tax-credit. They are pushing to avoid expense & complexity by eliminating the need for liquid-cooling. They are pushing both EV and HV efficiency results.

4-15-2017 **Who?** The hope was always a recognition of the true problem. That never happened. Now, change is leaving them behind. Lack of audience understanding problem... and appears it will continue to be, for the enthusiasts. The rest of us welcome the next chapter. A variety of affordable choices will be great. We know more isn't better. They still haven't figured it out. It's continues to be just dealing with the problem on a basic level, still avoiding detail: *"Anyone who wants primarily EV driving but still has the flexibility to drive on gas to eliminate range anxiety."* I had no idea my education from 15 years ago about regular hybrids would apply so well to plug-in hybrids. Oh well, it's their loss... which means my reply will just fall on deaf ears: That generically answers the question of who for PHEV choices. It does not tell us who Volt specifically targets. In other words, Prime specifically targets people shopping the Toyota showroom floor. They come in interested in Corolla, Camry, or Prius and end up being drawn to Prime. Volt clearly didn't target Cruze or Malibu shoppers. That was overwhelmingly confirmed for gen-1. Heck, even GM itself made a comment to that effective, identifying the first as a niche. That's why I ask about gen-2. Hearing emphasis for faster & further, at the tradeoff of size & price, suggests this newer Volt doesn't target Cruze or Malibu shoppers either. Notice how Toyota really focused on cost-containment, not giving into the temptation to deliver more, knowing all too well that resulting higher price would disinterest their showroom shoppers?

4-15-2017 **Question.** During a time of change, if you push really hard, sometimes new voices emerge. I got this: "*Question for you: All else aside, do you even like the Volt? Have you ever drove one? If not I'd gladly meet and let you take mine for a spin.*" This came from a die-hard enthusiast who lives in the area that hopes I simply misunderstand the performance benefit of Volt, that experiencing the power firsthand will alter my beliefs. He clearly has no idea how intense my effort in support of middle-market has been. Middle means not maximum. I'm simply not interested. Heck, that's why Model S was never of any interest. As great of a vehicle Tesla delivered, it was always out of reach for the masses. Model 3 is different though. That "*lite*" version strives to be affordable. I always hoped GM would deliver something similar for Volt. After 10 years, no luck. Ironically, Toyota did though. Prime is turning out to be everything Volt supporters had always hoped for. Unfortunately, Volt enthusiasts never agreed with that. Oh well. His question allowed me to climb up on the soapbox one last time:

Yes, I like it, And yes, I have. It was over on the GM Innovation track. That was a lot of fun. I even ended up chasing a Tesla with it. My assessment was the engineering was great, but it was a terrible configuration for high-volume business... too expensive.

So, I campaigned for a "*lite*" version of Volt, a second model that would be affordable for the masses. Leaving the existing version as a niche rubbed those here the wrong way, but they tolerated it with the hope gen-2 would deliver the hoped for balance.

Instead, gen-2 solidified the niche... and gen-2 from Toyota ended up becoming the very configuration I had suggested. So basically, anything I say now in that regard is unacceptable. It's why my focus shifted over to SUVs, the other obvious electrification choice.

Honda's introduction makes the bad situation even worse though... large seating, 42-mile range, 181 horsepower.. That's roughly what an Equinox with Voltec would deliver. Catch is, GM has no plans for that. Kia does with Niro, their plug-in hybrid SUV comes out the end of this year.

Long story short, change is coming. The spread of Voltec to other vehicles will dilute the importance of Volt. This is the closing of a long, drawn out chapter. That's never comfortable. I make myself a target by pointing it out.

It is interesting to look back at the "*range anxiety*" history. Bolt should have never been built based upon what GM promoted for many years. The anti-EV automaker shook up their own status quo.

4-15-2017 **Distorting History.** I get really annoyed when coming across claims like this: "*Then back in 2015, Toyota leaked that the next Prius plug-in would have 30-35 miles electric range.*" It referred back to an article on a popular green website. There were 325 comments posted. It proved to be a popular topic, but now serves as fodder for misleading... which was exactly what happened today. I jumped on that with: "*we heard from an industry source*" is what the article stated. It was unconfirmed speculation, a good topic for online comment posting, but quickly died after nothing was actually heard from Toyota. There was no promise. None of us had any idea what the next generation would bring. All we knew was keeping it affordable continued to be top priority. My guess was double the original target. For gen-1, it was 20 km (12.4 miles). Setting a target of twice that would put gen-2 at 40 km (24.8 miles). That seemed reasonable, especially when based upon real-world data from gen-1. We didn't hear anything from Toyota though, until the first reveal of the vehicle nearly 2 years later, long after production of gen-1 ended. It's easy get a distorted view of history from reading just a single article. Check the blogs of the time, those on-going sources of information. They bridge together speculation with what ends up actually happening, especially when looking back can provide such a different perspective. Also, keep in mind how automakers must be flexible to be competitive now. That means altering plans along the way, as well as allowing an opportunity for a mid-cycle upgrade.

4-15-2017 **Next?** Things are rapidly coming to a close. Those Volt enthusiasts still don't recognize they are about to be left behind. Interest in affordable configurations of plug-in hybrid vehicles is about to erupt. We've reached that point where they are now in reach of ordinary consumers. Those wandering the showroom floor can finally take the choice seriously. In the past, that decision simply wasn't realistic. That "40-mile" belief seriously messed up expectations. GM impaired the initial market with plug-in hybrids much like they did with diesel a few decades ago... they rushed a poorly designed vehicle to dealers. We all worried they'd repeat that mistake. It happened anyway. Now what? I ended the chapter with:

Taking the step from niche to mainstream has been the point of contention. It requires letting go of some of the original aspects of appeal. Niche traits are what made it special. Watching that get diluted for mass acceptance is tough. Since I had extensive experience with making that transition, it made me the focus of resistance. Change isn't easy. Being reminded that it is inevitable is much like the parent reminding the child to finish their homework. Neither likes it. That is necessary though.

With the case of Volt, that same message of change is being sent from multiple sources. There are several new plug-in hybrids. There are 2 major electric-only vehicles. There is GM itself. All are pushing Volt in a direction enthusiasts don't like. Upset about the market stability once enjoyed now being lost is not welcome.

Notice how the seemingly simple question of audience stirred such extreme reaction? It is confirmation of recognition. We witnessed the same level of emotion back when Ford joined in. Placing GM against Toyota was a basic tit-for-tat. Adding in another automaker created an unmanageable level of complexity. Mixed messages of purpose caused enthusiasts to oppose each other... which resulted in the quest to seek out a scapegoat.

Blaming me for the push to move on to that next chapter is a pointless as avoiding homework. Yet, that's exactly what we see with the negative votes. Pretend all is well still. Don't listen to the message. Shot the messenger.

It's really sad. The local plug-in owners group doesn't have any problems like those here. We focus on the building up of infrastructure, helping businesses & individuals setup charging stations. We get together to show our variety of plug-in vehicles. We share as much information as possible about strengths & weaknesses of each of the choices.

There is no conflict. There's a shared common goal. None of the faster & further nonsense even comes up in discussions. We strive to learn as much as possible with open exchanges, striving to find ways of overcoming the true competition: traditional vehicles.

The greenwash attempts each month to spin stories about sales has to stop. There are examples in this thread of generalizations & omissions which confirm that behavior. Look forward, not back. What should be done next?

- 4-15-2017 Repeating Mistakes.** A fundamental flaw with the approach for Volt from enthusiasts was ignoring the past, just like executives in GM did. When Prius hit mainstream sales levels, then exceeded them... without any tax-credit help ...it was GM who mocked, belittled, and dismissed what had been accomplished. They said a much better solution would be delivered by GM instead. That turned into a disaster. Remember Two-Mode? What a mess. The reliance on overkill vehicles for profit blinded them from actually addressing need. They followed want instead. Sound familiar? That's exactly the mistake repeated with Volt... twice! Far more speed & range was delivered than required. Now, it's Bolt. Same mistake, yet again. In the meantime, there's a growing obsession with Trucks & SUVs. That's what helped GM delay bankruptcy. Now, there's Toyota, Volkswagen, Hyundai & Kia, along with Tesla all putting new pressure on GM. There's also the struggle by Ford to keep in mind. How many GM customers are really interested in a hatchback like Volt or a wagon like Bolt? Seriously. That is not GM's market. Virtually none of their own loyal buyers want that type of vehicle. It's the very reason I kept asking "*Who is the market for Volt?*" Over and over and over again, all I heard about was conquest sales. Volt was only attracted outside buyers. Many jumped on the opportunity to lease a plug-in hybrid, dirt cheap. When the lease expired, they abandoned GM for some other automaker. All those tax-credits squandered... wasted... lost. Now, GM is shifting focus over to Bolt... and it isn't going well. We keep seeing articles about how much investors prefer the concise message of purpose from Tesla. They don't have a clue what GM intends to do next. Looking at Toyota, we see the same thing emerging. The initial reception to Prime is very encouraging. It's a very nice balance of priorities with clear steps forward. In other words, GM is in trouble. We are watching the problems unfold. Efforts to electrify are unraveling. No investment in infrastructure. Little interest in high-speed recharging. No message of change with their existing product-line.
- 4-15-2017 Prius One.** Toyota rolled out the newest generation with the model numbers starting at "*two*". No one really questioned why there wasn't a "*one*". Today, we found out there would indeed be a more basic model. It will be priced \$1,210 lower, subtracting a few amenities, but not losing any of the new safety features. It simply doesn't include a spare tire or a rear wiper and the interior of the door panels are different. The reason for this move stated by reputable sources is that this prepares Toyota to compete with Hyundai. The fake news out determined to undermine Prius claim it's an act of desperation to keep Toyota from having to discontinue production. I know, that's totally absurd... especially with other automakers selling far fewer hybrids... but that's what they claim. Realistically, the move to price aggressively is a natural one. You want the market to grow. So, this is very much expected. How many will be produced & sold is unknown. But the effort to test consumer interest is a normal part of long-term business.
- 4-16-2017 Automatic High-Beams.** I finally had an opportunity to really try them out. There was a long drive required on a country road with lots of turns. Late at night, I had to watch for deer. Use of high-beams was essential. A steady but staggered flow of on-coming traffic meant turning them on & off a lot was necessary. They worked great. I was surprised how quick & accurate they were. There was a bit of skepticism that all the little nuances would get picked up by the sensors. It was very easy to see why Toyota made this a standard safety feature. Sweet!

- 4-17-2017** **56 & 55 MPG.** The drive to & from the coffeeshop today was entirely without plugged-supplied electricity. I was quite curious how the efficiency would play out, especially when warming up the engine in temperatures just above freezing. Turns out, the system is remarkably adapt at dealing with the in-between conditions. With it being neither really cold, nor all that warm, it's hard to even approximate. I obviously hoped for a large improvement, but expecting too much isn't wise. That was realistic though... based upon reports from gen-4 Prius owner reports. Why would the hybrid mode for the plug-in model be any different. True, it has a battery-warmer. But then again, the temperature wasn't well below freezing. So, there shouldn't be a noticeable difference. Fortunately, it was easy to draw a conclusion on just that small sample, since it matched what others had stated so well. I can't wait for when those ideal temperatures do finally arrive.
- 4-17-2017** **Lane-Keep Assist.** The gentle nudge back into the lane when the system detects that you've drifted over a line is really nice. That warning-beep and visual-depiction on the screen sure makes it obvious what's about to happen too. I really like this safety feature. During the test-drive, there wasn't a good opportunity to try it. I had to much going on at the time. Now that I have my own Prime, there are better conditions to experiment too. Weaving from side to side in traffic with only a minimal hold on the wheel isn't recommended. But I wanted to witness firsthand what would happen. Like with the automatic high-beams, Toyota did a really good job of studying driving conditions. We got to try this in the rain at night. Despite the difficult lighting, with abundant reflection & distortion challenges, it caught much more than expected. It could see lines on the road fairly well. This obviously isn't any type of autonomous driving feature, but it sure could come in handy for those moments when your attention briefly wanders.

4-17-2017 Boom. Some recognize this disaster in the making: "*One can't help but worry, that the end of the tax break is a ticking time bomb for GM, and Nissan, the front runners of the plug-in market, and will reward those automakers who lagged behind.*" Witnessing such significant history unfold right before our eyes is fascinating. I feel the relief of vindication, a breath of aspiration following long, drawn out battles where the enthusiasts just plain did not care. It was attack at all costs. Now, we can see the end. The final ticks on the clock are becoming easy to recognize. The advancement of time will bring a end... with a boom:

GM rested on its laurels. That's what all the "*too little, too slowly*" concern was about. They had an opportunity, a huge lead over the rest of the industry, but chose not to use it. GM should have been taking advantage of the tax-credits to penetrate their own customer base, to stir interest in GM dealer showrooms. Instead, focus was only on conquest sales, no change among GM loyal buyers. Building their demand never happened. Interest simply faded away. So much time... wasted.

The failure of gen-2 Volt to make up for the loss made that bad situation worse. GM ended up abandoning their long-time position of being anti-EV in favor of starting over with a push for Bolt. All that effort to promote "*range anxiety*" as a plug-in selling-point turned into more wasted time.

Meanwhile, we see the other automakers... who supposedly "*lagged behind*" ...as now having a huge advantage. They have many more tax-credits still available. Most importantly though, they stayed true to priorities. Toyota never lost sight of the affordable goal. Ironically, it was GM who had coined the "*nicely under \$30,000*" slogan, which has become an industry target. Nissan has wisely held off with the reveal of their gen-2 upgrade, watching how things play out with GM as it continues to use up precious tax-credits.

Remember, the goal of that subsidy was to help establish & improve high-volume profitable sales... not to break speed & distance records. That's why still not getting a clear message of intent from GM is becoming more and more of a concern. The blind defense of enthusiasts (vote down what you don't like to read) is making this growing worse situation a ticking time bomb.

The suggested "*lite*" version of Volt, a second model targeted at GM's own loyal customers, never came to be. Ironically, that very offering is basically what Toyota delivered with Prime. The reward will come to automakers who paid close attention to priorities... delivering a configuration capable of high-volume profitable sales prior to expiration of the tax-credits.

Time is almost up.

- 4-18-2017 Automatic Wipers.** A new feature with my Prime I hadn't ever observed was how automatic wipers work. Without any basis of comparison, it was all new to me. The switch was in the AUTO position. I'm not sure if my actions inadvertently did that or if it was intentional but forgotten. Whatever the case, rain today engaged them. Seeing the windshield get wiped didn't phase me... at first. Then it hit me that I hadn't turned the wipers on. Cool. That made me wonder how the car knew there was rain. Drops got heavier. Wiping got faster. Eh? It finally dawned on me that the camera in front monitoring the road must have detected visual interference... which would indicate something is on the windshield. That makes sense. It's anecdotal, a plausible theory. The automatic feature obviously works, pretty well too.
- 4-18-2017 Diesel Disaster.** VW now has about half of the close to 400,000 diesels here in the United States violating emission levels bought back or modified. Among them, there are 11,000 which were never owned. They were trapped in the supply-chain when the scandal was uncovered. Those are now being made available for purchase. I jumped into the discussion about that today with: How will they be priced? MPG is no longer a selling point for diesel. What's the draw? Whirring along with electricity is far more appealing than the clutter of a compression engine.
- 4-18-2017 Better Buy.** To further stress the state of change, we now have an official recommendation from Kelley Blue Book for Prime over Volt. It's only a matter of time. Priority for keeping cost in check will pay off. It's great to electrify, but trading off an affordable price (that's profit) for a vehicle that goes faster & further simply isn't worth it. Balance is what middle-market seeks, not bragging rights. Enthusiasts have niche interests, making them quite willing to pay a premium. That certainly isn't the attitude ordinary consumers share. Their purchases are what sustain business. So what if mainstream vehicles aren't as exciting. My results certainly exceed what they are accustomed to, as I pointed out in the comments to an article featuring this latest recommendation: 999.9 MPG for my commute and 157.6 MPG for my first tank average. That result from my Prime speaks for itself. The \$27,100 base MSRP, which includes Toyota's safety package, seals the deal. Volt is going to become an extremely difficult sell when the \$7,500 tax-credit expires.
- 4-18-2017 Trophy Mentality.** It emerged in the manner expected: "*Pfffft! Is that all? Currently doing 349mpg in my Gen2 Volt.*" To see that bragging & belittling emerge again is incredible. Nothing was learned by enthusiasts. They are repeating the same mistakes again. Complete disregard for production-cost and cherry-picked data is exactly what we saw in the past. I was somewhat amazed by such disregard for being constructive. There's a same group of owners who just plain do not care. I responded to the nonsense with: Huge mistake if you think that will impress ordinary consumers. Understand who the audience is. KBB does. Ordinary customers will see 150 MPG and 350 MPG, then ask what the price difference is. Paying such a substantial premium for the extra 200 MPG simply won't be worth it. That is no different than horsepower, acceleration, or towing capacity. They simply don't see the value at some point.

- 4-18-2017** **Fallout.** It's getting messy. This new chapter is clearly not understood by commenter, many of which don't have the background. See, starting a new chapter means a new audience joins into discussions. We've seen that with each new generation of Prius. This fallout of Volt is bringing about the same type of participation shift. I attempted to provide some of that missing background: Not all offerings help speed up adoption though. Look at the differences with the automakers. I see GM racing toward a cliff with no solution going forward. Volt is too expensive to stir interest from GM's own showroom shoppers, even with the \$7,500 tax-credit. Seeing Toyota strive for a balance of traits makes it the winner. The much lower MSRP has a much greater potential of not only drawing attention, it can result in significant market growth. Toyota has a large base of Camry, Corolla, and Prius buyers to entice with a Prime. GM has small base of Malibu & Impala buyers who simply won't be interested in a hatchback with cramped seating in back. GM now offers a hatchback Cruze too, making the significant price premium for Volt a major challenge to over come. So yes, they are on the same side by offering plug-in vehicles, but their competition is not. Adoption comes from each automaker's own customers choosing something with a plug instead of another traditional option.
- 4-19-2017** **Vastly Superior.** Exactly as anticipated, news of the KBB recommendation made it to the old Volt blog, where just a few days ago they made it overwhelmingly clear that constructive discussion is not welcome. Immediately, the posts came claiming Volt was vastly superior and that the premium price is totally worth it... without any regard for production-cost. That's the same old nonsense all over again. No concern whatsoever for the well-being of the business. More battery is better, period. The fact that the EV range delivered pushes price higher is a complete non-issue. An expensive configuration is necessary in their mind, settle for nothing less... regardless of consequence... as this so eloquently states: *"Where are all of the inbred, political TV educated, lowlife scumbags screaming that Toyota must be losing money on every Prius sold? Odd, I don't hear them. The human trash certainly were loud and obnoxious when it came to the Volt. Not since the smear job against Tucker Motor Company has the automobile industry seen such a malicious and destructive propaganda campaign."* From the perspective of the enthusiast, they truly believe a great product is being undermined. Being too costly to actually compete with the rest of GM's own product-line is rubbish, an utter impossibility. It's a game of blame the scapegoat. So naturally, I've become the antitheist in this situation. Ugh. I never thought Volt would fall apart so abruptly like this. But then again, diesel did in a similar fashion. Enthusiasts became so desperate, their methods of defense had little merit. Anyone taking the time to think about what was presented would notice shortcomings with their logic.

- 4-19-2017** **Disregarding Facts.** Reading through the comments posted so far this morning, this particular one stood out: "*The Volt is simply a better EV in every measurable way.*" When you post a fact enthusiasts don't like, they'll negative vote it to make that post disappear once it hits a count of 10. When a publication publishes a fact enthusiasts don't like, all they can do is disregard it. Pretending that fact doesn't exist is their only means of conveying their distorted view of reality. In other words, that's a common method used for greenwashing. They mislead by omitting information. In this case, all you have to do is look up the actual EV rating for each vehicle. 31 kWh/100mi is the value stated for Volt. 25 kWh/100mi is the value stated for Prius Prime. That measurable way makes it absolutely clear that Volt requires an additional 6 kWh of electricity to travel the same 100 miles. Efficiency is the point of the plug-in vehicles. Prius Prime is undeniably better EV in that respect. Yet, enthusiasts continue to disregard that fact.
- 4-19-2017** **Back to Basics.** This summed it up nicely: "...*the company is out of touch with reality and public want.*" It was the start of a rant that ended with: "*Shame on you Toyota.*" We are clearly back to basics again. Enthusiasts cannot tell the difference between want and need. Toyota is an automaker that focuses heavily on need, which is why they are so often criticized as having such boring cars. That's also the reason why so many of those cars are purchased in great numbers. That's a reality enthusiasts don't like. They prefer a focus on want, which is why GM is their preferred automaker. Volt delivered exactly what they desired. A vehicle exceeding necessity is quite a challenge to sell though... since most of middle-market is boring. They seek out well-balanced offerings... not something catering to a maximum. The reason why is easy to understand too. More ability means more money from the buyer. Paying extra is not what mainstream consumers are willing to do. Shaming Toyota for delivering a vehicle to match purchase priorities of ordinary shoppers is absurd. But then again, not being able to tell the difference between want and need is too.
- 4-19-2017** **Dual-Wave Window.** There was a hard, steady rain yesterday. It brought about a surprise I was hoping to experience again today. Sadly, the rain was much lighter. But the impression of what I witnessed sure won't be forgotten. Too bad the next time I likely won't be in an area where filming while I drive would be so convenient. Oh well. What I saw in my rear-view mirror was quite different from all my previous Prius hatchbacks. Rather than the bubble of air keeping rain from hitting the window, there was a very obvious air-stream pushing the rain down through the channel the dual-wave window. I hadn't expected that aerodynamic characteristic. I had hoped there would be something like that with snow, but the thought of rain drops being swept away hadn't crossed my mind. Sweet!
- 4-19-2017** **Charge-Mode.** Today was the day I tried it for the first time... in my own Prius Prime anyway, under controlled conditions. It recharged the battery 22% in just 10 minutes. I knew the mode was aggressive, but didn't realize by how much. That explains reports of lower than expected efficiency. If you are choosing to use it, you are continuously choosing the trade. That works fine for me. I know when EV can be effective. I don't use it just for the sake of using it. There can be times when having the engine stay off is a better choice. Anywho, the temperature outside was 46°F and the speed I was traveling was 100 km/h (62 mph). The observed efficiency displayed was 35 MPG.

- 4-20-2017** **Guzzler Plug-In.** Who the heck would buy a vehicle that guzzles electricity? GM believes some will be interested in their Cadillac which does exactly that. 62 MPGe was the rating revealed today. That's low, really low. The 62 MPG rating was too, especially when using a 31-mile EV capacity to achieve it. From an electricity perspective, the 54 kWh/100 mile rating is mind boggling. Prius Prime only uses 25. In comparison, Volt uses 31... quite efficient when compared to the Cadillac. It's the disinterest for delivering something to the masses which continues to be the source of frustration. True, there is a BMW and Mercedes-Benz with similar designs, but those are both luxury brands... without any middle-market consumers. Neglect for such a large audience by GM, especially when promised that wouldn't happen, continues to be a problem. Where the heck is a choice for ordinary people?
- 4-21-2017** **Moderator Correction.** Repeat the same lie over and over again, until no one realizes the original source anymore. They grow use to hearing it. Some greenwashing efforts in the past have been surprisingly successful. Usually, there's a misconception emerging from an assumption which an antagonist exploits. Other times, there's an extreme repeatedly sighted as if it is a common experience. In this case, it was a total fabrication. An unknown "source" was claimed to be a person of authority who leaked the information. Referring back to that as if some credibility had been confirmed later on gave the impression of that entire exchange being genuine. Since people almost never research, taking linked articles at face value, repeating the same reference over and over adds to the believability. I was annoyed. The claim was Toyota was rolling out the next plug-in Prius with a 35-mile EV range. That most definitely never happened. Yet, that claim got posted again today. Fortunately, the blog moderator wasn't about to allow that nonsense to persist. It was an obvious effort to deceive. He pointed out the situation with: *"As for carmakers over promising and under delivering on range estimates, that has been true in many cases. More recently after the Prius Prime was unveiled in NY, Toyota put out press releases saying "22" miles range. It later announced EPA said 25, so that was a case of under promising, over delivering."* I was delighted to read that.
- 4-21-2017** **As Much As Possible.** We get this on a regular basis: *"I want to be in hybrid mode but avoid the engine turning on as much as possible, my understanding is this is how the Prius/Prime/Hybrids in general increase mpg's."* It's a misconception based on assumption. Most newbies fall into that logic trap. They fail to recognize the importance of overall efficiency by fixating on a particular segment of driving. Oh well, all we can do is provide coaching: That is the formula for poor MPG. Following instinct, rather than what the system was designed for, is exactly what not to do. JUST DRIVE IT has been the advice since the first Prius and continues to be for Prime. Here's a simple guide... Plug in whenever you can. EV mode for city & suburb driving. HV mode when out on the open road. CHARGE mode when you know you won't be able to plug in.

4-22-2017 Charge-Mode Data. Having the opportunity to do a full test of charge-mode on Earth Day worked out really nice. This comment about it was brought up yesterday and I've been wanting to try it firsthand anyway: "*The charge-mode uses more gas than you will gain from EV. Just HV should get you 60+ mpg.*" It was perfect timing for an observation of the process from end to end. So, I did, reporting these results:

I drove from Northern Minnesota back to the Twin Cities today. Here's some real-world data from that...

charge-mode = **40.0** miles

charge-mode = **37.8** MPG

It took 38 minutes at 66 mph with an outside temperature of 64°F and a light crosswind to recharge the battery-pack from 0 to 80%. I took advantage of that recharged 25 miles of EV (estimated) to keep the engine off while making our two stops along the way and when getting trapped in weekend traffic at a major highway junction. These were the final results...

overall = **153.7** miles

overall = **60.4** MPG

In other words, just charge it. If you'd like engine-generated electricity for use later, go ahead. There does not appear to be any penalty for doing so.

4-23-2017 Charge-Mode Details. As anticipated, my posted results ended up stirring some discussion. This was the quote which stood out: *"The additional 25 EV miles resulted from the forced charge were not achieved at 66 mph but, as I understand, mostly at city driving."* That provided a good basis for providing some detail. So, that's what I did:

First, keep in mind that "city" is a term that's very misleading. Some people think of it as slow speed with lots of stoplights. Other people think of it as anything goes suburb travel... not highway. They are labeled the same, yet the two yield very different results. They really should be separate categories, like the rating system in the UK.

Second, the use of the term "highway" is even worse. It spans any speed from 55 to 80, which vary drastically for efficiency results. It also includes hard-accelerations for some people's measure and is only cruising for others. Whether or not you are steady cruising or passing vehicles makes a difference too.

With all that said, my particular test yesterday included the variety of "highway" driving with charge-mode generated EV miles. I took advantage of that electricity elsewhere (scenarios thought of as non-highway) but did still include 2 hard-accelerations onto the highway and some electric-only cruising at high-speed. The goal was to collect data from an ordinary trip... which in my case was extremely realistic, since I was traveling in tandem with 2 other vehicles.

Long story short, this served as an example of diminishing returns. You can indeed squeeze out greater efficiency if you so desire, but there isn't much of a point. Once you achieve 60 MPG fueled by only gas, you can consume the resulting power as you desire. The sizeable gain has already been achieved. The next big step is simply plugging in when you can.

4-23-2017 Teaching Moments. The discussions are changing in this new chapter. The history of Volt cannot be changed. Antagonists of Prius now have the choice to join into the team of those pushing electrification efforts or disappear with a loss from their own personal "*vastly superior*" effort having failed. I prefer finding a way to welcome them. We can take advantage of "*teaching moments*" to help bridge the transition. Exchanging detail about each others plug-in vehicle is a gain for everyone involved. The catch is, you have to accept whatever is learned. Facts cannot just be dismissed, as we had to deal with in the past. Following a thoughtful post of one former foe about dealing efficiency impacts, I provided detail specific to Winter driving:

Prius Prime has a Winter advantage over Volt with it's more efficient heater. In fact, the vapor-injected heat-pump Toyota provides is currently the industry leading tech for dealing EV range reduction due to cabin warming. Another handy cold-temp feature Toyota has delivered is the ability to direct air-flow. If there are not passengers in back, it doesn't blow warmed air back there.

Prius Prime also comes with standard heated-seats and the ability to program the timer to pre-condition the cabin prior to driving. Getting warmth directly from electricity while plugging in is a handy feature all the automakers offers. It's really nice. I believe many offer battery-warming too, as Toyota now does. Using a warmed battery overcomes the added electrical resistance lithium-based batteries have to deal with when temperatures are below freezing.

Lastly, there's the heated steering-wheel in the advanced model. That certainly isn't necessary, but it sure is nice. Another advanced feature is being able to control the heater, front-defroster, and rear-defroster remotely (from your phone) while still plugged in.

In addition to all that, though it hasn't been cold enough for me to try it yet, is the possibility of taking advantage of added engine load from charge-mode to provide engine-generated heat more efficiently. It will obviously take some work to determine if the resulting EV from the higher RPM is truly a better use of gas. But one certainty is that will provide engine-generated heat faster, since Toyota provided that with the first generation plug-in using defrost-mode.

- 4-24-2017** **Not Free.** Attempting constructive discussion with Volt enthusiasts became a waste of time years ago. They simply aren't interested. The endeavor wasn't futile though. That old daily blog served as an effective venue for bouncing ideas around. The nature of instant criticism meant anything seemingly anti-GM would be called out with uncertainty right away. What didn't emerge as an intolerance problem clued me into what the larger audience would actually be interested in. Being dead set on being "*vastly superior*" blinds you to opportunity. I took full advantage of that, to the point of exploiting their blindness. Ironically, it was the Volt supporters who I'd bring my findings too. They have been very receptive to my constructive findings. In other words, I was using that daily blog for research. It was a treasure trove of material to work with, which they gladly provided... unknowingly, of course. Realistically, there is simply no excuse to be that naive still, after so many years of being informed what to look for. Oh well. It used that to solicit feedback. Today, there was a discussion about charging for the use of chargers. I jumped into the series of comments being posted with: We've found it helpful for all provider types to charge a small fee. That way, it no longer is an entitlement/obligation for owner or business and ICE blocks are reduced knowing they are preventing a monetary exchange (which translates greater likelihood of enforcement). The problem though is finding out what that fee should be. Basic L2 fees are all over the place. Some charge per session, some per kWh, some per time. I have even seen minimum fees on top of the time/kWh quantity. And that's the simple setup. It gets especially complicated when high-speed kW rates can be delivered. Any suggestions?
- 4-25-2017** **Prius PHV.** It's a strange experience to see your own vehicle drive away. After 5 years of enjoyment, that's exactly what happened today. I really liked driving that generation of vehicle. The 2010 was a nice improvement over the prior two Prius that I had owned. But when I had the opportunity to upgrade within that generation to a model with a larger battery-pack, giving it more electric power and much further electric-only range, I jumped on it. That 2012 served me well for all that time to follow. I plugged in a work, taking advantage of electricity whenever realistic. Unlike with the Prime, it was a blend of plugged-supplied benefit. You could clearly see the gain from it too. The resulting MPG made that obvious. So, I know the new owner will enjoy driving it for many years to come. It still was odd though to witness it pulling out of the driveway for the very last time. The final distance recorded was 92,012 miles. I refilled the tank to get lifetime efficiency data. That ended up calculating to 71.1 MPG.
- 4-25-2017** **Heads-Up Surprise.** While toggling through the HUD options (pushing the button on the dashboard repeatedly), I discovered the lane-keep assist will be displayed on the windshield when triggered... which happened at that moment... since I had caught myself off-guard by noticing something new. That was sweet! That feature wasn't anything I had even considered. It's like when the navigation system is being used. You really don't expect to see the arrow & distance to show up there. But when you think about what the heads-up display is for, it makes perfect sense. Duh! I wonder what other goodies I'll discover along the way. Taking ownership of a next-generation vehicle shortly into its life-cycle, there are things to stumble across. We expect that of Toyota. They provide extras for owners to find on their own, stuff reviewers aren't informed of. It adds to the participation feeling. Not everything is revealed right away. You can become part of the group experiencing firsts.

4-26-2017

Bigger Picture. I was rather flabbergasted to stumble across this comment in a GM press release: "*Chevrolet reported today that 3,492 Bolt EV owners in the United States have driven a cumulative 4,570,300 miles as of April 2, 2017 since the vehicle went on sale in December 2016. These all-electric miles have resulted in more than 175,000 gallons of fuel saved based on the average EPA-estimated 26 mpg for 2017 vehicles in the United States.*" Seeing history repeat in such a concise & predictable manner is quite surprising. They just keep trying the same thing. Rather than learn from previous mistakes, some acts are repeated with hope of a different outcome. We've seen thing before. The same old "*gallons saved*" approach fell apart with Volt. Simply pointing out how much more was saved by Prius made that an embarrassing situation. That's why taking a look at the entire product-line becomes such a huge disappointment. The audience is quite diverse. Taking such a tiny sample and bragging about those results isn't constructive perspective. That's why the push for spreading the technology was so important. GM shoppers don't want a compact hatchback. They don't want a compact wagon either. They are truck & SUV buyers. That's why Volt & Bolt sales are conquests. They attract those who wouldn't otherwise consider a GM purchase. Little to no change of GM's own loyal customers is a recipe for disaster. The precious few tax-credits available will be wasted. Volt enthusiasts are finally starting to realize that disastrous situation too. Ironically, they had argued Toyota was resting in its laurels with hybrids. Turns out, they were thoughtfully designing a plug-in hybrid for mass appeal, hoping to capitalize on the opportunity. Now looking at GM, turns out they were the ones resting. Rather than rollout a profound new Volt to attract GM showroom shoppers, they simply upgraded Volt to appeal even more to enthusiasts. Ordinary mainstream consumers simply aren't interested... and the enthusiasts now see that. I took advantage of this newest promotion attempt to point out that lack of progress: Looking at the bigger picture, it's easy to see the same being achieved by other means. Data from those Bolt owners was compared to owners of 26 MPG vehicles. Comparing the same to twice as many 52 MPG hybrid owners, you get the same gallons saved. That reveals, hybrids like Fusion & Prius are already saving far more gas, since they are selling at much larger volume... and without the benefit of a generous tax-credit subsidy. In other words, the use of "*gallons saved*" isn't a meaningful advertising approach.

- 4-26-2017** **Real Numbers.** You could feel the instant the anger boiled over. I had exposed the deception. Fans wanted something to celebrate. With both supply & demand falling well short of expectations, there was a desperate need to find a victory in that mess. I was correct again. That same old "*too little, too slowly*" concern applied. Shortcomings were being revealed and each attempt at damage control was only making the bad situation even worse. What surprised me was how easy it had been to find other numbers, something to provide a basis of comparison. Right away, I was worried about cherry-picked data. Not seeing anything whatsoever to provide perspective was a red-flag. Be warned whenever a seemingly large number is posted without any reference of any kind. That was definitely the case in this situation... and the enthusiasts new the effort to mislead was being called out... and I had caught them attempting to greenwash by spreading the misleading information. People often assume the entire story is being told. They don't take the time to research for omissions. I do. Pointing out what had been excluded to portray a different take on events was especially redeeming this time too: Looking at the bigger picture, it's easy to see 175,000 gallons really isn't that much. 143,370,000,000 gallons (yes, 143 billion) is how much gas we consumed in the United States last year. 391,730,000 gallons is what that averages to per day, which makes that 4-month total for Bolt a rather trivial quantity in comparison. Always consider the bigger picture.
- 4-26-2017** **More Discoveries.** I was playing with the buttons, scrolling through settings looking for new things. To my delight, I found another surprise. I had heard about "split" screen, but didn't actually know what it meant. Turns out, the extra large area for the speedometer can actually be shared with a choice of 3 different efficiency meters... one showing the battery-charge level... one showing the energy level... one showing the kWh/mile efficiency for electric-mode then MPG for hybrid-mode. That's quite handy. They obviously did their homework with this upgrade. In the past, I've seen how my Toyota studied driver usage. In fact, that's what the first-generation offering was all about. They rolled out to a decent sampling size, they stopped. Growing any further wouldn't have accomplished any more. The diverse spread, enough to really get an understanding of the market, was achieved by reaching out to those initial 15 states. Obviously, they took into account all the stuff we were posting online too. The forum & video knowledge sharing is a win for everyone. Complex things in the past, like finding out what the actual state-of-charge level was rather than only getting an estimated distance value, is now just simple choice on a menu. You get all kinds of detail display options. It's really sweet. Today's uncover of the "split" was really rewarding to stumble across. I wonder how many other owners take the time to look. Hmm? I'll create a new user-guide over time to point out goodies like this. In the meantime though, they'll be buried in the blog achieve... like this very entry.

4-27-2017 **Nice Try.** It's quite odd how you can see an end approaching. That's what all the blogging about a chapter closing has been. Signs of conclusion looking like this are posted: "*Consumers will look at the aggregate number and extrapolate to themselves, not the country as a whole, just as they do when they vote. But nice try.*" That's so generic, so vague, it could mean anything. The attempt to divert attention away from the bigger picture is what makes it obvious. As important as individual votes are, they don't matter if enough aren't cast for the candidate you choose. The race to win is that of plug-in vehicles verses traditional vehicles. No matter how compelling arguments in favor of EV are made, those electric-only vehicles don't have a large enough audience. This is actually was regular hybrids alone weren't enough either. The market-share they captured was struggling to grow. That aspect of growth is absolutely vital... hence the constant reminder of audience... Who? That comment with the "*nice try*" was a desperate effort to press the reset button. Hope of starting fresh and not having to deal with any aspect of the past is not realistic. I was happy to point it out too: What about Volt, Prime, Ford Fusion Energi, Hyundai Ioniq, Honda Clarity, BMW i3 and the other plug-in hybrids? How do they fit into the bigger picture? Remember, the inevitable phaseout of tax-credits will be reached mid-cycle for most all of the plug-in vehicles. Consumers will most definitely take the loss of generous subsidies into account.

4-27-2017 **What Happened?** Today was when I watched it all fall apart completely. That problem of purity, which Volt enthusiasts based their entire premise on, ended up causing it to become fundamental contradiction. This final comment snippet in the final argumentative post summed it up: "*...on a GM fan site to explain why a car using no gas is inferior to one that does.*" Remember how no matter how much I struggled to get them to focus only on GM's own product-line, they'd inevitably shift discussion over to Toyota and Prius? Diverting attention away from their own struggle was all they had left. I was now just waiting for closure. Exactly like with Two-Mode, the second year of sales would bring about conclusions. Remember how it fell apart? Supporters moved on to the next thing. In that case, it was gen-1 of Volt. Of course, when that fell apart, they moved on to gen-2. But now that gen-2 is struggling... focus has shifted to Bolt. That recent sign of change (this chapter in history having come to a close) was attempts to switch the topic away from GM failing. I was on a GM fan site discussing GM's own offerings, commenting about GM's own customers. Not a mention of my own plug-in hybrid irritated them to an extreme. I wouldn't bite any of the bait they were dropping. Remaining on topic and speaking of the audience the blog addressed meant I was behaving and they were not. My purpose was obvious too. I even asked: "*What happened to Volt?*" When that contradiction came about, nothing more needed to be said. It was over. They had backed themselves into their own corner. Bolt was what they wanted all along, not Volt... and it was only just then that they realized the predicament. The desire for purity was fulfilled by Bolt, not Volt. I noticed the pattern early on, how much they resented the gas engine running. All those insults to Prius also applied to Volt. They simply hadn't understood the precedent they were establishing until it was well solidified... long after they couldn't do any damage control... too late. That's why simply asking what happened is all that was necessary. They knew. Message received. Problem understood. Huge mistake.

4-28-2017 **C-HR Rollout.** My wife and I were at the dealership yesterday, visiting with my salesperson. When you know someone that long, you check in from time to time to exchange information. She really wanted an update, to find out what I had learned about my new Prime over the past few weeks. She also wanted to see the new receiver-hitch I had installed. We wanted to find out more about the market for Prime. Rollout to the Midwest has been very slow. With deliveries going to Japan, Europe, and the United States all at the same time, inventory is quite limited. That's a heck of a debut effort. Anywho, while we were swapping stories, a vehicle drove by and caught my eye. I ended up making a scene... yelling out that it was the brand new C-HR... a new vehicle type for Toyota not expected until this Fall. What was it doing here already? Maybe I had mixed up the rollout schedule with the hybrid model. No, this was a 208 vehicle and it is still only April. Huh? Needless to say, I got the attention of everyone nearby. They too were intrigued by the hints of a new vehicle driving by. I got up. Walked over. Someone immediately grabbed the FOB and handed it to me. I guess that type of enthusiasm gets rewarded. I got to take it for a short drive before any of the salespeople. Whoa! So, I did. It was nice... for a non-Prius offering. The hybrid model won't be anywhere near as efficient, but it most definitely will attract a new audience. And you know me, I'm all about market growth. I look forward to the stir this will bring... or better put, a continue of the excitement I started. It is nice being married to someone supportive of such excitement. She actually jumped in the driver's seat for a spin right after me.

4-29-2017 **Hypocrites.** It ended in a tangled web of hypocritical posts. The short-sighted approach of Volt enthusiasts was their downfall. It's what made them stand apart from Volt supporters. That fundamental differences is why the one group would celebrate any victory it could and the other would carefully weigh the benefits of alienating future allies. It was obvious from the beginning that their trophy-mentality was huge risk. Yet, it was one post after another declaring Volt was "*vastly superior*" to Prius, even if Prius or Toyota was never mentioned. That sounds a lot like our new president. Rather than actually work for progress, there's a never-ending battle to paint a positive picture. The other thing in common we seeing coming from the new administration is an effort to suppress information. When I point out a hypocritical claim, it immediately resulted in negative votes to hide the post. Make it go away by not being visible anymore. I was flabbergasted by the foolhardiness of such a move. What a senseless waste. Ignore the problem, don't actually deal with it. As time went on, the nature of their hypocritical behavior became obvious... the obsession for purity was causing blindness to logic. Bolt was described repeatedly as superior to anything that consumed gas. I couldn't believe the never-ending stupidity. These were die-hard Volt enthusiasts so hell-bent on the mission to "*leap frog*" Prius that they embraced technology in a self-deprecating manner... and never noticed. Bolt has become their weapon for victory. Using it meant destroying Volt in the process. None of those brainless buffoons were smart enough to realize the problem they had created for themselves. It became a fascination for me to witness their own destruction. I had no idea the madness would end with a self-inflicted wound. But then again, that is a similar manner of death the die-hard diesel enthusiasts suffered. They became so fixated on one particular battle, they ended up losing the war in a spectacular way. Watch what happens in the next few months with Prime. That balance Toyota carefully strived for will really pay off, the very trait enthusiasts poo-poo'd over and over and over again.

- 4-29-2017** **Closure.** It sure feels nice that's all is truly concluded. It's finally over. Phew! We did indeed see Volt as a "*game changer*" vehicle in the end. It triggered a paradigm shift; ironically, the outcome was the opposite of what had been hoped for though. Rather than delivering a technology resulting in strong mainstream sales, it delivered a configuration demonstrating what to avoid with that technology. Too much emphasis was placed on making it go faster & further. That sacrificed cost & appeal. GM's own customers simply have not been interested... even with the generous \$7,500 tax-credit. Some ordinary consumers were drawn, but conquest sales from enthusiasts are not a solid business model to follow. In fact, that's how the end was brought about. They were revealed to be the "*low hanging fruit*" of the industry. Running out of them has resulted in market saturation... the very "*too little, too slowly*" concern I warned about for years is now an undeniable consequence of such complacency. Enthusiasts allowed it to happen, gambling that a dramatic shake up of the industry (the tree) would result in more customers (falling fruit). That didn't happen. The risk never made any sense. They hoped battery-cost would drop so much, Volt would quickly become competitive. The catch is, there was no understanding of who the competition was. They assumed other plug-in hybrids would be competing for buyers. Turns out, the reduction of battery-cost ushered in affordable electric-only offerings... killing off any chance of attracting more sales to a cramped compact hatchback with much smaller EV capacity. Bolt replaced Volt. It became the "*range anxiety*" solution, leaving GM with an uncompetitive plug-in hybrid. Prime's capacity had been relentlessly mocked, belittled, and insulted by them... until recently, having discovered Toyota not making the same sacrifices means a much greater change of appealing to the masses. Prime is a configuration capable of drawing mainstream interest, even without tax-credit subsidies. Its balance of power & efficiency will triumph. That's a very painful lesson for those who refused to learn from the past. Oh well. Their loss.
- 4-30-2017** **Flexibility.** Don't undersell Toyota's ability to take advantage of the flexibility their design offers; other automakers are simply stuck when the market changes. That was all I needed to say. There's so much spin about what happened in the past, it's easy to overlook what should be obvious. We've seen HSD adapted to a variety of different platforms, each proving some type of claim false. Yet, there are some who still don't see it. Perhaps now seeing how easily a plug was added and how much that provided in return will finally get the point across. It never ceases to bewilder & flabbergast how a fundamental, like flexibility, doesn't get considered important. Of course, there is that tendency in our nature to prefer absolutes. The ability to adapt counters that stance, which forces actual thinking rather than the simplicity of yes or no. Oh well. You don't have to understand design decisions to benefit from what gets delivered.

4-30-2017 **Selling Safety.** We're seeing this topic pop up a lot, especially when it comes to Hyundai. More attention pushes GM further out of consideration. I'm intrigued how that will play out. The absolute of Toyota being the enemy is all messed up when a serious contender joins the mix. This is what provoked my response: *"Active safety system should be standard, just like the Toyota safety sense in Prius Prime. Volt sales going down."* There's no way to resist such a lead in. So, I didn't:

Yup.

- Dynamic Radar Cruise
- Pre-Collision Braking
- Lane-Departure Detect with Assist
- Automatic High-Beams

Those are all standard safety features that come with all Prius, including the Prime models. That's what will attract ordinary consumers. The nonsense of wanting more range & acceleration is just enthusiast banter, something mainstream buyers simply won't be interested in paying extra to get.

4-30-2017 **EV Efficiency Measure.** It's so refreshing to finally have constructive discussion. Today, it was about measuring EV efficiency. That got me excited, as you could easily predict: *miles/kWh* is a means of measuring efficiency for electric propulsion. *kWh/100mi* is another, for electricity. *gal/100mi* is the appropriate measure for gasoline, not *MPG*... which is highly misleading and often used to greenwash. Seeing that result of 5.1 is reason to celebrate. That's great. Many plug-in vehicles, aren't anywhere near that efficient. In fact, some actually guzzle electricity. That's why the new way to indicate usage is so prominently displayed in Prime. Results that nice are something to be proud of. Keep in mind that Prime offers roughly 6 kWh of usable electricity from the 8.8 kWh battery-pack. Multiple that 5.1 by that 6, you get over 30 miles of estimated EV range.

5-01-2017 **Prime Shines.** In Japan, sales came to 2,781 last month, bringing the total so far there to 6,011. Sweet! Unfortunately, there's still quite a bit of pushback here... much of which in the form of visual appeal. You know, how the owners of plain-looking SUVs give cars grief for actually having some style. Ugh. I find it amazing how so many people prefer plain, that anything which stands out is given some level of *"ugly"* factor... until it's been out for awhile. Then, attitudes change. Each Prius generation has seen that. Know your audience. Those buyers don't want ordinary. 60 MPG following depletion of the battery will help draw interest after awhile too. Seeing that on the few long trips I've taken so far is another great selling point. Lastly, there is a charge-mode available... which has proven useful on the long trip where I didn't have an opportunity to plug in. It took me 38 minutes to go from 0 to 80% charge. That was 40 miles of highway travel at 66 mph. The tradeoff was 37.8 MPG while that surprisingly aggressive recharge was taking place. In other words, using that EV wisely afterward will yield an overall benefit.

- 5-02-2017** **So What?** It needed to be asked after reading this: *"Anyone who sees the Volt for what it is realizes how great of a car it is."* We've heard the same thing since the day it was rolled out 6.5 years ago. It hasn't made much of any difference. Conquests sales are what resulted, not a measurable change to the status quo. GM customers continued to purchase traditional vehicles. There wasn't a shift to plugging in. Notice how even GM's new hybrid has barely even made a peep? I bet you didn't even realize there was a Malibu hybrid. It was supposed to squash the Fusion & Camry hybrids. That didn't happen. Gen-2 Volt didn't result in a stir either. I fired back: So what if Volt goes faster & further? It's too expensive to sell in large numbers even with the generous \$7,500 tax-credit. Prius Prime starts at \$27,100 MSRP and is loaded with safety features (Dynamic Radar Cruise, Pre-Collision Braking, Lane-Departure Detect with Assist, Automatic High-Beams). Toyota clearly positioned Prius Prime to compete directly with the actual competition, traditional vehicles.
- 5-02-2017** **Misconceptions You Thought Were Dead.** This was quite a surprise to encounter: *"Using the engine to charge the battery is never a benefit unless the charge is absolutely needed for a specific reason (ie climbing a very steep grade)."* Toyota knew there would be issues with charging up using the engine. That's why charge-mode is discretely hidden. The subtle nature of that extra feature makes the learning process more of a teaching opportunity, rather than a stumble-across-then-guess situation. Antagonists like to exploit misunderstandings, spreading them widely & often to create a misconception. People like me try our best to overcome that. This is my short & sweet response to today's effort: That misconception was proven false way back in 1997 by the first Prius. Hybrids have been doing it ever since, showing undeniable benefit. Yet, 20 years later, some still believe that's not the case. Ugh.
- 5-02-2017** **Understanding Hybrids.** Sometimes, an argument comes from assumptions. In this case, it was clear the person didn't actually read what had been posted... assuming it was a lack of knowing that energy cannot be perpetual. He didn't bother to see that conservation was the topic. I was annoyed by the snarky attitude. Not taking the time and turning on the poster is what scares away those genuinely trying to learn. That's sad. Oh well. All I can do is jump in with some type of helpful information, as with this attempt: The situation is a matter of using energy more efficiently. No part of that is *"free"*. Nothing is 100% efficient. In fact, there are EV guzzlers. Some are far better at conversion & transfer than others. Using more electricity to travel the same distance is a problem too. Just like with hybrids, it's a matter of seeking out efficiency opportunities. Used wisely, there can be a gain... put another way, a prevention of greater losses... which is exactly what charge-mode can offer, used wisely. The gas engine can be taken advantage of to control overall energy usage in favor of a better return by reducing waste.

- 5-02-2017** **Inventory.** Change is upon us: *"Although all totals aren't in yet, the major players have reported so I think it's safe to say April 2017 will be the first month the Prime leads all plug-in sales. It was only by 12 units but a win is a win!"* I couldn't resist jumping in with additional information: A quick look at inventory makes solid prediction for more wins... 4,683 Bolt. 4,288 Volt. 1,014 Prime. Prime is basically not available anywhere in the Midwest yet. Some people who placed orders there last year are still waiting for delivery. Word of mouth about how it actually performs is only beginning to spread just now. So, it's a very safe bet we'll see demand grow nicely.
- 5-03-2017** **Ironie Greenwashing.** Perceived obsolescence could be a problem: *"Look at how long Toyota has breathed life into its legacy hybrid synergy drive and how far behind it is today."* That same old brain-dead mindset persists. People are led to believe that EV range is the measure for progress. More indicates being further along. In reality, that's hogwash. Other factors are far more important, like reliability & cost. Simply having connected more cells together achieves greater range, but there very much is a tradeoff for such simplicity. That's why things like Tesla's effort to improve energy-density and reduce packing also come into play. It's complicated. Those who claim *"behind"* without anything other than an implication of short-range EV are clearly not helpful. They just contribute to the confusion most consumers struggle with. Repeated often enough, it becomes greenwashing. Intentional or not, it does cause harm. I find it ironic how that long-term investment is spun to sound like an effort to milk outdated technology. In reality, we are only now seeing hints of just how wise that continuous effort to upgrade really was.
- 5-03-2017** **Please Hurry.** Whoa! Reality set in surprisingly quick. The ultimate expression of acknowledgement emerged: *"Please hurry."* It was from a long-time Volt enthusiast who antagonized about Prius to an extreme. The same disappointment from gen-1 Volt sales is clearly repeating with gen-2 Volt sales. He sees the next step clearly as getting that technology into a vehicle format actually wanted by GM customers... a small SUV. I asked him the *"Who?"* question so many times, it was making him crazy. He just plain did not want to admit Volt wasn't appealing to an audience beyond conquest purchases. Those buyers are in no way representative of ordinary GM shoppers... which is why I fought him from well before rollout began. To make matters even more stressful, I pointed out the next-step problem by expressing the *"too little, too slowly"* concern over and over again. He finally gets it! Phew! The nightmare of endless disappointment may finally come to a close. Either that plug-in hybrid technology gets abandoned in favor of EV offerings or it finally gets put in a vehicle type GM shoppers will actually buy. His desperate plea would seem to favor the latter.

- 5-04-2017** **April Sales.** Things are getting interesting. I posted this on a green blog dedicated to open discussion for all types of participants: Anyone who still thinks faster & further is what will attract the consumers doesn't understand mainstream purchase priorities. High-Volume sales are the result of a nice balance of features & price. These safety features are standard, available on all models of Prius: Dynamic Radar Cruise, Pre-Collision Braking, Lane-Departure Detect with Assist, Automatic High-Beams. Things like that are what ordinary buyers want included. Volt is still lacking with respect to balance. Volt's efficiency following depletion isn't enough to attract interest. Little headroom in the rear and the legless middle seat doesn't help either. That's why a majority of the sales were the conquest type, attracting buyers who otherwise wouldn't have purchased a GM vehicle. Toyota configured Prime to appeal to their own customers. That's true change. They are striving to alter their product-line to become more electrified. That balance of features & price will allow Prime to survive the expiration of tax-credits. It's a genuine effort to replace traditional vehicles.
- 5-04-2017** **Yup.** Getting agreement on priorities is virtually impossible sometimes. With the case of Volt, that denial situation dragged on for years... throughout the entire first generation and well into the second. Now, we get this, starting with: "*It's simple...*" That was followed by this presented-as-if-it-was-new wisdom: "*MPG/Size/Brand/Price/Standard features are all more important than EV range...*" To those enthusiasts deep in denial, I could see that as a revelation to them. Even though that's what I have been saying for an entire decade, it's good to hear. Their hate for the messenger was so intense, taking the time to actually read & understand the message itself was clearly not of any importance to that. Any validation for the "*too little, too slowly*" concern was met with an emotionally overwhelming response. They'd lash out, negative voting to hide what had been posted. Such a childish head-in-the-sand response was remarkable to witness... until learning how many people live their lives that way. The presidential election was overwhelmed by a mindless need-for-change attitude. A shockingly high number of people voted for change just for the sake of change. It didn't matter what the consequences were. It didn't matter how unlikely it was that promised would be fulfilled. They just didn't want to deal with any more of the same... even though that stability and slow growth was exactly what was needed. A nice balance of priorities isn't exciting. The thrill of possibly finding a "*tremendous*" new outcome by taking an extreme risk was totally worth it, in their minds. We're finding out how terrible of an idea that really was... just like Volt enthusiasts finally seeing the same thing people like me saw right from the very beginning. What a waste. But at least there is still a dim glimmer of hope. Remember how I asked about goals? Agreement to them is a good start... all more important than EV range.

- 5-04-2017** **Pulsing.** The system in Prime automatically pulses. You can see the MPG go up & down even when driving at a steady speed on flat highway. I believe it was Hyundai who experimented with automation of that behavior, taking advantage of engine & motor interplay to squeeze out more efficiency by exaggerating it. Toyota obviously nailed it. The effect is so subtle, you wouldn't even know it was happening without a gauge to see what was happening. When that was first tried with Prius by owners all those years ago, it was an impairment to traffic and required a great deal of concentration. That's how the "*Just Drive It*" came about. I refused to endorse what ultimately ended up getting the term "hypermiling" coined to it. That distracted & annoying behavior simply wasn't worth it. That is no longer of any value anymore either. The system is more capable than human interaction. It doesn't take much to come to understand how a computer can be quicker and have more refined actions.
- 5-05-2017** **Potential.** Reality is setting in: "*Don't get me wrong I think the Volt is a fine automobile but I think its doomed to fail.*" There isn't much to say about the situation anymore. Arguing with those who won't ever accept defeat is pointless too. So, it's a short & sweet response: Phaseout of the tax-credit will be mid-cycle. Volume with the subsidy is too low to survive the loss of such significant financial help. There won't be anything to help it compete. Volt is a nice vehicle with a limited audience. Prime reaches out to middle-market buyers. There's a great deal of potential... and we are only just seeing it begin. Toyota will achieve what GM continues to struggle with... appealing to its own customers.
- 5-05-2017** **80 MPH with A/C.** Upon embarking on my long-distance, high-speed voyage, I was not expecting impressive efficiency. Instead, I'd be watching my lifetime average plummet. Going from heavy use of electricity to only gas with a massive amount of aerodynamic resistance, it's reasonable to set outcome expectations low. There's simply too much drag on the vehicle when traveling at 80 mph and passing at even faster speeds. To make matters worse, it was uncomfortably warm outside. That meant also running the A/C. With both those demands, I was delighted to see 41 MPG for the average. The long trek across South Dakota, from Minnesota to Wyoming wasn't as bad as I had anticipated. Nice.
- 5-05-2017** **Amazing Lights.** We finished dinner. It was a beautiful evening. There was a little over an hour available to drive from where we were in Rapid City up to Mount Rushmore. With the amazing lights on the Prime, why not see what climbing up a secluded mountain in the dark is like? The curves, the elevation, the possibility of encountering an animal all added to the thrill of seeing the monument lit up in the dark and having very few people to share the view with. We could even get a chance along the way to stop on what would normally be a busy road to enjoy the sight. Turns out, we were all alone, on the drive up and when we got there. A park ranger welcomed us to indulge, since we had the entire place to ourselves. The drive up was a pleasure and the journey down would recharge a large portion of the battery-pack. But to have that moment, in that place, all to ourselves. Wow!

- 5-06-2017 Reality.** The real problem revealed: *"Most of the comments I read from Volt owners is how they are able to stay on pure electric for their full commute and not really wanting to use the ICE."* It's a self-deprecating position enthusiasts have taken since the very beginning. They've pushed the idea of EV purity since way back when Volt was still being developed. Volt ended up a hybrid though, not the *"range extender"* it was intended to be. Now we have BMW i3, which truly is a range-extended design, and Bolt EV. The very weak marketing for Volt has all but vanished as a result. EV range is too short. EV efficiency is too low. EV charging is too slow. So, competing with an EV is unrealistic. HV efficiency simply cannot compare to Toyota or Hyundai. So, competing with the gen-2 PHEV market isn't realistic either. Pressure from competition, along with the reality of tax-credits running out soon, has brought about a reality shock. Volt is without a large audience and the enthusiasts have nothing left compelling to promote as a draw. Significant rapid growth is required and Volt is still dealing with flat sales.
- 5-07-2017 Precedent Set.** The world of plugging in seems somewhat divided, at first glance. Over time though, that impression fades away. It's not a matter of having an engine not having one. It always comes down to how much gas is consumed. Virtually none of the plug-in supporters actually mention how much electricity is used. I pushed for quite awhile when Prius PHV first rolled out to get people to post KWH values. There was a lot of resistance. Now, it's next to impossible to get that information... upon the revelation that some plug-in vehicles use electricity far less efficiently than others. And yes, Volt is among the worse offenders. You could see that coming. From the very beginning, I knew the trophy obsession, that primal need for faster & further, would create a blindness toward waste. As long as the energy source was electricity, they couldn't care less how much was actually consumed. That's sad and still quite true, even today: *"Thank You!! – and very well said. I also have a gen 2 volt, and in 18 months and about 21K miles have only used about 55 gallons of gas. It gets old getting negativity from the EV crowd."* Notice how solidified the precedent has been set. All we ever get for data is how much gallons were consumed. Knowing that would continue to be a problem for years to come, that's what Toyota now reports as a primary gauge for efficiency. You can of course look up the Miles/kWh data and see impact climate settings have. But it ultimately comes down to showing MPG, since that's what the others insisted upon for an overall summary. They did it. Actions of enthusiasts had a much greater influence than they will probably ever come to realize. To think they argued it was impossible to get an automaker to listen to requests, that all they could do was hope for the best. Ugh.
- 5-08-2017 Necessary Step.** It was interesting to see the message of influence finally sinking in. This was encouraging to see emerge from that: *"Maybe GM will finally take the hint now..."* I don't expect a moment of sanity amongst the chaos to make any difference right away, but I do suspect the pattern of painfully slow growth for Volt & Bolt along side strong demand for Prime to be a wake-up call. Eventually they'll notice the struggle to progress and figure out why. It's really sad that the solution was provided long before the problem manifested, but late is still better than never. Not liking it was the issue. They'd have to compromise on principal to reach the goal. Enthusiasts hoped that somehow wouldn't be necessary. They were wrong. It is necessary. I chimed in with: *Faster & Further* became GM's obsession with Volt a full decade ago. Their own *"nicely under \$30,000"* price target was abandoned in favor of pleasing enthusiasts. It's a simple matter of not wanting to take the necessary step to attract mainstream buyers.

- 5-08-2017** **Hypermile?** This request didn't make sense: "*We still would like to know the hypermile value average.*" Even if that was truly constructive to provide, what would it actually tell an ordinary person? I've never been in favor of sighting extremes. Most of the time, that's due to data being cherry-picked when attempting to mislead. But even if it wasn't, how does that set a proper expectation? I ended up rather annoyed trying to figure out the benefit, so I went with: What does "*hypermile*" mean now? That term was coined in a post arguing with me about how hybrids weren't up to the chore, a very long time ago. Over the years to follow, the definition changes quite a few times. Now, it doesn't make any sense. There is no interplay of power sources available to squeeze out greater efficiency. You just drive it. The only thing I can think of that could qualify now is taking advantage of charge-mode, forcing the engine to produce electricity for EV use later.
- 5-08-2017** **Camera Obscured.** While quietly enjoying the 80 mph cruising, the sound of an alarm broke the mode. It was an audible alert followed by a message on the screen, informing me the visibility for the camera had been obscured so cruise was disabled. It hadn't occurred to me at that very moment that the Dynamic Radar Cruise also used the camera. Observing lines on the road is a standard part of that. It requires a clean windshield, specifically that small area in front of the mirror... which had just be struck by a bug. Squash! Fortunately, there just happened to be a ramp close by. Unfortunately, I wasn't able to grab my camera fast enough. Coming to a stop for a thorough window squirting & wiping was all it took for the "Radar Ready" notice to pop back up. It's amazing how sophisticated the system actually is and how much effort Toyota expends to keep the interaction simple. That unexpected message that appeared on the screen (which sadly, I wasn't able to get a photo of) informed me of exactly what the situation was... something I need not be burdened with, unless necessary. That's much more like a computer than the generic problem like we all grew up with in vehicles. It reduces the learning curve significantly. You don't have to know everything to be able to drive now. Smarter vehicles, like Prius, having the flexibility of provided detail as in comes up due to having those 2 dashboard screens, in addition to the bigger one. Long story short, I squashed a bug. Eww!
- 5-08-2017** **80 MPH with Heat.** The return trip home, crossing all of South Dakota at very high speed, was cooler than on the way out to celebrate two birthdays with family. We ended up using the heater. What a contrast to using A/C a few days either. Heat would be more efficient, since waste energy from the engine can be used for warming, rather than having to generate it specifically for cooling. It meant that engine-only travel would be better. Turns out, there was a fairly strong wind blowing in a favorable direction too. It was somewhat pushing the back driver corner of the car. Not a tail wind, but it's still an improvement. Crosswinds are what we normally see along that horribly long stretch. Those are nasty in the Winter, causing surprise gusts and patches of ice. Anywho, the resulting average was a little over 50 MPG for that 80 mph travel. Sweet!

- 5-08-2017** **Charge On Highway.** I had a chance to play with Charge-Mode again. Cruising along at 80 mph, on that long highway stretch across South Dakota, turns out to be a great opportunity to replenish EV miles. I wondered if there would be a power penalty or a big efficiency hit. Nope. The charging process just goes about its business without any interruption to the driving experience. It's really impressive how refined the hybrid system has become. I was hoping for that type of response. There's nothing like flying down the highway witnessing it firsthand too. That's a good time for it, when maximum horsepower isn't needed. There's excess available, which can be optimized by balancing load. Remember how dynamic the power-split approach really is. The flow of energy adjusts constantly to take advantage of efficiency opportunities. That included sending some electricity to the battery-pack anyway. Switching to a more aggressive recharge mode isn't too much of a stretch to imagine. It's basically just refinements to the existing system. In this case, it worked very well.
- 5-09-2017** **Stale Gas.** There are many, many reports from Volt owners who clearly purchased the wrong type of vehicle. They point out how a single tank of gas has lasted nearly an entire year for them. Rarely ever traveling beyond that battery-pack's capacity is a clearly indication an EV with a larger one would have been a better choice. That's why the gen-1 Leaf is still selling so well. It's 107-mile range makes more sense than lugging around a system with have the range and an engine almost never used. This is why GM has moved on to Bolt. Proving the EV is quite capable with 238 miles of range makes selling one with a smaller capacity easy. Why bother with Volt, as a car anyway. In SUV form, that's a different matter. Volt forces a maintenance-mode, running the engine from time to time to use old gas. Letting it get stale can be a problem. That's far less of an issue for Prime, so much so, I doubt we'll ever here much owners. When the engine in Prime runs, it much more efficient than Volt. So, it's not as big of a deal. So of us actually travel too. Of course, some Volt households have old traditional vehicles for that. With a Prime, no need. I just proved that last weekend, in fact. The trip was 1,711 miles. So, no concern about gas from me. 80 mph for a bulk of that travel. Faster passing at times. 103 mph briefly, because resistance was futile. 50.1 MPG overall average displayed, without any recharging. It was totally worth it. Celebrating the twins first birthday isn't something you'd want to miss.
- 5-09-2017** **Missing The Point.** Wow! Talking about completely missing the point: "*Most Prime buyers are previous Prius or Toyota owners. Not the same for Volt buyers.*" It's somewhat bizarre trying to have a constructive discussion with a person who doesn't understand purpose. Sadly, that's quite common. Our terrible self-centered nature makes that far too easy. Fortunately, not everyone is that blind to what should be obvious. The goal of high-efficiency choices from automakers is to find a suitable replacement to their traditional offerings. Sadly, many get caught up with conquest, forgetting about change for the rest. Anywho, rather annoyed, I responded to that with: That fundamental shortcoming of Volt not appealing to GM's own customers was supposed to be dealt with by gen-2. That didn't happen. GM continues to struggle. Toyota halted gen-1 Prius plug-in, limiting it to just the initial 15 states after having recognized was the market truly wanted. Gen-2 stayed true to being affordable while delivering upon need to appeal to their own showroom shoppers. The goal is to replace traditional product-lines with high-efficiency choices, not conquest sales.

5-10-2017 **34.3 Miles of EV.** I'm watching the range estimate for EV driving as the temperature rises. No longer dealing with freezing levels, the system runs more efficiency. Even the battery itself works better (reduced internal resistance). There is obviously no need to run the electric heater anymore either. 6.4 miles per kWh was the resulting average from my commute to work this morning. That provided an estimated return of 34.3 total miles from EV driving. I don't know if that's what I'll actually experience upon returning home, but seeing 52 percent of the capacity remaining for that trip is encouraging. Unfortunately, traffic doesn't flow as well that time of day and hills are less in my favor. Of course, even if it just comes close, that's really encouraging. It means next month the entire trip could be without recharging at work. But then again, so little gas is used when the engine actually runs, does it matter? There is a certain thrill from witnessing MPG well above the low 50's estimate. It's much like the battery being rated for 25 miles, but returning actually EV miles well above that. It is the "*under promise, over deliver*" we get from Toyota. Yeah!

5-11-2017 **Why Indeed?** I was intrigued by the possible response answering this question could result in: "*Why can't GM offer a Bolt with electric adjustable seats, as one example?*" So, I jumped into the discussion with:

On Tuesday, we had a gathering of the local plug-in owners... Tesla, Nissan, BMW, Ford, Toyota, and of course GM were all represented. There are only 4 known Bolt owners in Minnesota so far. The one there I got to chat with for quite awhile had made her purchase in California and had the vehicle trucked home.

That comment about lack of content came up a lot. GM's effort to make an affordable EV offering faced the same type of tradeoffs as Toyota with PHEV. The catch is, Prime's design allows it to have a much lower production cost.

So, I got to show off the 11.6-inch screen (which is really sweet when you enable the multi-split feature and bring up info, like live weather radar), the color HUD (heads up display), and power seats which Bolt EV simply doesn't offer. There is the carbon-fiber hatch and dual-wave window as standout features. Other nice offerings, like heated steering-wheel, are often overlooked or not thought of at the time of purchase.

The complaint we heard quite a bit from Volt supporters about GM was the lack of advertising. There simply wasn't anything done by the automaker to draw interest. Toyota learned from that and has capitalized on that opportunity by making safety something to stir attention. All of the following are now being heavily promoted as standard in all Prime offerings, even the base model:

- Dynamic Radar Cruise
- Pre-Collision Braking
- Lane-Departure Detect with Assist
- Automatic High-Beams

That's something GM needs to do too. Their focus on conquest sales now has that obvious weakness. Safety is a strong selling point. New tech features like that are exactly what plug-in buyers seek.

Perhaps the 2018 model will have some package changes to make Bolt more balanced. Focus on EV and practical seating/cargo is not enough. There's more to purchase priorities for ordinary consumers.

5-11-2017 **Promoting Safety.** This topic comes up a lot now. Thankfully, it actually has substance. Remember 15 years ago when "*bigger is better*" was the approach for safety? Rather than avoid having an accident, as we see the desire for now, it was figuring out how to survive the impact. Ugh. People were gullible. Fear was a powerful motivator. Concern for those you squish with your vehicle was absent. People didn't care. I sure am glad we are past that ugly stage in automotive history. Phew! This is what I have to say about the situation now: Safety is a good way to promote the automaker's advancement. People end up noticing subtle aspects of the technology that really impress. That builds reputation. For example Toyotas' DRC isn't actually just radar. Over the weekend, I smashed into a bug while using it. At 80 mph, it's nice to find out how intelligent the system is. A warning popped up and cruise disengaged, informing me the camera had been obscured (direct hit by the bug) resulting in a safety compromise. I pulled off at a nearby ramp, squirted the windshield and wiped a few times, then resumed my cruise on the highway. Most people don't give much thought about what's actually needed to deliver tech like that. That bug smash was a great example highlighting of what was delivered.

5-12-2017 **Who? How?** Determining if progress is actually being made can be a challenge. Today's was how to interpret a response asking what "*NPNS*" meant. That was an antagonist chant of the past, now a very real problem for some. Saying too much reveals the hypocritical nature of their stance. Rather than having focused on goals, they belittled & mocked only later to find out those would become self-deprecating actions. Oops! It's too bad some get desperate to prove "*vastly superior*" at the expense of burning bridges. Oh well. This was the start of the response: "*No Plug No Sale. It was used a lot when new hybrids were being announced...*" Shortcomings of what has been stated were too plentiful to choose from, so I kept it to an overview:

Many things were said back then, but have since changed. In fact, some of the quotes above are out of context without knowledge how they were used, which confuses their meaning & intent. The situation now is that we are into gen-2 rollouts, putting some previous stances at odds with what the market has evolved into.

Toyota's latest delivery is what the "*lite*" Volt had been hoped to become... more affordable, more efficient, and more roomy. We still await that from GM. We also still wait for the first high-efficiency SUV offering. That's why there's such emotion stirred in some posts.

As the plug-in hybrid market expand & evolves, we are seeing similar advancement with EV offerings. That puts GM in an awkward position, having built Volt upon a "*range anxiety*" concern which no longer exists. What will they promote to sway their own customers to consider a plug?

This is why there are continued attempts push for a consideration of the bigger picture... asking who & how. The obvious example is public charging-stations. After all these years, there is still no clear message of intent. Who should be using them? How should they be used?

Another motto often quoted was this is not a One-Size-Fits-All situation. Notice the 11 reasons listed to buy an EV also apply to plug-in hybrids replacing traditional vehicles?

- 5-12-2017** **Charge-Mode.** I took advantage of charge-mode on my 1,700-mile road trip last weekend. To my delight, the impact to MPG from charging while going 80 mph was barely noticeable. There wasn't even a performance hit. The system is clearly configured seek out optimum operating efficiency to extract electricity. Those resulting EV miles came in handy later, when running around for dinner later in the evening after arriving at our destination and settling in at the hotel. It was also nice when driving to a coffeeshop in town for beverages before heading back out on the highway.
- 5-13-2017** **Beyond Desperate.** I stumbled across an article today comparing Prime to Jetta. Why such a bizarre pairing? I didn't take much reading to encounter the first outright lie, a dead giveaway this was a bias article written intentionally to undermine Toyota's effort: "*The high-tech Prius Prime Premium has an manufacturer's suggested retail price of \$30,060.*" Where the heck did that come from? Premium's MSRP is \$28,800. Advance's MSRP is \$33,100. Neither made any sense to compare to the Jetta anyway... since the writer put it up against a 5-speed manual. How is that even the slightest bit comparable? Plus's MSRP is \$27,100 and it is much nicer equipped than the \$21,715 Jetta in the comparison... which you are required to shift gears yourself. Ugh. Coming from a Tennessee publication and reviewed by someone with them for over 20 years, I just don't understand how such blatant greenwashing continues. That is a sign of being beyond desperate to impede change. On the opposite extreme, there was the less obvious, quite subtle "*no-nonsense body lines*" description of Jetta's look. That's the spin version of making "*plain*" sound appealing, very much an effort to retain the status quo. The really standout part of the article though was the fact that nothing was said about a test drive or any data presented related to results. Not a peep about actually driving the vehicle is good reason to be suspicious of intent.

5-13-2017 **Know Your Audience.** I keep pushing that message, over and over again. This time, it was to "*Awful awful design.*" That was the conclusion of a terse statement exclaiming disappointment for the acceleration times of Prime. That brain-dead belief of faster being an absolute necessity is what has blinded Volt enthusiasts from becoming supporters for an entire decade. The consequences of such unwillingness to accept want over need are becoming apparent now. Growth of sales is basically non-existent. Loyal GM buyers aren't interested. Sales are still stuck on the conquest type. The status quo has not been influenced. That alerts to upcoming trouble, especially with the tax-credit phaseout approaching. I pushed, yet again:

Comments here will have no influence on showroom shoppers, the target audience. They'll never see them, nor would they even care what an enthusiast has to say. They'll make their own decision by taking a test drive.

That was the secret of success for Toyota with Prius. It was available for the curious to try. They were aware of the reputation and saw it could be purchased for a reasonable price. No pressure, no doubt, no concern... just go for a test drive.

Prime builds upon that. Base model MSRP is competitive, even without tax-credit help. An ordinary 120-volt household outlet is all it takes to recharge too. That's a major challenge for EV offerings to overcome and a barrier other automakers strive to finally reach for plug-in hybrids.

In other words, look at why the reasons for purchasing electric are deemed important. Notice how nothing related to power is listed? That's because need has been exceeded and more simply doesn't achieve sales growth. It's not what buyers are looking for.

Know your audience.

5-13-2017 **Hooray!** A friend of mine picked up her Prime this morning. A few hours later, we got together for a brain-dump. I shared as much as I could based upon the type of queries she had. Not knowing what a new owner doesn't know is a challenge. Her willingness to let me bounce stuff off of her for User-Guide material was great. The experience ended up being quite a treat for the both of us. Parking in the 2 charging spots at the nearby grocery-store, we explored the screens in my Prime. All the while, we watched people walk by and check out her Prime. The charging-cord was quite visible the way she parked, so it was obvious that shiny new vehicle was something special. I'd pause my comments to point out yet another passerby stopping to admire. 2 people ended up taking photos. I was fun to witness. I got a lot of great feedback from that opportunity. I provided a bit of uncomfortable how-to information as well. To get that spot for her, I had to loudly say: "*She would like to plug in.*" A woman in a minivan parked in that spot, hoping no one would need the charger. The moment she realized her actions had been called out, she very politely vacated... and even said "*Thank you.*" That kind of polite response isn't what you'd expect. But then again, why did she attempt to park there in the first place? Needless to say, there is much about the ownership experience to share. Later when more charging spots are added to parking lots, they will be further back. Up in front for the first few is to promote their existence. You have to start somewhere... much like the one-on-one effort to share information today. Having great technology is a large step in the right direction, but far from the end goal of replacing traditional vehicles. Today's events contributed to that better future.

5-14-2017 **Claims of Sabotage.** I brought up that quote again: "*Why can't GM offer...*" That's what started a constructive exchange on the thread, so why not use it to conclude too? After all, there was a mix of responses... some not so friendly, others were a clear effort to move on to more intelligent discussion. So, I summed up with:

Enthusiasts absolutely insisted they had no way to influence GM, that we'd all have to be patient and wait for whatever the automaker determines to be important. Ironically, it was their own obsession with faster & further which sent a clear message to GM of priorities, never realizing those statements of preference in online posts would become the source of that determination.

Yet another example of Toyota's careful study of audience is the new venting system in Prime. If no one is detected in the rear seats, blowers back there are not used. Lack of weight in those seats cause the vents to automatically shut. In the front, if there isn't a passenger in that seat, that vent shuts too and all blowing is directed only to the driver. When a front passenger joins, the front vent automatically opens for them.

That automatic adjustment of climate control provides an efficiency gain. Energy for A/C & Heating is not wasted on unoccupied seats.

There's no reason GM couldn't offer that too. Unfortunately, priority was given to going faster & further instead. Nice amenities like that weren't considered important... because GM mostly just heard about a need to make Volt faster & further for gen-2 to appeal to a wider audience. Those enthusiasts screwed up their own fate. Growth is now struggling as a result, despite the generous \$7,500 tax-credit.

It's really sad that the message of balance was dismissed with claims sabotage, rather than the reasons for concern they actually were.

5-14-2017 **Higher Emissions.** Reports from first-drives of the new Hyundai Ioniq hybrid are revealing interesting results. MPG is indeed competitive with Prius; however, emissions are not. Measurements taken by an independent party confirmed the usual concern, that particulate & CO emissions are higher. Toyota's priority of keeping emissions as low as possible, even if it means sacrificing a little efficiency, are appearing to be something not shared with Hyundai. That's the very same problem we had with VW. Questions of how the MPG was achieved were drowned out by efforts to undermine Prius. I sure hope that nonsense doesn't happen again. You can easily see most people simply not caring, saying emissions are clean enough. That does echo similar concerns of the "*clean diesel*" campaign. It will be interesting to see how the MPG situation plays out. It may be a non-issue, if Hyundai didn't take into account the brutal impact Winter can have. Toyota has 20 years of experience with that. Will we see that level of sophistication from Ioniq owner reports? Reviewers rarely ever provide detail to properly portray what ordinary people see firsthand when leaving work after the car having been parked in temperatures well below freezing for over 8 hours. We'll find out in 9 months.

- 5-15-2017** **Charge Now.** It's the little things that get overlooked. I'm scrambling the best I can to find & document them. Today, it was emphasis on the "Charge Now" option. Toyota made the timer much easier to setup. You can now schedule repeatable events. The most obvious is morning departure. A time can be set, complete with climate-prep (running the electric Heater or A/C) prior to leaving. You don't need to do anything beyond just plug in when you get home. The system will figure out the charging & preparation time needs for you, then execute automatically... regardless of how much charge (if any) you ended with. It's quite handy. Unfortunately, the first few times with that, you'll probably forget about immediate needs... like plugging in to recharge while stopped for groceries. I did that today. Annoyed about getting 0 kWh while inside, I looked for a convenience option. Going through the menu is cumbersome, though sensible for scheduling. Where was a quick option? Yeah! I finally noticed. Rather than on the usual dashboard screen, there was a pop-up on the big touch screen. There's a simple "Charge Now" button which automatically displays when you shut down. I hadn't thought of looking there. Duh! I knew Toyota would have studied behavior and provided a convenience feature. Sure enough. There is was.
- 5-16-2017** **Hatchbacks & Minivans.** All those bold & meritless statements coming from GM on a regular basis is why that automaker gets blogged about so often. Bolt sales not meet hype expectations has resulted in a shift of focus over to profitability. GM wants to be the first to make a profit from selling EV. We know that they are currently losing money on each and that the \$7,500 tax-credit is absolutely essential for its rollout. Looking beyond that is a becoming more and more of a problem. Plugging in isn't discussed anymore on the big GM forum. Members simply aren't interested in small cars. A thread about Cruze hatchback barely stirring any customer interest highlighted concern. GM customers want Trucks & SUVs. That's why Volt never made any sense. That's the same reason why Chrysler's new Pacifica hybrid is already becoming an issue raiser. How many people are willing to pay that much for it? Being a high-efficiency people & cargo mover is great, but there simply aren't that many who is could appeal to. The importance of being affordable cannot be stressed enough. We need real efforts, not token gestures. Toyota has had a hybrid minivan for over a decade, but recognized the lack of potential here in this market. So, they tried a wagon and a SUV hybrid for diversification. When will GM finally try something else? How long will it take Chrysler? What about Ford? What about the others?

- 5-17-2017** **EVSE Shopping.** I have been doing some serious research lately. The goal is to purchase two level-2 chargers for home in the not-too-distant future. I held off even discussing the matter until getting my Prime. Waiting meant getting the latest & greatest. Not having Wi-Fi to monitor & collect information wasn't something I was willing to sacrifice. It's quite common to find 240-volt chargers with plugs now, rather than having to hard-wire them. Cords are much longer too. I wanted something waterproof as well, not just water-resistant. Waiting also means getting much higher capacity for the same price. Of course, the system in Prime won't be able to take advantage of that. But in years to come, you never know. It's very likely I'll have friends with plug-in vehicles visit. They'll be able to recharge while visiting. My particular situation is very nice. When hunting for a new house 2 years ago, I made sure adding lines would be easy. In this case, it will be remarkably easy. The 200-amp box is in the garage and the wall that would accommodate wires is completely open. Both lines can be run across the tops of the garage door and an outlet installed each side. We really got lucky with such a nice layout. Turns out, our electricity supplier (the local co-op) offers \$500 per line setup too. So, that effort will likely be entirely without cost. Sweet! Purchase of the two chargers (EVSE, which stands for "Electric Vehicle Supply Equipment") will be covered entirely by the rebate coming from my credit-card. I've been saving up that money for years to redeem toward the purchase of my next Prius. Needless to say, I'm quite excited about the upgrade opportunity. Though in no way necessary, the faster recharging could come in handy. But more importantly, the new lines will be setup for discounted service. They will be on a Time-Of-Use plan, which offers lower cost electricity when your use is during overnight hours and on weekends & holidays.
- 5-18-2017** **29.5 Miles.** EV range is increasing in my Prime as the temperature rises. I got 29.5 miles today from mixed highway/suburb driving, with it in the 50's. I can't wait until no jacket weather finally arrives. Warmer makes quite a difference. Of course, I do look forward to the return of Winter here in Minnesota, but not for awhile. The benefit of that vapor-injected heat-pump, battery warmer, seat warmer, and heated steering-wheel can wait. The remote climate and charging-prep can be used in Summer too. Both warming & cooling are full electric. What will make more of a difference... Heater or A/C ? Being able to run both from the charger prior to using the car will be interesting... and beneficial to EV range. I do really like driving with the windows open though. The next few months will be exciting. I really enjoy the discoveries made by owners about Toyota's upgrades during the first rollout year. This one, I managed to capture with my phone... [photo album 206](#)

- 5-19-2017** **Style.** Attacks on Toyota taking a risk by helping lead the way out of the bland styling rut automakers have fallen into continue. Ironically, it's with a surprisingly smug attitude: "*Hey, where's the Prime on that list? LOL*" And you guessed it, that came from a Volt owner proud about being vastly superior. Ugh. I swung back with: Many people want a "*blend in*" vehicle. That's why GM leaned heavily toward a Honda influence for gen-2 Volt. It clearly resembles the previous generation Civic, which was a very popular design. Ironically, the new Civic went in the opposite direction, taking a "stand out" appearance... which is proving to be popular. Prime's look abandons the expectation of what Prius should look like, with all the LED lights in front and aggressive grille. The curve of the lights & glass is back is obvious break-away from the "plain" we see everywhere else. In other words, some people define "*best*" as a good fit for what's on the road currently. Others prefer something that won't look old in a few years and take their chance on what could end up being a trend setter. After all, the status-quo is really getting outdated at this point. Looking at the dual-wave in person, you quickly discover there's more opportunity to styling than just what the industry has stuck with in the past.
- 5-19-2017** **Denial.** The extent a few individuals will go to undermine never cease to amaze me. A complaint was raised by a Volt owner who also owns an Iconic Prius. His claim is that hybrid system is terribly dangerous. Yet, all these years later (it's a 2007), he still drives it. That doesn't make any sense. Of course, his reply to mine was rather ironic: "*Your answer makes no sense.*" I pointed out how worries of traction-control issues with bad tires was overcome long ago, with the rollout of gen-3 Prius in 2009. He just plain did not want to accept that answer. I know that he's kept the Prius due to the credibility it supposedly brings to his argument and by the money he's saving from such high reliability. I was frustrated by the obvious effort to mislead. This is how I chose to deal with it: That's because you don't want it to. I could just as easily say GM gave Volt mountain-mode because battery was needed to supplement an underpowered engine. We know it was really to give owners greater flexibility... just like Toyota has done with the many extras for Prime owners. For example, a charge-mode is available. It's not necessary, but particular situations offer a benefit.
- 5-19-2017** **Audience.** This was especially amusing to read: "*Toyota is doomed.*" That came in response to an article pointing out Toyota's CEO comments about the upcoming paradigm-shift. It's something people without a business background just plain don't understand. Seen from only an engineering stance, they don't see the importance of balance... the fundamental barrier some Volt enthusiasts still haven't learned to overcome. Oh well. All I can do is treat it as a teaching opportunity: Know your audience. How much are you looking forward to GM finally delivering a plug-in for its own customer base? Buyers of SUVs are going to continue to guzzler. Neither Volt, nor Bolt, appeal to them. With Toyota, we can see how the Prime approach naturally just transforms their product-line... one which is well known as being boring... yet sell in massive numbers anyway. It's very easy to see how realistic adding a plug to the RAV4 hybrid will be. They are preparing for that transition by offering non-appliance appeal in the meantime. Prime is loaded with conveniences and creature comforts, along with a collection of safety features. Yet, it is already affordable enough to survive the loss of tax-credits. Toyota knows its audience.

5-20-2017 Distortions & Leadership. Yesterday's desperate effort to mislead about Toyota's goals & approach started with this: "*Contrary to popular belief, Toyota is not a technology leader. U.S. car companies created hybrids before Toyota under the "Partnership for a New Generation of Vehicles" program which started in 1993. For example, the GM Precept was a diesel hybrid that got 80 MPG. So Toyota basically copied U.S. hybrid technology for the Prius.*" I was really surprised by such a dishonest statement. So much of that isn't true, I wasn't sure where to start. So, I waited until this morning to confront it with a fresh mind:

It's distortions of history like that which keep me intrigued.

Toyota's exclusion from the PNGV program, which working prototypes weren't even scheduled for demonstration until 2000, led to an industry shock in October 1997. It was then that Toyota revealed Prius, stating it was already production ready and that sales would begin in December... just 2 months later.

Detroit got sucker punched. Those supposed 80 MPG cars were still just nothing but crude prototypes in 2000. There was nothing to copy. The anti-hybrid campaigning then began as a result of the expansion of sales from Japan to the United States.

Many years later, after the fallout of EV1, Two-Mode, and BAS had left GM with a reputation for disinterest in high-efficiency vehicles, there was the reveal of a new design effort for a vehicle to be called "Volt". It was then that problems got out of hand. Enthusiasts completely disregarded any of that past history, claiming GM was being innovative.

In reality, GM had extensive battery, motor, and controller experience at that point. That had already produced & supported all that. They even had a heavily promoted fuel-cell development program. Yet, the enthusiasts of Volt insisted their vehicle didn't leverage any of that prior knowledge... which is quite bizarre. Why wouldn't you?

Needless to say, it didn't work out anyway and the attempts to distort history continued... but now we know why. Toyota never lost sight of affordability. Keeping cost low was always a top priority... the very problem GM continues to struggle with.

In other words, Toyota is leading in the correct direction.

- 5-20-2017** **Behind.** The antagonist strategy is now becoming an effort to build the impression that Toyota is far behind. They avoid detail, just leaving you to the assumption that battery-size is the only thing that matters. It's quite annoying... to not have a way of countering the obvious greenwashing. Their desperation is telling though. Coming up with an effective means to deal with it seems to be going well. Here's what I posted on that today: Those who claim Toyota is "*behind*" are not taking cost, efficiency, or scale into consideration. Notice how GM's offerings are so expensive that they will be faced with a major challenge to overcome when their tax-credits expire next year? Notice how both Nissan & Ford have held off ramping up production for that very reason? Toyota is taking the leadership route that's slower, attempting to attract a much larger audience by offering a well balanced design. The obsession with faster & further is incomplete. It is only leadership to the first & second milestone in a long race. If the price is too high, its wasteful with the use of electricity, or only a small number are available, sales will be low. The ultimate goal of change won't be achieved until the shift away from traditional vehicles becomes the dominant sight on roads in ordinary traffic. Expect to be reminded of those other needs every time someone claims being behind.
- 5-20-2017** **Investments.** Some are so blinded by Toyota's fuel-cell investment, they simply assume EV offering could have been better off had the money not been split like that. It's a sad statement of our society. That one-size-fits-all view is so prominent, people are aware of the fact that they are not seeing outside the box. It's yet another example of not seeing the forest beyond the tree immediately in the foreground. Ugh. I fired back with: What are you claiming Toyota hasn't invested in? The chemistry & design required to propel Prime at 135 km/h (84 mph) without air-cooling was a serious investment. They found a way to make it cost-effective by augmenting the hybrid system too. So what if they invest profit into product diversification. That's ultimately more important than paying large dividends. And it's not like the electrical system in fuel-cell vehicles doesn't share some technology with plug-in vehicles. Optimization of motor production & efficiency is a benefit to both. Higher efficiency of Heater & A/C operation is a benefit to both. Lower cost and higher density of batteries is a benefit to both. Again, claims of falling behind simply don't have merit. The technology advancements are obvious. Toyota is clearly striving to deliver a profitable plug-in for the masses.
- 5-20-2017** **Terrible.** I was baffled by the lack of substance in the reply I got. It was just a ramble that Toyota could have developed more. There was literally nothing to work with. The claim was void of any merit. Yet, I responded anyway. This gave me ample opportunity to point out actual deliverables: Development of what? The lack of any detail whatsoever indicates it is not "*absolutely fair*" to make that "*falling behind*" claim. Vague doesn't cut it. All the components for EV propulsion are entering high-volume production. Prime is being rolled out to Japan, Europe, and the United States all at once. I'm tired of the statements without any supporting information. Ignoring other innovation isn't fair either. Why aren't you giving Toyota credit for embracing carbon-fiber, by delivering a hatch for Prime made from it rather than metal? Why aren't you giving Toyota credit for advancing curved glass technology, by delivering a dual-wave window for Prime to improve aerodynamics and introduce some style rather than just settle for plain?

- 5-20-2017** **Wrong Vehicle.** How do you point out buyer's remorse to an owner who doesn't realize yet they will end up having it? This statement pops up surprisingly often: "*Most people that drive PHEVs would prefer to drive them in EV mode for 100% of the time.*" I routinely hear from Volt owners gloating about how little gas they use, going 6 months or more without having to refill. Some of whom make that statement simply didn't have any other choice available. So, they bought a Volt. Why not when combined with the great incentives? The major price slash and generous lease discounts made that decision easy... back then. Now, things are rapidly changing. Prius Prime is more efficient in both EV and HV operation. It's also better loaded, even on the affordable base model. But if you still cringe from the idea of using gas, why not consider the choice of only having a plug? It's a fundamental question that abruptly ends arguments, as I witnessed firsthand upon posting this: That extreme would be an indication of having purchased the wrong type of vehicle. It makes no sense paying so much for an engine and hybrid system, then trying to avoid ever using it. What a waste. Just buy an EV instead.
- 5-21-2017** **VW Diesels.** Approval of fixes for the larger TDI vehicles and sales of the fixed 2015 inventory have stirred interest lately. VW diesels are the last of the dieselgate legacy. That intentional deception across the industry has really left an impression. Why bother? The MPG from plug-in hybrids is so much better, what's the point? Emissions are obviously cleaner too. It simply makes no sense. How will people be drawn to such an outdated & crude technology. The fuel itself is more expensive here as well. It's nice to finally see the status quo broken. Oddly, GM is still planning to push both Equinox and Cruze hatchback with diesel as an option. Thankfully, VW is focusing on plug offerings instead. They are investing in charging infrastructure... in the form of environmental damage payments, but that still counts as movement in the right direction. They are embracing the mandated change too. So, after all that nonsense hybrids owners had to deal with, at least things finally worked out. What a waste though. Imagined if none of the "*clean diesel*" deception had never taken place. Defeat in an honorable manner would have been interesting. Sadly, we know that the opposition almost always prefers to go down fighting instead.

- 5-22-2017 Ford CEO.** Very little has happened in the past few years from Ford. Remember the MPG scandal? There was a huge marketing campaign giving the impression C-Max was larger and more efficient than Prius V (the large wagon model). Neither was true. People didn't actually bother to compare though. We just got advertisement after advertisement. It was a "*halo effect*" approach that ended up resulting in sales of the vehicle itself... until it was discovered that MPG had been misstated. Oops! That resulted in a sales drop and payments to owners who had be misled. No only was the hybrid hurt, the misleading included the plug-in offerings. Neither Energi vehicle actually delivered as many EV miles as the rating claimed. Oops, again! Making matters worse was the complete disinterest in selling Focus EV, which ironically wasn't a problem with Toyota attackers. Those supporting plug-in vehicles weren't happy though. Producing so few made the purchase of one nearly impossible. Complaints about no inventory were common. Anywho, all that contributed to disappointment among my colleagues. From the point of view for stockholders, the entire market has been shrinking. Pushing the status quo with Pickups & SUVs has become a sign of worry... so much so, the CEO is leaving. We don't know if he quit or got asked. Whatever the case, this has become a sign of hope. With electrification a new source of opportunity in the saturated guzzler market, we needed some good news.
- 5-22-2017 Warm-Up Misunderstanding.** We are now getting deep into new ownership, where fundamentals are getting asked about. It's like starting all over again. I really feel like we are reliving the Classic rollout. That same sense of discovery & potential is easy to recognize. Examples are plentiful, like: "*As soon as the EV range hit 0.0, I could feel the ICE go on -- it did not stay in EV range pulling from the hybrid buffer of the battery. The green EV MODE light immediately went off and the ICE came on right away.*" Statements just like that is what I thrived on all those years ago. There was a group of us who handled the teaching moments. We'd provide information to empower, seeing that not doing anything would contribute to the growth of misconceptions. Those who found value in what was shared became the next teachers. It was quite nice watching them take over like that. Anywho, it's happening again. My contribution today was: That is a misunderstanding of how warm-up takes place. With an aftermarket gauge, you'll see that RPM of the engine is held back by using HV capacity. The battery is used as a buffer to keep emissions lower until waste heat for cleansing is available. Once warm-up is complete, that HV capacity is restored by the engine running to recharge as part of the usual hybrid operation.
- 5-23-2017 Whoa!** There's a photo of me taking a photo of my Blue Magnetism with a sunset in Wyoming as a backdrop speaks for itself. In fact, I didn't need to say anything. My sister-in-law on the other hand screamed out: "*Don't move, I'm getting my camera!*" I didn't realize how amazing the entire scene looked from the on-looker perspective. I'm quite thankful to her for capturing such a unique photo moment. It be added to my homepage, eventually. There's quite a collection of photos growing. Lots to learn & document. So little time.

- 5-23-2017** **Fake News.** We're not seeing that as often for Prius now. It certainly hasn't went away though. Today, it was an article about "*massive failure*" of the latest generation. As expected, I was annoyed. There was no data whatsoever. All we got was a series of comparison adjectives... *faster, nicer, biggest* ...along with vague measures... *big, more, better*. That complete absence of detail is how the misleading continues. Those sources attract readers who aren't interested in facts, they just want validation. It's the same nonsense many of the blog comments do. People just latch on to what they want to follow and ignore anything that reveals contradiction or hypocrisy. Antagonists do that too. Think about how effective that was in the previous election. Was unbiased news sought out or were some just following a feed automatically providing "*you might like*" content? It's a dangerous trap to fall into that many had no idea could happen. Being naive is dangerous and there are those who intentionally exploit weaknesses of that nature. Watch for it. That type of activity is common. It's a similar problem to those who enable. They don't even realize their own participation serves as validation & support. Oops!
- 5-23-2017** **Last Diesels.** It's rather bizarre to hear about attempts to sell the last remaining diesel cars from VW. Their vehicles with TDI were sold with the "*fun to drive*" trait as the primary purchase incentive, followed by great efficiency. That aspect of performance has been lost, due to the pollution-control measures needed to be taken for reducing emissions. That leaves MPG as the big appeal. 33 is terrible though. Yet, that's what the automatic delivers. The value is derived from 40 highway and 29 city. Neither of which is impressive either. Prius unquestionably delivers better. The manual transmission only increases the combined to 34 MPG. Such a tiny bump for the requirement of having to shift yourself is a joke. I see 54 MPG combined without any effort whatsoever, not even plugging in. Thank goodness the nightmare of diesel deception is finally coming to an end. No more new diesels will be sold in the United States after those last 2015 models are gone.
- 5-24-2017** **First Data Photo.** Lots of data collection taking place. Organization for sharing isn't exactly coming along smoothly. Eventually, I will get caught up. This initial ownership experience is always a challenge. It certainly is fun though. There's lots to discover. Toyota upgrades are always quite comprehensive. That means lots of anecdotal observation, looking for patterns until you recognize something to further research. That's where the photos come in handy. You can look back later to confirm what you think you found. I'm only on my first. Much to go still. It's a start. Each of the previous 4 Prius have been rewarding to document... while doing everything else still. Wish me luck.

5-25-2017 **Great News?** I questioned this claim: "*Great news that PHEVs already outsell gas hybrids in CA. That's the real reason Mr. Toyota is scared of EVs.*" The attempt to change what was actually said to instead project a sense of fear isn't something I'm willing to tolerate. Antagonists did that years ago with what Toyota had stated about lithium batteries. The automaker said cost was the issue. Rhetoric changed that to fear by claiming Toyota was afraid of fire risk. It was greenwashing, just like this attempt today. So, I fired back:

That's called anecdotal reasoning. It is actually that gas prices are very low and plug-in hybrid choices are growing. There's also the reality of first-year surge combined with the rapid approach of tax-credit expiration. That's also a distortion of what was actually stated. The comment was "*boring and expensive*", not scared. It was for good reason too.

Notice how GM is keeping quiet about Bolt sales expectations? They is uncertainty about the market. Staying quiet about it is their choice, especially since a compact wagon doesn't target their own customer base of SUV and Truck buyers. Ford has been almost completely out of the picture too. What about them?

The true situation is the industry is approaching a tipping point. Notice how Volt doesn't have an audience anymore? If you want to drive as much EV as possible, just buy an EV. Why sacrifice EV range for the sake of having an HV system you try hard to avoid ever using?

Prime is the first of the affordable plug-in hybrids offering a clear path away from both traditional vehicles and hybrids without a plug. Its MSRP for the base model is so low, the tax-credit isn't even required to reasonably justify the purchase.

None of the current EV offerings can hold their own without the \$7,500 subsidy. In a few years, that situation will hopefully change. That's what Toyota is planning to capitalize on, as are other automakers. In the meantime, there is battery-production and charging-infrastructure to focus on.

5-25-2017 **More Diesel Trouble.** What an unexpected turn of events. A class-action lawsuit was filed today, claiming GM also cheated on diesel emissions. The scope of this is over 705,000 trucks. Supposedly, the diesel Duramax offering from 2011 to 2016 exceeded regulation levels too. These aren't smaller cars either, like Jetta. These are giants, guzzlers even when using diesel. That potentially could result in a fine from the EPA greater than that for VW. It will be interesting to find out what our government agencies do. CARB will obviously get involved at some point. It depends upon the data. GM's response has been flat out denial. You can imagine how defensive they'll be to protect high-profit vehicles like that, even if they didn't do anything wrong. VW lost their case when the actual software coding revealed intentional deception. If the same is found with GM, there doesn't seem to be any way to save diesel. Their abandonment of Two-Mode was always highly suspicious. Refining that gas hybrid to deliver greater efficiency than diesel made sense. Seeing that Toyota continued to push with Highlander hybrid's efficiency and towing-capacity should have provided incentive, especially since large SUVs continue to be so popular. Oh well. We'll find out how this next chapter in diesel trouble plays out soon enough.

5-25-2017 **Hypocrites.** I really get a kick out of how some people back themselves into a corner. When Toyota ceased rollout expansion of Prius PHV due to the trouble it observed GM having with Volt, the spin turned ugly. I knew real-world data collection in the markets already reached was more than enough to properly determine what the next generation design should deliver. Knowing requirements is vital. Setting goals confirms that consumer interests are being pursued. The ending of Prius PHV indicated to me that Toyota had indeed taken that step. Antagonists went nuts though, exploiting the opportunity to mislead. Quite a number of their claims are now a regrettable chapter in history. Reminding them of what they stated calls them out as hypocrites, knowing there's not a thing they can say to recover from such a wrong assumption. They didn't want to accept what had been learned. Fortunately, that feeling of having made such an obvious mistake actually passes. Phew! Looking forward is possible if you give them a sense of hope. In the most recent example, it's stating the impressive technology used by Toyota in Prime will benefit the entire industry... rather than pointing out the shortcomings of others. I kept it simple with, but included a reminder of the past: The more important matter is to consider all those posts that claimed Toyota wasn't investing in EV advancement only to now discover they've delivered the automotive industry's most efficient electric heating solution.

5-25-2017 **Obsolescence.** I'm on the offensive now. There's no reason to tolerate antagonism anymore. Enough real-world data is now available to fight back. Claims of being not he defense don't work when you are calling the shots. This is what caused me to pull the trigger today: *"The rapid pace of development makes obsolescence a factor in declining EV values. Remember, the first LEAF and Volt appeared just 6 years ago. At 235 miles the Bolt's range represents a more than 160% improvement over an original LEAF's 70 miles..."* I took the time to put Volt enthusiasts in their place, along side other plug-in hybrid supporters. No more of the "vastly superior" nonsense. They need to learn to focus on goals. It felt good to post this:

What does obsolescence mean? Lower EV range? If so, that disregards the fundamental problem many have struggled with for years... understanding diminishing returns. At some point, range doesn't matter. When a plateau is reached, people focus on other priorities, like affordability.

For example, Volt reached it with gen-1. GM chose to increase EV range for gen-2 anyway. Why? It directly contradicted their own studies of how much was needed and made the sacrifice of not being affordable in return. What is the point of having an engine if owners do all they can to avoid ever using it? Just buy a Bolt instead. 235 miles is profoundly more than 53. That's an improvement of 443%.

Watch what happens with Prime. There isn't any reason to extend range beyond GM's original goal of 40 miles. Owners routinely see 30 miles already. Improvements from battery advancements will materialize in the form of increased profit for dealers, a vital factor in sales growth. That rise in demand will keep resale values from plummeting. Prime also delivers a very high return when the engine is used, keeping it competitive with even the most efficient hybrids. You're getting more than just a "range extender". It doesn't feel like a penalty either. MPG is impressive under all circumstances.

In other words, obsolescence is defined as those vehicles unable to co-exist with EV offerings. We'll see other priorities playing a strong role in the next few years. That will weed out the choices which struggle to be competitive without tax-credits... making them obsolete.

- 5-25-2017** **Terrible, continued.** We've had a series of posts claiming he isn't "*bashing*" Prime, yet it continues to anyway. Bashing is stating a negative stance without providing anything constructive. That absence of any type of detail is the problem. What are we supposed to do when nothing is shared to respond to? With Volt, I point out aspects like price and time with specific values. That clearly declares expectations. Heck, even those complaining about acceleration-speed state the desired measure. For that matter, we get that all the time for EV distance too. This was the latest from him, wondering why some people are so defensive: "*The *Prime Boys Club* all hate me. Maybe it's because I expressed an opinion that the car is overpriced.*" At least criteria was included this time, but still... no value. Ugh. I posted this in return: Nope. It came from making such a vague generalization. We see a lot of cherry-picking and data omission. But to not include anything at all, there was no way to respond to a complete absence of information. To get useful feedback, provide some type of detail to work with. Also, keep in mind that being "defensive" turns after being provoked repeatedly. It's an invitation to play offense, armed with a wealth of real-world experiences to share.
- 5-26-2017** **Chargers & Meters.** The 7-year anniversary of having upgraded from my Iconic Prius was to arrive with high expectations. Not only would that potentially be the same day my wife could have her Prime arrive at the dealer, it was also when her first aftermarket accessory for it would be delivered... the fancy floormats. We were also expected delivery of upgrades. For the 2 plug-in vehicles to be parked in our garage, we'd be getting high-speed chargers. Since those aren't necessary, I never bothered for my Prius PHV. Waiting for a newer charger model offering more power than necessary and Wi-Fi connectively, all for a price lower than in recent years was good reason. The delay would result in both of us upgrading at the same time. Today was that day. 2 boxes arrived at our doorstep. Each could draw 40 amps of electricity at a rate of 10 kW. That's far more than what Prime will utilize, but forward-compatibility is nice and friends visiting with newer recharge systems someday would be able to recharge while parked in the driveway. The other delivery today was 2 meter-boxes. Both would get have a Time-Of-Use meter to control pricing for the 240-volt connection they'd each have a dedicated line for. This is a new approach for my service provider. That co-op hadn't dealt with the request for 2 in the same garage before. That's interesting situation, which shouldn't be a big deal... since they already know I'll be helping to promote what they offer, my reputation for leading was already common knowledge. In fact, I had already chatted with that main contact about my plans back at a plug-in owners group a few months ago. Little did either of us know I'd be requesting those services so soon afterward.

- 5-26-2017** **Average Buyer.** Sometimes, you get a response that actually shares your observations: *"For the average car buyer, this argument has just never gathered much steam. Up front cost is first and foremost in the mind of the typical buyer..."* Hanging out on hostile venues means that won't happen often. So, I was happy to see that. It's too bad the perspective of enthusiasts is so selective. They don't notice the average buyer. All they see is the expertise they share. Oh well. They are happy. They just don't understand why others wouldn't be too. I try to explain: That's why references to engineering have also fallen on deaf ears. It doesn't matter how favorable those other numbers are. They simply aren't interested in any presentation beyond up front cost. Heck, that's even the reason why there has always been a push for point-of-sale rebates rather than filing for a tax-credit for your purchase a year later. That up front payment is what sells the high-volume vehicles. Like it or not (and clearly some don't, hence the *"nicely under \$30,000"* issues), that's the way it is.
- 5-27-2017** **Mounting Chargers.** The units themselves are heavy & robust. Seeing how thick the cord was, placement for the charger took extra consideration. I had already called an electrician to get an estimate scheduled. For maximum flexibility, as well as saving some money, the plan was to do the mounting myself. I came up with a method of hanging oddly shaped items that weighed a lot in the garage already. It involved a 2-foot metal bracket, allowing the ability to drill into studs directly while still offering the ability to adjust placement. That's how the bike-rack was hung from the wall. It was proven an effective approach. There were slots every inch. I could bolt anything needed to attach anywhere it was needed. In this case, that was perfect for the aluminum hanger on the back of the 240-volt charging unit. That was really important, since location of the thick cords was a very big deal. Length of the one for the 14-50 outlets we'd be having install were only 12 inches. I wanted to maximum the reach & convenience of the other too. You'd be surprised how short 24 feet can be. Thank goodness I waited. Years ago, 16 feet was considered long. Thankfully, aftermarket builders have been able to offer more for less such a short span of time. And fortunate for us, our garage has a 200-amp service-box near by, close and without obstruction. In fact, both will be surprisingly easy to accommodate. That's something I looked for when we were house hunting, knowing years later that location would be a nice benefit years later when adding chargers. Some builders still don't take such a need into consideration. Having to drill through floors & walls isn't something many homeowners want to deal with. Anywho, I got both mounted today. The placement worked out great. We'll both be able to plug in without tripping over cords or having to spend much for the convenience.

- 5-27-2017** **Why 199.9 MPG?** That's a good question. It was stated as a comment this way in a post: "*Why Toyota changed to MPG reading on the car to max out at 199.9 is beyond me (even though it goes up to 999.9 MPG you just can't see it).*" We, that's people here in this United States, have been greenwashed into believing the larger the number, the better it is. In reality, efficiency consumption doesn't actually work that way. The results are non-linear... in other words, misleading. This is why most of the rest of the world doesn't use that type of measure; instead, results are stated in terms of distance/fuel units. When outcome of a drive is stated in those terms, you know exactly how much fuel was actually used. As telling as MPG may seem, incremental gains in efficiency aren't actually as telling. 1 MPG improvement on the lower end, when the vehicle only gets 30 MPG, is far more of a gain compared to a vehicle already getting 100 MPG. The math is simple too; unfortunately, most people don't bother. 1/30th is much more than 1/100th. Now compare 1/200th to 1/999th. That's 0.005 gallon compared to 0.001 gallon. The difference is tiny when you look back at the 30 MPG, which calculates to 0.033 gallon. It's a shame so many people fall for the greenwash. Success of that effort to misleading was so effective, the EPA's attempt to introduce distance/fuel unit of measure is still barely getting any attention. Thankfully, EV efficiency is measured in terms of miles/kWh. The hope is to avoid the same MPG from the start, not allowing the deception any chance of spreading to electric-only vehicles. We do still have to address the problem with plug-in hybrids. Here's how I stated Toyota's decision: Study of the market revealed an issue with diminishing returns. Customer understanding of the system overall showed little value reporting numbers higher than 200 MPG. Most people have no clue how the electricity & gas interplay. That's why Toyota only shows one electric motor on the display, even though there are actually two.
- 5-28-2017** **G-7 Summit.** The start of an article highlighting outcome stated it as: "*The other six members reaffirmed their commitment to swiftly implement the 2015 accord to limit greenhouse gas emissions.*" That situation was doomed anyway. We knew the other 194 nations participating wouldn't matter, since our new leader doesn't believe in cooperative efforts. Having to also listen to a close relative complain about the previous administration and claim that nothing good came out of Tesla was a harsh reminder of how poorly informed many people are. He also believed our new president's claim that efforts like this are job killers. That's more of that scare tactics we've seen countless times in the past. Ironically, in a twisted way, it's actually true. If we don't invest in the new technology, we'll miss out on great economic opportunity. He believes the opposite, if we move away from the tried & true, we'll end up losing what we've worked so hard to establish. Sadly, that backward mindset is quite common. We've become complacent... so much so, we now praise ourselves for accomplishments that don't actually achieve goals... hence why I've been so hard on Volt enthusiasts. Poor implementation of great potential is such a profound loss, which some still don't see. They make excuses & dismiss, just like this president is doing now. Rather than strive for a better future, it's a desperate effort to hold on to what we currently have. That's really going to cost us. It won't take long to come to the realization of having made such a huge mistake either.

5-28-2017 **Mistakes.** There are a few who still don't understand: "*And btw, GM's original research centered on 40 miles, not 25.*" That entitled me to return a BTW of my own, which I didn't hesitate to do:

That was what had been heavily promoted. It wasn't the actual focus of development though. Big difference. Think about how early that "*nicely under \$30,000*" target had been set and the hope for "*50 MPG*" following depletion.

Whenever I brought up how unrealistic that was for the 2010 rollout, it was enthusiasts who brought up the "*40 mile*" expectation. That wasn't GM. In fact, what we got from GM quickly became a disaster. Remember that terrible "*230 MPG*" campaign? That didn't bring up mention of EV range.

So, I continuously brought up the topic of heater use, pointing out how much of an impact that would have on Winter driving. That was always met with denial & dismissal, even after rollout when confirmed correct.

That's how the 25 came about. It was an effort to look beyond the gen-1 shortcomings, shifting focus to what would actually help sell Volt profitably at high-volume levels. Toyota took all that online banter seriously, adding it into the consideration factors for their gen-2 design. Combined with the wealth of real-world data they had collected from their own gen-1 experiences, there was a great deal of potential to tap into.

Prius Prime was the result. It delivers a "*25 mile*" rating, even with heater usage factored in. It also delivers upon the "*nicely under \$30,000*" target. And for the "*50 MPG*", that hope has been greatly exceeded. Owners routinely see much higher following depletion. In other words, it is the version of Volt enthusiasts had always hope for.

Too bad if that's not what you want to read about. It's not like GM doesn't have the ability to deliver something similar. They just don't want to. Like enthusiasts, they feel the word "*compromise*" has a stigma, rather than being an effort to deliver balance as it is actually defined. Having increased EV range to 53, rather than just leaving it at 38 was a mistake.

5-28-2017 **No Charge-Mode.** It has been interesting to read about gen-2 Volt owners use of Hold-Mode, how they keep wishing there as a Charge-Mode available instead. They'll use regen to push EV range beyond that of when they pushed their "*Hold*" button. It's what Prius PHV owners called "*stacking*". You could add to the EV capacity available, but only by reassigning electricity generated from braking. You couldn't actually just run the engine to recharge the battery-pack, as the system in Prius Prime offers. The reason GM avoided it was the MPG penalty is quite noticeable. Their HV operation isn't anyway near as efficient as Toyota's design... and enthusiasts hate when I make any reference to that reality. So, I tend to quietly just lurk when things like this are posted in those discussions: "*The Prius, 135 miles, 55 mpg, 2.45 gals used @ \$2.579/gal = \$6.31. The Volt, full charge 16 KWH, \$1.80 (all cost taxes, fees, delivery charge, everything) 65 miles on gas 1.24 gals @ 2.579 = \$3.20 + \$1.80 = \$5.00, savings of \$1.31 over the Prius.*" That caught my attention. The poster had avoided mention of Prime. Such an obvious exclusion is clear evidence of not being constructive. Looking closer at the data itself though concerned me. Notice how he didn't actually state MPG for Volt? Dividing that 65 by 1.24 gives you 52 MPG. How is that an attempt to be honest? The highway rating is 42 MPG. Of course, the 55 for Prius wasn't right either. I'm thinking his embellishment of one was used as a justification for the other, even though their values weren't realistic. What got me those was the 65 miles itself. To travel a total of 135 miles for that comparison, the Volt would have had to deliver 70 miles of EV on the highway. How is that even remotely correct? Was his hope that no one would actually do the math to check the figures that were posted? Grrr. I'm so sick of greenwashing like this. There's no excuse for such misleading efforts. Makes you wonder what they'll do when it becomes common knowledge about Prius Prime offering a charge-mode.

5-28-2017 **Understanding EV.** Now that we have Prime, the first Prius with a plug available nationwide, hope has been that understanding EV would be less of an issue. The larger pack offers more power, enhancing the design already part of the system. True, it was an augmentation with PHV. With the next-generation, that line is blurred, since the addition of a one-way clutch technically changes operation. Nonetheless, the perceived behavior is no different. It's just more power is delivered. Reaching mainstream consumers means finding a way of conveying benefit in terms you don't need any type of background for. If they can pick up on the basics quickly, the desire to find out more comes naturally. That's why the test-drive has been such a powerful tool for stirring interest... which some certain enthusiasts still don't grasp the importance of. Oh well. It's not like I've having been trying to convey that message. In this case today, it was on the big Prius forum to an owner wanting more information. I replied with: Electric-Only operation is based on kW draw from the battery. If demand is low, the top EV speed will be faster and automatically engaged. This is known as "*stealth*" mode, since it is an inherent part of the hybrid system. That EV button offers a mode you manually engage. It draws more from the battery, giving you more power but at the tradeoff of a slower speed maximum.

5-28-2017 **Signature Change.** How to display my real-world data at the conclusion of each post, in an automatic signature, was a problem with the switch from PHV to Prime. This is what my final entry was before the upgrade: "**91,355 miles 1,286 gallons 7,544 kWh 71.0 MPG**" With the precedent having been set about not reporting either gallons or kWh, I had to seriously consider the value of reporting MPG. Those terrible Volt enthusiasts who fought the effort to exclude gallons and kWh clearly didn't care about misleading. Just MPG was their focus. They'd tell you what it was and how many months between fill-ups. Actually fuel consumption of either type wasn't included. Heck, it was rare to even be told a distance. So, after all those years of their insistence to report that way, they have no choice but to deal with it is now coming from Prime owners too. The antagonist posts, always claiming vastly superior stance from their MPG number, was incredibly disruptive. Irony can provide ammunition though. I can fire back the very same thing now. Treating Prius as player on the same team was never acceptable. Too bad for them. If their goal really truly is to replace traditional vehicles, they have no choice but to accept another vehicle actually achieving that. So, to all who read my posts on the big Prius forum, they will now see real-world data in this format: "**2,075 miles so far, overall average: 100.5 MPG**"

5-28-2017 **EVSE Purchase & Installation in 2017.** I started a new thread on the big Prius forum:

Doing a search, you'll find a lot of outdated information. Too much has changed since plug-in rollouts began. So... let's start a new thread with facts relevant to 2017.

Since back in 2012, I have been recharging my Prius (originally a PHV, now a Prime) at home by plugging into a standard 120-volt outlet. In a few days, we will have 2 Primes in the household. That means capacity must be added to the garage so my wife and I can both recharge at the same time.

Taking advantage of faster recharging from 240-volt service and discounts from Time-Of-Use meters requires purchasing EVSE (Electric Vehicle Supply Equipment) chargers and running new power lines. The following documents what I have done so far...

We decided to get hardware as forward-compatible as possible. If we ever upgrade a vehicle in the future or a friend with an EV visit, we'll have a nice plug already available. We also get \$500 per vehicle setup from our local electricity provider. So, why not?

Prime has a maximum draw of 3.8 kW (as observed when plugging into a public station). The charger we found with a Wi-Fi interface is capable of delivering 10 kW. That's plenty good. With a 200-amp service-panel in the garage, feeding each 40-amp charger with the needed 125% capacity requirement wouldn't be too much of an effort for an electrician. #8 gauge wire and 3/4 inch conduit is more expensive though. Smaller chargers wouldn't need sizes that heavy or large.

The cord for the outlet plug is only 12 inches. But having a line put in specifically for the charger shouldn't make that an issue. It won't be hardwired either. So if removable is ever needed, no big deal. The cord for the car plug is 24 feet, so that will reach anywhere in the garage and parked outside in the driveway.

JuiceBox Pro 40 is the EVSE we purchased. \$599 each. I now have them mounted on the wall to confirm cord placement and internet connection are well suited for both of us prior to getting an estimate from the electrician. I also got meter boxes for each of the lines.

Progress updates & photos to follow.

Anyone else have a recent purchase & installation experience to share?

- 5-29-2017** **5,700 Available.** The anticipation for this month's sales results is becoming apparent. Threads in forums are popping up ahead of time. That's unusual, but May 2017 is expected to be rather significant. Last month, Prius Prime beat Volt for the first time, despite Midwest rollout having barely begun by the end of April. That heightened awareness of the struggle GM has had with sales growth... the very problem I emphasized as a major concern for gen-2. The biggest issue though is Bolt. GM chose the following states for inventory availability by May: CA, OR, MA, MD, VA, NY, NJ, WA, CT, ME, RI, VT, NH, CO. Ordering began for the last 6 in March. The others were stagger earlier, with the first 2 starting in October last year. Needless to say, if there was a waiting list, those would have been fulfilled by now. Having 5,700 listed as available is a lot. Dealers don't want the upcoming clearance markdowns (they usually start shortly after the 4th of July) to include first-year offerings. The next 2 states are FL and IL. Both have very small counts already. Is that the result of dealer orders or GM assignments? Needless to say, there's quite a bit of uncertainty... hence the lively discussions. My perspective is Bolt's resemblance to Fit & Versa and unfamiliar body type to GM customers spelled doom from the start... a pattern we recognize as a problem for Volt. With Tesla & Leaf arriving in the next few months, things aren't looking good. Remember, the phaseout of tax-credits will be yet another issue to deal with in the next year. Sales will become even more difficult then, especially with Hyundai entering the mainstream plug-in market.
- 5-30-2017** **Delivery Confirmed.** The holiday weekend didn't include a shiny new Hypersonic Red Prime. Oh well. It's worth the wait... which didn't turn out to be that much longer. My wife and I couldn't commute to work together today. Her commitment this evening meant I was on my own. So, I took a detour on the drive home and swung by the dealership. Sure enough. There in the back lot, delivery confirmed. What great timing. I was able to see it even before our salesperson. Sweet! That means tomorrow will be trading in the old car and driving home with another plug-in hybrid. Hooray! Of course, we only have one outlet to share in the garage. Thankfully, that won't be for long. And rather than just adding another 120-volt line, we'll be going all out with 240-volt for each. Yeah! What a rare opportunity. It's a bit of a cheat too. We just happened to be at exactly the right place at exactly the right time. The order wasn't actually ours. There was a customer who must have had financing or some other circumstance mess up plans for that purchase. We pounced on the chance to snap it up. So, rather than the usual painfully long wait other had to endure (which included me), my wife only had to wait a few weeks. That's amazing luck. We'll do our best to pay forward the blessing by helping out those seeking their own Prime purchase. Much can be shared about the purchase & ownership experience... which starts tomorrow for my wife. Yippee!

- 5-31-2017** **Prime Purchase.** It was a memorable experience. Neither of us had anticipated getting a second plug-in vehicle so soon. Things just fell into place though. There was that beautiful new Prime waiting for us to finish with the paperwork. That's takes awhile. There's some setup to complete in the meantime as well. Timing looked perfect though. Recharging of the battery would be done very close to when we'd be ready to drive home. Sweet! All went as hoped. No surprises. It was a beautiful evening too, quite a harsh contrast to the torrential downpour of rain when experienced when placing the order. Arriving at home sure was surreal. When the garage opened, there was my Prime. The red & blue would soon be together... sharing a single 120-volt outlet. What a rare experience. Fortunately, it will only be another week or two before the new 240-volt lines are added. Knowing we'll get \$500 for each vehicle from our electricity-provider for doing that sure made the decision to upgrade easy. We'll be set for many, many years to come. My wife and I now have Advanced model Primes. This sure is going to be interesting.
- 6-01-2017** **Huh?** I wasn't the only one confused upon reading this: "*However looking at the two vehicles, one screams appliance, the other statement.*" I think it was intended to be an insult to Toyota. But it was a comment emerging from a discussion of i3, which is definitely a unique looking vehicle. It doesn't look like anything else on the road. Prius is well known for being basic reliable transport from point A to B. The radical styling gen-4 welcomed broke that stereotype and Prime refined it. I was truly baffled what the poster actually meant. Others sound off to that affect as well. Confused and without a point made it too irresistible to pass up. So, I jumped into the discussion: BMW i3 compared to Prime. Huh? What statement? I constantly get compliments about the surprisingly sporty front and curved back. The array of headlights and that wavy glass certainly don't resemble any appliance. Prime... it's not your father's Prius.
- 6-01-2017** **Excuses.** Sales results for May brought out the spin, specifically GM defenders. Bolt inventory far outweighing purchases isn't a good sign. The supposed demand was expected to struggle with supply shortcomings. Instead, the hotspots have many available for immediate ownership. The lead ahead of Model 3 and the new Leaf isn't amounting to much. Volt is in a worse position. This is the second year for gen-2 and sales are flat. We saw between 1,600 and 1,700 monthly for a large portion of gen-1 availability. Seeing a balance of 1,800 is a clear sign of not having achieved growth. We do expect a growth in the outlash against Prime though. Enthusiasts won't be happy with the reality of Toyota having kept focus. I took the offense and fired off this before anyone could get a chance to attempt that type of attention: GM set a target of "*nicely under \$30,000*" for good reason. It's what the bulk of their car-buying customers would be willing to pay for a plug-in offering. The MSRP for both is simply too high. GM chose not to configure either vehicle for mainstream acceptance. The size of the packs and power of the EV impresses enthusiasts, but that doesn't compel their own showroom shoppers to purchase... even with the generous \$7,500 subsidy... which will be yet another barrier to deal with when phaseout begins mid-cycle. Toyota didn't make that same mistake. They kept focus of making what they offered something that could realistically result in high-volume profit sales, then rolled it out worldwide in the first year. No excuses anymore. It's not badging. It's not advertising. It's an unwillingness to accept their own pricing target by configuring a choice that's affordable for their own loyal customers... those who just choose to purchase a Cruze, Malibu, or Equinox instead.

6-01-2017 **Fallout Coming.** What a monumental day. It was the first having 2 plug-in hybrids at home... and only 1 outlet to plug into. Fortunately, we also had an electrician scheduled to estimate cost of running 240-volt lines for each Prime. We're not skimping on specifications either. Both will have excess capacity, so no need to upgrade years later. Good thing too, since the need to promote starts with understanding what is to come... and today just happened to bring the biggest newest **ever** in the history of environmental efforts. Hearing that the United States will not support measures to reduce carbon-emissions impacts every aspect of clean. Putting America first means turning our backs on allies. What a terrible thing to do. Regardless of climate impact, these were partners. You don't just walk away from people working with you like that. No support from the government means a lot of grassroots sweat those here. It will be up to us driving the affordable solutions to help influence change. Being part of that is great, but the necessity is unfortunate. Who knew our president would choose to do something so careless? In the name of saving jobs, he said we would withdraw from the Paris Climate Accord. That's so embarrassing. Not investing in the future is what causes job loss. We are literally abandoning opportunity. Rather than choosing to be part of the new manufacturing endeavors, he is guiding us to a dead end. Investing more in oil, natural gas, and coal is absolutely nuts. All are dirty and non-renewable. What an idiot. I can't imagine what those who voted for him will think when they realize the damage they contributed too. Of course, they may not ever find out. Their children will though. What a sad day in our history.

6-02-2017 **Spreading Electrification, push.** There will be some winners and some losers. The point is to continue pushing forward, not to celebrate flat sales. Yet, that denial of the true situation persists. Ugh. This was my push that started out the day on a thread highlighting May results: What compels a GM salesperson to convince a GM customer to choose Volt rather than Cruze with a much lower price? Take a look at Prime. The array of headlights in front, the dual-wave glass in back, and the distinct LED flare of the brakes, all make it difficult to label as an regular Toyota offering. Upon closer inspection, you'll notice the carbon-fiber hatch and the translucent grille. You wouldn't expect those as a mainstream choice either, especially with a MSRP of just \$27,100. That positions Prime well for standing a chance at attracting someone who would otherwise choose a Corolla. GM hasn't delivered anything like that. Volt as has suffered as a result. Bolt is in an even more difficult situation, with its higher price and the mindset challenge associated with not having an engine anymore. Rapid sales growth is required to overcome the approaching tax-credit expiration. GM is racing toward a cliff and there's celebrating that sales have or haven't fallen. That kind of denial is so harmful to the effort of spreading electrification. Much more is needed right away!!!

6-02-2017 **Spreading Electrification, draw.** Remember one of your first lessons taught in kindergarten? It was to not judge a book by its cover. That meant looking for substance within, rather than deciding worth upon visual appeal. It's important advice. Yet, that lack of substance is what enthusiasts continue to push. For example: "*After taking a look, I try to look away...*" That's becoming the universal response to anything related to how the system actually operates. So, it is somewhat of a futile endeavor to argue those points. Focus on other aspects of interest seem to really be gaining traction. That's how overcoming the obsession with faster & further will ultimately be won; otherwise, antagonists will just keep pushing the brainless acceleration & range arguments. I summed up the situation with this today: Customers want more than just a plug and the needed sales growth won't come from just EV driving. Toyota made an effort to think outside the box, offering some other features to draw interest. What did GM do to provide appeal from an aspect that has nothing to do with the propulsion system?

6-03-2017 **The Pebble.** Playing offense again is necessary. I went all out this morning to convey the message some continue to refuse to accept:

Prius has always been the protagonist in the story of plug-in hybrids.

Way back in 2003, we knew of the 100 km/h (62.1 mph) electric-only aspect of its design. Batteries simply weren't able to deliver that in either an affordable or a practical manner though. So, a prototype exploiting the inherent part of that design wasn't even revealed until 2009, which served as a demonstration of what could later be delivered.

The next generation Prius saw battery energy cost & density reach a tipping point, where small-market rollout became realistic. In 2012, we saw a mid-cycle offering to select locations to collection real-world data from ordinary consumers willing to purchase the predecessor to a future all-market design.

That generational upgrade to follow was indeed that design. It confirmed the original milestones GM had targeted for their gen-1 offering were reasonable for high-volume profitable sales. Ironically, those very milestones had become goals abandoned by GM for their gen-2 offering. The enthusiasts who set high hopes for those original targets ended up becoming antagonists, upset that Toyota had actually delivered.

Too bad if you find the messenger of that story a pebble in your shoe. Ignoring the message by hiding it doesn't make it go away. You know all too well what needs to be done. The enthusiasts hear once cheered for a "*lite*" version of Volt. So what if Toyota beat GM at its own game. Swallow your pride and finally get on board. Acknowledge the problem. Take your damn shoe off already. Geez!

The concern of "*too little, too slowly*" has overwhelmingly been confirmed. GM screwed up by not adhering to their original plan, so much opportunity wasted. Delivering a vehicle with a MSRP price "*nicely under \$30,000*" is even more important now than it was way back in 2007 when that target was first set. The upgrade of range & power for gen-2 has not proven an effective means of growing sales either; rollback to what gen-1 offered would help achieve that required cost reduction. It would also help improve depleted efficiency, to finally reach that original target of 50 MPG.

That pebble isn't going away. Change is necessary. It's time to accept what needs to be done.

6-03-2017 **Sales Fallout.** As anticipated, it has been quite intense. The rapid rise of Prime, despite limited availability, is emphasizing just how big of a problem GM has. The well-informed always had a fear GM would repeat mistakes of the past, causing the same fallout. Quite specifically, it was concern about how they soured the diesel market back in the 70's. What they delivered was so bad, it made all diesel offerings unappealing across the entire automotive market. That's why the push to make sure Prius was recognized as different has been so vital. Knowing the configuration of Volt was for conquest sales from enthusiasts, rather than something to draw ordinary middle-market consumer interest, was sign of trouble from the very start. It was obvious to those recognizing need. Those obsessed with want couldn't see it though. A reminder of that is quite clear to all... now that sales are reflecting the anticipated fallout: Prime is the result of Toyota carefully studying what their customers will actually purchase. That's what the limitation of the mid-cycle Prius PHV rollout was all about. They collected a massive amount of real-world data. Adhering to an affordable target was absolutely vital. They clearly delivered, making sure power & range did not exceed need, so profitable high-volume sales would be realistic without tax-credit dependency. GM messed up with both Volt & Bolt by giving in to the faster & further temptation. That delivered a very pleasing design for enthusiasts, but left their own showroom shoppers without a realistic choice.

6-03-2017 **Discounts Already?** I really liked reading this: "*Several reports suggest the prime has very low inventory. So it's strange they would offer a discount.*" That's a good sign. Rather than having to deal with rhetoric, there's some constructive discussion emerging. People are thinking through the factors influencing sales. Yeah! I jumped into that with: The multi-market rollout can contribute to confusion of overall intent. It turns out to be an effective means of measuring consumer response though. Why not test out promotional offers in isolated areas initially, prior to going nationwide all at once? It is unfortunate for those of us in the Midwest still waiting for delivery of orders, but it does set the stage for high-volume sales sooner. After all, the goal is to have inventory on the lots ready for purchase at appealing prices prior to the tax-credit expiration. Experimenting with potential long before that is a sensible move. Learning what is most effective early is a big benefit in an emerging market with lots of uncertainty.

6-04-2017 **Arguing Semantics.** That's how you know the antagonist has become desperate. It's their last resort. They have nothing left to argue. This morning, I woke up to: "*Since it has no AER... it is a hybrid at best, and should not be considered a true "EV".*" " Seeing that same old rhetoric return brought mixed feelings. True, was confirmation that they have nothing of any substance to fight with. However, they keep fighting anyway. I responded with: That's called an "oops". They made a mistake in the review, not realizing there was a difference between EV and EV-Auto mode. Putting the vehicle in the wrong one results in an incorrect conclusion. As for exploiting a classification label to mislead about how a system actually operates, that's called "greenwash". After having been informed of the situation, here's what actually happens from the words of an owner: PRIME FUNCTIONS AS AN EV FOR THE FIRST 25 MILES. The propulsion system provides pedal-to-the-floor acceleration with just electricity, allowing speed to be maintain up to 84 mph. Both the Heater & A/C are electric too. Use of the gas engine is for when you deplete the plug-supplied electricity, want to save that plug-supplied electricity later, or want to force-charge the battery while driving. The point is, the system delivers an EV driving experience. For me on my 19-mile commute. That is achieved entirely without using any gas. Though the absolute isn't necessary, it does prove driving in that variety of traffic (suburb & 70 mph highway) is totally realistic with only electricity.

6-04-2017 **Return of Smug: Failure.** You wouldn't think that level of cockiness would still emerge, after so much attention to that attitude was given over the years. Yet, there it is. Some of it is surprisingly entertaining too. The same old mindless roar & chest-beating does draw interesting reaction. Ultimately though, it is an effort to counter progress. They do all they can to undermine progress. Claiming superiority is how you impede the advancement of a better solution. That's why real-world data can have such a powerful effect, given the opportunity. Nonetheless, I do expend a little effort to make sure lurkers understand the facts. In today's example, it was an attempt to label Prius PHV rollout as a "*failure*". That's easy to do, long after people are no longer of the goals it set out to achieve. Antagonists simply state they were something different. That's why I pushed so hard on the Volt enthusiasts to state goals... knowing the written record of what they claimed would come back to haunt them later. That's why they continue to be vague and evade the questions whenever possible. Anywho, this was my reply to the "*failure*" claim: Toyota delivered a plug-in hybrid, by far the most efficient blended offering of that time. The fact that their design & approach was flexible, allowing them to adjust to the changing market, has clearly paid off too. We see that success in the sales now. Consider how "*failure*" is defined. It made no sense whatsoever to squander tax-credit opportunity by rushing to market like GM did with Volt. Yet, somehow that is still regarded at the better strategy. Ugh.

- 6-04-2017** **Online Battles.** Purpose of engaging in them often gets questioned. Revelations like this speak for themselves, the antagonists unwillingly provide debate material and practice to go along with it... which prepares us well for dealing with their rhetoric: Looking closer at the EPA sticker information, there's an interesting observation to make. That range stated for all-electric miles is a subtle indication of the system's efficiency design advantage. Prime offers a higher rating for both EV and HV driving. 25 kWh/100mi for Prime is quite a bit more efficient than the 31 kWh/100mi for Volt. In fact, that makes Volt appear to be an electricity guzzler in comparison. As for gas consumption, there's no contest that Prime uses less. 1.9 gal/100mi is far more efficient than 2.4 gal/100mi. Focus on labels of "AER" or "EV" only distract from what's actually important. Those numbers tell the true story of efficiency, the very purpose of EPA rating values.
- 6-04-2017** **No Replacement.** The denial and damage-control has become so bad, having to respond to claims like this make you wonder: *"More Volts are sold per month in the US than half of all other car models. We say that IS mainstream."* Do they really have a clue just how desperate that sounds? It should be obvious. The numbers certainly make it easy to understand. The situation is bad, really bad. Oh well. All I can do is point what has happened: The purpose of Volt was to lead the replacement of traditional vehicles, not to be trivia statistic. The counts for May reveal the obvious sales growth problem: 20,908=Equinox; 20,718=Malibu; 17,120=Cruze; 7,841=Camaro; 3,269=Impala; 2,535=Corvette; 2,143=Sonic; 1,817=Volt. The cold hard reality of the situation is that even with a \$7,500 subsidy and a generational upgrade, attracting buyers is still a major struggle. Sales are falling well short of replacing GM's own traditional offerings. No vastly superior. No leap frog. No replacement.

- 6-04-2017** **Misplaced Anger.** Blaming the scapegoat is their plan, but what happens when that planned effort gets exposed? *"We have a group who wants to learn about and discuss the Volt and Bolt. The idea of continually bringing up the Peeus (for years and years now) just boggles the mind."* That was a post to me, implying I was the source of the problem. Whether he was confused about who was actually starting the problem each time or was intentionally trying to make me a scapegoat didn't matter. It was clear I couldn't be labeled as a troll, since posts were very clearly about the thread's topic. Sticking to that prevents antagonists from turning the table on you. It also always me to state my case on them: They have indeed been bringing up Prius for years. The reason why is simple. It's to get focus off of GM. Haven't you noticed the stir caused with each month's end report? I'd bring up the concern of too little, too slowly. Sales results overwhelmingly confirm there is indeed reason for concern. The needed growth simply isn't happening. Between discounts & upgrades, all we have seen is the average climb from 1,600/1,700 sales per month to 1,800/1,900. That is so far below the required 5,000 monthly level required for profitable sustainability, it's a very real problem. And once the tax-credit phaseout begins, it will become even more difficult to achieve that growth. To complicate matters, the very premise of Volt has been cancelled out by Bolt. How come I'm the only one who seems to see the hypocrisy an anti-EV automaker, who heavily pushed the *"range anxiety"* fear to promote Volt, is now selling an electric-only solution called Bolt? Everyone avoids the topic whenever it is brought up. Ironically, the distraction brought up for years by others has become the protagonist in the quest to deliver a plug-in hybrid for the masses. Ask them why the suggestion of a *"lite"* model of Volt keeps getting dismissed. They'll do everything they can to deny saying that proposed configuration is what will attract ordinary GM showroom shoppers... because it now resembles what Toyota delivered... which has been selling very well.
- 6-05-2017** **Looking Beyond.** The reply of misplaced anger included this opening: *"The rest of us have enough of a brain to realize that EV's, even with longer ranges still have public charging issues."* Not seeing further than what's immediately in front of them is a common problem, the cliché of seeing the tree instead of the forest applies well to this. I was happy to point out what is still being missed: Looking beyond that barrier, you'll discover there are even more issues with household charging. Many homes are limited to 15 or 20 amp connections in their garage, if they are lucky. That makes any type of higher draw a very real problem... both logistically & financially. For my household, you'd think a home less than 10 years old would not only avoid that issue, but it would also be able to support more without challenges. Nope, it even has some. We're the very first customer for that electricity provider to request adding more than one 240-volt high-amp line for charging in the garage. They haven't ever supported two lines to deliver 10 kW each and both be on Time-Of-Use meters. Fortunately, all that should be setup next Monday. It won't be cheap though, despite having the service-panel right there in the garage. How many customers do you think will be well enough informed to do the same, in addition to being able to afford it? For that matter, being able to just get one 40-amp charger for daily use? Don't forget how intimidating all that is for most people either. It's the reason why a VOLT LITE has a great deal of potential.

6-05-2017 **Approach.** You can feel the regret. Virtually all feeling of superiority has melted away. The reality of needing to become a player in the plug-in hybrid market, rather than being king of the hill has sunk in. Finally! This is right on schedule, exactly as predicted. The second year of the second generation has ended arguments. Facts confirm goals were not achieved. I stressed that with this summary & reminder: GM's approach hasn't paid off for high-volume sales so far. To go faster & further, there was a design tradeoff resulting in a challenging price-point, lower electric efficiency, and lower hybrid efficiency. The struggle for sales growth will become even more difficult when tax-credit phaseout begins next year. The mistake GM made of trying to fulfill enthusiast requests for gen-1 of Volt was repeated for gen-2. Sales have barely grown, falling well short of expectations. Their own traditional vehicle buyers simply haven't been interested. Toyota's choice not to follow that approach is looking good so far. Hyundai & Chrysler are planning to take alternate paths too. Odds are, we'll see that from Ford as well. Not sure about Honda or VW yet. The goal of getting large quantities of plug-in vehicles on the road, at a profit, requires careful consideration of what is really needed... not what is wanted. Approach to fulfilling that is vital.

6-06-2017 **Prius History.** What once had been the daily blog for Volt has become a venue for terse exchanges of emotion toward competition in the plug-in hybrid market. Only thing is, I don't take the bait. So, today's article posted exclusively about Prius was not welcome to them. I wasn't willing to play along. Their antagonism doesn't work. Instead, my response was to post this recall of Prius history:

The natural progress from hybrid to plug-in hybrid is playing out. Toyota's plan from the very beginning was to increase battery power & capacity as cost would allow, keeping the design affordable along the way.

That first generation back in 1997 used D-cell batteries and had a plug, in Japan. The plug was dropped right away. Introduction of prismatic format batteries came with the rollout to the United States in 2000. Power from the gas engine was increased too. Diversifying the platform by creating a detuned version of the vehicle, giving it a less expensive interior & exterior, allowed the first profit to be made. (That's how Echo came about.)

The next generation to follow in 2003 included the ability to travel at speeds up to 100 km/h (62.1 mph) using only electricity. Unfortunately, battery capacity simply wasn't dense enough to power any benefit from including a plug; cost was far too high too. Despite being unrealistic, a plug-in demonstration model was revealed in 2009. This was to solicit feedback, as well as acknowledge the very expensive aftermarket upgrades some owners had endorsed.

The generation to follow in 2009, which replaced what had now become the iconic hybrid, was loaded with improvements. It laid down the foundation for offering a plug, including a redesign of the system which added a second power-split device for two-speed operation. Only a larger battery was needed. The design already included all that was needed to provide the significant MPG boost owners had requested.

Mid-Cycle rollout in 2012 delivered that larger battery, switching from NiMH to Lithium at the same time. Unfortunately, it was still too expensive and the market had become very uncertain. Volt was struggling to attract sales and Leaf had stirred expectations. So, Toyota changed national rollout plans to be for the next generation instead. After all, they knew what that upgrade would deliver, could continue collecting real-world data in the meantime, and wouldn't have much legacy to deal with since rollout had been limited to just 15 states.

4th Generation introduced a new design architecture in 2015, one with heavy emphasis on cost reduction. At the same time, the body had been stiffened significantly and the rear suspension got a major upgrade. Use of lithium battery chemistry had proven effective in the previous plug-in model and the 7-seat wagon model, so it became standard for 4 of the 5 regular Prius package offerings. Styling was changed to a dramatic standout appearance, a clear effort to break the prior stereotype and to distinguish it from the upcoming plug-in model.

The following year brought reveal & rollout of the first worldwide available plug-in model of Prius. That meant simultaneous delivery to Japan, Europe, Canada, and the United States. The result has been strong demand and limited supply. As of June 2017,

first deliveries in Canada are still being waited for and early orders in the Midwest are finally being delivered. That approach of keeping the design affordable, along with the careful balance of purchase priorities, is proving to be a wise choice.

Popularity of the plug-in model of Prius is growing at the rate necessary to achieve a sustainable high-volume level, enough to continue with profitable sales even as the tax-credit is phased out... an absolutely essential step in that natural progress toward making a plug the common choice.

- 6-07-2017 First Sighting.** My wife gets the prize. We couldn't commute together today. So naturally, so encountered another Prime. It was the Blue Magnetism, just like mine. As far as I'm aware, that was the first to be reported. With so few of us so far, it's easy to keep track of each other online. We knew of other deliveries, but hadn't actually heard of any sightings yet. I wouldn't have expected that color to be the first either. Lots of deliveries of the ordinary choices took place elsewhere. Everyone had to wait for models having that unique color. It's not shared with anything else. Being Prime only is nice. Of course, I'm not sure what other vehicle could support a blue like that. Anywho, I posted a comment about that. No one was aware of who that could have been. Cool. I wonder how long it will be until sightings become common. They certainly are rare still, even in areas with more deliveries. But here in the Midwest, there are only a few so far.
- 6-07-2017 200 MPG.** Watching the pattern repeat enough times is a good incentive to push really hard. Breaking the cycle was utmost on my mind. What new element could be introduced? One of the long-time antagonists who claimed it was the messenger, not the message, was doing his usual enabled. Rather than actually confront those intentionally spreading misinformation, he was going out of his way to provide a means of them being more effective. Ugh. To intentionally promote dishonest posting... it still boggles the mind how that is believed to be unnoticed. I see exactly what's going on. So when that predictable series of posts come, it was always the same old choice of how to respond... until today. The moment of epiphany finally came. I had been able to end the "catch up" rhetoric, but had nothing effective to move forward with. Then it hit me: "NPNS" That had been included at the end of countless posts for years. It stood for "No Plug, No Sale". That was a motto chanted so often, few ever really took the time to realize how vague it was. That was like saying "hybrid", so generic the seemingly useful slogan really didn't amount to anything... which is why it died. The idea caught me though. Diminishing returns has proven the greatest source of frustration for the antagonists. That particular pattern was easy to see. I could ramp up its impact by stating a specific value. What to use for that step away from the shortcomings of generalization was obvious too. Toyota had already done that research. Prime gauges top out at 199.9 MPG. You can actually see beyond that maximum with the Advanced model using the phone-app. But all that did was provide data confirming 200 MPG was the correct value to stop at. Gallons & Kilowatts never made any impression. MPG will though. So, that's what I will begin promoting. "200 MPG" will become how I conclude posts. Stressing its importance will reduce the influence of the talking-points the enthusiasts of Volt had exploited, without actually reaching ordinary consumers. They were so preoccupied with conquest, they hadn't noticed the ineffectiveness. It makes you wonder what would have happened had GM stuck to their original "230 MPG" campaign. Hmm?

6-07-2017 **Commute Distance.** The argument for years has focused entirely on commute distance. I found a study that used 2011 census data to analysis 96 metro areas. The results were surprising. Most people drove distances less than 12 miles. When you think about that, it makes sense. But from a talking-point perspective, most people obviously had not. That's why when I posted the entire collection of data, it freaked out the antagonist. That much detail is difficult to dispute. So, he didn't. The tactic of changing-focus was tried instead: "*People drive more in a day than just to/from work. You have lunch-time travel, work time travel, trips after work, etc. And why are you cherry picking metro areas?*" I anticipated that. It's a predictable outcome. Being cornered is nothing new. We've seen that quite a few times in the past. This is yet another example: Metro area means not rural. It includes the suburbs. Many people don't actually drive to the downtown area. They work locally, which is why those real-world numbers are lower than you expected. Driving destinations other than work tend to be quite a bit closer than work too. Their grocery, retail, and other stops are close by. That's why 25 miles covers a majority. Watch for the video I filmed last night. I drove to my favorite coffeeshop with the Prime, that very same drive I did a few months ago with the Prius PHV. Round-trip is 15 miles. It's a nice mix of suburb driving, varying between 30 and 55 mph with a few stops here and there. I did the drive twice to use the entire supply of electricity available. 30.6 miles of EV before it switched over to HV. More is nice, but clearly not necessary. That's why this particular configuration has great potential for high-volume sales. Prime is that natural progress from hybrid to plug-in hybrid playing out. No amount of negative votes can hide that. 200 MPG.

6-08-2017 **Flooring It.** In a traditional vehicle, that usually means requesting maximum RPM from the engine. People instinctively avoid that, unless absolutely necessary. With a hybrid, the maximum is artificially limited. That RPM is much lower as a result. It means you can be generous with the pedal, yet still get rapid acceleration. The reason is simple, there is also a motor & battery contributing propulsion power. That makes up the difference. It was concept easy to understand... until recently: "*Flooring the pedal and pushing through the click switches on the 1.5-liter 4-cylinder engine...*" That comment came from a first-look report of the upcoming new hybrid from Honda. That's exactly what you'd expect, right? Not necessary. From a hybrid with a plug, some respond that way, others don't. Knowing which would had been a simple matter of checking how big the motor was. Very small meant the engine would need to supplement power. The new plug-in hybrid Clarity will have a very large motor, but will still offer the ability to fire up the engine using the pedal. That means flooring it simulates an engine response familiar to traditional drivers. With Volt and Prime, that behavior is intentionally excluded. Drivers want to avoid that from happening via a pedal drop; instead, you push a button to request engine-assist. You confused yet? If not, consider how difficult it will be keeping track of which offerings behave in a certain way. For that matter, think about which depend on the pedal and which a button. Needless to say, those of us trying to be constructive have our work cut out for us. Here's my attempt to exchange knowledge and solicit feedback: Note that Prime will remain in EV mode, even when maximum acceleration is requested. There has been a lot of confusion lately from older reviews who unknowingly reported the engine starting, when they were actually in EV-AUTO mode instead, which is configured to allow the engine to start. Finding out that Honda Clarity will behave similar to Hyundai Ioniq and Chrysler Pacifica should make us wonder how mainstream consumers will interpret the plug-in hybrid choices. Since Prime & Volt deliver an "always" mode for EV, what influence will that have on the purchase decision? The simple question of how the heater works will likely become a bigger issue. Prime's vapor-injected heat-pump is much more efficient than Volt's resistance heater. Both use only electricity though. Ioniq must run its engine for heat.

6-08-2017 **Drawing Conclusions.** It's in our nature to do so, even with little information available. In this case, there basically isn't anything yet. Nonetheless, people are drawing conclusions about the plug-in market already. Rollout of a technology can be fairly rapid to those well informed. That's why enthusiasts get so excited. They know. They understand. Education simply isn't needed. That most definitely isn't the case for ordinary consumers though. Willingness to invest is far more involved. That's why this can't be taken seriously: "*Most ordinary consumers don't buy anything with plug anyway...*" How could that possibly be known? The choice to do so is almost non-existent. Having to place an order for a vehicle, then wait months for delivery is so far removed for the usual purchase experience, that alone is a deterrent. People move on to the next choice even when the technology is well understood, simply from not having to wait. In the case of a plug-in vehicle, there's a wait for the tax-credit in your returns the following year too. Needless to say, I wasn't about to let that comment slip by: Most ordinary consumers don't even know about them yet. So, there's no possible way such a generalization can be claimed. Even a number of readers here haven't learned about how the newest plug-in offerings work. Saying a bulk of the population won't be interested cannot be done some data from those new offerings to analyze either. Prime is barely just rolling out in the Midwest. We're waiting for Chrysler, Hyundai, Honda, Tesla, and Nissan to all make debuts this year. Heck, we may even hear something from Mitsubishi and Ford too. There's also VW to consider. That means anything related to purchase decisions is far to premature.

6-08-2017 **Launching Attacks.** Out of the blue, on a thread discussing Prime's rapid rise in interest, this came from a Volt owner: "*I am going to raise the old topic of "EREV" again! Volt deserves the special designation of EREV compared with the rest of PHEVs! ...there are still NO PHEV out there to even match the EV range of gen 1 Volt. That is 7 years already!*" He has been ever since we first crossed paths a few months ago. His very first post replying to me was an attack claiming something to the effect that I was protecting the oil industry. That gave the impression he was an EV supporter against all engine use. Finding out later he owned a plug-in hybrid was quite a surprise... though, the attitude wasn't. The bizarre need to label Volt differently than all the other automaker plug-in hybrid offerings is that same old trophy-mentality. It impairs progress and makes cooperation nearly impossible. That means having to deal with each random attack. Those claims of superiority sure are annoying. I guess he realizes winning the war alone is impossible, so he's settling for victories in small battles instead. I wonder how this will be taken: EV range is the only original criteria remaining, and that was only vaguely important. The rest of how EREV had been defined has eroded away entirely. Other offerings have joined in with competitive design. Prime offers both more efficient EV and more efficient HV. Prime also delivered the industry's most efficient electric heater. Prime is also the lowest priced plug-in hybrid. Saying Volt is somehow special simply doesn't hold any water. It's a plug-in hybrid, since it has a gas engine. What's wrong with that?

6-08-2017 **New Greenwashing. Old Techniques.** An article is published from either a poorly informed writer or from a source with the intent to mislead. It's really difficult to tell the difference sometimes. If your response is timid or vague, there will be antagonist to exploit it or an innocent reader to spread it. That too is very difficult to differentiate. For example: "*Many thought the Prius Prime might function like a Volt, but were disappointed to find out it still worked like a traditional hybrid...*" How do you address that with no context or references to work with? I have encountered that situation countless times in the past. It never gets any easier. Those same old techniques carry over to new greenwashing. Ugh. I tried my best to deal with that one this way: Sounds like you are unaware that Prius Prime is an upgrade just recently rolled out, a next-generation successor to the Prius PHV you describe. The incorrect assumption is understandable. Early orders of Prime are still being delivered. It is very, very new. That older offering used plug-supplied electricity to boost MPG, not to deliver an EV driving experience. Back when it was introduced, that's what the market wanted. Preference changed over time, as added battery-capacity became affordable. Driving for the first 25 to 30 miles is all EV, only electricity. Function is very much like Volt. The only resemblance to a traditional hybrid is after the battery has been depleted, delivering MPG much higher than Volt.

6-09-2017 **Price Matters.** There is some deep resentment among a select few Volt enthusiasts, because I kept pushing so hard for an affordable choice. That meant compromise, agreeing upon a balance of configuration rather than trying to justify an extreme. Having proven my concern was valid and not simply an attempt to undermine Volt, a few have given in to the idea... finally. Of course, it isn't without a little remaining animosity: "*If John the Prius addict has any leg to stand on (he really doesn't), it would be his point about Prime showing that price matters.*" Being so outspoken about making plug-in choices for the masses is very much a bittersweet situation. I can contribute a great deal toward the replacement of traditional vehicles, but that requires a partnership rather than superiority. Agreeing upon goals is how that's done... not getting so tied to principal that change is nearly impossible. That status quo is very difficult to overcome and their naive assumptions really hampered the effort. Oh well, too little too slowly is better than nothing ever. I hit back with, making sure to end with that simple perspective reminder: Nicely under \$30,000. The reason you associate my efforts to promote affordable plug-in vehicles with Prius is that Toyota was the first to actually deliver. Don't be pretending I haven't pointed out the need for VOLT LITE countless times in the past. Eventually, GM will figure out that target which they set is vital for mainstream acceptance. Perhaps even some here will finally recognize that's what I have been pushing right from the very beginning. That's why I was never impressed by the desire to go faster & further. It was always a matter of seeing how much you could deliver for that target... which has always been nicely under \$30,000. And when a model of Volt is rolled out that actually meets that affordability criteria, we can all breathe a sigh of relief... and less polluted air. 200 MPG

- 6-10-2017** **Video - 30 Miles of EV.** I setup the cameras to capture my drive to the further of my favorite coffeeshops. This time, it would be with my new Prius Prime. A few months ago, that drive was with the Prius PHV it just replaced. This is a route I'd like to capture throughout a year, to show how well the system handles each of the seasons. Watch for new videos. Turns out, the nice summer evening was great for just driving around. Upon finishing what I intended to share, I realized the situation would be ideal to show how far a Prius Prime can actually go on a single charge in ordinary driving conditions just like that. So, I did. At that point, you can see the 15 miles EV traveled and the estimated 16.6 miles of electric-only capacity remaining with the cabin blower on. That was clearly enough to repeat the trip. When I returned, 30 miles of EV had been traveled and the estimate showed 0.9 mile remaining. I continued on, repeating that route again. At 30.6 miles total, the EV capacity had been totally depleted and the engine started up, switching from EV to HV mode. That's well above the 25-mile EV rating listed on the window-sticker, achieved without doing anything special at all. I was simply driving along with traffic on those suburb roads. Speed ranged from 30 to 55 mph, with a few stops along the way. Here it is: [Prius Prime - 30 Miles of EV](#)
- 6-10-2017** **PHV to Prime.** There's growing excitement emerging from the prospects of Prime. It seems obvious that Prime has more to offer, but PHV really wasn't well understood. So, I am now getting asked questions like this: "*Since you driven the previous Prius PHV for so long, how does the driving feel compare do you say?*" That was the first comment posted on that new video I just shared. It's nice having context already, a thorough background viewers are already aware of. That made this reply an easy one: Figuring out how & what to film took awhile, but that gave me a decent chance to play with the system in the meantime. There's much more EV power available now. Between the larger battery to supply electricity and the one-way clutch added to allow the second motor to contribute to propulsion, the only needed reply is to suggest a test-drive. You'll see for yourself how much potential Prime has for interest from ordinary consumers. The system itself is more efficient. That final 4.8 miles/kWh result tells us a lot about how refined the design has become. HV performance is routinely above 60 MPG too. I love it! Even the trip my wife and I took across South Dakota at 80 mph was amazing, with the A/C running. It handles well and is efficient no matter how you drive.

6-10-2017 **Divergence.** The opportunity to discuss big picture issues emerged today. That came about from a thread with posts about Hyundai. Having another prominent automaker take a chance at competing directly with Prius is stirring interest... promoting questions of purpose & motive. Far too often, assumptions are made with respect to automaker intent. It is nice being able to look at what's really involved. I obviously have much to say in that respect:

We are about to see a divergence, just like the computer industry went through once upon a time... so long ago, many are unaware of that history.

CPU speed indicated how the computer package was configured in the retail world. Faster meant more memory and larger hard-drive. It was elegantly simple, making the sale of them to newbies far less of a challenge. That worked great. It helped establish the industry, making their product a household device. Eventually, the device became personal & portable, taking on traits well beyond the original concept.

The idea of an EV fulfilling all roles of transport was a good means of proving the technology worthy. That isn't ultimately how to sell it though. Households with multiple vehicles could easily exploit the abilities of a lower-capacity EV. Who cares? All you're running around for errands and short commutes could be done with a vehicle like that. What if you're retired and don't need to travel long distances? For that matter, same could be true for a student.

We need to take a serious look at the problem "*faster & further*" is causing. That mindset is not helpful when attempting to attract the masses. Some simply see that as overkill, an expense they are unable or unwilling to accept. Also, think about how long it would take to fully recharge a large battery for a person who is limited using to a 120-volt outlet.

Take a look at "*computers*" now. We see far more than just desktops of the past. There are notebooks, tablets, and phones. All have a common purpose. All provide computing in their own way though. All get the job done. Yet, prices & configurations varying tremendously.

6-11-2017 **Only Facts.** The nature of hypocrisy boils down to comments like this: "*If they were only facts instead of slams against Volt and GM we'd let it slide.*" They certainly don't react that way when the situation is reversed. Ironically, that's how the slams came about in the first place. Had only facts been considered, no reason would have emerged for bringing attention to source. I try to avoid getting the last word in, since giving the perception of defeat is an effective means of concluded pointless arguments. But in this case, since the facts themselves were disregarded, it was worth it. They chose messenger, rather than message. So, I responded. After all, there was a look of undermining in the past that took advantage of facts not being available. I posted: We know that isn't true. Facts alone get voted down too. And why not call out GM to prevent repetition of the same mistakes? That's how progress is made. You learn and adjust accordingly. We also know that facts are exploited by the omission of context. In fact, that's how the videos came about. Some here would make vague claims. Showing detail debunked those efforts to mislead.

- 6-11-2017** **Executive Ranks.** We hear a lot of rhetoric from the top. A friend of mine started a thread today suggesting: "*Do the job; deliver the product, and; move on.*" That's good advice. With the automakers, it has been an ongoing problem. I jumped into that with: That's quite unlike the hype machine we know as GM. Their ever-changing story, along with many examples of "*over promise, under deliver*", has staged the market in favor of Toyota's quiet advance. How Tesla fit into the big picture had been a head-scratcher for mainstream consumers. There was never any way that amazing vehicle simply referred to as Model S could become mainstream in that form. We (the well-informed pursuing electrification) knew from the start it was only a stage toward reaching the mass-market goal. Model 3 is what will bring Tesla a very big step forward. There are many steps to go still though. Seemingly simple efforts, like home recharging, end up being rather complicated for more reasons than we care to admit. That's where I see Toyota contributing heavily to the quest Tesla is on. With such a wide & diverse market, we need to hit every aspect the consumer will have to deal with. Toyota can help greatly with the transition from hybrid to plug through Prime. They have a massive Prius owner base to leverage. They have also configured Prime in a way that will stir some interest from those wanting a Toyota but were not interested in Prius or any other hybrid. In other words, Toyota is working on bringing up the base at the same time Tesla is establishing the target. It's a win-win situation. We do wonder how other legacy automakers will handle the transition. GM will run out of tax-credits sometime next year, triggering a phaseout which will result in profit loss. The current high MSRP and low sales doesn't cast the situation in an appealing light... hence things like that rant.
- 6-12-2017** **Recognizing Change.** When a former foe says this, take notice: "*Really comes down to cost, range is just one attribute, we have the remember the Prime which has less than half the range of the Volt already is outselling it...*" Why some continue to insist upon one particular path is beyond me. Thankfully, he saw the light. Heck, Toyota did too. Taking notice of market change is how Prius PHV rollout ended up stopping. The recognized how more could be offered without impacting cost... hence multiple attributes. The catch is finding balance. Volt's range is too much, since it pushed price too high. Prime seems to have hit much closer to the mark. We'll find out as the year progresses just how close. I've said all along there are different purchase priorities for mainstream consumers than there are for enthusiasts. The response was for the enthusiast to quote me out of context, making it seem as though I was in support of only one aspect. It as an ironic approach, especially when their own favor was the very thing they highlighted. Accuse your foe of the very thing you are guilty of. Those days aren't over. But what was said today does provide an aspect of hope. Change can be slow & painful for some. Progress is still progress though.

6-12-2017 **Charging At Home.** Our 2 new lines for high-speed charging at home were setup today. The install was for 2 standard 14-50 outlets to feed 240-volt chargers. We had 6-gauge wires run through new conduit across the ceiling in the garage. Each had its own individual 40-amp line out of the house's 200-amp service-box. Each will have its own time-of-use meter installed in a "can" on the outside of the garage. That's what will follow today's service, which established the lines themselves. That contractor will arrange to have the city-inspector come over to approve the work that was done today. (They also submitted paperwork for the permit and configured the design.) The result is a sticker showing approval, which allows the power-supplier to come over and swap out the hard-connection with a measuring device. In our case, we'll be the very first customers of the local CO-OP to have 2 of those meters. More than one is something many people need yet. That required some extra work, since the software programming & billing for both must be setup to monitor kWh draw during each of the time-categories. For us, there are 3 of those categories. Each has its own pricing. The one for overnight charging offers a significant discount, hence the effort to install equipment to take advantage of the opportunity. Also in our case, the service-provider will not be charging a service-fee. It's just a one-time hardware investment. I was delighted to find out how well the bracket I had fabricated to hold the chargers & outlets worked. It's a great looking approach that put both exactly where they needed to be. Location of the cord for inside & outside garage use, in addition to keeping them safe while still maintaining a strong Wi-Fi connection, was a very big deal. Think about your garage layout. How would you achieve maximum return for 2 cars plugging in? For that matter, wouldn't it be nice to offer a recharge opportunity when friends come over with their plug-in vehicle? Needless to say, there is reason to celebrate. Both are now active. Rather than taking 5.5 hours to recharge, we can do it in just 2 hours. We can also take advantage of grid power for heating & cooling before leaving the garage. Think about how great that will be in the dead of Winter, here in Minnesota. This is very exciting! Imagine getting into a pre-warmed vehicle in the comfort of your garage on those freaky cold days. The rapid recharge is obviously nice too.

6-13-2017 **Air Cooling.** There has been an on-going effort to misrepresent Nissan's gen-1 approach with Leaf as an industry-wide standard. They attempt to portray the choice of using passive cooling with air, rather than active cooling with air, as the same thing. In other words, Nissan has a sealed system. That contributed to batteries aging prematurely from getting overly hot. Toyota didn't do that; instead, it had an open system that forced air through it with fans. Circulating comfortable A/C cabin temperatures through the pack is a huge difference, one they go to great lengths to evade recognition of. It's always glossed over in a way to make efforts to reveal detail the work of a troll. Comments like this is how they attempt to bring that to a close: "*Enjoy your ever slowly-degrading Prime battery with its air cooling!*" That oh, so familiar vague & misleading type response. It's a clear sign of concern. Bringing up a topic on a regular basis without any actual data to support it is how I know. The chemistry upgrade Nissan rolled out a few years later ended reports of heat issues. Trying to get me to stop reporting that is quite difficult. The plug-in owners group here is very well informed and we address topics like that on a regular basis. Sharing among that group is easy. They don't let pride get in the way. Here's one thing related to that I learned... which got the enthusiasts very upset: Liquid cooling is beneficial for rapid charging. That just plain isn't necessary for a smaller battery, like that in Prime. There simply isn't a need to receive electricity from the charger that fast.

- 6-15-2017** **Perspective.** With the reach of Prime rapidly spreading, it's good to provide a reminder of perspective. That is so easy to forget... especially now with every automaker striving to deliver something with a plug. Getting caught up in a muscle-flexing demonstration happens on a regular basis. Online exchanges make that a common occurrence. The voice of ordinary consumers gets drowned out by the volume of fans loyal to an automaker, unwilling to consider what's best overall in favor of willing a particular battle. Ugh. That's such a waste. Oh well. All you can do is keep providing those reminders: Mainstream consumers don't care what enthusiasts have to say. There's 17 years of Prius history overwhelmingly confirming that. Toyota designed a vehicle for the masses, balancing the configuration with what their own buyers would be willing to pay. Think about what owners of their high-volume profitable vehicles have shown interest in. Camry & Corolla are often labeled as appliances... affordable & reliable.
- 6-15-2017** **Reality.** Hearing reports from Prime owners. Seeing reports of Prime sales. Witnessing the shift of attention to Prime. Reality is setting in, bringing the message to antagonists by means I haven't been able to express. Conveying how this change will impact that market hasn't been easy. Understanding how it will react is though. Having been such an active participant in Prius history, recognizing the potential Prime holds is very exciting. I'm really looking forward to it. In the meantime though, there's more message to deliver: Over 200 MPG with the latest tank on my Prime. I have no idea what the actual MPG will end up calculating to. It takes forever to use up the gas. There's still a 1/4 of the tank remaining. It has been over a month. MPG has been pegged at 199.9 the entire time. Do you really think ordinary showroom shoppers at Toyota are going to care if some other plug-in offers more EV miles? That impressively competitive MSRP of just \$27,100 makes Prime a serious consideration for someone interested in purchasing a Toyota. GM had it's chance with Volt, but instead just let opportunity pass by. Now gen-2 is struggling with sales growth and it must share the few remaining tax-credits with Bolt. Sales are primarily just conquest type too. GM's own loyal customers simply aren't interested.
- 6-15-2017** **Repetition.** How many times have you heard the nonsense? Thank goodness it is so easy to see change coming. Phew! It is only a matter of time now. They will finally learn the answer to that long time question: Same old spin we've read about for years. Because Volt offers more EV range and more power, it will appeal more to ordinary car buyers. Even with a \$7,500 subsidy being offered, that's clearly not working out. We're watching GM shoppers continue to purchase Cruze, Malibu, and Equinox in high numbers while Volt gen-2 is struggling with monthly counts only slightly higher than gen-1... despite much wider acceptance of plug-in vehicles now. Prime is an example of striving to attract those interested in purchasing a Toyota. That audience wanders into the showroom, then takes what they find for a test-drive. It's a simple & informative process. They discover claims of being slow were just automotive rhetoric and the low MSRP finalizes the purchase decision. Loaded with an array of safety options, standard, it's easy to see the effort to deliver a well-balanced vehicle. That is understanding audience. Toyota is working to raise the bar, not to deliver a halo. Prime offers enough to entice those who may otherwise choose a Corolla & Camry. Who is the market for Volt?

- 6-15-2017** **The Wait.** It seems to be taking forever. Thankfully, change is near. I look forward to blog entries changing and no longer having to listen to the brainless faster & further arguments. Patience is a fundamental component of Prius, as is with change. It's a matter of understanding when. Like who, knowing the target is vital. They don't. Those senseless posts of rhetoric are void of thought. Though, some of the spin does at least show effort. Unfortunately, it is to undermine, rather than promote change. Oh well, all I can do is point out what the wait is for: Spinning comments is part of the wait. They attempt to draw conclusions prematurely. We have seen a lot of hypocritical behavior and even more superiority declarations lately too. Simply letting them get all of it out of their system so we can move on to constructive discussion is the logic step forward. The article nicely lays out the variety of shopping criteria for someone in the now, without any particular brand preference, someone specifically looking for a plug-in hybrid. That's a very limited audience, as is the current choice of vehicles. One year from now, the market will be quite different. Prime will finally have first-year owners reporting enough real-world data to draw interest (remember the importance of winter driving & heating). Currently, numbers are so few, there is almost nothing to work with. My average for the month right now is at 196 MPG. It's taking forever just to use up the tank I filled 5 weeks ago.
- 6-16-2017** **Wrong Question.** I found this annoying: "*The best way for a potential buyer to answer this question is to take test drives.*" It meant the audience is still not understood. Ugh. Oh well, it's not like I haven't pointed out the importance of "*who*" countless times... and will continue to: The question only applies to those who cross shop. There is a large chunk of the population who don't. They shop within a brand. So, the comparison is a moot point. That's how Prime really shines. Toyota configured it to not only appeal to those looking to replace their aging Prius, but also those considering a Camry or Corolla. That's why the standout features... like the array of headlights, the large touch-screen, and the dual-wave glass are exclusive to Prime. That is also why there isn't a middle seat. Being unlike the other choices with a "*step up*" appeal, yet not compromising on price, is key. \$27,100 for a MSRP of the base, with safety options that Volt doesn't include, gives it great potential. There is no dependency on tax-credit subsidies. It is carefully configured to compete with the true competition... traditional cars choices, not other brands.

6-17-2017 **What's your point?** Every possible avenue of opportunity has been completely exploited. They've run out of excuses. Prime sales are tapping into the potential Volt strived to achieve, but wasn't ever targeted for that... which made this so appropriate in response to be asked that question...

To ask this question: What's the point?

Failure to achieve mainstream sales volume, despite the gen-2 upgrade, has pushed Volt even further into a niche. Denial of the inability to draw interest from GM's own loyal customers went on for years with gen-1. We are witnessing the same problem repeat with gen-2. Notice how GM has shifted focus over to Bolt and enthusiasts of Volt are back to saying the same old things they did back when gen-1 sales struggling to grow?

The goal has been to replace traditional vehicles. No amount of spin or excuses will change the fact that needed growth has not happened. Believing that the act of belittling Prime will somehow help Volt is disillusioned. Not understanding the appeal of Prius has always been a fundamental problem for Volt enthusiasts. They attempt to apply the criteria they find important to the purchase decision, never coming to realize that mainstream consumers have very different priorities.

Toyota knows the EV experience delivered by Prime combined with a nice balance of features and the affordable price will draw interest from their own loyal customers. They'll achieve growth by appealing to a variety of buyers, their own shoppers looking for an upgrade to replace their aging Toyota. Some will be owners of older hybrids. Some will be new to hybrid consideration. That's the point of Prime.

Growth is not about conquest. Growth is not about delivering the most distance or power. Growth comes from offering something better, an improvement upon choices of the past.

6-17-2017 **Growth.** Reading post after post of attacks from Volt owners on Prime has been overwhelming evidence of change. Prior to the recent sales growth, there were attempts on many fronts. They'd attempt to undermine any way they could. Now, it's just claiming Prime's acceleration is too slow and electric-only range is too short. Exactly as anticipated, the mindset of "*faster & further*" has become the theme. Returning to the trophy-mentality problem confirms they have nothing left. Phew! What a massive waste. All those tax-credits squandered on conquest. When leases expired, many Volt owners moved on to something else with a plug. The status quo remains intact. What was the point? Remember that huge anti-Prius campaign back when gen-2 sales raced past mainstream minimum? Annual totals exceeded 100,000 here in the United States, without any tax-credit. Volt hasn't come even remotely close to that, with a very generous federal subsidy. Much needed growth hasn't happened. The enthusiasts were so wrong about cost, complexity, and timing... It is so much of a mess, the fact that Prime has emerged from the ashes is amazing... and they can't stand it... hence all the attacks. Having to endure all that was quite a challenge. What was learned from this experience has proven priceless though. That was my point.

6-17-2017 Dishonest Spin. It's annoying when the very message you've been conveying for years gets parroted back. But when they are dishonest and it is easy to prove that's what they are doing, you have to wonder: *"We've been telling you for years about 200+ mpg, and you never got it! Instead, you stayed with your 47 mpg hybrid. Now somehow, just because you can get that in a Toyota, it's incredible!"* Where the heck did that 47 MPG come from? I have been posting about diminishing returns and the upcoming next-gen PHV for years. There are countless posts I could refer back to. How could anyone believe they wouldn't get called out for such false claims? Oh well. That does provide me with the opportunity to point out some history: M's campaign to promote "230 MPG" had such a huge backlash, enthusiasts of Volt did everything they possibly could to distance themselves from MPG references. In fact, the fallout is how that *"gallons saved"* advertising came about. Focus shifted to EV purity instead. Mid-Cycle rollout of Prius PHV focused on MPG boosting. The resulting average was around 75 MPG and there was a clear expectation that the first full-cycle offering would increase battery capacity, which would result in more power being available. 20 km was the original offering. It was large enough to differentiate the plug-in model Prius from the regular model without making the price too terribly expensive. Unfortunately, lithium cost hadn't come down fast enough and there was a clear problem developing with the acceptance of plug-in vehicles in general. Double the capacity was the expectation for that next-gen rollout. Turns out, 40 km is exactly what got delivered. The bigger battery did indeed bring about more power too. It was now realistic to offer an affordable choice, something able to compete directly against traditional vehicles. Spinning of history won't change any of that outcome, nor will it support the claim of 200+ MPG. There is nothing from GM able to compete directly with traditional vehicles either. The faster & further obsession has made the choice of Volt too expensive. Prime makes more sense.

6-18-2017 **Stating Goals.** That's how you avoid trouble. That's also how you gauge lack of progress. Understanding effective measure is very important. Remember the "*5,000 per month*" sales goal from back when Volt was still being developed? The reason for quite clear. It was the minimum required to have a sustainable seller that was both high-volume and profitable. Maintaining that level meant the goal had been met. It was how the progress of Prius was measured by others... which is how GM ended up adopting it too. Remember the timing of that for Volt? It was to be reached by the end of the second year of sales. When that didn't happen for gen-1, things got ugly. Everyone could see the count fell well short of expectations and all excuses had already been exhausted. Sound familiar? We are approaching that same significant timing milestone with gen-2. Only this time, Toyota already has a strong alternative in the market. Backlash from it is truly bizarre too. Avoidance of any goal that had been stated in the past is so obvious; the enthusiasts of Volt simply declare victory. No facts to that affect are offered. There are only claims of superiority. Denial of the situation is so deep, you know a turning point is about to be reached. That should be easy to see too. Not only is Prius Prime extremely well positioned for mainstream growth, there's also the new EV rollouts to contribute to the progress forward. Both Tesla's Model 3 and Nissan's next-gen Leaf are about to push the market. Both are expected to be affordable for their intended audience. Enthusiasts of Volt avoided answering the question of "Who?" knowing they'd be held accountable later, just like with the sales goal. It's an ugly situation. Not all attempts to move forward are successful. Toyota put a hold on Prius PHV, then ended up stopping it as the changing market showed new priorities. Low MSRP is what the market with this particular timing has placed high importance for. That leaves Volt in a very difficult position. Ironically, that vindicates the "*nicely under \$30,000*" goal for pricing... which has absolutely infuriated enthusiasts. They are very, very upset and the lashing out at me as a result has been quite pronounced. They think having a scapegoat will somehow makes things better. See why I put so much more emphasis on "*too little, too slowly*" when I saw how stating goals wasn't working?

6-18-2017 **No Growth.** He saw the opportunity to twist my words. It was a push to spin intent and misplace context to a point I hadn't expected. Rather than just ignore with the hope all mention will vanish, it was this provoke: "*So the Prime's 25 mile AER is perfect and there is no need for Toyota to release at vehicle with more?*" What a great setup for me to explain how diminishing returns actually works. I had a feeling references in the past fell on deaf ears due to them not understanding the concept. Now, I could provide detail. So, I did... making sure it could not be ignored:

That's not how "*diminishing returns*" works.

The measure of what you'll get as a result of your investment for that product-cycle shows there is a drop in effectiveness. Spending a lot more for little in return doesn't make sense. That's why study of the numbers is so important. That is also why it is a moving target. Each generation will have a new higher level, especially when it comes to battery advancements. You find a level where more doesn't accomplish much, then stop before exceeding it. Pushed too far, more can actually have a negative impact, causing a loss instead.

Remember that "*5,000 per month*" goal? Look at annual sales of Volt, excluding 2011 due to rollout and ramp-up inventory limitations:

2012 = 23,461

2013 = 23,094

2014 = 18,805

2015 = 15,393

2016 = 24,739

2017 = 22,049 (annualized using results thru May 2017)

Where's the improvement? You'd think with the growing popularity of plug-in vehicles, there would be a noticeable increase. The design choices for gen-2 of Volt kept MSRP too high. Offering more power & range had the consequence of higher cost without any resulting increase of sales in return. GM's gamble doesn't make sense for this market at this time.

6-19-2017 **Makes More Sense.** When you want to really make a point, quote yourself: "*Tax-Credits will run out before something able to compete with Cruze, Malibu, and Equinox is securely in place.*" That was especially useful in this case. One of the regulars on the Volt blog wasn't able to participate in the attack on the "*makes more sense*" thread. Comparing Volt to Prime was an exciting topic for the others. He felt like he totally missed out. I took advantage of the opportunity to summarize & remind: There has been quite a bit of spin attempting to misrepresent my stance. That has been it all along... with GM, with Ford, with Toyota. Each of the automakers need to offer something actually able to compete with the true competition: traditional vehicles. Toyota carefully considered configuration to ensure it was up to the chore. GM did not. That's why Prime makes more sense.

- 6-20-2017** **Prime in the Wild.** Unfortunately, my commute home wasn't filmed. I wanted to, since I time that day and the weather was quite pleasant. Work was rather demanding though, so I just wasn't up to setting up cameras. My postponement to some other day was actually rewarded. The delay would have prevented spotting my first Prime in the wild. While waiting for the light to turn green, it appeared right in front of the path I was about to drive. Making a left with the driver starring directly in my path, I flashed the lights, waved a hand out the window, then switched to honking. There no way he could have missed me... especially since he also owned a standout color... Blue Magnetism. Sweet! I was a bit bummed that moment wasn't digital documented. But the location meant it could happen again. It was just a few blocks from my house. The odds of another encounter someday is entirely realistic. Of course, nothing is as impressionable as actually seeing them for sale on a dealer's lot. I remember when that first happened with the Classic Prius. Painfully long delivery waits for orders transformed to ordinary shopping experiences. Being able to see one, take it for a test-drive, then draw up purchase papers all within a single visit to the dealer is a noteworthy turning point for a new technology. Hopefully, that time isn't too far off with Prime. But then again, demand so high that supply remains a challenge isn't necessarily a bad thing.
- 6-20-2017** **How Far?** I was quite curious how far 200 MPG would actually take you. After EV capacity is depleted, the engine running in HV mode isn't apparent. In fact, it takes a surprisingly long time for the MPG to finally drop below the 199.9 maximum. With the gauge topped out like that, most owners will get use to seeing that number. Who doesn't? How much driving does it take with that single charge used up before 200 MPG no longer applies? Remember, this is the value antagonists had been arguing about for a very long time. They assumed it was so high, that would only apply to Volt drivers. The thought of Prime being able to deliver it too hadn't crossed their minds. I participate on the hostile websites to stir feedback. It doesn't take much either. They are happy to shovel as much crap as I can handle. Trouble is, every now and then they accidentally throw something valuable my way. In this case, it was that "200 MPG" coming back to bite them. I kept driving, past my house on the commute home. I figured the coffeeshop would be a perfect destination, something I very realistically could do anyway. So, I did. It wasn't until I was about a third of the way home when EV depletion. The engine fired up. Distance was 50.7 miles. Cool. That was further than anticipated. Arguing 25 miles of EV wasn't enough is more difficult to argue now. Having a plug-in hybrid isn't about exclusive electric-only driving. If you want that, it makes no sense carrying around a large engine too. That's why BMW's i3 actually delivers on the EREV promise and Volt still comes up short. (1398 cc is more than twice as large as 647 cc.) That's also why the 54 MPG rating for Prime is so rewarding. When you use it, no big deal. The real-world outcome I witnessed today confirmed it too. I found out how far. I can't wait to share that information.

- 6-21-2017** **Looking Back.** It certainly was insightful to look back at the attacks last week. They know their last remaining card has been played and there's no chance of winning that game... so, they attempted to change it... desperately tried. I was rather shocked how dishonest some were, making claims that were blatantly false. That's how you know. There was some spite too, where they simply want to go down with a fight. That's the problem with progress. Not every attempt is successful. You keep trying and go with what works. I summed up the situation like this, for a latecomer who felt like he missed it all: Their spin is interesting, they take time to come up with something actually thoughtful. It doesn't hold much merit though when compared to goals, but that's still better than the outright lies others tell... which there were plenty of this time. In this particular thread, it was the lack of understanding what 200 MPG actually represents. For driving a Prime during summer, the distance traveled from a single charge yielding that result is a little over 50 miles. Assumptions that 25 miles of EV isn't enough fall apart when that real-world outcome is witnessed firsthand.
- 6-21-2017** **Camry Hybrid.** More proof that the end has come wasn't hard to find. The embargo on Camry Hybrid reviews was lifted today. We were told what the next-generation design delivers. There's a lower cost NiMH option and the full step forward with a Lithium battery-pack, just like what Prius offers. The results are amazing too. That more efficient choice delivers a whopping 52 MPG combined (53 city, 51 highway). For a larger more powerful vehicle, that's remarkable. Like with the newest Prius, you get a substantial improvement to the body & suspension. It's very exciting to know that not-so-obvious improvements are adding into the mix. Now, it's just a matter of waiting for rollout of the 2018 model. This is very exciting. The market has been patiently waiting for the long overdue upgrade... which clearly has been worth it. Expectations were met. Toyota will be delivering a very nice improvement, something which could end up being a standout hybrid offering. Of course, there is still a little bit more wait required.
- 6-22-2017** **Poor Decisions.** He should have known better than to utter such a statement: "*I say let the market decide.*" We've seen disasters with self-regulation. For that matter, we're now seeing a disaster play out with letting poorly informed and emotionally influenced people vote. I wasn't surprised. That came from a member of that blog which up-votes intentional misleading. Today, it was a blatant lie about Volt outselling Prime... a claim easy to disprove. Dealing with enablers certainly is a challenge. Anywho, I decided to this way: That's exactly how the problem of "*halo*" vehicles and the lack of subsidies comes about. Mandates have overwhelmingly proven more effective. Some automakers take advantage of the situation. Knowing the regulation is coming, they step up their game instead of just delivering a minimum. Look at how the market has shown preference for large guzzlers instead of small sippers. There simply hasn't been any incentive to endorse a vehicle like Volt... which is why it is still stuck as a niche offering. Regardless of enthusiast praise, interest has floundered. What is there to get consumers to change? They already have speed, power, and cheap gas. Dealers certainly haven't been interested either. Reality is, the market doesn't care... hence California's push. They can balance increased regulation with HOV incentives and charging infrastructure.

- 6-23-2017** **Tank Refill.** The potential to drive for months without refilling the tank is a new situation, a paradigm shift for which few have any experience or even reference. If you don't drive much beyond the EV range available, the gas will last a very long time. Only highway trips are when you notice an impact to the gauge. Otherwise, the miles remaining really doesn't change much. Having 2 plug-in hybrids in our household now makes it especially odd. We'll take the Prime with more EV available when going out in the evening, trying to carpool as much as possible on weekdays. On weekends during Summer, the carrying of bikes & kayaks will be exclusive to mine. But then again, what if I can plug in at those destinations? We both carry squeegees in our Prime so the window can be cleaned, if necessary. Rarely ever going to a gas station makes you do things differently. What a great new situation!
- 6-24-2017** **Attack Spin.** When all else fails, the antagonist will claim the problem is with branding. With Volt, it's understandable for GM supporters to play the Toyota card. They figure with such a terrible reputation for "*over promise, under deliver*" that customer distrust alone is enough to undermine a product... regardless of how bad it actually is. We know Volt is small, expensive, and inefficient. That doesn't matter to them though. They still feel strongly that brand is the problem: "*The very minute Toyota comes out with a greater range, watch John change his tune and explain why the new figure is *superior*.*" It's that trophy mentality. If you point out any advantage whatsoever about another vehicle, they think you are claiming superiority. The same is true if you point out a shortcoming of their favorite. Pride blinds them from having constructive dialog. They feel they are always being attacked. What a waste. That obsession with range makes it even worse. The very idea of a moving target evades them. Toyota focuses on price-point. So naturally, the range offered will increase over time. You offer what's affordable for that particular time. When an upgrade is realistic, that becomes the norm. It's not a fixed value. It will change. No amount of spin will convince shoppers that good enough is competitive. The balance of cost & need allows improvements. Greater is not always necessary though. But looking at the big picture, you'll always see why the next step was taken.
- 6-25-2017** **1.1 Miles.** Backing into the garage with that much EV available isn't the ideal. To get the most from the battery-pack, you should arrive at your destination without any electricity remaining. On these warm days of Summer, that's what is happening if I don't recharge at work. Curious about how far that single charge will take me, I drive EV continuously. With all those consecutive miles building up, not taking advantage of HV mode is a missed opportunity. I've seen a little over 33 miles a few times now. That means the engine starts up close to home (for the 37-mile round-trip commute). Unlike with the PHV, the system in Prime warms up aggressively. It can be a very efficient approach, if that added load (which results in electricity being generated) is used effectively afterward. In my case, it has not been. I need to finally start using HV prior to running out of EV. That way, I will be able to take advantage of that 1.1 miles. Why not exploit a 55 MPG for 999 MPG trade opportunity, knowing that I can?

- 6-26-2017** **One Sentence.** Participating in venues where there is a diverse set of opinions is how you learn. After all, avoiding group-think is very important. Of course, even on the friendly forums, you do have to deal with the "reset" experience, where antagonist simply pretends you haven't already discussed that topic. The only way to avoid that repeat is to not take their trolling bait. That doesn't work in hostile forums though. You have to respond in some manner. What I've come up with to deal with that is the one sentence reply. It's an approach that doesn't leave them much to work with. You come up with a message so concise, they really struggle to spin it. Brevity is key. There's little opportunity provided with just a short stream of words crafted into a thought with the precision of careful consideration. This has proven very effective so far. Too bad it took so long to come up with the method. But then again, things were never this bad. There's a strong sense of hopelessness emerging from the status quo being shaken by Prime.
- 6-26-2017** **Great Expectations.** You hope for the best. When it actually happens, you celebrate. In this case, I shared the experience online. The cheers of rejoice was nice confirmation of others also seeing reason to celebrate. Many have great expectations. But with so few deliveries so far and it simply taking awhile to encounter situations to exploit the systems design, you have to live vicariously thought others. That's what I help to provide. This time, it was: Today was a 27 mile drive home from work with my wife. We started with a full charge. The climb out of the river valley at 55 mph with the A/C on was rather demanding. That changed to a 65 mph cruise a good chunk of the way. I passed twice in excess of 70 mph. Got home, still 1.4 miles of EV left. The entire trip was all electric.
- 6-27-2017** **Spreading Misinformation.** This got me really riled up: *"It can't regen the LI battery, it can only regen the Hybrid battery. It's a two battery system..."* There were already some posts attempting to figure out what the situation was. How could such incorrect claims be spread? Was that particular post intentional? Was the source of which it came attempting to greenwash? We wanted to know, especially me: It's hard to believe anyone would attempt to spread such extreme misinformation. Where did you get that belief? There is one battery-pack. A large portion of it is dedicated to EV driving. It's what gets recharged when you plug in. The other usable portion is for HV driving. If you drive down a mountain or turn on charge-mode, the EV portion is replenished. 6 weeks ago, I took a trip to Wyoming from Minnesota in my Prime. One stop along the way was Mt. Rushmore in South Dakota. The trip down from it resulted on about 10 miles of regen. Stop spreading that clearly incorrect information about Prime.

- 6-27-2017** **Purchase Analysis.** As a lurker, it's really easy to get drawn into arguments. You start reading to learn about the various points being posted. You want to learn why those are important. What does all that mean? Not knowing up front what topics apply to what outcomes create a lot of confusion. It's easy to focus, forgetting the overall purpose. For example: "*As a cost conscious consumer I really struggle with the whole Volt vs Prime purchase analysis.*" Sadly, there is no simple solution. Today, I got into it with: Notice the level of desperation of some to paint an ugly picture for Prime? That extreme is confirmation of a paradigm shift. They see the true competition. It isn't other plug-in vehicle. It's traditional vehicles... and reality is about to come crashing down soon, when the tax-credits trigger phaseout. The measure of success comes from replacement of those guzzlers. A plug-in with a "right sized" battery will compel the masses to buy. Drawing attention isn't enough. It's all about high-volume profitable sales. Change doesn't come from someone like you who takes the time to consider detailed analysis. Change comes from those shopping the showroom floor who take an unexpected pause to consider the purchase of a plug-in vehicle, a thought they hadn't ever entertained.
- 6-27-2017** **50 miles = 200 MPG.** The teaching moments are plentiful now. EV range posts were popping up all over that very active Japan sales topic. Focus only on "25 miles" is the classic, not considering the big picture problem. That's an invitation for me to jump in... which is what I happily did: 50 miles = 200 MPG. That's what you get when taking the time to study Prime. 30 miles of EV from a 25-mile rating is nice, but it really does come down to looking beyond electric-only range. As more Prime fill our roads, that real-world data will become more prominent. Seeing 199.9 MPG on the screen is what will solidify the purchase decision. No complicated math or detailed spreadsheet is required. It really is that simple. Plug. Drive. Get great MPG.
- 6-27-2017** **Inventory.** It's amazing how hypocritical some people can be. The same individuals who screamed "*foul*" when conclusions were being drawn prior to rollout having commenced in all states think nothing of doing that themselves now. We've seen that recently with both gen-2 Volt and Bolt. Watching those same individuals do exactly that with Prime is remarkable. It goes so far beyond double-standard, there's no excuse. In fact, after being called out on it and watching the behavior continue, you know they are intentionally trying to mislead. There's no excuse. So, I attempt to prevent those opportunities by posting inventory information before they get a chance, like this: Midwest deliveries of Prime began in April and have only been in very limited numbers. No supply for January, February, and March provides a misleading impression of true demand. Note that there are many still waiting for their orders to be filled. Worldwide rollout is underway. Inventory available for immediate purchase is a long way off.

- 6-27-2017** **Hope.** Some of those from that old daily blog have begun participating on other forums, ones not so welcome to the idea of superiority. So, their posts really stick out. It's looked upon with dismiss. Why in the world are you fighting the effort to spread acceptance of plug-ins by attempting to undermine a new popular choice? I jumped in to point out some history they would not be aware of: Watch future posts. You'll recognize the pattern after awhile. Sales results infuriate those who push for "*faster & further*". They don't appreciate ordinary consumers who just want a good buy, something well balanced & affordable. It's unfortunate some spin intent to undermine mainstream offerings. They want standout, not common. Pressure from the upcoming phaseout trigger of tax-credits will only make the trophy-mentality worse too. Hopefully, sales of plug-in vehicles genuinely trying to replace traditional vehicles will overwhelm their rhetoric.
- 6-27-2017** **Home Charging Discounts.** Hope of getting that starting today didn't work out. There was a programming issue with the meters. Watch for an update, soon... The point was to take advantage of discounted charging rates by having dedicated lines & meters installed. They offer a \$500 rebate to help cover the cost too. Since we'll be doing that for each vehicle, double that is a really nice opportunity to take advantage of. Why not? That's the point of getting into a program early on. Of course, I know of someone who did when it was first established. She pays even less. That's ok though, it's still a good deal for us. The reason for the discount is for demand to be off-loaded to non-peak times. For use, the 8AM to 4PM range is the same usual billing rate of 11.68 to 13.08 cents per kWh. That in itself is lower than what many others pay elsewhere. Our area of the county strives for lower cost, despite getting rid of most imported coal in favor of local natural gas. We are establishing local solar-farms and wind-turbines too. It's a nice place to live in that regard. Anywho, the discount from 9PM to 8AM is a lower rate of 6.74 cents per kWh. Nice, eh? Of course, Prime will only consume about 3.5 kWh for the commute to work. That isn't much electricity anyway. But the point is to lead by example. So, that's what we are doing. The catch is if you recharge during peak hours. That's from 4PM to 9PM. The rate then jumps to 41.44 cents per kWh. That's only during the week though. On weekends, the rate for all hours on Saturday & Sunday is the low 6.74 cents per kWh. Overall, it's a great setup, especially since there is no monthly service fee. We only have to pay for the equipment up front. The car is \$75 and the meter is \$70. Knowing we'll be living & charging in this house for a very long time, and the fact that it would be a selling-point years later, makes it a very good investment... which would eventually return a benefit from the discounts.

- 6-28-2017** **Clashing.** More questions arose about the head-butting. Seeing a Volt enthusiast lash out at a Prius Prime support is rather bewildering for a Volt supporter. It makes no sense to see something with such potential to be attacked. It's not like Volt, which clearly has a high MSRP concern. Toyota really strived to deliver on the affordable aspect. Striking a balance rather than playing up strengths is a confusing concept for the trophy seekers. In other words, they simply don't care about ordinary consumers. The purchase of a reliable vehicle that gets people from point A to point B in a clean & efficient manner without any demonstration of power is of no interest to them. So, basically, you'll never win. There is no recognition of something for the masses. They wouldn't be caught dead driving something common. Effort to appeal with something they detest is futile... unless you're like me, who uses them to flush out detail about what the market truly find important. Anywho, I added this to the on-going post clashing: His priority is faster & further. My priority is high-volume profitable sales. That fundamental difference has been a major problem. I couldn't care less about enthusiast wants, it's all about mainstream consumer need... sustainable business.
- 6-29-2017** **Spin.** Some have an extremely difficult time accepting change, still attempting to spin a picture of leadership using more to draw interest. It's the faster & further belief. Appealing to the primal urge that more is better, the dominate discussions. That doesn't translate to increased sale though, which is why the stance has turned to such desperation lately: *"Now Toyota has a weak offering and you are claiming superiority in the plug-in arena, any which way you can spin it."* Pointing out the initial success of Prime and laying out reasons for the potential makes Volt enthusiasts crazy. They don't see a partnership as the Volt supporters do. They want superiority, hence that becoming the focus of their fight. It's really sad they don't see traditional vehicles as the competition. Isolating their world to just other plug-in vehicles is how they deal with *"too little, too slowly"*... since from that perspective, all appears to be going well. But when look upon from the larger perspective, the entire market, things look grim. I pointed out that cold, hard reality this way: Ordinary consumers just plain aren't interested in getting the most, they simply want a good buy. That nice balance is why Toyota will sell a lot of Prime.
- 6-29-2017** **Recognition.** Eventually, even the most stubborn of naysayers will give up. Either they become silent & disappear or their opinion ends up becoming what you had been saying all along. They'll make it seem the idea is new & obvious though. What you had struggled to point out for years won't be recognized. In fact, they'll do their best to ignore you. What I've found very effective in this regard is to keep replies to just one sentence. They cannot say much in return, since you give them almost nothing to work with or any reason to lash out anymore. However, you are still entitled to point out and ask about the transition itself: Remember how often I sighted the *"too little, too slowly"* concern and no one else agreed, instead insisting that a solution would soon be delivered. GM was going to do this and do that and... If we are at a turning point, which Tesla Model 3 would clearly highlight, discussions can finally be turned toward traditional vehicle replacement. Are those who blew off the concern ready now?

6-30-2017 **We Already Did.** Sometimes, you can't help but to wonder: "*The biggest savings would definitely be in the biggest vehicles, which hasn't been discussed very much at all.*" A reaction like that from an ordinary consumer is quite understandable. But having this come from a frequent poster who has expressed quite the opposite, it's hypocritical. The change of stance is encouraging though. You know they will never admit such a move. Seeing a shift away from the status quo is the best you'll get. So, I pushed that step in the right direction: That topic has been discussed to death... to the point of people getting angry whenever reminded about it. All those reminders of Two-Mode cannot possibly be forgotten. Remember what its purpose was? We have since moved on discussions of to putting Voltec in a SUV, like the new Equinox. We know Mitsubishi & Kia are both rolling out plug-in SUVs. We also know that Nissan & Toyota have easily augmentable hybrid designs to offer a plug. Recent rumor is that Ford has a mule they are now testing too. Then of course, there's Chrysler approaching the same issue from a different angle. If anything, the lack of discussion is from GM remaining totally silent on the topic. There's nothing to discuss. btw, another reminder is how much pushback there has been about discussing the topic of diminishing returns. That also addresses the topic of bigger vehicles offering the biggest saving.

6-30-2017 **Problems Beyond the Technology.** Lack of being able to see the bigger picture has plagued Volt enthusiasts for an entire decade now. They focus so intensely on the engineering with a belief that superior technology is all it takes to achieve mainstream sales. It boggles the mind how some people lack business background to the extreme that they never notice what's contributing to the lack of progress. That was my minor in college, so I took the study the discipline intensely. My engineering emphasis (the software type, studying all aspect of programming) was what came easy. Those business classes were quite a challenge. I struggled to pick up on the fine details of economics, accounting, and legal. It was a lot of work... which I didn't realize would serve me so well later with this. But when it comes to programming, understanding user need and recognizing market pressure is absolutely vital. That's why finally seeing this was encouraging: "*Dealer acceptance remains a huge problem.*" Talking about too little, too slowly. Though correct, it is only a start. There is still much more to see. Hopefully, some will find this informative: Sadly, that is a big problem. Why bother trying to sell a vehicle that will generate a lot of questions & concern, consume a lot of personnel time & resources, and result in a low-profit margin? Once we finally get past that hurdle, there's still the issue of infrastructure. How many of you have the capacity to handle delivery of two 10 kW draws at the same time? Setting up for decent charging at home of just one car presents challenges... and that's the low-hanging fruit. Adding a second is not a simple next step. Think of the extra expense and the physical limitations.

7-01-2017 **Unrealistic Expectations.** Vague comments contributed to problems. Even when innocently stated, they can become a source of misleading. A review of Bolt from a highly respected green website did such a thing today by posting: "*Buy a 240-volt Level 2 charging station to install at your home. It's roughly a \$600 investment.*" The omission of vital detail contributes to incorrect assumption. We don't want that. We want to set realistic expectations. I quickly jumped into the discussion to interject some of the missing information: The odds of someone having a 240-volt line in the needed location with available capacity are extremely unlikely, to the point of worry that you're setting up unrealistic expectations. If they are lucky enough to have a service-panel in their garage and it can support that addition, the cost of hiring someone along with the wire, conduit, outlet, and permit will easily double the sighted investment price. If you have a second vehicle in your household that would also want to plug in, that's going to add quite a bit more... especially if also want to take advantage of off-peak or time-of-use discounts. Since I just did that for my home a few days ago, I know it's best to make sure the true cost is known up front and not trivialized. The benefits are great, so it's worth consideration. Having 2 lines each able to deliver 10 kW to both cars at the same time is really handy. No messing with inconvenient cord locations either. I did end up having separate cans installed to get a sub-meter for each car. That simplified the setup, but added some cost; however, it did provide an extremely convenient way of tracking true electricity expense for each of the cars. The detailed billing should be quite informative. Long story short, that rough \$600 is way off for the typical household. Don't be afraid of quoting a more realistic cost. Saying \$1,500 isn't that big of a deal when stated in terms of how much you won't be spending on gas.

7-02-2017 **Better Warm-Up.** This comment was part of a brand new discussion: "*i prefer to make the decision to switch from ev to hv, rather than have it happen when i'm not aware. one for the reason stated, and two, to do a better warm up while i'm still in ev.*" It's interesting to feedback from PHV owners about Prime. Their perspective is unique. Most people will only know Prime, so their observations will be quite different. The power & feel are not the same. You do things differently with more EV capacity available too. I joined in asking: Better warm-up refers to what? Toyota's choice to emphasize the switch was intentional, making the driver well aware of the transition so the subtleties of operation to follow won't be overlooked. For example, the MPG remains unchanged. You can drive for 50 miles before MPG drops below the maxed out "199.9" value. I did that last week to find out how far I could go on just a single charge before efficiency in HV would actually go unnoticed. 50.6 was the distance traveled, just on my ordinary commute, followed by a run to the coffeeshop. Had I plugged in between, the MPG would have stayed at 199.9 for all my driving that day. Another thing to keep in mind is that warm-up is more aggressive in Prime than it was in PHV. If I drive my entire commute on just a single charge, the engine will fire up around 33 miles. Shortly after warm-up completes, I notice EV capacity available. This newer system takes advantage of stoplight & acceleration activity. How many owners would notice that, especially if the transition from EV to HV wasn't emphasized?

7-02-2017 **Backfired Advertising.** The on-going discussion with Volt enthusiasts now is the effort to improve efficiency of the biggest vehicles, in this case, pickups. Inevitably, a reference to Ford was finally made: "*Chevy responded by bashing aluminum in their pickup truck ads.*" Sales have confirmed Ford's gamble really paid off. The market has embraced aluminum. There's worry the same thing will happen with Prime, despite the smaller EV range. I was happy to point out some history to draw a comparison:

Chevy bashed Prius about lithium in their Volt ads.

They were attempting to portray Toyota's approach to technology as outdated, using technology from the long-ago past. Problem was, Chevy's timing was horrible. Shortly after the new advertisement campaign began, Toyota revealed the next-gen Prius. Rather than using NiMH batteries, as the television commercial stated, this new Prius would be using Lithium instead. The commercial abruptly vanished.

GM's struggle to leap-frog with Volt never materialized. That entire first-generation was haunted by sales they simply couldn't ever match, not to mention exceed as so-often boasted. It was a disaster, now getting worse... because the gen-2 Volt about to be rolled out didn't fulfill those original goals GM had set either. MSRP was still above \$30k and depleted efficiency was still below 50 MPG.

No distraction was available either. All they could do was hope the next-gen plug-in Prius didn't deliver too much of an improvement. Turns out, it did. Now, there's this on-going efforts to label the elves as trolls for providing reminders. Well, too bad. Acknowledging shortcomings is what makes a product better.

Those here, you know who you are, ragged on Prius PHV relentlessly. Although the arguments were weak and quite a stretch at times, they were taken seriously nonetheless. Remember the shortcomings that were claimed? Notice how they aren't anymore?

We know Chevy is pursuing aluminum pickups too. The lesson learned with Volt applies to this effort as well, it must be competitively priced. Cost of aluminum is very expensive. Cost of lithium is also very expensive. Notice how much emphasis MSRP gets? People want improvement, but few are willing to actually pay a large premium for it.

- 7-03-2017** **Time-Of-Use Meters.** It took some work to finally get them installed. The first attempt last week was a bust. All they needed to do was swap out the hard-connection in the socket with a meter. It is literally just a device you plug in. The catch is, that device must be programmed correctly. It wasn't. They should have tested it prior to delivery. Oops! Oh well, I thoroughly enjoyed chatting with the installer. He was very well informed and was happy to answer my questions. This took place only an hour following the inspector having sign-off on the contractor work. He found the lines from the service-box in the garage, which punched through the wall for outside installation of the 2 socket boxes for the meters (known as "cans") then returned back into to the garage, nicely done. The lines & outlets were too. He even liked the brackets I came up with. What he didn't like what the chargers themselves, since they are not UL listed yet. Fortunately, I'm well informed. My study of that hardware confirmed the redesign early this year was for certification. The obvious part of that was the shortening of the outlet cord. For UL approval, it must only be 12 inches. That meant the convenience of the prior 6-foot length would be lost. The thickness of the cord had been increased substantially too. This is why I had to so carefully consider mounting. Anywho, I knew papers had been officially filed and what I had purchased met all the criteria. Testing would soon be complete. So, my use & endorsement later would be no big deal. The inspector took the time to share detail I could provide our plug-in owners group with. It worked out nice. We got the needed sticker. The service guy from our CO-OP (the local power-supplier) came over shortly afterward and popped those time-of-use meters in the cans. All 3 categories registered. They cycle through the display, allowing us to see how much kWh of each we'll be billed for. Very nice!
- 7-04-2017** **Holiday Travel.** We have been doing some in my wife's Prime. So far, the average for 251 miles of driving comes to 58.1 MPG. That's with the A/C running the entire time. It also included taking advantage of Charge-Mode. For just a recharge from the wall, I'd say that was pretty darn good. Think about what a regular Prius would get under the same conditions, especially when taking into account the spans of highway at 70 mph. It's nice knowing that even under demands of vacation, you can still enjoy the benefits Prime has to offer. Consider what a traditional vehicle would deliver under the same circumstances. Visits to see the family over a holiday are quite routine. Today though, we were all over the place. That's what happens when it occurs during the middle of a week, rather than on a weekend.
- 7-05-2017** **First Tank.** This was her first refill after 5 weeks of ownership. Being on vacation required far more use of the gas engine than usual. But that's ok. This is what the system was designed to deliver. Regardless of drive demands or availability of an outlet to plug in, you still get great efficiency (and clean too). In this case, it was 1,278.5 miles for the tank. That worked out to an average of 130.3 MPG overall. That certainly isn't anything to look down upon... though seeing the maximum 199.9 MPG on the display everyday while commuting is nice. That certainly is higher than my average too. Our round-trip to Wyoming in my Prime was over 1,700 miles with lots of the travel at 80 mph. So naturally, my average overall is lower. No big deal. It will creep back up over time. I wonder how high. Hmm?

- 7-05-2017** **Misrepresentation.** It's easy to find examples of cherry-picking. They are often used to make generalizations. For example: "*Most Prime drivers will have to use gasoline quite a bit, while lots of Volt drivers will avoid it 95+% of the time.*" What's difficult though is to dismiss that example, especially if you are not certain that it represents an extreme. Vague claims make that even more questionable. How many is "*most*" and how much is "*quite a bit*" are valid things to ask. Most of the time, you don't have to though. The real-world data emerges on its own. Patterns begin to emerge. That's why they attacks on Prime are so intense now. They know the opportunity to undermine is limited. Owners sharing stories will drown out the rhetoric after awhile. I pushed back with some of my own information and points to consider: 2,074 miles with the most recent tank in my Prime shows potential for that to be false. No real-world data indicates the claim speculation only for now. 53 could be overkill, especially if "*most*" Prime owners are like me. Currently, that range pushes cost out of reach for "*most*". In other words, drawing a conclusion based of a specification isn't a good idea. Also, don't overlook the big picture. Sales of more Prime would offset a lower volume offering anyway.
- 7-06-2017** **Predictive Efficient Drive.** Did the Prime just brake on its own? That certainly wasn't a question I had ever thought I'd be asking myself. It was as I approached a turn into my neighborhood. After some research, it turns out the Prime did. I had driven enough for data to confirm that location was easy to predict. There's a feature called "*Predictive Efficient Drive*" that the Premium & Advanced models have. Toyota included this without really promoting it. Owners with enough miles are just discovering the feature now. It's designed to "*help boost real world fuel economy*". I suspect it will for many too. Think of it as an automatic hypermiling behavior. That's something which no quick review or rating would ever include, a nice extra discovered long after purchase. Cool. After some poking, I did find an option on the screen to indicate were data had been collected so far. They show up as bright green diamonds on the map. Sweet.

7-07-2017 **Panelist Discussion.** There we were at a convention in a room filling up with those interested in finding out more about plug-in vehicles. Volt, Prime, i3, Leaf owners and an expected Model 3 buyer (who had a Leaf) were all there representing the future that audience wanted to know more about. We could have easily gone twice as long, especially if the room had been bigger. There were a ton of questions... none of which included anti-EV sentiment. That's quite different from showing many years ago. Battery technology has proven reliable. Now, focus has shifted to cost and how recharging takes place. That's undeniable progress. Yeah! I thoroughly enjoy the experience. It was very encouraging. It did point out how much longer we still have to go though. People simply have no idea what they are considering... but at least consideration is finally taking place. That's where Prime comes in. New rollouts like the upcoming next-gen Leaf and Model 3 will validate the market shift toward electricity. The crude roar of a combustion or compression engine is being replaced with the smooth & silent of an electric motor. No more noise. No more shifting. No more worry of excessive wear. Think about how long an engine in Prime will last. That high-optimized power source simply won't be worked as much or as hard. And with a pure EV, that electric-only propulsion comes exclusively from a brushless motor. Ever hear of a Prius motor wearing out? Nope. It simply hasn't happened. Those electric motors keep going and going and going. Eventually, the battery-pack will loss capacity, but replacement basically resets the vehicle to almost new status. That doesn't work with a traditional vehicle. You still have a transmission to consider even with an engine replacement. Anywho, it was very rewarding to be part of that.

7-07-2017 **Parking Lot Presentations.** There we were at a CON, the 4-day event where sci-fi exploded into a celebration. We had reserved a room for a panel talk about plug-in vehicles, which was clearly too small. It was a great opportunity. I was one of the speakers. When it finished, we all left the hotel to see those cars in the parking lot. With so many people walking through that area, it was a nearly ideal venue. Lots of questions were asked. With everything from my Prime to a Tesla Model X, the variety really drew a crowd. Being parked next to a Volt was nice. You could compare them side-by-side. The smaller size of the seating for Volt was obvious. The higher cost for Volt was obvious too. Seeing that Toyota had chosen to just raise the floor for the added battery capacity made it quite clear why that design was so much more affordable. You take an already well-refined hybrid, then augment it with more electricity. That's a strong business case for reaching the masses. You can give GM credit for making an appealing niche, because people there checking it out were definitely intrigued, but that falls short when it comes to common consumers actually purchasing it. The same was true for Tesla. It's an impressive as you could imagine, but far too much for competing directly with everyday vehicles like Camry & Corolla... hence the approach with Prime. Interest in the Leaf there was intriguing. People were clearly excited about the potential the next one could offer. That's likely why I was asked so often about plugging in at home. Fortunately, I had my 120-volt charger there. Showing people that it plugged into an ordinary household outlet made the discussion short & sweet. They understood the simplicity. I can't wait for more opportunities to do presentations.

- 7-07-2017** **Model 3 Production.** It began today. Tesla rolled out the very first one. What an amazing coincidence that we just happened to have a panelist discussion and vehicle showing scheduled for the same day. It was extremely well timed. This particular audience was one that felt the original Tesla offerings were simply too expensive. That's why when I mentioned a base MSRP of \$27,100 for Prime, which included 4 key safety features, really caught the attention of those checking out of our display in the parking lot. Knowing that Tesla is aggressively working toward having their own affordable offering is quite a message to convey... something GM failed miserably at with Volt. How can you reach the masses if the price is too far out of reach? Progress like this is wonderful. Think about how the work Nissan has done in this regard. Rather than suffering from the Osborne effect, quite the opposite happened. The heavy investment in a next-generation Leaf has stirred more sales of the older one. That wasn't anticipated. GM may have hoped the same would happen with Bolt, showing an overall investment in support of plugging in. The outcome has been leaving Volt in a very awkward position. Had Volt offered a larger interior like Bolt or Model 3, things could have been different. Unfortunately, it's still quite cramped in back... not at all the approach Tesla has taken. It's easy to imagine Model 3 becoming quite common as a family vehicle. We'll find out soon enough. Projections are that 20,000 will be delivered by the end of the year.
- 7-07-2017** **Leaning Down.** Being parked next to a Volt during an event showing, you learn a lot about the supposed competition. Our effort is to replace traditional vehicles, so that belief of competing with each other quickly melts away. Supposition is replaced by an effort to find strengths. With Volt, it obviously offers greater EV range & power. The obvious tradeoff is a much higher MSRP. The not-so-obvious is what caught my attention for the first time. It wasn't until today that I noticed the deeper storage area in back is actually disadvantageous for some. That fact was pointed out by someone simply seeing both side-by-side. Virtually everyone focuses on the depth. This person pointed out leaning down. With Prime, you simply slide out cargo. Things like grocery bags are easy in, easy out. No bending required is a big deal for some. After all, how much more do you do that rather than cargo something so large it needs to go on the lowered seats instead? I hadn't ever thought of that. Heck, even an idea like that hadn't crossed my mind. This is just like seating. We had the comment today that Model X was more appealing than Model S simply due to the entry & exit height. The owner of an S was looking to switch to a X for that very reason. Heck, this is why Toyota is giving C-HR a try. It's a Prius with the platform raised... for that very reason. Interesting discovered, eh?

7-08-2017 **Why further discuss?** The past few days have included an intense sparring session between Volt and Prius. It wasn't from me either. True, I was the one responsible for shifting the rhetoric away from the daily Volt blog over to the general audience blog, but I didn't actually provoke. The new participants are responsible for that. It's all new to them; however, the arguments are not. They are much more diluted too. There simply isn't enough vague anymore. Too much real-world data readily available is helping prevent any of the old material from gaining any traction now... which was the point. You bring up the topics again and watch how they play out differently this time. Only thing is, I'm not just watching. I jumped it to response to that question asked of an obvious antagonist struggling to undermine Prime:

There is no point to his "*not a hybrid*" argument. Gen-2 of Volt blends engine & motor operation even more so than Gen-1 did. Neither operates as a "*range extender*", which is a serial design that never provides any momentum power to the wheel. The only hybrid that does that is BMW i3.

Since Volt's initial rollout, there has been a desperate effort to separate it from Prius. Yet, as this discussion topic clearly highlights, that hasn't been possible. It has a gas engine and electric motor, using them to squeeze out maximum efficiency... and falls short with both.

25 kWh/100mi is the EV efficiency rating for Prime.

31 kWh/100mi is the EV efficiency rating for Volt.

54 MPG is the HV efficiency rating for Prime.

42 MPG is the HV efficiency rating for Volt.

With the 52 MPG rated Camry hybrid LE about to rollout, there's a new fear of Volt being left behind. So, it's quite understandable seeing so much semantic bickering at this point. That's a sure sign of having run out of "*facts*" to support the effort of realistic replacement for traditional vehicles. It's very easy to imagine it supporting a plug in the not-too-distant future.

7-09-2017 **Misrepresentation, opinion.** This round of attacks included trying to misrepresent the cargo area by not stating an opinion. He figured by posting a link for a video to have someone else say it for him would be looked upon as passing along information instead, that he was just provided facts. That, of course, is a load of crap... and I was unwilling to put up with his continuing stream of posts: Incorrect information posted with "*opinion*" is yet another example of misrepresentation. Leaving out purpose for stating "*just the facts*" is a problem too, since it contributes to false assumptions. In this case, it is not "*around 8 inches under the cargo cover*" as claimed. It is actually 10.5 inches. It is not impractical as implied either. In fact, that's quite the opposite. After showing my Prime to enough people, I have discovered the advantage of the raised deck. It's at an extremely practical height for carrying routine cargo. You don't have to bend over and lift. Getting items out of the back, like groceries, is a simple matter of sliding. If you do have an item larger than the area above the cargo cover, you simply drop one of the seats to hold it. No big deal. In other words, your vague attempts to undermine have not gone unnoticed.

7-09-2017 **Misrepresentation, labels.** Use of labels to misrepresent is something we have to deal with on a regular basis. It's really a pain when that type of endeavor to impede is taken. Since official ratings or certification is sighted, it gives the impression of whatever you post as a desperate measure to spin the truth. What the antagonist hopes is you won't bother to actually look at the detail of what that label represents. They hope you'll assume what they are implying rather than what it actually means. The on-going nonsense included this: *"GM is not just saying it seats 5, it is the official government passenger rating of the vehicle..."* That's frustrating to read. What a waste of time having to deal with stuff like this. All it takes is a few seconds in the vehicle itself to confirm the effort to misrepresent is quite desperate, that they feel threatened by the idea of losing yet another argument point. Unfortunately, online exchanges make that a challenge to overcome. Oh well, all I can do is stuff like this: We've seen the *"official"* word be exploited again and again to misrepresent. You know all too well that the spirit of the *"5 seat"* label is not being acknowledged. No one in their right mind would ever call a location without a place to put your legs a proper seat. Having to straddle a hump to squeeze your legs into the area being used by other passengers is absurd, especially with a car that's narrow in the first place. The firmer padding for that middle area results in a reduction of headroom too. It's quite telling when the message of *"facts"* is really an effort to portray something obviously false as no big deal. If this is how Volt comparisons to Prius will continue, be prepared for a serious backlash. Effectiveness of misrepresentation can take an abrupt turn.

7-09-2017 **Misrepresentation, doubt.** The technique of raising doubt has been a very effective means of undermining for decades. You don't want your product harmed by new evidence of a problem, you raise doubt. We saw that for many, many years about smoking. We've seen the same thing for climate change. When facts are diluted or dismissed, it gives pause to the effort to deal with the problem. That delay is exactly what the antagonist wants. They know an end is coming. Slowing it's progress is all they have left. We're certainly seeing that now with the introduction of affordable plug-in choices. The expensive ones unable to reach their intended demographic are in trouble. With this misrepresentation, we are witnessing attacks on Prime by Volt enthusiasts. They know that when Hyundai's new offering, the plug-in hybrid model of Ioniq, pressure will grow significantly... especially since GM will also be facing the phaseout of tax-credits at the same time. I kept the discussion going with: Again, you are misrepresenting. This time, by posting moot points. The use of *"more"* and *"longer"* and *"some"* are all extremely vague, which leaves the reader concerned by raising doubt. Taking advantage of assumptions is a common tactic for undermining. The purpose of a PLUG-IN HYBRID is to significantly reduce consumption, not to eliminate it. So what it the engine briefly runs. That's what it is there for. By repeatedly posting the message over and over again to create a stigma, you are misleading people about what the system was designed to deliver. You get an extremely efficient gas engine to supplement the smaller battery-pack. It is not an emergency backup. It is there to supply power when desired. If you want to save electricity for later, generate electricity while driving, or get an extra boost for high-demand use, the engine is readily available. The spin about purpose has become quite evident. We see what's happening. It misrepresents.

- 7-09-2017** **Misrepresentation, power.** Since way back when Volt first rolled out, the thought was power would overcome all other shortcomings. That approach failed to attract anyone beyond niche buyers. Mainstream consumers simply aren't willing to pay a premium for power. They obviously like it, but that is far from a leading priority. Their purchase decision falls upon other much more important factors. Nonetheless, they keep trying and keep failing. Our drive to dinner with friends last night provided yet another great example of how their effort to undermine falls desperately short. In reply the latest effort, I posted: My wife floored it yesterday in her Prime to pass someone on the highway who clearly didn't place driving as a priority. For our safety, she wanted to get past them quickly. We shot up to 75 MPH effortlessly, never triggering the engine. It was all EV. There's nothing else to clarify. No gas was consumed to supply that burst of speed.
- 7-09-2017** **Misrepresentation, purpose.** All I can say is "Wow!" After those many exchanges, he continued to be belligerent. Outright dismissal of doing anything to misrepresent is a blatant sign of concern. That lashing out is the panic we witness whenever something goes horribly wrong and all other opportunities have been exhausted. This is how I decided to end the nonsense: **YOU ARE COMPLETELY MISSING THE POINT OF THE TECHNOLOGY. IT IS NOT FOR AUTOMAKERS TO COMPETE WITH EACH OTHER. THE PURPOSE OF THE TECHNOLOGY IS TO REPLACE TRADITIONAL VEHICLES.** Got it? Do you honestly think a customer shopping the dealer's showroom floor looking for a GM vehicle is going to care whether or not that Volt there in front of them is better than a Prime? No, they won't. That ordinary mainstream consumer will be comparing that Volt to a Cruze or Malibu, other vehicles from GM's own product line. It boggles the mind how **PURPOSE OF THE TECHNOLOGY** is completely overlooked for the sake of bragging rights. Our market's obsession with winning small battles has the consequence of losing the war. Traditional vehicles must be replaced with choices that are actually competitive. A simple look at the MSRP of Volt causes that shopper to walk away. That is a fact you continue to evade.

7-09-2017 **Misrepresentation, excuses.** It never ends. The concern over "*too little, too slowly*" has been overwhelmingly validated. Time is rapidly running out and some continue to make excuses. I'm in utter amazement how enthusiasts are becoming apologists. That was unexpected. They see what's happening and try to defend it. Unfortunately, all that does is soften the impact. The inevitable failure to achieve goals will still happen. You'll just feel better about having been so wrong. Even writing about it makes me uncomfortable. Knowing the purpose of replacing traditional vehicles will have been missed by not addressing shortcomings is a big let down. You learn from mistakes and move on... not make excuses! Ugh. Oh well. It's not like warnings weren't provided: Tax-Credits will trigger phaseout next year for GM and you're making excuses for delay of dealing with the situation. We need affordable choices now. The dependency upon subsidies to compete will come to a painful end and refusing to deal with it by portraying the market as a tiny niche is unacceptable. Refusal to acknowledge mainstream buyers through redirection of "*EV curious consumers*" is denial of the need to replace traditional vehicles quickly. Your claim of "*They aren't comparing Cruze or Malibu to Volt*" supports that. They simply don't bother. Why waste time on a expensive compact specialty vehicle? Look at purchase priorities of ordinary consumers. So what if Toyota did a much better job of matching Prime to them and GM didn't with Volt? That's no reason to deny their importance. Sighting reasons to wait is not a good plan. Like it or not, next year's phaseout trigger is coming.

7-09-2017 **Misrepresentation, who?** Pressing the reset button each time something new rolls out is how shortcomings are concealed. When I called out the antagonist, he tried to spin it right back with: "*Why such a desperate effort to ignore/exclude/marginalize key feature differences between the the Prime and the Volt?*" I wasn't about to take his bait. I'm not going to press the button. The goal will remain fixed upon traditional vehicle replacement, period. None of the conquest nonsense is acceptable. So, I jumped right back into the routine of retaining focus by asking: Who is the market for Volt? That question has been asked countless times over the past 7 years. The answer was always the same. GM was targeting Volt for conquest sales. That's why the red herring of Prius verses Volt has persisted. Enthusiasts couldn't care less about actually changing GM's own loyal customers. All attention was placed on winning over new buyers instead. What a terrible waste of tax-credits, squandering them away for the sake of bragging rights rather than actually replacing traditional vehicles. We continue to be told to be patient, yet no progress is actually being made with the replacement. Cruze, Malibu, and Equinox owners keep replacing their old models with new models. Volt isn't of any interest to them. Say whatever the heck you want about Prius or Toyota. The problem for GM isn't going away. A void & Distract only works for so long. The product-line must change.

- 7-09-2017 Misrepresentation, disagree.** The effort to get me to compromise was not going well. You could tell there was growing frustration related to my unmovable stance. It has been 10 years. Being told GM would leap-frog the competition gets old... when it never actually happens. Even with a \$7,500 subsidy, the mainstream sales we had been promised never materialized. They didn't understand the market. They had no idea how many challenges Toyota had actually overcome. GM continues to struggle... which would be fine if there was an effort to address the problems, then they too could overcome them. It's not unrealistic. It's quite reasonable. The catch is to shallow pride so direction can be changed. Acknowledging efforts had been targeted the wrong way is how you get back on track. Pretending their isn't a problem doesn't help. I'm not going to agree that all is fine, that we only have to be patient. Waiting for a product not targeted at mainstream consumers doesn't make sense, as I replied: No, I don't agree. The goal of "*nicely under \$30,000*" was set an entire decade ago and promised for gen-1... then gen-2... now gen-3. No more excuses. Toyota already delivered a MSRP of \$27,100 for a base model Prime loaded with safety features. Camry, RAV4, and C-HR hybrids are all being positioned for plug-in models. No more delay. Why must we continue to wait for GM to catch up, despite having such a supposed huge lead? Where is the affordable model? What is the plan? Who is the market? When will traditional vehicles finally be replaced?
- 7-09-2017 Misrepresentation, repetition.** It's rather remarkable to see so many of the same old nonsense resurface again. There's no point to following the path it take us this time though, since all of that research is complete. The antagonists of the past provided information to steer away from the same traps the next time around. That's how you avoid repeating the same mistakes. I learned. They didn't. It's so simple. Just pay attention, then remember. In fact, if you are reading this, you know how I remember. Taking the time to document the detail as it was playing out is the source of study material later. Watch for patterns. React based upon what the past taught us. Don't just try the same old thing again. Ugh. Seeing that repetition play out another time is truly remarkable. Those who don't learn from failures of the past are doomed to repeat it. I summarized the absurdity of the situation with: Volt never attracted GM's own loyal customers, hence the "*who*" question in the past and the tax-credits having been wasted by conquest sales. You can continue playing the game... There is 10 years of that spin to work with. Read up on that history. You'll be surprised by the similarity... and lack of progress.
- 7-09-2017 Misrepresentation, resentment.** It's getting intense. GM set the goal of 60,000 annual for good reason... and the enthusiasts know it. They've got nothing else left to defend their lost cause though. So, there's lot of posting going on to dissuade its importance. If find it intriguing what they'll claim. Simple dismissal doesn't always work. They have to get creative about missed goals. It's often a reinterpretation of what was stated. That's why I so clearly document comments from when we first hear of something. Anyone can distort long afterward with some degree of success. But back when it first happened, that's extremely difficult... especially if you saved the exact quotes from those in favor of what was said. You can later catch that same person changing their story later... which is where the resentment comes from. Some get really upset from you using their own words against time. We'll too bad. I'm not going to allow their misrepresentation to continue.

- 7-09-2017** **Misrepresentation, flat sales.** The most irritating of shortcomings with GM's struggle for Volt has always been the most important. It's sales, which have been flat. The most recent month's outcome was just 1,745. That isn't any improvement over the previous generation. Growth has not been achieved. Each report just adds to the stream of disappointment. Witnessing the continued lack of progress is how such misrepresentation has gotten so out of hand. The enthusiasts have run out of options. There is literally nothing else to work with. What else can be said at this point? Every imaginable argument has already taken place. It's over. They just don't want to acknowledge it yet.
- 7-10-2017** **Timing Gamble.** Toyota's decision to not use up tax-credits with gen-1 is paying off. Pointing that out today sure stirred the pot. Discussion branched all over the place. There was confusion, denial, and some lashing out. What a mess. The worry that GM would screw up consumer perception like they did with diesel decades back was warranted. They rolled out such a terrible product, it disenchanted the entire market. Diesel was all but totally abandoned as a result. Fear of that happening with EV came about for the same reason with EV1. Thankfully, the claim of there not being any consumer demand was exposed as farce. They did still mess up perception though. This is why Toyota keeps their distance. If fallout comes, they won't suffer from it. The gamble of waiting sure looks like a good one. Claiming that timing is "*too late*" don't hold merit. The market as a whole is only now starting to notice plug-in vehicles. Those ordinary consumers who just want a reliable form of transportation for a good price are the great untouched still. They have yet to begin research. Actual shopping is still a few years off. Until they start seeing them on the road and noticing public charging-stations, the game of sales hasn't really begun. That's why saving the bulk of tax-credits for now makes so much sense. Toyota chose wisely. GM on the other hand, has almost used them all up already. Oops! It's like sprinting early in the race. You end up tired long before anything important even happens.
- 7-10-2017** **Two Vehicles.** The topic of "*streetlight charging*" came up yesterday. Coincidentally, I had actually just witnessed that. It's a nice opportunity to take advantage of, when offered. Unfortunately, it isn't as convenient as you might think. Not all charging ports are located in the same place. Some have them in front. Some have them by the driver's door. Some have them by the passenger rear. It varies, which means parking situations will be beneficial to some more than others. For Prime, being able to park next to a streetlight, then plug into it is no big deal. The port is on the needed side. For Leaf, it's port in front could take advantage of the opportunity too. But with a GM or Ford plug-in, the cord would have to be wrapped around the car and the charging handle stick out into traffic. That's obviously not good. But rather than stress that awkward placement in a circumstance some may never even witness, I thought it would be better to bring up a far more realistic situation. What do you do at home when there are 2 vehicles sharing the same garage? Hanging a cord from the ceiling may be an option, though the cord would still be in the way at times. For us with having 2 plug-in vehicles, it worked out really nice. Here's what I shared & asked: My wife parks her Prime on the right side of the garage, to allow maximum room for the driver's door. I back in on the left for the same reason. That makes plugging in very easy for both and completely eliminates stepping over cords. It also makes plugging in while parked in the driveway possible. How are other 2 plug-in vehicle homes dealing with recharging?

- 7-11-2017 Emissions.** Notice how no value whatsoever in the comments is placed on the reduction of smog-related emissions? That's really a sad statement about priorities. Sadly, I've said it countless times over the past 17 years too. Almost none of the reviews ever take them into account. Focus entirely on efficiency payoff is such a waste. Since when do those driving guzzlers care anyway? It's all just a stall tactic. They know they'll ultimately lose. You can only ignore the younger generation for so long. For the perspective of our children, it simply makes no sense not embracing new technology. It's an expectation in their mind. A constant state of improvement is the norm. Imagine never upgrading your phone. Gasp! When a better technology comes along, you replace the old with the new. Why in the world would you keep buying the old. That kind of purchase makes no sense. Yet, we see that with the traditional vehicles. Buyers pretend there isn't a better choice available. Ugh.
- 7-11-2017 Statistics.** Now that things are settling down at home with the 2 new Prime and the 2 new chargers, it's time to start gathering some easily sharable real-world data. For example, how much recharging can you achieve in just 1 hour? Today, I measured... though I missed my timer by 2 minutes. So, after 1 hour and 2 minutes, I have something to share. Starting from empty, the battery-pack was able to utilize 3.66 kWh of electricity. This is data shown on my phone, using the app that connects via Wi-Fi to the charger. In the Prime itself, the charge-level stated it was at 62%. I bet that isn't what you were expecting. Since a full recharge takes 2 hours, most people assume half would be 50%. But in reality, the charging isn't linear. You get more electricity initially, then it tapers down. That gradual drop as it reaches "*full*" is part of the longevity approach. It doesn't put as much demand on the chemicals within. Another part of that is "*full*" not actually being full. When it states 100% on the display, it is really about 85% of the battery-pack's actual capacity potential. Not recharging entirely helps prolong life too. Anywho, that 62% on the display worked out to a EV distance estimate of 21.3 miles. Not bad for just a little over 1 hour of charging.
- 7-12-2017 Top Plug-In Hybrid Sales.** The website moderator published this blog topic, knowing it would stir quite a bit of posted activity. Right away, the trolls emerged too: "*So to jump from 0 to 200,000 sold per year in 8 years is quite an accomplishment...*" The expectation as an elf is for me to immediately squash that attempt to mislead with solid fact corrections and a jab... to stir even more posting. So, I did: No, not even close. 227,800 Prius alone were sold in 5.4 years **WITHOUT** any tax-credit help. There wasn't a \$7,500 subsidy back then. The only thing available in those days was a \$2,000 deduction, which worked out to roughly \$350 as a credit for most taxpayers. The first actual credit started on January 1, 2006...well after the 200,000 milestone had already been reached. And that's just Prius, not an entire industry added together like the supposed "*accomplishment*" celebrates. Volt was too little, too slowly. Watch how things change when offerings of the first affordable plug-in hybrids are finally available in dealer lots. Prime's base MSRP of \$27,100 is nicely under \$30,000.

- 7-12-2017** **Prius Attacks.** Turning personal is inevitable. They start with attack Toyota first though, then lash out a Prius. It's quite lame. Somehow, it makes antagonists feel better. For everyone else, they see desperation. Ironically, one of those antagonist actually posted something to that very affect, supporting exactly what I wanted to point out: "*Desperation is the first sign of a losing battle.*" That was handy to have put aside for use later... in this case, now: Saving that post from the forum yesterday is proving helpful already. "*Ugly*" is not what people were saying at the plug-in presentation on Saturday, in the lot where my Prime was parked next to a gen-2 Volt. That isn't what they expressed. No amount of posting here will drown out their compliments of the new look. Claims otherwise are a sign of denial, if not desperation. "*Slow*" is becoming increasingly difficult to spin. Like the attempts to make people believe the gas-engine will start upon heavy acceleration, it just obvious misleading... desperation. I merge onto the highway and pass people in EV mode. It works fine. It is clearly not slow. You are losing. Fortunately, that loss doesn't represent failure. It just means the attempt to replace traditional vehicles with Voltec in Volt didn't work. The technology itself has proven successful, just not in a compact car attempting to deliver too much. It just needs to be reconfigured. The long discussed "*lite*" version would be more affordable. The often mentioned SUV would better target GM shoppers. Too bad if GM lost this particular battle. That's no reason to give up entirely with posts of desperation. Remember, the war is traditional vehicle replacement.
- 7-12-2017** **Get Over It!** I got attacked right away, prior to the rebut post. This particular individual hates the fact that I was correct about the market and absolutely refuses to look forward. Somehow, he thinks spite will make things better. Ugh. It's really sad when losing a battle prevents the continuation with the war. You win some. You lose some. Who cares. As long as the ultimate goal is achieved, all will be fine. Needless to say, he doesn't see it that way. So, I fired back: Get over it already. There is much work to do still and tax-credits are almost all used up. Personal attacks are an undisputable sign of desperation and they contribute nothing to progress. Scapegoats are just an excuse. Face the reality of traditional vehicles posing far more of a challenge to overcome than you had anticipated. Real-World data is the best way to take that next step. With a 38-mile commute (recharge at work) and a 1,700-mile vacation (much was at 80 mph without recharging), I've driven just under 88 hours with my Prime. The resulting EV ratio is 58%. The average for those 6,208 miles is 96.4 MPG. In other words, Toyota delivered a 100 MPG for \$27,100. What should GM's goal be?

7-13-2017 **Pressure.** It has been building up for awhile. Each posting of monthly sales results would trigger quite a bit of anger. The growing intensity signaled change was coming. Sure enough, it came too. Rather than just a few days of exchanges, then it blowing over. This continued. Indication of an end approaching is quite a relief. They were getting quite desperate. How many times can you ask about goals and get nothing instead of the usual red herrings? My guess is they grew tired of month after month of disappointment and finally decided to give up. That's when you post a reminder summary... with the hope that stirring burns out the remaining ashes:

Volt was designed to alleviate the concern of range-anxiety.

Bolt was designed to alleviate the concern of range-anxiety.

See the problem? The purpose of the 2 are at direct odds with each other. Rather than offering choice, GM ended up confusing the market. They compete rather than compliment. Remember how GM used to compete with itself prior to the bankruptcy? Resources were spread thin as a result of the variety of GM dealers competing with each other rather than other automakers.

That's why knowing the goal for GM now is so important.

The situation for Bolt is about to get ugly too. Both Tesla & Nissan will be putting an enormous amount of pressure on GM in new market of gen-2 EV offerings. Fallout will be a loss of attention to Volt. Notice how it is almost non-existent in the news already? Ironically, the effort to suppress this concern by hiding posts with negative votes will end up making the situation worse.

Purpose of a Volt with a smaller battery-pack would have been obvious to potential customers. Those here were strongly opposed to that idea. Now, it's about to come back to haunt them.

Realistically, the best next step would be to make the goal to deliver a short-range plug-in hybrid SUV. Offering Trax with a 25-30 mile EV range seems to be the approach with the greatest potential. Equinox is too large & expensive of a base to build upon so late in the game, especially now that the traditional version is such a huge seller. That level of self-competition with such a high premium isn't a good idea.

Don't forget about BMW, VW, or Hyundai in the either. There's also Ford, Chrysler, and Toyota that will be adding to the pressure.

What should GM's goal be?

- 7-14-2017** **Not The Same.** When things go back to basics, you've got your confirm of a reset having happened. Abandoning failed objectives in favor of a simple goal is exactly what you want. Of course, they'll never admit what has happened, nor will they declare any targets of any sort. It's still progress though. Notice the fundamental being asked: *"Isn't that what Toyo-duh did when it added a credible plug-in to the Prius hybrid line?"* That's far better than any rhetoric of the past. It's fulfillment of the goal I had for all those posts too... to finally step back to consider the big picture. Phew! My response to what had grown to a hostile attack on his part was this simple message: Not at all. The progression to a larger battery with a plug is so obvious of a next step, that has been a natural expectation of many. Toyota's effort to offer a low MSRP, to completely avoid tax-credit dependency, is what makes them different from GM.
- 7-15-2017** **EV Ratio.** What a nice discovery. I wondered what Toyota ultimately decided to do to convey overall electric efficiency. Since there isn't a measure of kWh anymore, some type of simplified approach must have been used. I didn't dig to find out though, since I wanted my discover process to mimic what an ordinary owner would experience. It's too easy to just jump ahead to the answer. A few quick searches through the manuals is all it would take. But I want to write my own, again. Another user-guide could be quite helpful. That requires patience. You must make observations. Discover what's important based on questions asked and comments posted. Reaction from others is priceless. That tells you far more than any documentation. So, I waited. Today, it was revealed. I hadn't realized the EV Ratio value wasn't just for the immediate drive (the one that resets each time you startup the car). It has a value for each of the separate odometers. Sweet! Though sadly, I had already reset the "A" odometer as my tank meter. The "B" odometer still had lifetime data collected. It stated 59% for EV Ratio. Cool. I was quite curious how much plug-supplied electricity went toward those miles. Of course, the HV miles are not included, regardless of whether they include EV driving. There's the question of climate-control tracking too. Hmm? Anywho, it's nice having such a simple means of providing a general idea of plug benefit.
- 7-15-2017** **Designed Around.** Ever notice how some often-stated claims don't actually have any substance? Simply asking for a little clarification ends up stirring emotion rather than detail. That's a sign of rhetoric, where the person either has no clue what they are talking about or they are intentionally attempting to mislead. Either can be a major obstacle. Both are quite bad. For example: *"Toyota could've championed a Prius with a plug for the masses that was designed around a battery pack vs. what they did which was vice versa."* What the heck was he actually talking about? There has been a lot of bewilderment around GM's choice to have an intrusive tunnel for the battery in Volt yet having avoided that entirely with Bolt. That's why I have been asked about goals. What are they? That's also why I responded to that vague statement with: EV efficiency. HV efficiency. Heater efficiency. A/C efficiency. All are battery-centric designed. As a result, the system is competitive with traditional vehicles and is not tax-credit dependent. Simply delivering a larger battery to compensate for efficiency shortcomings has never been a good plan. Notice how offering larger hasn't resulted in expected sales growth? Toyota delivered a plug for the masses prior to the paradigm-shift about to begin when phaseouts are triggered. Having that already in place puts them ahead of the other legacy automakers.

7-15-2017 **Pointless Naming.** An obvious sign of desperation is attempts to change the topic of discussion. Several have been made recently on the thread addressing the issue of what happens when tax-credit expire. This particular attempt was worthy of response: "*GM had switched from "EREV" to "EVRE" (electric vehicle with range extension) to stress that it's an EV first.*" The reason for posting something is it provides an opportunity to supply detail. Vague claims are pointless, especially when it deal with nothing but a name. My response was:

BMW showed the world what a range-extender actually is. Their use of a very small engine in i3 used for the sole purpose of generating electricity is what they delivered. GM's approach with Volt is a plug-in hybrid... which isn't a bad thing.

Consider what Toyota delivered for Prime. Even without the ability to recharge at home or a large battery-pack, there is still opportunity for the design to thrive.

CHAdEMO is an option currently available for Prime in Japan. With that, you can recharge 80% of the 8.8 kWh battery-pack in just 20 minutes. Speculation is that the United States will get that option later in the form of CCS (which appears to be the CHAdEMO successor).

CHARGE-MODE is a standard feature in all Prime offerings. At 66 mph (outside temperature of 64°F and a light crosswind), I observed an 80% recharge in 38 minutes. Distance covered during that was 40 miles. Efficiency reported on the display was 37.8 MPG.

For Prime owners who will be limited to only opportunity charging with 240-volt stations available at stores, coffee-shops, restaurants, and parks, 100% recharges at 3.6 kW takes 2 hours. With only 1 hour of recharging time, 62% of can be delivered.

In other words, it is pointless to dwell on naming convention. What the vehicle itself actually delivers will be the basis of purchase decisions.

- 7-15-2017** **Growth Needed.** That's the point. With gen-1 and gen-2 of Volt, there has been a reckless use of the tax-credit. Enthusiasts state price as if that discount will always be available. They absolutely refuse to deal with the reality of it going away as having any impact to sales. That's a fatal mistake. Sales aren't that good anyway. Growth is desperately needed and the extra \$7,500 of help isn't achieving it. There is a serious reason for concern. Sales have been flat and well below what they must be for sustainable business. Still remaining a niche is not what anyone had hoped for after so many years. Meeting goals is vital. Mainstream volume (5,000 per month) is required, at a minimum, for it to be a realistic high-volume traditional vehicle replacement. I reminded those antagonists: Those who have been carelessly taking the subsidy for granted, hoping costs will drop enough to offset the loss just in the nick of time, are in for a rude awakening. The phaseout period will draw attention to how much lower sales still are compared to what they should be for profitable, sustainable business. Tesla is providing some guidance to the legacy automakers about how much is involved with such major chance. Too bad if the necessary steps for them are not as exciting. That's part of being common. Think about what needs to be done to achieve on-going high-volume sales without government incentives. The effort to evade discussion of growth is reason to be very concerned. It's a sign that tax-credit dependency is still a big problem for some.
- 7-16-2017** **Understanding Statistics.** Yet another attempt to change the topic was made: "*Note that over 80% of the U.S. population can install a charger where they live. Specifically, 60.3% live in single family detached structures...*" That's how the post began. A variety of statistics and encouragement followed. No detail was included though. That's a warning sign. Statistics can be used to mislead. I pushed the new subject, but made sure tie the original topic back into the mix: Note that 100% of the population could purchase a hybrid. See the problem with those assessments? Neither takes into account the desire to do so. That's why there are tax-credits offered. The subsidy stimulates market interest in new markets. It only focuses on the low-hanging fruit. In other words, mostly just those who can easily install a charger will bite. What happens after the tax-credit is no longer available is the key. We have no clue how the loss of subsidy will impact Model 3. Selling 400,000 certainly would be impressive. It would also be enough to become an established automaker (convenient sales & service network). There will be competition by then though, with quite a variety of choices. Point is, we are looking at potential, without any solid indication of what the market will actually do. Just because an outlet could be available doesn't mean the owner has a convenient way of plugging into it. Matters complicate quickly when the expense of new wiring comes into play too. How many of those 60.3% could accommodate recharging 2 vehicles at the same time?

7-16-2017 **Market Saturation.** There's a desperation at play now. It's intense. The antagonists are lashing out with their final attack. All they have left is to focus on visual. No other argument has any substance. At least with emotion, there's a sense of having something. It falls apart when you actually consider detail. But with these in the attack messages, who could resist replying: "*extremely ugly, felt nauseated, ugly car, insulting our tastes, I feel sorry, get a barf bag*". With an invitation like that, I certainly couldn't:

When you have nothing of substance left to argue with, go for emotional appeal.

The writing has been on the wall for several years now. The plain, ordinary, basic look is everywhere. Market saturation of anything is a warning sign for business. Sustaining sales becomes an increasingly difficult problem. Switching to a standout look is inevitable.

Honda was quick to jump onto the change with noticeable acceptance. The trend is now becoming apparent with Toyota. The big names here... GM and Ford ...have yet to respond. They will find themselves scrambling to catch up as a result.

The choice to make gen-2 Volt look even more like a traditional sedan was a bizarre move. That decision targeted it at traditional buyers... which seemed sensible when it was designed. But the upcoming shift was overlooked and traditional buyers didn't show interest. Needed growth didn't result.

C-HR is Toyota's effort to reach buyers who are seeking a choice that doesn't look ordinary. It's built upon their new lower-cost architecture too. The platform itself is based upon Prius. So yes, there is a hybrid option (in Europe currently) and could become a plug-in.

Enjoy your market-saturated look while you can. History shows us change is coming.

7-17-2017 **93°F Commute.** The first truly hot drive home from work with the Prime was today. A/C blowing generously was all it took to satisfy curiosity of potential. We were comfortable. There was clearly no impact to EV power. It simply worked. The fan running to cool the battery-pack was pleasant too. It was more of a surprise to hear it with the PHV. With this, the sound was just a subtle noise in the background. I suspect that had to do with the larger vents and new placement of them. I bet the fans are larger too. Thankfully, we don't have heat that intense too often, here in Minnesota. The radiant feel coming from the cooking concrete surface of the parking ramp informed us how much hotter it seemed. The thermometer in the car confirmed it. Having cool air blowing so quickly, from the electric A/C, sure is nice. Of course, what would be even nicer is if I would have brought my Prime into the dealer sooner. When I go there tomorrow, I'll be having them program my FOB to provide the all-windows-down feature. You just press the "unlock" button and hold it until there's a second beep, then all the windows open. That's a great way to always cool the interior of the Prime quickly.

- 7-18-2017 Dealer Sighting.** What are the odds of encountering another Prime coming in for routine service at the dealer the exact moment when you arrive? For the only other vehicle there in the entry area at the very same time to also be one was virtually impossible. Yet, it happened. There are so few still in the Midwest, I was blown away. Then another drove by. Whoa! Being at the right place at the right time is remarkable. What a sweet treat! I couldn't have planned that any better. To think that someday the sightings will become routine. There are not a ton of gen-4 Prius yet, but I do see them pretty much every time I drive now. That give a general idea when Prime will become common enough for the same. In other words, the expectation is 2 years from now. Cool. In the meantime, there apparently is a high concentration of them near my local Toyota dealer.
- 7-18-2017 Reversal, diesel.** Today's daily blog topic is about holding onto the past as long as possible. We're seeing very large efforts to retain the status quo emerge. In an interesting twist, the issue often sighted as a major problem with Toyota is now haunting GM. Enthusiasts don't support diversity. To them, it's plug only, period. No support for anything else is given. So naturally, there's rhetoric about fuel-cell advancement. The fact that those vehicles are fully electric is disregarded. Improvements to motor efficiency, cooling efficiency, heating efficiency, and cost reduction of related components like the inverter are completely ignored. The idea of mutual benefit is dismissed. That's really sad... but true. So when I point out GM's new investment in diesel, you can imagine the hysterical responses. Saying they panic is putting it mildly. Whoa! This opportunity to poke came from: "*Just breathe in those wonderful Koch Brothers' diesel micro particulates!*" That sarcastic remark was the perfect opportunity to reply with: 2018 Chevy Equinox Diesel is what GM will deliver instead of one with Voltec. Why?
- 7-18-2017 Reversal, hypocrite.** There's no excuse; yet, the hypocritical posting continues. This time, I was stunned by the irony: "*It's a sad world we live in, where tin-foil hat wearing, **** wannabes, consistently type into Google searches the results they want to see, and as soon as it pops up they say 'I knew it!'. Rational thought, on any topic, is becoming extinct.*" That is precisely what the Volt enthusiasts have been doing a lot of lately. Being able to call out the biggest of the antagonists with his own words of being guilty of exactly that is an odd situation. It wasn't unexpected though. Surprise would have been if it didn't happen. The build up to a major lashing out that exposes what's been happening was inevitable. That's what we've seen every time fallout approaches. This is the turning-point they could see coming. It's regret that will really sting. That's how next steps are taken though. Revised goals will emerge from the fallout. Learning from mistakes is part of the process. Volt was a mistake. Too much emphasis was placed on faster & further. I pointed out what had just occurred: Like hiding posts you don't want to see by negative voting them. That's exactly what this group here has been doing on a very regular basis. Makes you rethink the situation now, eh? This type of behavior is why I have been repeatedly asking for GOALS from participants. That's how you overcome the rhetoric.

- 7-18-2017** **Reversal, panic.** Wow! I had a feeling this particular subject matter would bring out the worst. The daily blog today was about a new anti-EV campaign from oil lobbyists. It's quite nasty to see such publicity against plugging in. But with an industry dependent upon consumption of non-renewable energy that's dirty, the reaction was expected. The information conveyed is not only very misleading, some of it is just plain not true. What's most interesting though is how the Volt enthusiasts are taking the news. Anything that shakes the status quo causes panic... and this certainly did that. Within minutes of my posts, there was a lashing out at me, the messenger. Typical. Always look for someone to blame for your own self-inflicted problems. Ugh. I posted this upon observation of their behavior: I see a frantic effort to hide what I posted. Getting caught with a hypocritical post will stir such an extreme. On this particular topic, it's ironic too. Continuing to vote down the message to make it not visible by default won't make the problem itself go away. What should GM's goal be?
- 7-18-2017** **Reversal, mandates.** Bolt production has come to a halt. Inventory is piling up. There are only 6,000 unsold now. That's a very real problem. Some of it comes from only the CARB states issuing Zero Emission Vehicle (ZEV) credits being the only place a Bolt could initially be purchased. That's California, Connecticut, Maine, Maryland, Massachusetts, New Jersey, New York, Oregon, Rhode Island, and Vermont. Why rollout to the rest of the United States didn't happen sooner remains a mystery. Aren't mainstream sales the goal? By the end of next month, that should happen... finally. In the meantime, the situation looks grim. Tesla's new Model 3 and the upcoming next-generation Leaf from Nissan are taking away attention from Bolt. That is what is making the situation with Volt so much more of a problem. With market change comes winners & losers. GM's failure to branch out with Voltec, offering it on another vehicle is long overdue. Enthusiasts had expected it years ago and boasted about that would be so much faster than Toyota's expansion of HSD. Now that the time has pasted and it didn't happened, the reality of having fallen behind is crushing. This new anti-EV campaign makes it even worse.
- 7-18-2017** **New Voices.** I don't have to listen to the rhetoric anymore. The antagonist posts are getting overwhelmed by new content coming from new sources. That equates to a quieting of voices that had once been so loud, nothing else could be heard. They were not the voice of reason either. They were just the most prominent... who hated my never ending chatter. It was a steady stream of logic that the new voices are now echoing. I'll never know if they picked up on what I had posted or were simply in agreement based upon their own study. Whatever the case, those members are the change taking place. Yeah! To that, I posted: When there are no excuses left, when all you can do as pretend everything's okay by evading facts, it's over. The faster & further approach clearly didn't work. It was too little, too slowly. Watch how the market responds to newcomers, those who didn't follow the same path.

- 7-19-2017** **Real-World Data.** It goes a long way toward squashing misconceptions. It can also help snuff out intentional misleading. The catch is figuring out what data to actually convey. True, all real-world observations can be informative. But knowing what won't be subject to cherry-picking or bias dismissal takes some careful observation. Much like the data itself, you have to look for patterns. The more common you see it, the more likely it is to stand the test of time. You have to start somewhere. Since the duration of ownership for me is brief still, there isn't much to work with yet. So, all I can do for now is mention totals & highlights: 6,479 miles. 60% EV ratio. 99.9 MPG. That includes a 1,700-mile trip from MN to WY and back, driving at 80 mph the entire way through SD and in WY with no opportunity to plug in. \$27,100 base MSRP (not including tax-credit) is very good reason for interest shifting over to the plug-in hybrid model.
- 7-20-2017** **Perspective.** Saying the reaction was explosive would be underselling it. Witnessing the extremes a few will take to avoid & dismiss Prime has provided a very clear picture of how Toyota has adapted to the changing market... and how they have taken notice. We only need to wait for inventory to finally settle. There is still a lack of availability in the Midwest. In fact, some areas have long waiting lists still. The switchover to 2018 models and the very high demand in the domestic market (sales in Japan) give good reason for expectation of strong sales. As with all things Prius related, patience is required. Time will resolve issues of perspective. What's perceived as a problem may not be in the long-run. Basing hope on what we've seen recently is an encouraging sign. The naysayers see it and have reacted accordingly. Whoa! Makes you wonder what they'll do next, eh?

7-20-2017 **What A Waste.** I asked the goals question, again. This was the response: "*We refuse to answer this question when *you* ask it...*" The self-deprecating nature of their problem makes it impossible to ever get a straight answer. Of course, that isn't what I was actually going after from the enthusiasts anyway. My purpose was to finally get acknowledgement of need. To do that, it required elimination of want in every regard... revealing what remained in the end as necessity. That sure was a challenge to get though. But today, it finally happened. Phew! This is how I replied to having to deal with such counter-productive behavior:

We know why. It is a simple matter of want versus need.

The problem first emerged when Two-Mode was being developed. Goals were set to surpass requirements without regard to cost. Desire for more than what was necessary clouded judgment, leading to a fundamental misunderstanding of the market. The result was a system too expensive to be competitive.

Later, when gen-1 Volt was being developed, echoes of that past were dismissed and warnings were not heeded. There was a blinding obsession to deliver more than was necessary. The original intended audience was forgotten. Same outcome resulted. The system was too expensive to be competitive.

When gen-2 Volt was being developed, enthusiasts lashed at those pointing out the obviously recognizable pattern. Those same mistakes were being repeated, yet again. The desire for faster & further had become such a preoccupation, nothing else mattered. Goals of the past were entirely abandoned. The result is now becoming all too apparent.

Stating a goal requires recognition of need and how the gamble on want failed... which would validate what I have been saying all along. So, I totally understand the reason for refusal.

7-20-2017 **Closure.** With tax-credits about to run out and no clear message still about what GM intent is, there's reason for concern... especially since all the hype has had such an undermining effect on the market. The very thing well-informed green supporters worried about a decade ago has been playing out. Just like with diesel, they offered something that wasn't actually competitive. Promises were made that were not fulfilled. Worry is that GM will claim there was no interest and will abandon the idea of plugging in all together. Making "*green*" transform to "*ordinary*" is no where near as easy as enthusiasts understood and their role as enablers is proving quite costly. So much time wasted. So much opportunity missed. All we can do at this point is to attempt to get some focus on the self-inflicted disaster, to make those who contributed understand the resulting damage and find a way to overcome it. My attempts at closure today included: Notice the timing? Countless posts here shifted focus from Volt to Bolt... with little clarity. It didn't matter much when it was just rhetoric. But soon, we'll see offerings from Tesla and Nissan stirring mainstream interest. Rubber hits the road. That closes the chapter on the 3 prior stages from GM leading up to this. It also brings about the very topic I have been pushing: GOALS

- 7-20-2017** **Using Charge-Mode.** I like responding to questions like this: "*And then the question is whether there's really much value in driving that part in EV mode?*" The fact that Toyota offered a charge-mode is making people think. Rather than it being academic, there is a real application of what had only until recently been hypothesized. What if you could recharge the battery-pack with the gas-engine at times? When would it make sense? How much is too much? Would the penalty be significant? Could there be a net gain? In what manner would we convey the potential advantage? Is there potential for misuse? Could the ability be misrepresented in some greenwash effort? There are lots of questions with few answers, so far. Fortunately, I already have a little bit of some real-world experience with on-the-fly charging to share: For us on vacation, there was a very obvious payoff. Running out for something, once settled at your destination, EV provides the opportunity to avoid the warm-up penalty entirely... especially if you need heat or cold. Charging while cruising on the highway has been a very efficient, while that extra power needed has minimal impact.
- 7-21-2017** **Surprise?** This was the result of a very significant news break today: "*I cannot decide if this is good or bad.*" It was the reveal that GM is struggling much more seriously than realized. Union issues are arising due to production halts. Inventory problems can no longer be denied. Some plants have inventory piling up and others cannot build fast enough. That's a very big deal. Jobs are at stake. Lots of money will be lost. It's a big mess. Plans for vehicle production are now getting lots of attention. That exposes Volt as a serious problem. Sales did not grow, despite gen-2 upgrades. Significant growth was required to overcome the loss of tax-credit help. No subsidy available is big trouble. Needless to say, ending production of Volt is being considered. That has set off explosive reaction online. The variety of emotion is stunning too. I jumped in immediately, using that comment as my launch point: It's good. The expectation for years has been that GM will move on from Volt... hence the answer to that much asked "*Who?*" question about market. The interior layout of gen-2 all but confirmed that when they didn't address complaints about back headroom and created a legless middle seat. The catch is we had hoped this move would be sooner, especially knowing the European demand for Outlander plug-in and the potential for Pacifica plug-in. Now with Kia about to rollout a plug-in SUV, it totally makes sense that GM is finally looking ahead too. And of course, Toyota is preparing for the opportunity to offer Camry, RAV4, and C-HR hybrids with a plug. Don't court out Ford either. The new expectation from GM would be for Trax to become the first Voltec offering in a package that appeals to GM's primary audience. Volt proved the technology. Trax could be the first for a larger group of customers, something dealers will embrace & promote.

- 7-21-2017** **Holy Crap!** Online reaction to the news was amazing. Pressure had obviously been building. Despite Prime's limited availability, it has already become a major irritant for Volt enthusiasts. GM's shift of emphasis away from Volt (to the point of almost abandoning it entirely) for the sake of building up Bolt as a true competitor with Model 3 and the next-gen Leaf made that situation even worse. A rumor emerged yesterday that BMW will be pushing i3 even harder soon, with a big upgrade in the works too. Then there's the reality of Hyundai attempting to undercut everyone with a very affordable plug-in hybrid offering. VW is, of course, taking electrification serious as well. Needless to say, it was no surprise that today's revelation came when it did. I certainly saw it coming. The reaction to my posts from enthusiasts confirmed they felt change coming too. The status quo had been crumbling. Everything they could do to avoid acknowledgement of that fact didn't work. News finally penetrated their stubborn domain. The supposed "*troll*" had been vindicated and they were exposed as "*fanboi*" posters in a state of desperation. Who knew the denial would result in such a build up, then dramatic response. Whoa!
- 7-22-2017** **Consequences.** This particular quote really sent me off on the role of play offense: "*Heed these warnings GM, or suffer the economic consequences of your one track (advertising) mindedness.*" Wow! Talking about a revelation far too late!! I posted this and the following log entries to give that group in denial a serious wake-up call: That's what Volt enthusiasts did for an entire decade. They kept pushing faster & further... over and over and over and over again... an endless stream of Volt being better because it delivers more. That was so blatant of a fanboi obsession, it was obvious their priorities would be a very real problem. An absence of balance is reason for serious concern.
- 7-22-2017** **Consequences: Who is the market for Volt?** That question is what came about as a result. It was a deliberate effort to draw attention to the self-destructive behavior taking place. Fanboi cries were becoming the voice of potential buyers, even though it was clear they were not the audience required for achieving high-volume profitable sales. GM fell into that trap, choosing to cater to cries rather than listen to the whispers of their own loyal customers.
- 7-22-2017** **Consequences: Too Little, Too Slowly.** That had been the biggest concern from the start. Regardless of what happened with rollout of the technology initially, it needed to be adapted & adopted quickly. We were assured that was no big deal... by enthusiasts. They proclaimed GM's rollout & diversification would "*leap frog*" what we saw with Prius and its spread of HSD to a Sedan, Minivan, and SUV. Assurances came in the form of "*vastly superior*" chanting... over and over and over and over again.
- 7-22-2017** **Consequences: Significant cost reduction.** It became the theme for gen-2 Volt. Rather than seriously consider diversification in the form of offering a variety of battery & power choices (search for "*Volt lite*" discussions), all focus was placed on the next-generation design bringing down cost so significantly, there would no longer be any concern about being competitive with traditional vehicles, even without the benefit of a tax-credit.

- 7-22-2017 **Consequences: Yesterday's revelation.** As with other failed attempts to overcome the status quo, a day of reckoning arrived. Predictably, it was at the conclusion of the second year of sales. That's exactly what happened with both Two-Mode and the first generation Volt. It is inevitable. The future must be addressed before unwanted speculation emerges. Volt faces a struggle just to maintain sales. With the upcoming phaseout of tax-credits, the hope for growth to mainstream levels was futile.
- 7-22-2017 **Consequences: Shoot the messenger.** That is no longer possible. Having a scapegoat was a sign of trouble routinely disregarded. It was easier than making excuses. You place blame for stirring the status quo, which ironically was the goal anyway, by just dismissing what was posted as an attempt to undermine. Seeing the effort as outside assistance to help overcome challenges of legacy barriers were instead labeled as "troll" posts... even though they were actually on topic, which by definition is not what a troll does.
- 7-22-2017 **Consequences: What should GM's goal be?** I started asking that recently, many, many times. It was a strategy to point out what was coming soon. Enthusiasts obviously couldn't see it. I could. The pattern was very easy to recognize. Stating a goal is how you get beyond personal conflict. Focusing on an objective makes taking that next step easier. Rather than do it though, there were attacks from antagonists and a lot of enabler reaction. Sure enough, the bottom fell out. Disappointing news did indeed come.
- 7-22-2017 **Consequences: Caught totally unprepared.** What a mess. Despite countless warnings of this coming, there is upset. Rejection of the importance of business objectives was a self-destructive choice. The original sales goal of 60,000 annual (5,000 monthly) was set for good reason. It was a minimum for sustainability. Recognized as a "mainstream" level for other technologies, there was no valid reason for refusal to accept it. Yet, that's exactly what happened and now the consequences must be dealt with... after the fact. What a terrible waste of time.
- 7-22-2017 **Consequences: So, what comes next?** Looking at Volt, it should be indisputable that it does not match the purchase priorities of GM's own loyal customers. Those shopping dealer showroom floors overwhelmingly prefer a SUV of some sort. Equinox has become a top-seller. The smaller Trax is gaining popularity. Looking at the production plant situation. 9 are severely under capacity and 8 are severely over capacity. Writing is on the wall that change is necessary. Build plans will need to change.
- 7-22-2017 **Consequences: Voltec's Future.** Volt never made any sense. Denying it was anything other than a niche was horribly counter-productive. So much opportunity was missed as a result. GM customers simply weren't interested in a compact car with limited leg & head room in the back seats. Strong demand has been on the form-factor SUVs deliver. Despite obvious efficiency sacrifice, there was a clear preference for tall vehicle bodies. Fortunately, the excessive battery & power capacity of Volt can be carried over effectively to a SUV, making it a more balanced offering that's actually competitive... something GM's own shoppers will be drawn to.

- 7-22-2017** **Consequences: Interest for SUVs.** Sitting higher up has, by far, been the biggest reason for SUV purchases. Getting in & out is easier. It's that simple... now. In the past, they were marketed as safer. When that was revealed as false, we saw the reasoning shift. Combined with cheap gas and a complacency for oil & emissions, those high-profit vehicles have been the focus for many. Unfortunately, that has led to market-saturation... hence some of the challenges emerging now. Smaller and more efficient choices, in tall design vehicles, appear to be the solution.
- 7-25-2017** **Signs of Change.** This observation confirmed it: "*Lots of new commentators...*" It's a repeat of the pattern I have observed several times in the past. The fact that others are now seeing it too is informative. Ironically, that particular message came from an antagonist in response to a new commenter. He's finding himself quite alone now. So many troublemakers of the past have simply vanished with no sign of why. Of course, I know why. If you've been reading the blogs, you know too. Yet another chapter has closed and a new one beginning. This is when new characters and new plot is introduced. Right now, it's happening. Sweet! This was my one-sentence reply to that post: When common voices of the past fade into the background, replaced by new ones, it is confirmation of the next step forward.
- 7-25-2017** **Grid Operation.** Having the opportunity to experiment & observe has been scarce. There's lots to learn still and I want to enjoy Summer at the same time. So, doing things like comparing operation of chargers while drawing electricity from the grid simply hasn't been a priority. I did get to give it a try recently. The curiosity was how much electricity for remote running of A/C could be from the plug rather than the battery. Could all of it be supplied that way, some, or none? This was my brief observation posted, with hopefully detail to follow in the not-too-distance future: Just tried the test on a second charger. With my charger at home (JuiceBox 40 Pro), the grid draw took place while the A/C was running. With the ChargePoint station at work, the grid draw didn't begin until after the A/C had finished. In both cases, I started with full battery-pack. The difference I noticed was 3.6 kW verses 3.1 kW. (Home provides more power.) Anyone know what the A/C draw on max is?

- 7-26-2017 Business Approach.** There is a certain pleasure from reading stuff like: "*We are all waiting for the day your posts fade away.*" Coming from such a hypocritical source, the irony leaves me scratching my head sometimes. What is he thinking? Anywho, I responded with: Being correct about GM's flawed approach means you will be hearing the message for a very long time still, even without more posts. *Who is the market for Volt?* That question got asked scores of times for good reason... which is now overwhelmingly obvious. Back then, there were lots of excuses for the mismatch though. GM built a compact hatchback, a vehicle GM's own customers simply were never interested in. *Too little, too slowly.* That was the concern expressed over and over and over again to get across the point that a minimum production volume must be achieved for the vehicle to be sustainable. Again, there were lots of excuses for the delay. There was no merit for all the boasting either. *One size fits all.* Raising awareness about the importance of diversity was an endless & thankless effort to get GM back on track. 2 suggestions were repeatedly made. Making a "lite" version of Volt would have put GM ahead of the industry that is now working to flood the market with choices just like that. Making a SUV which reused the technology already in Volt would have aligned price & demand. *Ironically.* The fade won't happen in a desirable fashion. Success means becoming common. Becoming common means no longer having the spotlight. When a technology is accepted by the masses, that thing that made it special changes. In other words, rather than fade away, you'll see reminders everywhere & often about the business approach that worked.
- 7-28-2017 Renewed Attacks.** OMG! Did it really have to come to this: Listening to this group exclaim "*vastly superior*" and boast about how much faster GM would be at rolling out technology has earned me the opportunity to point out missed goals and ask questions. Why is the first CUV/SUV using Voltec still 5 years away? That is a reasonable question to ask, especially in a thread loaded with FUD and red herrings attempting to paint a rosy picture for GM. Reading an op-ed this morning about GM electric vehicles, the writer highlights the very thing I've been saying for years. Volt didn't target GM's own customers, who prefer larger vehicles. Finding out it will take 15 years from of development to finally reach that required target audience is good reason to comment here. Too little, too slowly was a legitimate concern. Delivery expectations were indeed missed. Profitable high-volume sales continue to remain uncertain. Not having a form-factor shopping want is a major contributor to that problem. In other words, it's your turn to listen now.

7-28-2017 **Reset Button.** The end of Volt as we know has left some in dismay: "*Why are you still commenting here?*" Or is it really just an impression they wish to portray? Having endured their relentless attacks only to be redeemed in the end would leave a person that way. He gave his all for something he truly believed in. Though misguided and poorly informed, he really did think consumers would find Volt compelling. Not understanding either the market or the audience set him up for trouble... which is exactly what I became to him. Oh well. Maybe he'll walk away from this defeat having learned from mistakes. After all, anyone that persistent has demonstrated a strength you want in allies. Friendships can emerge from fundamental misunderstandings. After all, a shared experience is something to cherish. Think about game playing. Just because one loss happened doesn't mean they will have the same outcome. Press the reset button, then try again:

For an entire decade, Volt enthusiasts attempted to convince people that Volt was a vehicle for the masses. They even went as far as saying mainstream volume would be realistic by the end of year-2. When that didn't happen, we were assured year-2 of the next generation would achieve that milestone instead.

Whether you consider those reasons stated as sound assessment with strong merit or they were just desperate excuses didn't matter. Patience was required regardless. So, we all waited. Now with the end of year-2 gen-2 coming to a close, it is undeniably clear things went horribly wrong. The tax-credit will soon be used up and sales are still at the low level they had been prior to the upgrade.

That presents the Volt enthusiasts with a choice. Their want failed. That means taking a serious look at need now instead. Will they do that or will it be more holding firm to talking points? There is opportunity. After all, virtually none of the mainstream buyers have actually shopped for a plug-in vehicle yet.

We know for a fact GM shoppers couldn't care less about a compact hatchback. This market is obsessed with taller vehicles... to the point where even the raised cargo floor in Prime is seen as advantageous, since it prevents the need to bend down and lift to remove contents. Like it or not, that's the way it is.

Taking the same battery-pack and same propulsion system in Volt and placing it into a compact SUV body makes a whole lot of sense. The power & capacity are clearly overkill for the little car but would be a nice fit for the larger vehicle. Customers would be much more likely to pay a premium for that, since it is in the body style they prefer.

It's really unfortunate certain individuals here fought so hard to push change in a direction the status quo would not accept. They absolutely refused to read the writing on the wall. But now that so many voices are saying the same thing, it is time to decide. Press the reset button or make more excuses.

7-29-2017 **Recognizing Change.** The belief that hiding facts somehow makes the situation better: "*We will just keep pressing the down-vote button.*" After 10 such votes, the message disappears. That's so idiotic, I'm in dismay. It is the literal online equivalent of sticking your head in the sand. The belief is that if you can't see the problem, somehow it isn't a problem anymore. Ugh. This is how I dealt with that absurdity in today's nonsense:

With Tesla & Nissan pushing GM from the EV direction and Toyota pushing GM from the PHEV direction, you'll find there is no group of deniers to down-vote anymore. That past of blind hope is now an ugly chapter in history they want to distance themselves from. GM screwed up. The choice now is to pretend that didn't happen or finally embrace change.

Look at all the PHEV choices coming to market. None shared the configuration of Volt. People don't want a compact hatchback with that size battery. The vehicle is too small and the price too large. Let it go. This isn't the death of plug-in hybrids for GM. This is just a reset. The original configuration failed to obtain mainstream sales.

The next offering from GM will likely break the ideals Volt enthusiasts held dear. Well too bad. They are not the intended audience. GM will be shifting focus away from conquest buyers and over to their own showroom shoppers. Instead of trophies, they will be working to deliver commissions for salespeople. Ordinary purchases has become the goal.

It is truly amazing how the mismatch of priorities carried on for so long. Fortunately, the group of enablers continued to shrink. Now, there are only a handful remaining. Remember all those voices of the past who are long gone, who have let go and moved on? Give yourself credit from remaining strong & true, but also be sensible enough to recognize the need for change.

7-30-2017 **Move On.** The desperation has become so extreme, even shooting the messenger doesn't work: *"No one reads your false narratives or takes any points you try to make seriously. You have soiled yourself with anti GM rhetoric and Toyota fanboism."* He knows that's not true. Posts in response to what I say are becoming too abundant. Dismiss, evade, and ignore failed. Defending a lost cause is a wasted effort now. So, going down with an insult is all he has left. I enjoyed writing this detailed comeback to all his wasteful rhetoric:

It is truly bizarre to witness a few individuals fight so hard for the opposite, to maintain the status quo. They don't want to see the world around them changing and hope ideals of the past will somehow triumph. Ugh.

Orders for Tesla Model 3 have surged to over 500,000. That puts legacy automakers in a position of deciding how to compete with plug-in offerings of their own. For Toyota, that means pushing forward to the next stage in lithium battery technology as well as offering a collection of new technology features. For example, the following are all standard on all Prime models:

- Dynamic Radar Cruise
- Pre-Collision Braking
- Lane-Departure Detect with Assist
- Automatic High-Beams
- Quad LED Headlights

That focus on safety, rather than catering to the obsession with faster & further, is how you reach ordinary consumers. Move on means recognizing what sells and what doesn't. Emphasis on speed & range was clearly something legacy automaker shoppers were unwilling to pay a premium for. This is why Volt failed to attract mainstream buyers. Loyal GM customers simply were not interested. Toyota is also pushing forward with other new technology features with Prime. The most obvious are:

- Dual-Wave Rear Window
- Carbon-Fiber Rear Hatch

There are other options too, like the large touch-screen, heads-up-display, and self-park. But what appears to be a offering that Prime strives to break new ground with is:

- Predictive Efficient Drive

This technology monitors driving pattern. When frequent repeating data-points indicate a location where you would normally brake, the system will automatically trigger regeneration. In other words, without touching the brake pedal, the vehicle will slow itself down. This makes stops, turns, and roundabout more efficient without requiring anything special from the driver. It's like the car hypermiles for you. Like the ultra-efficient heating system, you take for granted that it strives to save electricity.

Notice how all of those efforts advance the entire fleet? Legacy automakers have a lot to deal with. Move on means recognizing what sells and what doesn't. They must

continually try new things to see what will attract their own wide variety of customers over to a plug.

- 7-31-2017** **Alternative Facts.** That's the new term for internet spin. It had emanated from distortion of actual events, in the past. Now, people sometimes just make up stuff entirely... hence this new rhetoric tool. How does one combat this: "*Years ago, Toyota was upset about a group making Prius into PHEVs.*" That just plain isn't true. It does sound convincing though. It tried with this relatively short, purpose reminding rebuttal: No. There was never any upset response. They simply pointed out how unrealistic it was. Lithium batteries back then were extremely expensive and energy density was very low. Volt is small, crippled by its MSRP, and heavily dependent upon tax-credits... which is what makes endorsing it an issue. Toyota steered clear of those barriers, instead, delivering a configuration very realistic for high-volume profitable sales.
- 7-31-2017** **Ignoring Facts.** The response to my previous post was: "*The Volt isn't small, especially the Gen 2. It's actual selling price after tax credit is about the same as the PP.*" He simply dismissed what was said. Gen-2 Volt actually got a little smaller. Why in the world GM would reduce headroom in back is bewildering. But to pretend it wasn't small in any regard is outright denial. My head sticks out of the hatch when attempting to sit in the middle seat. That cramped no matter how you spin it for a man only average height (5'8"). The real problem though is the total disregard was for price. The sticker is a major deterrent for buyers, even with the federal subsidy. The fact that it will be expiring next year makes that bad situation even worse. But rather than acknowledge that, all he cared about was competing with Prius Prime today. Who cares about long-term well being of the business when you can win a bragging argument today? Ugh.
- 8-01-2017** **July Sales.** They were so bad for the struggling Bolt & Volt, it was no surprise to see such weak damage control: "*Almost 3500 plugins combined. Not too shabby.*" When the count of both fall so far short of necessity for business, what else can you say? Expectation for this close of year-2 for gen-2 Volt was to achieve mainstream sales volume. With the tax-credit phaseout approaching, being well established before that is a very big deal. Not achieving that means trouble... if the status quo doesn't change. Knowing that Prius Prime is seeing strong demand and that Ioniq PHEV is about to stir growth puts Volt in an even more difficult position. Bolt is equally challenged. Model 3 is seeing strong demand and Leaf is about to stir growth. Of course, you cannot point that out and not expect to be attacked. Sentiment of anything to that affect is looked upon as being anti-GM. Constructive discussion is totally unrealistic... especially now that there has been mention of gen-3 facing major economic barriers. Needless to say, the numbers revealed today clearly indicated a turning point.

8-02-2017 **Missed Opportunity.** It's quite remarkable how antagonists eventually end up backing themselves into a corner. For example: *"Note that GM is at 146,400 total plugin sales in the US now. If they continue with 3500/mo in sales, that leaves 15 months of the full tax credit left."* Reading this was redeeming. Only now, after all the years of fighting, is there the first glimmer of the situation playing out. Despite literally hundreds of warning this was coming, he always resisted. Being told was unacceptable. Finally noticing the trap he had guided people into was far too late... hence the lack of any fight back this time. Nothing came from what I posted. Coming to the realization of me being correct all along isn't a good idea to draw attention to. Just like all the other antagonists, when cornered, they become silent. I was thrilled by this. Progress comes from recognition of the problem. It's not too late, but there certainly is a cost from having missed so much opportunity along the way. What a waste. Oh well, it's not like I didn't provide an enormous amount of concern about this very outcome, hoping to prevent or at least minimize it: What part of *"too little, too slowly"* isn't understood at this point? Volt growth is not happening as needed and the outlook you just provided recognizes flat sales. The business must significantly increase to be competitive; otherwise, it's missed opportunity.

8-03-2017 **Save the Volt.** What a mess. So much of this could have been prevented. Oh well, all I can do is provide observations. In this case, there is now an effort emerging to save Volt. It's history repeating yet again. Do they really not see the same mistakes being made? Ugh. I'll try to draw attention to the problem:

We've seen this before. Recognize the pattern?

Enthusiasts seriously thought Volt would be killed upon the start of year-3 for gen-1 due to sales coming up well short of expectations. Disagreement of what should come next divided the support. Many discussions left here as a result of unclear goals. The remaining ended up suffering from group-think that didn't match market-need. That lack of clarity is now causing the process to repeat.

What should the next "Volt" have for specifications?

Notice how there is nothing resembling consensus on how the next offering from GM should be configured? Regardless of body type, there isn't any sort of common theme. What size the battery-pack should be... How the battery-pack should be charged... How the battery-pack should be cooled... Which features should be standard... Who the competition should be... What the sales goal should be... How long rollout should take...

Without a solid idea of the target, there's simply no way to actually hit it... especially with a bullseye result. Hoping for the best is futile. This is what doomed Volt from the start. Lessons learned from Two-Mode were disregarded. And sure enough, gen-1 suffered from some of the very same problems. Then when gen-2 support began, it was the same chaos mess. Goals were not stated. Results have been disappointing.

Expecting a gen-3 offering to somehow overcome those same barriers without addressing them is not a recipe for success. In fact, it is an invitation for inevitable defeat. Vague is how an outcome is sabotaged. Consider how lack of detail could be an effort to undermine.

You want to save Volt, you have to tell us precisely what that means. Define success. Spell out what needs to be achieved & delivered.

8-03-2017 **Abandon the Volt.** We are witnessing the end. It makes writing blogs very interesting. Documenting this chapter in history as it plays out is fascinating. We know what will happen. We just don't know how. Enthusiasts are acting like the President. What happened in the past doesn't matter as much as how it is reacted to. Will they continue to deny the obvious? How can they believe the evidence will somehow be dismissed? It's absurd. I'm scrambling to write down and analyze as much as possible before the next news brings new reaction. Today it was posting this:

Supporting Bolt means a careful look at the market for Volt. Who are the potential buyers?

Tesla is positioned to overwhelm GM in the EV arena. Economy of scale benefit as well as the volume of them spotted on the road put odds heavily in favor of consumer interest for Tesla. What will GM do in response for Volt?

Knowing there will be Toyota & Hyundai pushing hard in 2018 with their much lower cost offerings and the fact that they will still have tax-credits available, the idea of conquest sales for GM is a lost cause. It's simply not going to happen. All that low-hanging fruit has already been picked.

The cards are stacked for GM turning to SUV plug-in offerings. That is what their own showroom shoppers will want. Heavy preference for SUV purchases now makes that difficult to dispute. Interest will be lost for Volt the moment an announcement is made about plans to deliver its tech in a SUV. All but enthusiasts will abandon Volt. What would compel them to support a compact hatchback?

You don't think that will happen? Watch market reaction to the gen-2 Leaf. The expectation is for Nissan to undercut GM by offering a much lower price than Bolt. That's even more pressure on EV sales... which will force GM to take a big step in the plug-in hybrid market.

8-03-2017 **Selling Points.** Back to just ordinary discussion about Prius: "*The two biggest criticisms against the Prime that i read over and over again are lack of 5th seat and poor cargo space.*" I had to ask: From who? We have found (2 Prime in our family) that the 5th seat is of no real value anyway. Large adults just plain don't fit. No one wants to be squished together like that. Oddly, the center-console helps to keep items tossed in the back seat from sliding around, an unexpected benefit. The extra storage is nice too. As for the raised floor in the cargo area, that has actually become a SELLING POINT. It hadn't occurred to us that not having to lean over to lift cargo set down onto a low floor would be so nice. You just slide it out. Stuff is at arm level. That's so handy of a benefit, I'm at a loss at how to promote it. The design should be obvious, but clearly it is not... until you've taken advantage of it firsthand several times. In other words, don't put too much weight in criticism of those who make quick observations. Owners like us can really do a lot to shake up assumptions.

- 8-03-2017** **Not Paying Attention?** Sometimes, the discussion get way out of hand. This snippet came out of the selling points remark: "...so I can easily grab something in the back while sitting in one of those 2 seats." Talking about bizarre. That is such a strange twist from what I said, you have to wonder if the person was not paying attention or had ill intent. What would possess someone to think that is what I was saying? Others found it odd too. Thankfully, we all kept focus on comments that were actually somewhat constructive: "*You want a low loading height such that you can reduce the height needed to lift an item off the ground.*" I followed up with: When would the item be on the ground? It would be at arm height already... which is the very thing we've experienced. Again, this is real-world observation from actual ownership. Toyota is willing to try different approaches and figured out that practical is more important than perception. Try carrying groceries out from the store or taking off your backpack when approaching the car. Then reverse the process when leaving. The benefit quickly becomes obvious.
- 8-03-2017** **Estimate vs. Actual.** The difference can be really big. Some owners don't pay close enough attention to notice. That becomes an issue when you're driving an EV, not so much with a plug-in hybrid though. But when people are quoting values, you should know what's truly happening. We're hearing unusually large numbers from Bolt now. How do you know they are accurate? It's very difficult to imagine them driving for days on end without plugging back in. And of course, how close do they actually push it? At least with Prime, it's very easy to get the exact value. You just drive and note when the engine starts. You can repeat the process easily too: "*After 5 full charge cycles, the estimated miles remaining finally display slightly more than 30. I've been getting around 35 since the beginning (no high speed driving). Looking good.*" I was happy to join into that discussion: Mine said 33.4 the other day... then I went on a 55 mph drive with the A/C cranked and 2 bikes on back. When we got to the park, there was only 0.6 miles of EV left. I plugged in to recharge while out on the trail. Upon our return, we repeated the same high-demand drive home. The next day, the EV estimate for a full charge plummeted to 26.9 miles. Eek!

8-03-2017 **Understanding Scope.** The importance is like understanding audience; there are major consequences if you misidentify. In that regard, this particular comment sure stirred trouble: "*They were actually listening to owners of the previous generation and customer research.*" Problems arise online when you engage in a discussion with someone who never participated elsewhere. If their perspective comes from only participating in that particular forum, be prepared for trouble. I've had intense arguments with some people in that regard. They either dismiss other groups entirely for some reason or aren't even aware of them. This was the problem with that daily blog for Volt. There were outspoken Prius supporters who had no clue as to the influence that group had on GM. I recognized the patterns... and documented them in great detail here. It became quite obvious GM was heavily focusing on them for input. Their feedback became the guide to gen-2 development. It doomed that design to be stuck as a niche... since those individuals clearly did not represent mainstream consumers. Ugh. That's how we end up with antagonists on the big Prius forum. They don't believe that ever happened. That means a struggle for me to convey the history and how it influenced both GM and Toyota decisions. Limited scope means limited understanding: Closely following advice from early adopters & enthusiasts is a fundamental mistake GM made twice. Sure glad Toyota didn't do that. Prime stayed true to the keep-it-affordable approach which has been an overwhelming attractive attribute of the Prius design. PIP broke that rule, but it was only a mid-cycle rollout to a very limited market... which allowed Toyota to collect a priceless assortment of real-world data to design their first wide-audience offering. They delivered that with Prime. \$27,100 is a very compelling start price for the masses, who are only now taking their first look at plug-in hybrids. Of course, with so many people complaining about the cramped seating in back, the fact that GM actually reduced headroom a little bit for gen-2 contradicts the claim of GM listening to Volt criticism.

8-03-2017 **Enthusiast Blinders.** They only see what's directly in front of them. Looking around simply doesn't happen. It's really unfortunate. You run into comments reinforcing that perspective all the time too: "*The volt improved everything that was derided on with the second generation.*" The most definitely is not true. Some things were indeed upgraded. Not everything got the priority needed though. That's a very real problem for growth. Random improvement isn't enough. Those enthusiasts are only now starting to see the consequences. They were so focused on faster & further, they had no idea other needs were also important. The obsession blinded them from seeing the bigger picture. Oh well. It's not like I didn't keep trying to convey that message. In fact, I still try: The most important aspect still falls short: PRICE. Sales growth hasn't been achieved, despite the \$7,500 subsidy. When that tax-credit expires, then what? 5,000 per month is a minimum for realistic sustainable, profitable sales. Not coming anywhere close to that by the end of year-2 for gen-2 is the reason for consideration of cancel. Using the tech in some other vehicle is viable, but Volt itself simply doesn't have a big enough audience for the production-cost and resulting price.

8-04-2017 **New Camera.** My oldest video camera overheated. I was really annoyed. Finally getting a chance to film a drive into work and just 60 seconds from finishing that commute, I hear it beep then shut off. Ugh. It had a polarized-lens glued onto its case, so that had been the ideal for capturing window footage. It was really a pain to setup and control though. The replacement for it failed the following day. That one was for other play. It too was quite a few years old. 4 minutes into that drive, I lost the Wi-Fi connection. 18 minutes into the drive, it overheated... despite having a just a frame rather than a case and no secondary component attached. Ugh, again. Since neither had stabilization, the time had come to upgrade. Yeah! I could get a much better camera. It may take awhile to get setup with it, but the wait should pay off. This one will be must more robust and will deliver higher quality. The easier use will be a plus too. I still remember all those years ago trying to document what the driver saw & experienced. That was a clumsy series of experiments. Since then, the process & equipment is much improved. Stay tuned for new videos.

8-05-2017 **Reflection.** It's truly amazing how some still don't see it: *"That the UAW was first to boast "Volt is dead" (when that decision is not final) tells me that they are exactly in the same camp as nasty fossil interests."* They are putting up their own barriers. In the meantime, their position continues to erode. Having a different and powerful source draw attention to the issue is wonderful. You wouldn't expect anyone to be so clueless. Getting lost in a hopeless cause will do that though. Perhaps they will finally notice what has happened:

Turning a blind-eye to what was happening on the other end is just as much of a problem.

Volt showed the world you could have a great performing plug-in hybrid, if you were willing to pay. That message of it being worth the premium was conveyed relentlessly. We've endured 7 years of enthusiasts reinforcing that idea, setting a precedent against affordability for mainstream consumers. Volt enthusiasts were their own worst enemy. When confronted about the vital nature of production cost, we were always assured that the vastly superior design would triumph.

The UAW is now bringing up those same concerns the so-called "*trolls*" had been saying for years. Lack of high-volume profitable sales *SOON* will be a very real problem, one that would threaten acceptance of the technology. That's why there was so much of a push to get a "*lite*" model and a SUV version built. That diversification would establish sustainability, a vital aspect of continued employment.

Enthusiasts stood firm, preventing the status quo from changing. Efforts to show progress toward mass-market acceptance were shunned. There was a constant stream of belittling comments and insults to supporters. There was a trophy-mentality that prevented being affordable from rising as a priority. The obsession with faster & further still continues to be a problem.

Take a serious look what camp those here are in.

- 8-06-2017** **From The Beginning.** I couldn't resist contributing to this: "*Actually Toyota have not made the plug-in Prius from the beginning (1997).*" It was an interesting comment posted about an article highlighting Toyota's upcoming 20th anniversary for Prius. I jumped in to point out: Actually, the original model sold in 1997 had a plug. That was discontinued, since capacity was small and price was large, that simply didn't make it worth it. When the second generation was rolled out in the United States, we discovered it had the ability to drive up to 100 km/h (that's 62.1 mph) in an electric-only mode. Catch was, battery technology of the time couldn't deliver the capacity to sustain that. Same problem. The energy-density was still too low and the cost was too high. Aftermarket providers attempted to exploit that untapped design feature anyway, but interest was very low. It wasn't until 2012 when the energy/cost ratio actually made the approach realistic, but not for the mass market yet. Early adopters were happy to purchase & drive that though... which provided Toyota with a wealth of real-world data to design a high-volume offering... which is how we got Prime. Think about what consumers are willing to pay. That's been the hold up all along, not the ability to propel the vehicle. After all, EV1 demonstrated it was possible. Battery played a major role, especially when you add in the requirement to provide heating & cooling with electricity.
- 8-06-2017** **On-Going Greenwash.** This is quite common when a new generation of Prius is rolled out. Some online source will publish some type of greenwash material, then it gets referred back to over and over and over again. The reason is simple... there's not enough real-world experiences from actual owners shared yet. That means any uninformed reporter or some writer with bias can exploit the knowledge gap. It's unfortunate. It happens every time. Thankfully, it doesn't last much beyond the first full year. It sure is annoying in the meantime though. I chimed in about the situation with: It's amazing how far an article like that can persist. As an owner who commutes with a Prime using only EV, it makes me wonder what could have happened for them to print such a blatantly incorrect claim. Saying "*it cannot function as a complete car without gasoline*" is just plain not true. That statement is so easy to disprove too. How could it continue being passed as a reputable source? 7,000 miles into ownership has convinced me that retractions of error, or at a minimum a revisit report, is good reason to make a point of drawing attention to misleading articles. In this case, that is definitely one of them. The first 25 miles of travel (at least, I'm seeing low 30's during the warm months) Prime operates as a full EV. Regardless of power demand or need to heat/cool the interior, it's entirely run using electricity. The engine does not start.

- 8-06-2017** **26,867 Sold.** That worldwide count of Prime sales for the first half of this year is bringing out a lot of hate... to an extreme. Outright lies began to emerge over the weekend. That Volt blog has become the nastiest. On it, there's a claim that Prime only delivers 11 miles of EV. The person stirring this new greenwashing effort is hoping that rating from PHV will be mistaken as what is offered now delivers. It's a common type of deception. Using outdated data gives the impression of being trustworthy. After all, you can even provide a handy link for verification. The hope is readers won't realize something newer is now available. That type of desperation is telling. Rather than the usual FUD (Fear, Uncertainty, Doubt), they take advantage of assumptions with the hope to mislead. It's easier. It tends to work too... when you know most of the posters will go along with the rouse and readers won't bother doing any research. In this case, I have that one video published to refer to. In the past, that was an effective debunking tool. Hopefully, I have a number of them available. But for now, that single bit of footage has already been viewed over 3,100 times. So, we're off to a good start. Just think what will happen when production ramp-up kicks in. That sold count will really stir the rhetoric.
- 8-07-2017** **300 Miles?** You ever wonder how this claim can actually be made: *"I'm getting up to 300mi per charge currently... and that's with occasional A/C use."* I highly doubt there will be a constructive reply to my questions. But I really want to know. Don't you? Is that actual miles or just an estimate? What type of driving would they even consider normal? For that matter, does it actually matter? Prime uses Miles/kWh to indicate efficiency. What is the value for that Bolt owner? When you think about it, there are many unknowns. Since this was a first of such claims, I started my quest for information in this simple manner: How are you measuring that? It's difficult to imagine an owner driving for several days without recharging or pushing the pack to almost empty, and we all know how estimates are often very optimistic. At what point do you plug back in?
- 8-08-2017** **Quoting Extremes.** It was an obvious attack, but not on me this time. The classic undermine-by-understate was being used against Prius: *"On the highway you will only get around 12 miles EV range in the Prime."* I was quite curious about source & intent, so I proceeded with this response: Where do people get such incorrect ideas from? That is just plain not true. If I take the back way on the commute home, it is almost exclusively highway. Starting with a climb out of the river valley at 55 mph, it changes to 65 mph, then ends with a stretch back at 55 mph. Even with the A/C on, I can just barely make it home with a little bit of electricity left. Total distance traveled on that drive home 25.4 miles. Where ever that 12 mile nonsense came from, it ends here. You've been told by an owner... who routinely sees EV distances in the low 30's ...that it was incorrect, by quite a bit.

8-08-2017 **Lost What?** The rhetoric has become weak. Antagonists really don't have any substance available anymore. This was rather lame: "*Toyota has lost a lot of EV ground since the beginning with the Prius...*" It did have me yearning for more. In their mind, what ground are they referring. We know most consumers only have a vague idea what EV availability is. Basically, they've heard about them being available and may have noticed a few on the road. That's it. Charging stations go unnoticed. Knowledge of actual operation vague, at best. And detail about an actual purchase is basically just a myth. They have no clue. Some people drive them, that's all they know. So, the idea of somehow being behind is meritless. Behind what? I was curious how the "lost" claim could be substantiated, especially with such dependence on tax-credits still. We basically haven't even passed the first milestone in the race yet. So, the idea of progress is extremely difficult to measure. Think about how many actual plug-in vehicles a dealer has in stock at any particular moment. It is such a tiny quantity, the count of zero is often quite realistic. I fired back with: What was lost? Prime delivered the industry's most efficient heat-pump, aero-improved glass, carbon-fiber components, and EV drive. Combine all that with high-volume use of the newest lithium chemistry, claims of somehow being behind don't add up.

8-08-2017 **Winter.** Things will get interesting when it arrives. Rather than cold-season rollout, we basically all started with a warm-weather perspective. Those months of low temperatures had been when the other generations of Prius were rolled out; consequently, that resulted in a bunch of reviews only reflecting Winter performance. Catch was, people didn't understand impact of heater use and engine warm-up. In many cases with Prime, there may not be engine warm-up. Trips could be entirely with electricity. That means heat for the interior will come exclusively from the battery; though, the well-informed will experience pre-conditioning from the plug. Whatever the case, it will open up new dialog. Current discussions don't even begin to address the topic. I'm attempting to change that: We've addressed speed & distance, which is important. But I don't see any comments about WINTER, which is also important. The impact cold has on efficiency is a big deal, something not to be casually overlooked. Prime offers the industry's most efficient choice, a vapor-injected heat-pump. No contest. It consumes the least amount of electricity. The next is a regular heat-pump. You'll find that in a variety of plug-in vehicles. A few still use resistance-heating, which requires the most electricity to operate. Prime also offers battery-warming, as do some other plug-in vehicles. It maintains the temperature of pack to prevent the efficiency hit caused by the cold. For lithium batteries, electrical resistance increases significantly when below freezing. Keeping it warm means more EV miles will be available.

8-09-2017 **Let Me Tell You.** There's some very real abhorrence when that phrase is uttered by the president. It's so obvious how poorly informed he is, especially when telling us that. We don't get anything of substance to follow. That is his closing remark. Ugh. It makes you wonder how clueless those supporting the performance aspect of Volt are when saying this: "*That is worth the price difference, let me tell you.*" If they gave equal weight to other aspects of appeal, then it may be worth listening for more. But when all they do is quote acceleration-rate without anything else, it's just brain-dead power trip. The obsession, known as "*trophy mentality*", has blinded enthusiasts for an entire decade. All they cared about was being "*vastly superior*". In fact, they even said that for years. Fortunately, that time has been used up and I now get to tell them: There is no audience to receive that message anymore. All the low-hanging fruit has been picked. After 7 years, it should be obvious. Time to recognize the larger market.

8-09-2017 **Charge-Mode Video, part 1.** I finally got a chance to do a little bit of filming. It was on the return portion of a biking trip. There was a stretch of highway I could take advantage of. Unfortunately, all I had to work with was 1 camera. But it was still an opportunity to exploit. After all, the busy Summer schedule doesn't allow me to play that often. There would be construction to deal with and the warmer weather meant depending upon the A/C. So, my choice to capture Charge-Mode would mean a longer drive than my first experiment back in the Spring. It's a topic that needs much discussion, since so little is understood about it. This is definitely a new topic when it comes to plug-in hybrids. GM's offering isn't efficient enough to make the option worthwhile. Toyota's is though. So, there's a very real possibility of showing advantage... if we can clearly convey the circumstances. This is my first attempt:

Wisely used, the choice to consume EV miles generated by the gas-engine rather than from plugging in can result in an efficiency gain. Poorly used, the resulting MPG will be lower.

In most cases, you are better off just using plug-supplied electricity. However, I have discovered on long highway trips with my Prius Prime and no place to plug in, it can be handy to take advantage of charge-mode.

This video footage is a capture of the complete charging cycle, presented at 15 times normal speed. Pop-Up of the DRCC (Dynamic Radar Cruise Control) is usually a pleasant visual experience; the car automatically slows down upon detecting a slower vehicle ahead of it. At this speed, the display can be a bit disruption. So, pause the video from at times to see detail.

Overall efficiency, including acceleration onto the highway and deceleration to exit afterward, was 40 MPG. That's incredible considering the A/C was at the coldest setting (that's "LO") with the blower on medium the entire time. This caused the recharge to take 10 additional minutes, but 50 minutes is much faster than when plugging in anyway.

Watch the video careful. Keep in mind that brief recharging is likely what you'll end up using, not the entire 80%. When you do, choose wisely... [Prius Prime: Charge-Mode](#)

8-10-2017 Charge-Mode Video, part 2. There was follow-up to what I originally posted. This was in the form of a comment reply to myself. I wanted it to stand out and to give people the opportunity to respond directly to it, should they find that point compelling. My point was to stress that this wasn't a blanket endorsement by any means. Only certain circumstances would yield a benefit. Others could result in an efficiency penalty. Knowing the specifics is how to stir discussion and begin the understanding. It's an on-going process. You pick up more as each example is shared and analyzed. Having provided detail is a good first step. Hopefully, people will take the time to watch the video entirely and take time to think about the detail in comments posted. Here's more to ponder:

Additionally, do not overlook this important comment, which influences consideration of use: NO PLACE TO PLUG IN

When you are out on vacation, there can indeed be a benefit from having some EV available. Rather than going through the warm-up cycle, you can avoid HV entirely. Under some circumstances, that will result in higher overall efficiency. For example, going out in the morning for breakfast. The engine is cold and you only need it for a brief time. EV could easily cover that real-world circumstance.

Also, there was the concluding comment about briefly recharging: NOT THE ENTIRE 80%

It is unnecessary to recharge as much as possible. Just a little will do. Choose wisely.

8-10-2017 Production & Sales Worldwide. Today's discussion topic on the daily blog was a question asking if Prime would outsell Volt this year. I quickly got labeled as a troll for posting this: *"26,867 Prime have been sold worldwide between January & June of 2017. That puts Toyota on target with a production build capacity approaching 60,000 for the year."* Taking into consideration any type of distribution outside of this market was looked upon as an effort to disrupt the status quo, therefore inviting attack. I see limitation of scope as a clear effort to undermine. We've hear a lot about "*narratives*" lately with political issues. They attempt to paint a picture based upon selective data, rather than taking all information into consideration. This is very much the same thing. For Toyota to strive to reach a wide variety of markets all within the first year requires quite a bit of work. Actually delivering a production quantity greatly exceeding that of the supposed competition is worthy of attention, not omission or dismissal. This is quite hypocritical too. Volt enthusiasts demanded exactly that when gen-1 was first rolled out. Refusing to accept the same for Prime is just plain wrong. There's no way to even spin it as a double-standard either. Production costs are driven down by volume. Where those sales take place doesn't matter. The economy-of-scale benefit happens regardless of location. Worldwide is great for shifting the paradigm too. Stir as much interest as quickly as possible.

8-11-2017 **Nothing Offered.** Things are getting ugly as the market takes a step forward. Not all will advance. Some will even drop out of the race. New entries will join. It's very much a time of change. A few don't want to recognize it though: *"If there are more/better plug-in SUV, CUV, and Trucks, vs. just plain hybrid versions, then they will quickly surpass hybrids."* That look toward the hypothetical is a sign of trouble. We should be refining design at this point, not just considering the possibility of offering something. Ugh. Needless to say, that quote came from a die-hard GM defender, who refuses to listen to any type of attempt to be constructive... hence reverting back to "IF" considerations. Dealing with fallout is simply too much for him to handle... which is how you step forward... acknowledging an issue, then trying a different approach. Oh well. It's not like I don't keep trying to provide insight: Cost is the issue. Cost has always been the issue. That's why GM abandoned hybrid SUV production. There was simply no way to deliver something with a profit even remotely competitive against traditional counterparts. Remember Two-Mode? The plug-in prototype was grabbing media attention before reveal of the Volt concept. Difference was that SUV with a plug would retain parallel hybrid abilities and Volt would be a series hybrid. None of that worked out though. Cost continued to be the reason why. It was simply too expensive... and still is. Upcoming phaseout of tax-credits will make the situation worse. Needed growth has not happened. Loss of the \$7,500 subsidy will make competing with those traditional counterparts much more difficult. Of course, the reality that GM doesn't offer any type of electricity-focused SUV pretty much makes it all a moot point.

8-11-2017 **Know Your Audience.** Nothing has emerged from the ashes. We've watched the same old rhetoric being given another chance. There's desperate hope that something will be different this time, that failure in the past won't repeat. No change of audience is a fatal oversight. Enthusiasts attempting to appeal to mainstream buyers didn't work in the past. Why would it work now? That mass market of ordinary car buyers simply are not interested in what excites an enthusiast. I especially liked this comment: *"This, coming from you, on a GM-Volt website?"* That perspective comes about when you are trapped so deep into a group-think issue that you've lost touch with expectations. That's usually referred to as not seeing the forest. Focus is so tight on a single tree, all the others are forgotten. It's a fatal mistake. Crucial clues go unnoticed. All you can do is wonder. Comment outright dismissed on the sole basis of being an outsider is lost opportunity. It's easy to confirm too. If nothing constructive is given in return, they are ignoring what isn't liked. Bad news is a challenge to accept. Refusing to accept is harmful. Fallout will come. There are consequences from not dealing with a problem. It won't just go away on its own. Ugh. Oh well. It's not like I don't keep trying to point out that audience still unknown to them: Being one of the few who recognized early on that Volt wasn't targeting GM's own shoppers and getting pushback for raising attention why, I wonder what that comment is intended to mean. Bolt is in a similar situation. As nice as it may be, those looking to replace their old GM vehicle with a new one simply won't be interested and there is little potential for profitable high-volume. The popularity of Equinox should make that obvious. Think about why loyal GM customers are paying a premium so they can guzzle cheap gas. What draws them to it? Notice how well even Trax is selling. Why is that?

8-13-2017 **Electric Bill.** I'm still waiting for it. Turns out, the prior month isn't represented in the bill I just got. Tallied electricity consumption is for the month before that. I didn't realize there was a lag. I never occurred to me to look that close at the statement. I simply noted which day meter values would be read. For this new setup with the 2 sub-meters, I was expected 7 values to be noted. There's the 1 for regular electricity consumption throughout the house itself, then there's the breakdown of 3 billing categories used by the chargers for the 2 Prime. From the middle of the day is a cost of 11.68 to 13.08 cents per kWh. That variance is a warm versus cold season pricing difference. It spans from 8 AM to 4 PM. The killer cost comes from peak demand. During that 4 PM to 9 PM span, the cost per kWh is 41.444 cents. That much higher pricing is a deterrent to help minimize usage during that time. The late-night hours are the best for recharging. It gives your battery-pack a chance to cold soak, which is important for longevity. That wait is rewarded with a cost of 6.74 per kWh. It goes from 9 PM to 8 AM and also covers the entire weekend (all 48 hours). This isn't what the typical household will encounter for billing. My association is one of the leaders in the market. They take pride in not requiring customers to install entirely separate systems for charging... which can provide even better discounts, but includes a monthly fee. For me, it's just the one-time setup, then a cost-reduction of roughly half price. The meters are really nice too. They just cycle through each billing category, displaying the kWh tally. On the next electric bill, it should be nicely broken down to show the charges for charging from each. I can't wait! How often do you hear someone make a comment like that about getting a bill in the mail?

8-15-2017 **What Next?** It's like watching an accident in the making. You know the outcome will be a mess, even if there's a last minute course change: *"Everyone is actively killing off diesel and GM is making new ones. Why?"* I knew this would stir the pot. But it didn't matter. The pot was about to boil over anyway: GM has an extensive history of trying out a new technology, then abandoning it later... EV1, BAS, and Two-Mode. This is why the *"too little, too slowly"* concern was expressed over and over again. There was good reason to worry that Voltec would not be expanded upon... just like those other abandonments. Much emotion was expressed in regard to that concern, with personal attacks on the messenger and reassurances this very thing would never happen. Enthusiasts here could not see beyond the impressive engineering. They'd remind me over and over again how well Volt performed, every time business issues were brought up. Now those enthusiasts are seeing the same thing and questions of dismay emerge. Rather than a step forward with electrification, which reduces oil-dependency as well as emissions, we see a step backward to fill in the gap other automakers left with their step forward. Instead of an Equinox using Voltec, customers instead get the choice of diesel. So, what happens next?

- 8-15-2017** **Changing Stories.** A few keep trying: *"Those technologies mentioned were not abandoned, they were improved into the Volt/Bolt tech we have today."* One attempt too many. He backed himself up to a cliff and actually stepped off. That's far worse than being cornered. There's nothing to do when you get caught spinning a situation and end up contradicting yourself. Over and over and over again, I pointed out GM's past motor & battery rollouts. They dismissed them when acknowledgement would reveal a mistake being repeated. But when the mistake is the rollout itself, there's a very real problem. You cannot ignore it. So, they try to embrace the very thing they had shunned. You can't do that. The internet makes it very easy to prove you are being hypocritical. In this particular case though, it isn't just check, it's check-mate. Neither story works. Both cast GM in a bad light. Whether endeavors prior to Volt count or not, the fact that Volt itself is 7 years old means time is up. This isn't a final. It's graduation. All the grades for each class have been tally. GPA shows the difference between "A" students and those who will struggle to get by. I found it redeeming for it to now be over. No more having to deal with a bully. What was learned, and what was not, will be obvious to others. I brought not having to deal with changing stories anymore this way: All those years of supporting the claim that Voltec was new and we needed to be patient and wait... Now what I've been saying all along is the story? In that case, why is it taking so long? What is GM waiting for? Too little, too slowly...
- 8-16-2017** **Characterization.** The outcome of getting caught having made a mistake or overlooked something vital is to spin the situation. Done often enough, the spin itself becomes spin: *"Characterization as abandonment instead of improvement is yet another cheap troll shot."* The catch this time though was that every noticed what happened. Spin only works if someone goes along with it. Being totally alone means defeat. It's over. I get to sum up the situation: I get the *"broken record"* characterization for staying true to goals. We have now heard both that experience with motor & battery prior to Volt apply to the development effort for Voltec and do not. What does that make the contradictory timeline you posted? Realistically, it doesn't matter anymore. As of this discussion topic, the timeline has expired anyway. Year-2 of Gen-2 is when the critical decisions get made. 7 years after rollout, GM has chosen to promote diesel instead. Cruze diesel will be joined by Equinox diesel. Eventually, another technology that takes advantage of GM's now even more expansive experience with motor & battery will be rolled out and characterized as new. The reason why is simple... not to be associated with failures of the past. Odds are, it will be successful... but will resemble what's being offered by other automakers... due to goals. They never change. Replacing traditional vehicles with clean & efficient choices is essential for the business.

- 8-16-2017** **Choice.** The push now is for enthusiasts to make a choice. Since the original rollout of Volt went horribly wrong, they have refused to take a stance. In fact, that's what makes them an "*enthusiast*" rather than a "*supporter*". That decision in the past to just observe and forgive GM for mistakes is no longer acceptable. They have exhausted that position, which as proven ineffective. That's why claims like this are no longer going to be tolerated: "*I don't see Volt being summarily discontinued because of an Equinox diesel offering.*" The perspective spin and lack of any type of commitment on their parts is very much a problem. They have become anti-plug by the simple act of holding it back. Impeding advancement with a "*good enough, let's wait & see*" attitude is terrible. We waited for gen-2. Now what are we waiting for? Asking questions like this is well timed. With so much polarization of sides in the political world, you can no longer sit on the sidelines. You must make a choice. Put up or shut up. I stated the situation this way: Too little, too slowly doesn't mean discontinue. It means not enough. Remaining a niche offering fails at the goal of replacing traditional vehicles. There's no way for you to spin sales count falling well short of mainstream competition upon start of the 8th year, especially with so much of an industry endorsement for electrification now. The reality that GM is dragging its feet... which ironically, is exactly what Toyota was said to have done... is a problem you have to face. The choice is to excuse & enable or push for a next step. Which is it? Choose.
- 8-16-2017** **So Vague.** What do you do with a Prime supporter that is a very frequent forum poster, but had higher expectations and won't actually purchase one as a result? He's always so vague and has the one-size-fits-all perspective. Today, his comment was: "*Toyota is being forced into plug-ins.*" I found that particularly annoying due to the complete absence of detail. What does that actually mean? On the surface, it sounds like it has merit. But that's the basis of rhetoric. When you take a close look, there isn't anything there to support the claim. That is the case with this too. No substance is frustrating. So, I shot back with: That is so vague, it could mean anything. Try again with some detail, any sort of specific will do... like time, volume, cost, capacity... Then, think about how those comments apply to all legacy automakers. I see the continued push from Toyota in the form of electrification, not EV range as most. What's the point if you don't have an efficient & affordable collection of components. It should be obvious with Prime's design under the hood. The ramp-up of lithium production for both Prius & Prime/PHV is not so obvious, be just as vital. How will expansion to other vehicles, Camry & RAV4, happen without the production & reputation of the needed components well established first?
- 8-17-2017** **Recall Hypocrisy.** If anything whatsoever was updated for Prius post-purchase, for any reason at all, there was a huge outcry... There was an intense effort to create a stigma for "*recall*" work. Treating it as an upgrade was unheard of. The vehicle was supposed to be perfect at the point of sale. Improvement was looked upon as apologist spin. What a pain, especially now with such hypocrisy playing out with gen-2 Volt recalls. There have been 3 recently. Recall #16185 was "*Replace fuse and reprogram Hybrid Powertrain Control Module*". Recall #17058 was "*Reprogram Drive Motor Power Inverter Module*". Recall #17197 was "*Inspect Evaporative Emission Pipe. Installed Protector*". Remember the claims we were all going to die from Prius? Ugh. It's really unfortunate how they change their tune when the shoe is on the other foot.

- 8-18-2017** **Too Late?** The attacks on gen-2 Leaf coming from GM supporters are weak, at best. Though, I still find them annoying: "40 kWh is too little, too late." It's a desperate effort to portray GM as somehow being so far ahead of the other automakers, that it is pointless to even try to deliver anything less. In reality, that's a desperate attempt to conceal cost issues. There is a very real problem coming when the federal subsidies run out. Necessary growth hasn't happened. The loss of that help and increased choices for consumers will make that even more difficult. That know that though. You know that too, from reading this blogs. So, there's no need to dwell. My responses was very simple: Too late for what? The battle for sales without tax-credit help has yet to begin.
- 8-18-2017** **Sudden Power.** There's a growing concern from newbies about there being enough power in EV mode for Prime to suddenly accelerate. This is fallout from the greenwashing effort. Those hoping to undermine are working hard to spread FUD. That stands for Fear, Uncertainty, Doubt. The hope of that assurances from owners won't be satisfy concern. From owners, the message was to simply switch to EV-Auto if there was any discomfort about being able to accelerate fast enough. After all, that is the point of offering it. At times of high-demand, why use up precious electricity when you've got a perfectly good gas-engine available? That doubt part comes from conveying a belief that the gas-engine not being warmed up yet somehow won't be able to fulfill the request for sudden power. But then, you have stuff like this to respond to: *"I honestly don't understand ev-auto. How is it good for an engine that has been cold for hours to be fired up all of a sudden and running at full power?"* Fortunately, PHV owners like myself already have years of experience to share... to snuff out any reason for concern: In this case, it was a simple reply: It's basically like a gen-1 Prius plug-in mode, which never was a problem for me starting cold on a ramp.
- 8-19-2017** **Affordable Choices.** There has been an obvious pattern emerge recently as the reveal of gen-2 Leaf approaches, making it an clear point of worry: MSRP is being avoided & downplayed. \$33,220 for the LT (base) model Volt is simply too expensive. \$26,000 is the MSRP for the LT (base) model of Malibu and the Premier (fully loaded) model of Cruze is just \$24,820. GM has a very real problem already. \$36,620 for a LT (base) Bolt makes it even worse. What will compel GM's own loyal customers to replace their aging GM vehicle with one offering a plug? That's a huge premium to pay, especially with gas so cheap. Knowing that Prime has a base MSRP of \$27,100 and gen-2 Leaf is expected to be priced \$29,990 for the base, there's no point trying to spin them as competitors. Hyundai is expected to undercut GM pricing too. They are all legacy automakers striving to deliver affordable choices for showroom shoppers. Why is there still no "lite" model of Volt offered? Will there be one for Bolt? What about Voltec rollout to Trax, the platform GM customers prefer... a SUV? We don't need expensive choices. We need models actually capable of high-volume profitable sales able to sustain GM's own business.

8-20-2017 **Handling Risk.** It's rather remarkable how easily the most basic of concepts get overlooked. But then again, that's only for those who have studied marketing, economics, or accounting. Without that background, those approaches probably aren't obvious. You learn right away that the product alone is far from enough to being successful. Business is a complex equation of variables, many of which are not even tangible. How much is customer satisfaction worth? If it results in a recommendation to someone else, who ends up making the purchase, that is worth quite a bit. There's no way to quantify it though. That's a very big problem, especially when quantities aren't available either. Nonetheless, you have to start somewhere. Toyota's approach is to focus on this intangibles. They've learned that value from that is substantial for reducing risk. Great engineering can become a major financial loss if consumer confidence is uncertain. That's why I have always been in favor of the way they've been handling the technology penetration. Each step has been small. Impact has been enormous though, since it moved the base forward. GM's approach with their attempt to take one giant step clearly hasn't worked. We're not seeing a market shift from GM like we are with Toyota. Notice how popular the RAV4 hybrid has been? As insignificant that may seem, it is a genuine step away from traditional vehicles. Those buyers are showing confidence in what a battery-pack can deliver. That's absolutely vital for true progress to take place. I conveyed that message this way today: Establishing a plug-in reputation with Prime in the meantime makes sense. They'll have all of the EV tech itself already proven in the minds of dealers & consumers, making the high-volume investment in solid-state batteries a reduced risk for the business. Basically, it's a chicken or egg situation. We know how under-developed the infrastructure is for plugging in the still. Why not get that electric-vehicle technology well established in the meantime?

8-21-2017 **Back Route Home - Video.** 25.4 miles driven with 2.1 miles remaining, all using only electricity. Taking this back route home on my commute was a demonstration of what the system has to offer. In this particular case, I had to deal with construction detour backup in the cities and climbing out of the steep river valley once on the highway. The trip from there to home was almost exclusively at fast speeds, which uses up EV miles faster. So, seeing real-world EV distance exceed that of the 25-mile EPA rating is good confirmation of Prime delivering on expectations. Watch the drive for yourself... [Prius Prime - Back Route Home](#)

8-22-2017 **Quantitative Value.** The fundamental flaw EV advocates makes when trying to promoting plugging in is not having anything substantial to present. They just generically mention benefits, like no oil changes. References that vague have little impact. People just plain don't care. That's because mainstream shoppers don't care in the first place. Not wanting to truly know how much their guzzler actually guzzles is key to its appeal. Driving a large vehicle that roars when you stomp on the pedal is what's important. How much it costs to purchase or operate is pushed aside and never really directly addressed. That's why efforts now are somewhat futile. For that matter, it is why Volt failed so miserably with attempts to appeal to ordinary consumers... who don't pay attention to detail anyway. blah blah blah, sign here. How does a plug-in vehicle compete with that simple of a guzzler purchase? Basically, they don't. You have to empower buyers. Sneak in learning moments here and there. Eventually, they put the puzzle together on their own. I'm going to do that here with the following. It will likely be meaningless the first time you encounter numbers like this, but it's a start. That's why Prime is so important. It lays down the foundation, building an understanding that will very beneficial years later when looking to upgrade. It's really too bad gen-1 Volt owners never bothered to educate. They figured the technology would somehow sell itself. Thank goodness that naive attitude is quickly becoming a thing of the past. For example, my real-world numbers to share:

Rapid recharge is quite handy. I tend to avoid the after dinner recharging though, since we got our outlets wired into sub-meters for Time-Of-Use discounts:

11.68 - 13.08 cents / kWh = 8 AM - 4 PM

41.444 cents / kWh = 4 PM - 9 PM

6.74 cents / kWh = 9 PM - 8 AM

By the way, our electricity association provided \$500 per charger rebate. That incentive worked out really nice.

8-23-2017 **Quick Impressions.** That is the stage we are at now. Plug-In vehicles are finally getting attention... but it is brief. People recognize the technology and the benefit. That's all though. Nothing else. You simply get acknowledgement upon mention. That's definitely progress, not at all what enthusiasts had hoped for though. Remember where Volt was supposed to be at this point? Success was expected to be so high, demand would make the choice of EV unnecessary. There wasn't plans for Bolt. In fact, that was the very thing GM had campaigned so intensely against. Technology implemented in Volt was to be the ultimate "*range anxiety*" solution. That would make hopes of the next-gen Leaf unnecessary. Instead, there is now Tesla dominating one end and Prime striving for the other. Nissan would obviously like to shake up that new outlook. Hyundai obviously would too. This is why an overly simplistic look at the entire plug-in market is taken now. That's ok though. Quick impressions are fine while initial rollouts & inventory build-up take place.

- 8-24-2017** **Eco Experience.** Just like with the past few years, the Minnesota State Fair will have a plug-in vehicle display in the Eco Experience building. Today, it begins. Tomorrow, I get to see it. Our owner group got the training recently about how to greet & inform those who stop by to check it out. There will be a Bolt and a Pacifica, along with a charging-station. Unfortunately, I cannot participate in the volunteering this year due to family obligation. But at least I'll get to see it. On this upcoming weekend, there will be the usual parade which a few of the vehicle join in with. That obviously would have been a lot of fun... especially with the standout color of my Prime. Oh well, its not like there won't be other events. In fact, there will be an Energy Fair just next week. Anywho, there is a good way to draw in environmentally conscious consumers for a closer look. They visit that particular building to learn more about green options. So, our group fits in really well.
- 8-25-2017** **Plug-In Promotion.** My day at the fair allowed me to pay a visit to the Eco Experience. Sadly, it was a bit disappointing. Unlike last year, this display wasn't in the middle. That made it harder to notice with some of the other larger exhibits also there. The small back seat of the Bolt was a surprise too. It was obviously bigger than Volt, which is why I never took a really close look. Most of the time, I'm too busy answering questions for others. But at this particular time, there was opportunity to explore detail. It wasn't as spacious as hoped. Why? Was it that important to squeeze out every last mile, rather than offering more room? Knowing that Prime is larger, you'd think GM would try to compete better with Toyota. On the other hand, Chrysler did an excellent job with Pacific. That plug-in hybrid minivan appears to offer quite a bit of potential. It is an oddity though. Despite minivans being a Chrysler specialty, there simply isn't much of a market. The potential consumer-base to appeal too is quite small. Much like GM, it will be quite a gamble not if they don't diversify right away. Whatever the case, the display today is good plug-in promotion. You have to reach out to ordinary consumers somehow. Groups like us can really help that process along.
- 8-26-2017** **Too Bad.** Complaining about price. I never ends. It shouldn't either. The past 20 years of hybrid sales clearly reveal that to be the highest purchase priority. The reason is simple too. That's the way people shop. As a result, that's the way automakers design their vehicles. They are building & selling to make a profit. The motivation for offering something green is to remain competitive. In this case, it is both competing with themselves, as well as with other automakers. That's why I get terse when comments like this are made: "*We need to compare average sale price, minus federal tax credit.*" It's a clear disregard for the bigger picture. Focus solely on what's happening with the early stages of rollout is a terrible approach; yet, that is the underlying theme in virtually everything I deal with online outside of the big Prius forum. And even there, a few just plain do not want to look at the automaker's overall production. It's really unfortunate. Only considering the low-hanging fruit, rather than what comes next, is a very real problem. Mainstream acceptance is far more difficult than the antagonists want to accept... or even understand. To them, I say too bad. Today, it was stated this way: Short-Sighted perspective is also known as cherry-picking. Business sustainability is essential to plug-in survival, which requires a competitive price. A dependency on subsidies to lower the price means little to no growth... which is exactly what has happened. You can't just choose to disregard a key reason why traditional vehicles are selling so much better. Too bad if you are tired of hearing about it.

- 8-26-2017 Gas Coupons.** The grocery store with free charging-stations is just a few blocks down the road from my house; so close, I can see it from my driveway. That means, even with a very short stop, I can recharge the battery with more electricity than what's needed to drive home. That helps extend the already mostly electric driving even further. It's quite handy to stop there on the commute home to buy something fresh for dinner. That type of only-buy-what-you-need approach works really well. There's pretty much no waste and you get exactly what you want. Anywho, some purchases result in a discount for gas. A substantial per-gallon value is accumulated over time. Normally, that would result in a great savings at the pump. Unfortunately, it doesn't work that way when you have a Prius Prime. Each of those discounts only have a 30-day lifespan. You only have a rolling-month total available. Going much longer than that between fill-ups means watching some expire. My best tank so far was 2,074 miles. Oh well. You win some. You lose some.
- 8-27-2017 Commute To Work - Video.** This newest capture of one of my drives is representative of a typical Summer commute for me in the Prime, including the road-construction slowdown. I arrived at the ramp where I park for work with 50% of the EV capacity still available. That shows overall electric driving availability is well above the 25-mile rating estimate. And since I recharge there, taking advantage of the 85 kWh solar-array, the drive home is exclusively with just electricity too. Watch the video closely for detail. Notice the hills and variety of speeds. Also, keep in mind that the maximum efficiency reported is 199.9 MPG. Beyond that, there really isn't much of a point. Diminishing returns makes the value less meaningful. Here it is... [Prius Prime - Commute To Work](#)
- 8-27-2017 Ford's Response.** Plug-in & Hybrid SUV options were only a matter of time, despite the cancellation back in 2012. We still have to wait 2 years. It is progress though. In fact, this is exactly what we were hoping for from GM... simply stating the intent to move forward. The hopeless rut Volt is stuck in is wasting time. There's nothing else to prove at this point; the technology works and needs to be refined to become affordable. With Toyota & Hyundai already at that stage, dragging on the mismatch with Volt makes no sense. GM customers want SUV choices, not a compact car. Not offering one with a plug, or even just a hybrid, goes beyond missed opportunity. It's a shrug of unwillingness. Thank goodness Ford is finally moving on. Perhaps when Mitsubishi and Kia hybrids with plugs start to make appearances on roads here, then things could change with the incredibly stubborn GM executives. In the meantime, how will Ford's announcement of intent today impact the Volt enthusiasts who have been fighting so hard to retain the status quo? This represents quite a change.

- 8-28-2017** **Left Behind.** Now that tax-credit expiration is rapidly approaching, the inevitable spin to defend poor choices has emerged: *"They get to cherry pick all the best technology, designs and efforts from Tesla/GM/Nissan and build essentially a Gen II EV with little risk and have most of their tax credits left in place."* Spinning that situation of being "left behind" overlooks the advantages we've been told about for years. Scrambling to catch up doesn't actually work if the market is still just a niche. In other words, high-volume production is not a factor of generation as implied. Telling them that is pointless though. So many have that mentality of more being better, it's obvious they don't have an understanding of economics. For the business to thrive, there must be some on-going profit return. That comes from those vehicles they couldn't care less about. The ordinary "blah" vehicles they shun are absolutely essential. It's like never eating vegetables. You may enjoy the meal, but the behavior will lead to wellness problems. The focus entirely on the exciting sales, not realizing how important the other sales actually are. That's why that "left behind" perspective is such a problem; yet, they don't see it. And with phaseout being triggered within the next year, losing the help subsidy money provided will really hurt. Ironically, they'll find out at the last minute their own choice was cherry picked. Like a well-balanced meal, a well-balance vehicle will have a become outcome.
- 8-28-2017** **Bugs & Automatic-Wipers.** We made an interesting discovery today. When doing long-distance travel during the buggy season, make sure to shut off the automatic-wiper feature. That lesson was learned the hard way today. As the cruise down the highway progressed, the impact splatters from each bug grew in count. Not a big deal if that is only what happens. Unfortunately, it wasn't. A squished bug triggered the wipers. That resulted in a horrible series of smudges across the windshield. What a mess! You cannot conveniently clean that off either. Spray from the wipers doesn't work well at highway speeds. You really don't have much choice but to stop at some point. Looking around smears can get annoying after awhile. Fortunately, we had been planning to anyway. So, a quick wiping with the car no longer in motion cleaned most of it off. I got the rest with a squeegee.
- 8-29-2017** **Education & Support.** I was intrigued where this claim would take the discussion: *"Can't rely on tax credits forever. Those who have invested from the beginning will reap the benefits of being ahead with lower costs for electrification/batteries/etc."* Knowing that the price of Volt won't magically fall when phaseout is triggered, what will be relied on instead. If GM was holding out and actual production cost is much lower, they'd need to ramp up sales considerably to make a price cut matter. No growth defeats the entire purpose. Something must be done quickly. For Toyota, the situation is quite different. That's why they are focusing on education & support instead. With far more time & credits still available, growth can be given much more attention without any consequence. I diverted attention back to GM though. Those enthusiasts really don't care anyway. But at least having focus on their own favor is better for continued discussion: Depends upon what those investments contributed to. We certainly haven't seen dealer-support resulting from GM's effort with Volt. After 7 years of sales and 2 generations, they continue to exhibit disinterest. In other words, investment should not be only in the design & production of physical components. The value of education & support has been a serious overlook.

- 8-29-2017** **Disappointment.** It means a lot when someone else makes this comment in response to your post about having a reason for concern: "*I'm disappointed that GM hasn't brought out a whole bunch of Voltec based cars, SUVs and truck Plugins.*" I was assured by those providing negative votes we'd have many to choose from by now, that there was no reason for concern. They were wrong, very wrong. All those assurances that "*too little, too slowly*" wasn't in any way applicable to the situation. GM was doing just fine. Despite literally no sales growth as a result of the advancement of time, greater market acceptance, and the generational upgrade, all was just fine. 7 years later, there's no reason whatsoever left. No excuse. No circumstance. It's over. Opportunity was missed. How that transformed from hostile denial to genuine disappoint is a bit of a mystery for those not looking forward. For those well aware of what will happen next week... it's obvious.
- 8-29-2017** **Avoidance.** I like when they invite me to post about what's coming: "*Where is Toyota's Prius Prime additional models or EV?*" Despite the obvious change of topic, it works out nice: Divert attention away from GM by inviting me to discuss Toyota. That's rather desperate. But since you did that... My post was about the value of education & support being a serious overlook. Toyota is directly addressing that by establishing a variety of Prime choices. They started with Prius to demonstrate the technology itself, while at the same time rolling out RAV4 hybrid, an all new Camry hybrid, and C-HR hybrid... each of which could offer a plug-in model. Toyota is also investing in the next-generation battery (solid-state lithium). They are laying the foundation for an easier transition for both dealer & consumer to embrace the plug-in choices. That variety of hatchback, sedan, SUV and CUV covers each of the major passenger (non-pickup) categories. Each has affordability as a primary goal. GM is avoiding SUV entirely, despite it being their primary sales product. Your list avoids that too.
- 8-29-2017** **Commute To Home - Video.** I filmed my drive home too. It was a fairly typical Summer commute. Bridge construction was finally completed, but a stoplight wasn't working. So, I ended up dealing with some stop & slow traffic anyway. Oh well. Prius thrives with that. Prime abilities kick in when I hit the highway. Merging onto the highway, then climbing out of the river valley is effortless. There's plenty of electric-only power for that. It was a beautiful sunny day. Traffic was normal. The number of lights that were red was too. That 18.4 miles of driving used 61% of the battery-capacity available. That left me with an estimated 13.4 miles of EV still available. I've seen values like that all throughout the warm season. Choosing to not recharge at work, I witnessed a total of 33.6 miles driving that same route before the engine started. So, there's no question whatsoever about the 25-mile rating. That is effortlessly exceeded with real-world driving. It's too bad our official testing process can't portray a more accurate expectation. Oh well. It doesn't really matter. The resulting efficiency average just says 199.9 MPG anyway. That maximum is all you get. It's really all you need too. At that point, gas consumption has been so significantly reduced, you can say "mission accomplished". Here's a link to that video... [Prius Prime - Commute To Home](#)

- 8-30-2017 Leadership.** Calling them clueless doesn't seem accurate, since they dismiss what I say. It's more a matter of denial: *"GM has more plug-in models than any other manufacturer. Why would we expect GM to follow Toyota when GM is leading?"* That's like judging a book by its cover. The thing may look appealing, but the actual substance is lacking... or absent. In this circumstance, we see several automakers moving to offer SUV models electrified in some fashion. With GM, there's nothing at all. Enthusiasts pretend all is well though. No big deal. That's amazing. To leave such a huge problem unaddressed. Ugh. Oh well. All you can do is continue pointing out the problem: Dodging the issue of SUV doesn't make it go away. Equinox is a major profit-making vehicle for GM. We were shown a plug-in prototype SUV that was to be delivered in 2009. Instead of finally delivering, GM is rolling out diesel instead. Those here fiercely insisted that Voltec would be diversified much faster than HSD. That didn't happen. The start of year-3 for gen-2 shows disinterest, where focus is shifting from PHEV to BEV with a heavy dependence on tax-credits still. Remember, each automaker has their own distinct audience. For GM, they are primarily SUV buyers. Neither Bolt nor Volt targets them. Leadership comes from getting ordinary people to change. What is GM doing that mainstream consumers... their own showroom shoppers, not early adopters ...have responded to?
- 8-30-2017 The Real Problem.** This was an noteworthy comment: *"When the big 3 get lazy on product development they tend to lose market share to the import brands."* That isn't the actual situation playing out; nonetheless, it is a reasonable theory. I would give GM credit for pushing plug-in technology. It's not in the direction of need, but following a want is still a type of advancement. With climate-change and oil-dependency such monumental problems, not addressing them directly is a very real problem. They haven't been. High profit-margins from large vehicles has been too great of a temptation to resist. People here crave size & power. It's really unfortunate marketing has exploited that. Clean & Efficient becomes a challenging sell as a result. The fact that those clean & efficient vehicles return a much small profit in return makes them unappealing to build & sell. What incentive is there for dealers to carry them? Sales of dirty & wasteful vehicles are very easy. I replied to that comment with: It's a matter of disinterest. GM doesn't want to undermine its own product. SUV sales are highly profitable as guzzlers. Adding a plug brings that cash-view to an abrupt end.
- 8-31-2017 Obsolete.** That word is carelessly used. People don't really know what it means. The reference is actually an indication of trouble. From today: *"GM will be obsolete if they don't follow the trends which includes EVs and PHEVs. So will Toyota."* In the software industry, a more concise term is deprecated. You know it will be discontinued at some point, but use in the meantime is acceptable if you are making accommodation for replacement in the meantime. That end of support is clear though. We don't have that in this case. It's all quite muddled for the automotive industry. I jumped into that discussion: Obsolete already applies. That's why all automakers are already shifting. How is what's at issue. Toyota is rolling out plug-ready hybrids. 52 MPG rated Camry ends all those pointless arguments about Prius size, power, and looks. RAV4 has been selling really well as a hybrid. The expectation is for GM to do something like that too, rather than pursue diesel. It's as if Malibu hybrid doesn't exist.

- 9-01-2017** **Look Forward.** The feeling of contradiction and double-standards is building. The next-generation of Leaf will push the market out of the status quo. It was stuck in a rut. Sales were flat for Volt, the vehicle which was supposed to lead the way... rather than struggle to survive. I had to endure quite a bit of hate for having to deal with the backlash of pointing out facts and providing clarifications for the obvious efforts to undermine. Prius plug-in had been made the target, since it aimed squarely at the audience GM was never able to appeal to... and consequently gave up trying. That sense of abandonment has made me the scapegoat for their anger & disappointment. Look forward is the only suggestion I have available, with a reminder of goals. Those enthusiasts get far too hung up on specific configurations and let pride prevent them from taking the next step. They don't want to acknowledge what went wrong and simply move on. Dwelling on failure can be a serious setback, rather than the advancement advantage it can be. You learn from mistakes. What is that so difficult to accept? Hmm. Oh well. I'm asking what's next with the hope someone will look forward: Anyone have any idea what GM's strategy is for Volt will be? Knowing the tax-credit phaseout will be triggered mid-2018, the struggling sales will become even more difficult. Think of the variety of new plug offerings other automakers will be promoting. Volt's opportunity to stand alone is gone. A clear message to consumers is essential, something blatantly absent so far. Don't forget, the purpose of Volt was to alleviate "*range anxiety*" concerns. Bolt very effectively does the same thing.
- 9-01-2017** **Misinformation.** The intentional spreading of it is what kept me coming back to the daily blog for Volt. They'd just spread lies. A few would post the misinformation and the rest would be supportive, enabling the greenwash material to be validated through acceptance. When you're the only one pointing out the error, it makes you look like a troublemaker... countering the information everyone else has accepted as fact. That happened endlessly. I remember the "*6-mile*" range claim going on for years. It was an outright dishonest attempt to mislead. Some just plain did not care though. Ultimately, I squashed their efforts by filming my drives to prove they were wrong... very wrong. When that happens, they move on to the next lie. The latest is a type of range claim: "*A car that won't get 10 miles of electric range in Winter?*" With so much real-world data from other plug-in vehicles showing the less efficient vehicles losing roughly one-third of their capacity to heating, the claim of double that from a more advanced design is absurd. Yet, they try it anyway. Sadly, I have to endure the greenwash for awhile. It's quite warm here still. Taking advantage of cabin pre-conditioning and the battery-warmer, combined with the vapor-injected heat-pump, I expect far less impact... which I will film and share as soon as the data can be collected. In the meantime, I have to just put up with their rhetoric: Spreading misinformation about any plug-in is helpful to our effort of promoting electric driving how? That claim about Prime is uncalled for, totally inappropriate. We here know that is false.

- 9-01-2017** **Dragging.** The spin when it comes to tax-credit expiration is that those automakers with a lot still available weren't trying hard. The very idea of a certain automaker having wasted them is impossible. If something was offered for sale, that's all that matters... to enthusiasts. Those who believe in quality over quantity see it very differently. The concept of waiting until you've got a viable product for the masses doesn't make any sense... to enthusiasts. It's all desperation, an act of pride. Excuse after excuse comes from not having delivered a design capable of competing directly with traditional vehicles. Needless to say, there is very real concern about the subsidies running out. This was the spin today: *"I doubt that congress will leave American car companies at a disadvantage to the foreign companies who have been dragging their feet on EVs (like Toyota)."* I was amused. How much do they think the government should provide? Think about how much money was lost bailing out GM. Who's actually paying and what are they paying for? If new credit funding was allocated, shouldn't the criteria for eligibility be re-evaluated? After all, the current availability is based upon understanding of implementation for 2008 and without any clear guidelines. It was nothing but a basic acknowledgement of battery-capacity. What if the eligibility was based upon MPGe instead. Less efficient use of electricity would get rewarded with less money. After all, it makes no sense promoting a guzzler of a different fuel. Waste is waste. I sounded off about the situation with: Dragging? Toyota's first nationwide plug-in rollout is affordable without tax-credit help. GM is still very dependent on subsidies and hasn't expanded to their primary market yet (no SUV), despite 7 years and 2 generations. In other words, the measure of progress is based upon how well the technology actually replace.
- 9-02-2017** **Faster & Further: Sad.** The idea of leadership coming from the *"faster & further"* crowd is just an adolescent desire for more. There's never enough. There no sense of balance. It's just an obsession to go faster & further. That makes any type of response to this pointless: *"Someone like Toyota should be near the front of the pack, if not leading. Releasing two generations of anemic PHEV Pruis is just sad."* Understanding anything other than an increase of power or capacity for the electric system simply doesn't happen. There's no priority given to other aspects of the purchase. Heck, even affordability is dismissed as something of important. Those particular enthusiasts simply are not interested. So, I just stuck to the one-sentence reply: \$27,100 base MSRP with an assortment of included new safety features is leading the pack.
- 9-02-2017** **Faster & Further: Some.** The reply to my comment was weak: *"It may be leading some pack, but not the PHEV/EV pack. They would have to double EV range, cut 0-60 time by 33%, and have five seats to even be in contention to do that."* Acknowledgement that it wasn't actually an absolute opened up opportunity to actually have some dialog. Though, I knew that would be brief. That audience doesn't need a reminder of audience. What ordinary consumers consider important is nothing they share in common with these enthusiasts. So, I kept it simple again: That *"some pack"* is mainstream consumers, the group that matters far more than early adopters.

- 9-02-2017** **Faster & Further: Priorities.** Coming from the trophy-mentality perspective, the need to appeal to the masses isn't a consideration. In fact, there is an outright dismissal of attempts to match traditional vehicle configurations. That isn't important, period. Why bother? Needless to say, they still don't understand: *"At the moment the PP is cannibalizing standard Prius sales from people who don't do research and blindly buy from Toyota."* To not see the audience is so different, comparing ordinary people to early adopters, boggles the mind. How can they not recognize priority differences? Oh well. It was just another thread with deaf-ears not hearing what needs to be accepted: Thinking conquest is better is a fundamental mistake. That is just purchases from new customers. Legacy automakers must get their own loyal existing customers to change. Replacing older offerings with new is the goal. It's called an upgrade. This is why MSRP is so vital. Falling into the trap of thinking faster & further is better happens all the time. Don't let that distract from the purpose of attracting ordinary shoppers, who have very different priorities.
- 9-02-2017** **Promotion.** What aspect of this can be taken seriously: *"...Toyota did a terrible job of promoting it."* Some supporters of Toyota are understandably upset. That's what happens when you make assumptions about the market. Without study, that's very easy to do. The big picture isn't easy to see... unless you participate online routinely. Then, it's difficult to not notice what's going on. We have a diverse array of buyers, but the actual quantity is still extremely limited. Supply simply isn't there. Dealer incentive isn't either. With many more profitable vehicles so much easier to sell, what is there to actually draw interest? This is why to focus isn't exclusively on plugging in... especially since knowledge of that topic is so limited. It's attention to other aspects of appeal that need to be established in the meantime. Think of the advanced new features that have nothing to do with the hybrid system. Then think of how plugging in enhances the ownership experience. While all that is being discovered by the first owners, reputation is being built. Those impressions from firsthand observation go a long way. This is why having the worldwide rollout take place all right away is so valuable. It makes more of an impression. Anywho, this is what I ended up posting: That wasn't a priority for year-1. Remember, focus was on production & penetration. Delivering a new model with the waved-glass and carbon-fiber into 3 major markets was a major undertaking for just 12 months.
- 9-02-2017** **Problems.** They are rather significant. They are quite clear. They are all undeniable. I wonder how people will react to them. Nonsense of the past won't even pass as weak excuses at this point. Heck, even a claim of desperation is pointless. What does any of it achieve? So, it looks like the best choice is to simply state the facts... or in this case, the problems: Tax-Credit phaseout will be triggered mid-2018. Voltec is still uncompetitive with other GM offerings. Voltec is selling in volume well below other GM offerings. Voltec is not available in SUV or CUV format.

9-02-2017 **Attacks.** Will they ever end? Yes, in just a few days. It's quite clear that things are about to peak. That's very good. Pressure has been building for quite awhile. The timing was easy to predict due to the rollout of Model-3 and the new Leaf so close together. Remember how Bolt was expected to be a strong seller at this point, having demand so high that Volt would just naturally ride that wave of acceptance to victory? None of that happened. In fact, the slow & steady pace GM had set was followed rather closely. None of the hype materialized. Yet... we still have to deal with attacks. Ugh. For now, they are annoying. In about a week, I wonder how they'll be perceived. Hmm? Here's what I have to say about the build up: Year-3 of Gen-2 means looking at the big picture. Honda discontinued the first Insight much sooner, for the same problem Volt continues to struggle with... being too small and too expensive. Attempting to distract from GM's problem by diverting attention to Toyota won't change that. Volt has fallen well short of the business-sustaining level, despite 7 years of trying with a very generous tax-credit.

9-03-2017 **Who is the market for Volt?** I posted that question over and over and over again. The purpose was simple. It was to stress the importance of audience and to bring about acknowledgement that GM did not target Volt at mainstream consumers as enthusiasts continually claimed. It simply wasn't true and they were in deep denial about it. Their resistance to accept that was building a barrier to progress as a result. They were holding back the advancement of plug-in technology by setting a percent of unrealistic expectations. I was determined to overcome that, as well as point out why. When confronted with something like this today, I really push back: *"So you say. Feel free to research and provide reference to the forum supporting your position in the future."* That was my opportunity, which I took full advantage of:

According to Google, I have said that 303 times on this website alone. Who is the market for Volt? It was the question raised each time someone hear claimed Volt was a vehicle for the masses. I pushed to expose the reality that it was not over and over and over again.

Enablers here pushed the idea faster & further was actually the solution, countering GM's original goal of delivering a plug-in with a MSRP that was nicely under \$30,000. When things went horribly wrong with gen-1 Volt sales, we were ensured gen-2 Volt would be different. It was to be targeted at mainstream consumers instead. Upgrades to the design were to make shortcomings just a memory for early adopters.

Who is the market for Volt? As sales of gen-2 struggled, that question continued to be asked. Growth wasn't happening. Sales were flat and attention was shifting away, to Bolt instead.

Volt continues to be portrayed as a competitor to Prime. Why? It makes no sense. Toyota clearly targeted Prime at the masses, their own showroom shoppers. In fact, the price is so affordable (very nicely under \$30,000), that there have been countless claims that Prime is stealing away sales from Prius... which is indisputably for their ordinary customers.

GM doesn't offer anything for their ordinary customers, still, after all this time. Sales of Equinox, Malibu, and Cruze are brought up every month, as a reminder of the audience Volt was supposedly designed to appeal to. Who is the market for Volt?

My position now is the same as it was 10 years ago when the bold promises about Volt were first being made. GM showroom shoppers need something affordable to replace their traditional GM vehicles with.

Two-Mode was a disaster, with *"too expensive"* as its primary shortcoming. Both gen-1 and gen-2 Volt suffer from a repeat of the same design mistake. \$33,220 for the LT (base) model Volt gen-2 is simply too expensive. \$26,000 is the MSRP for the LT (base) model of Malibu and the Premier (fully loaded) model of Cruze is just \$24,820. Shoppers just plain don't care about going faster & further when they can get such a better buy for their money from GM.

My position makes no difference when such an obvious problem persists. Loyal GM shoppers will see that for themselves.

9-03-2017 **Few Days Remaining.** What else can be said? Remember how Volt was supposed the ultimate solution to "*range anxiety*" concerns? It was to be so superior, the appeal of electric-only vehicles would simply fizzle. The very idea of an EV wouldn't make sense... according to the enthusiasts. They went on and on, relentlessly, during the development years that Nissan's Leaf wouldn't be able to sell. People would find it pointless with the fear of running out of battery power so high. It was an intensity they continued to spin, even after sales remained strong. Eventually, they finally gave up and started attacking Toyota's Prius instead. It required a disregard of purpose & goals. It became more a matter of pride. This is when the "*faster & further*" idea got out of hand. Enthusiasts began to obsess with power & range of Volt, focusing entirely on that to make it appear superior... to Prius, since Leaf was selling quite well. It never worked. Interest in a plug-in Prius persisted. They got angry and hostile and resentful... The situation was really quite a profound moment in history... because even GM admitted failure. Even the second-generation upgrade did nothing to promote growth. That's how Bolt came about and has continued holding the spotlight ever since. It was to be the solution to range-anxiety instead. Now, we see Nissan about to reveal a Leaf upgrade so impressive, the expectation of significant sales growth is quite realistic. We have already seen the same potential building up for Toyota with Prime too. Only a few days remaining to remove whatever doubt may remain. Yeah!

9-03-2017 **Rhetoric.** It never ends. What gets posted changes though: "*I was speaking last week in the parking lot with a guy that owns a Prius. He asked me about my Volt in the winter, and I said it does great. He said his Prius is horrible in the winter.*" That was the latest undermining attempt. There's always a confusing & vague message. I used my reply as an opportunity to convey some facts:

Why would anyone compare a regular hybrid to a plug-in hybrid that way? It makes no sense.

Comparing a used gen-1 Volt to a new Prime would be an entirely different matter. You can get a steal of a deal for Volt. Of course, the depreciation of any vehicle makes it a great consideration for purchase... especially when there's technology upgrades and tax-credits involved.

Comparing a Prime to a gen-2 Volt is what will have an impact though, since new purchases are what change the status quo. Prime is more efficient with both EV and HV driving. Prime uses a more efficient electric heater. Prime has a lower MSRP and post-subsidy price. Prime comes with some safety features standard that Volt does not.

I'm quite curious about real-world data that will emerge during Winter extremes. With Prime's battery-pack warmer and ability to pre-condition from the grid, it's going to be a lot tougher than enthusiasts think to position Volt as a better buy.

My commute is 18.6 miles. EV distance observed for Summer months has been low 30's. The Prime will be plugged in at both ends to a 240-volt charger. Errand running in the evening is usually within 3 miles from home. The grocery store, our most frequent stop, has several chargers. Nothing about that fits a "*horrible*" description. In fact, the word "*competitive*" will be quite realistic for Winter.

9-03-2017 **Finally.** The end is drawing near. Having to put up with such desperation. None of the other plug-in vehicles were trouble. It was only Volt with its small group of enthusiasts working damage-control to save pride. They had a great vehicle serving their niche. Mainstream buyers just plain were not interested. Neither generation was able to draw interest. Sales remained flat. Growth never happened, despite all the supposed evidence they had saying otherwise. It was a colossal waste of time... is what I'd like to say. Unfortunately, it was actually a squandering of tax-credits. That money was lost opportunity. What's the good attracting those who move on as the vehicle ages? Most didn't stay loyal to GM when their leases expired. And now that enticing EV offerings are beginning to hit the market, they are abandoning the very concept of "*range anxiety*" solutions. Why be concerned when you can just have a larger battery-pack instead? It's quite hypocritical, especially for it to happen prior to the third year of gen-2. It's the very disaster I had warned about. Unfortunately, they did everything they could to suppress historical references pointing out the pattern repeating. It was amazing how much they fought to prevent discussion of Two-Mode. Oh well. Finally, it just about over now. Posting this will do: Ordinary consumers are the target, not enthusiasts. That's why the obsession by some here with faster & further makes no difference to them. That is also why MSRP is such a big deal. Toyota will use up their tax-credits much faster than GM, but won't get stuck afterward like GM.

9-04-2017 **Charger Progress.** There is a really nice park where we like to bring the kayaks. It is such an appealing destination because there had been an entrance-fee to pay years ago. That money was invested to build recreation paths, provide picnic tables, and for finishing & launch docks. Last year, they added charging-stations. Unfortunately, they were often unavailable due to traditional vehicles blocking the spots. That became a problem often complained about. Park officials finally did something about it... a solution so effective, we can spread this as a successful example others can implement. Sadly, we often see abandonment after the initial setup. Owners of the charging-stations are clueless about what to do when someone who shouldn't park there does. This is the first instance I know of where they actually tried something to improve. All they did was absorb the 2 adjacent parking spots, then paint the entire area green. That made purpose & violations quite apparent. There's no way to make a "*mistake*" parking in one of the charging spots anymore. It is very obvious what that location is for. Interestingly, that location was off to the side, not by anything. So, it was somewhat bizarre that people would park there. Why not by the facilities instead? Choosing far away, rather than close to your destination, should have made the choice to avoid the chargers an easy one. But for some reason, people without plug-in vehicles would park there anyway... until now. We're making progress. Yeah!

- 9-04-2017** **Vastly Superior.** This level of smug is truly amazing: "*HAAAAAAAAAAAA! You bitter and conceited complete fool!*" That type of attitude cannot be dealt with. The person making such proclamations is so far gone, all you can do to address everyone reading it. Lurkers must find it quite enlightening to witness such an extreme. I was rather stunned by the arrogance... but not surprised. The feeling was to be expected. The visible out lash though, I wasn't certain. But with so much stacked against the old beliefs, something was about to peak. I let it go this way: With only 2 days left before another player in the plug-in market makes their big reveal (Nissan Leaf gen-2), the attitude of vastly superior to the very end was expected. That's the way paradigm-shifts play out. There's always someone who wants to go down fighting. When cornered like that, lashing out at a scapegoat somehow makes them feel better. It's sad that the sell for Volt is still so difficult. A simple message of purpose never came about from either GM or owners. Neither made an effort to explain what made the design compelling for a traditional vehicle shopper to consider. The solution ultimately delivered to prevent "*range anxiety*" concerns was Bolt, which left Volt in an position of uncertainty. Who was it for? With a price clearly higher than that expected from Nissan & Hyundai and significantly more than Toyota, the appeal is missing. Drawing GM showroom shoppers over to Volt simply won't happen with a sticker so much higher... and only now enthusiasts are coming to realize.
- 9-04-2017** **Anti-GM.** Lack of commitment on GM's part is causing enthusiasts to spin excuses. The most obvious is to blame reputation: "*The fact that people are still buying Nissan Leafs in decent numbers definitely shows an anti-GM bias in the market.*" That's definitely not the case. It's those killer discounts to clear out gen-1 inventory prior to the big reveal of gen-2 are what's playing a major role in sales recently. The reluctance to address actual quantity is how to confirm the true situation. Enthusiasts are still playing the percentage game, rather than looking at full market counts. Oh well. They know they are in trouble and they know most of their efforts are futile at this point. It's basically a matter of pride now. Thankfully, that should fade away rather quickly. Expectations from Nissan are quite high, from an automaker who doesn't over promise. I sounded off to that spin with: GM is well known and well liked for SUVs. The fact that GM has not endorsed any type of green technology for SUVs sends a message that Volt & Bolt aren't primary products. It's a consequence the lack of advertising... which everyone here complains about... reinforces. Think about how GM thrives on promoting future offerings. We get announcements years in advance. Many have been unrealistic, hence the "*over promise, under deliver*" reputation. GM kept Volt a small car. GM made Bolt a compact. GM chose diesel for Equinox. These are all recent decisions which send a message of uncertainty. Where's the commitment to their core product, a SUV with a plug?

9-04-2017 **Delivery Plan.** Feeling the end of Volt rapidly approach as the reveal from Nissan will soon arrive is strange. We all know the technology itself isn't a dead end, but the vehicle it was put into clearly doesn't appeal to GM's own shoppers and the end of the tax-credit will only make the bad situation with sales even worse. Fortunately, there is now some recognition of the problem. That's far better than the terrible denial of the past. It sure is nice not having to deal with the constant attacks for raising awareness of the problem. Who would have thought getting acknowledgement would be such a problem? Of course, they do say acceptance can be the most difficult stage. This looks like progress to me: *"My brother said he'd buy one...if it was an SUV. And there you go. People want a EREV or EV SUV or truck. GM will get there, but they sure are taking their sweet time."* I was happy to chime in to that, hoping they are all done arguing. After all, much will change tomorrow when we hear about Nissan's delivery plan...

It is with mixed feelings about getting vindication for the *"too little, too slowly"* concern.

The hope was finding an ally in the pursuit of electrification. People warned that GM would undermine battery efforts though, just like they did with diesel back in the 70's. Offering a product that their own customers didn't like would impede the entire market. And sure enough, that is exactly what happened.

It's really unfortunate GM abandoned Two-Mode. A next-generation offering would have reinforced commitment to electrification, as well as demonstrated what upgrades can deliver. Fortunately, we now have few automakers stepping up to overcome the barrier created by GM.

Volt was overkill, engineered without affordability as a priority. That made it an expensive car too small to appeal to GM's own customers. Those loyal buyers interested in another GM vehicle to replace their aging GM vehicle simply purchased another GM traditional choice instead. So much opportunity missed. What a waste of tax-credits.

GM really needs to step up to the plate and commit. None of this rollout of Cadillac & Buick low-volume nonsense. They need to address their primary buyers by announcing a solid delivery plan for an Equinox or Trax with a plug.

9-05-2017 **Gen-2 Leaf.** This evening was the long-awaited reveal. \$29,990 will be the base price, exactly as expected. Range is expected to be rated at about 150 miles. That's really going to stir the perception of 200 miles being required. That was the target years ago, prior to the goal posts being moved. It represents a solid 100 miles of EV travel under basically any circumstance. The fact that claims are now that more is needed is just part of the faster & further rhetoric. More importantly, Nissan did an excellent job of "normalizing" the look. That basis of merit put on aspects without actual measure are much more difficult to battle. Quantitative arguments endlessly go back & forth. Aesthetic appeal doesn't have any basis of measure... so antagonists focus on that a lot. Fortunately, with this next-generation offering for Leaf, that won't matter as much. People will focus on the MSRP being much more in line with what people are willing to pay for a traditional vehicle anyway. So, even without a tax-credit available anymore, it will be competitive. That concern of being able to appeal to showroom shoppers has clearly been addressed. Yeah!

9-06-2017 **Comparison Tool.** I did indeed find that interesting: "*This is interesting, apparently Chevy has a comparison tool for their cars against other competitors. Including the Volt vs. the Prime...*" The webpage link he provided revealed a highly bias list of features... compiled in a fashion to clearly favor Volt. Some obvious omissions were very difficult to claim they had been innocently overlooked. It was blatant marketing spin. To confirm how gullible some people are is disturbing... but understandable. I'm still amazed how some people don't recognize how they are fed specific facts to lead them to draw incorrect conclusions. There really is a sucker born every minute. Oh well. I'll just keep providing the missing information with the hope they'll become better informed, as I did today in response to seeing that so-called comparison:

Whoa! Talking about cherry picking. Notice how the standard Prime safety features weren't included:

- Dynamic Radar Cruise
- Pre-Collision Braking
- Lane-Departure Detect with Assist
- Automatic High-Beams

Also, notice how the efficiency ratings are all missing too:

- MPG
- MPGe
- kWh/mi

9-06-2017 **Bizarre Twist.** It's bizarre to hear some owners asking for exactly what the previous generation owners complained about. Remember the, literally, thousands of times we heard the request for the engine to stay off under all circumstances? To now hear the opposite is bizarre. Yet, that's exactly what's happening. A handful of new Prime owners made the suggestion that the engine should start when the pedal is mashed to the floor. That is in fact what the upcoming Honda Clarity will do. Why? If you want extra power, just switch to EV-Auto mode. That's exactly what it is for. If you use the default of EV mode, you're instructing the system to provide propulsion using only electricity. This twist of want is likely the result of not paying close enough attention. After all, not understanding what the buttons do was a common problem among reviewers. They either guessed incorrectly or didn't even know the option was possible. Oh well. You have to start somewhere and each new generation does bring twists. This particular one wasn't anticipated though. How bizarre.

- 9-06-2017** **It Matters.** I certainly got a kick out of this today: "*It most definitely matters!!!*" Those were always the words uttered when a Prius owner achieves the next level of efficiency awareness. It's amazing how empowered we become upon discovery of how much those seemingly simple displays actually tell us. You really don't know what you're missing until you start looking. The selection of data values to observe is quite plentiful now. Prius has a variety of choices you can configure the 2 small screens for. They all present real-world driving data in easy-to-follow formats. You find yourself poking through them, clicking the buttons to scroll from one to the next to see what else is available. Anywho, there's an obvious passion that develops upon discovering just how much power is at your fingertips. This is why Prius owners end up getting that generic stereotype of being rather obsessive. It gives that impression from those who are unaware just how easy it is to see that information. Imagine if more people knew about that simplicity.
- 9-07-2017** **Random Thoughts.** An article was published with this title: "*Toyota Prius Prime Could Take Chevrolet Volt's Plug-in Hybrid Sales Leader Crown*". That will obviously stir trouble. Sales are the ultimate measure of progress. With the tax-credit phaseout to be triggered the middle of next year for Volt, there's a lot of pressure coming from Toyota & Nissan. Both offering lower MSRP is a clear point of contention. That faster & further approach clearly isn't working. Enthusiasts are getting desperate, which means I need to get ahead of their undermining efforts. With this article, I was the first to post a comment. It was just a series of random thoughts, enough to draw interest and avoid the obvious traps. Fortunately, they have become quite predictable. I know what to focus on as a result: EV mode works great cruising home at 70 mph. I have even passed others at 80 mph without any trouble. The test-drive experience, low sticker-price, and reliability reputation makes it an easy sell for curious shoppers. 8,100 miles so far on my Prime, of which 1,700 were a trip to Wyoming from Minnesota and back. That 80 mph travel with no opportunity to recharge was surprisingly efficient though (upper 40's and low 50's). Overall average so far is 114 MPG and still climbing every day. I've had 2 tanks with about 2,000 miles between fillups. I'm looking forward to winter, when I can take advantage of the pre-conditioning and find out how well the vapor-injected heat-pump and battery-warmer work.

- 9-08-2017 Leadership.** They still don't get it. Now that the shift to electrification is looked upon as inevitable, the discussion audience is considerably larger. The enthusiasts of Volt who obstructed for so many years are just voices in a crowd. Their influences is considerably less. Reducing the faster & further belief they pushed is wonderful. All those arguments with them worked out favorably too. I have refined my approach: Leadership is getting ordinary people to change. Toyota has worked hard not to waste tax-credits on conquest sales; instead, focus has been drawing in their own loyal customers as plug-in buyers. The base Prime comes with unexpected features, like Dynamic Radar Cruise and Pre-Collision Braking. Yet, the sticker price is only \$27,100. That's clearly an effort to attract their own showroom shoppers. Early adopters are low-hanging fruit. What happens when that market is saturated and the tax-credits are used up? Toyota has already addressed that with such a low MSRP. Their effort to address that more challenging audience is clear and had already been delivered. Toyota understands the vital nature of remaining profitable, despite the obvious paradigm shift to plugging in. They aren't rolling out niche offerings to win awards & praise. They are working to appeal to their own buyers. That's leadership. Think about what happens next year when GM triggers phaseout. The struggle for Volt to appeal to GM owners looking to replace their own GM vehicle will become even more of a challenge. How will plug-in growth be achieved?
- 9-08-2017 Get What?** The reveal of Nissan... more like the confirm of what had already been leaked... has really stirred the antagonist posting. The enthusiast of Volt last out at Prime, using it as a scapegoat for their trouble. Ugh. It's annoying, but does offer a nice opportunity to promote what Toyota actually gets: Prius Prime delivers full EV drive. Camry, RAV4, and CH-R hybrids are all Prime-ready platforms. They are clearly pushing their base forward, an undeniable effort to move away from traditional vehicles. Saying they "*don't get it*" makes no sense. Get what?
- 9-08-2017 Changing Definitions.** This was very much expected: "*Big ICE + Small Motor(s) = PHEV (Prius Prime). Big Motor(s) + Small ICE = EREV (Volt)*" Each time a shortcoming is exposed for GM or an advantage discovered for Toyota, there are attacks from Volt enthusiasts. It's so predictable. They simply change the definition of EREV, which has been more of a marketing term rather than an actual identifier... until recently. The EPA actually provided a formal definition which enraged Volt enthusiasts... hence the increased sense of desperation on their part. The lashing out in this direction makes sense. Since actual material points fall apart, like sticker-price, they attempt to divert attention to immaterial points instead. The lack of merit doesn't deter either. They just keep at it. Oh well. I just keep pointing out what they are up to: Changing definitions is just another way of moving goal-posts. We all see the desperate effort to mislead about EV drive Prime delivers. Owners are enjoying their all-electric experience and no amount of labeling will change it. The engine stays off for their entire drive.

- 9-08-2017** **Narratives.** That's the latest way of looking at forced perspectives. References to "*spin*" are using a term of the past now. It's all about telling a story, rather than actually acknowledging all the facts available. So basically, it's the same dance but to a different song: "*I would expect there to be 200+ mile versions of the Clarity EV and Prius in the works, for example, which we'll only see on the market once the companies feel they don't have a choice.*" Portraying reactive steps rather than proactive is much easier. That view of looking back is always easier. True vision means seeing what others don't yet... which often means dealing with a lot of FUD. That fear, uncertainty, and doubt can be intentional too, spread by those attempting to prevent the status quo from changing. With respect to the problematic stance of Volt, that means undermining offerings with greater potential for mass appeal.... hence the recent posts I've been responding to. In this case, it was: That narrative requires the reader to ignore vital facts... Prius already delivers high-volume production lithium cells and Prime already delivers full EV drive. Just because fewer cells are used now to make the smaller battery-packs doesn't mean the rest of the business need to support more later hasn't already been delivered.
- 9-08-2017** **Falling Into The Trap.** One of the highly respected regular posters on the EV blog did today. He unknowingly got sucked into a semantics argument. Forgetting about purpose and get hung up on definition & labels is a trap that's very easy to fall into. In this case, it was in a series of posts about what "*Full EV*" actually means. An antagonist kept posting over and over again how the electric-motor power output must be more than the gas-engine for the full-hybrid to be said to have full electric-only driving abilities. That makes no sense whatsoever... if you take a moment to actually think about what was claimed. Why would that make any difference? I can drive my Prime on the highway at 80 mph with the heater running and not use a drop of gas. How is that not "*full*" in any respect? What makes it incomplete? Not being full means something is missing. Nothing else is needed. You get everything you need for that drive exclusively from electricity. Ugh. It's too bad he fell victim to that effort to undermine. Remember how they used to call it AER (All Electric Range) instead? That shift to something new is the changing of definition & labels. Hide the past by talking about the present in a different way. A clear sign of undermining. I tried the best I could to respectfully point out his oversight: Full EV means you can drive under all conditions using electricity... hot, cold, fast, slow, whatever. The fact that some systems deliver more power from the electric-motor than the gas-engine is simply a configuration difference to target a different audience. It has absolutely nothing to do with the EV itself.
- 9-08-2017** **Goals Reminder.** The attitude from some faster & further pushers goes beyond smug. They clearly don't understand accounting and don't care about economics. To them, it's all about marketing. If you have a good product, people will pay anything the business asks for them to acquire it. All that's supposedly required is lots of advertising. That's so poorly informed of how things actually work, most of the effort expended to explain their incorrect perception is a waste. They aren't interested in learning. It's a decide beside on feeling disaster. Rather proactively educate, they react to feeling. Ugh. You'd think they'd at least recognize goal. Unfortunately, not even a simple message of purpose resonates. So, I continuously remind: Replacement of traditional vehicles is the goal. GM is carefully avoiding electrification of their SUV models so cannibalizing doesn't happen. How does that achieve the goal? LOL all you want to distract from the importance of that low MSRP. No one taking the situation seriously will be laughing.

- 9-09-2017** **Guzzling Reminder.** The faster & further mindset is a truly desperate perspective at this point. With 7 years of not being able to attract mainstream buyers, you'd think that level of failure would be a sign of needing to try something else instead. Unfortunately, that's not the case. In fact, the consumption of electricity for the sake of improved acceleration is still very much a draw... which reveals the current market is still just for early adopters. The ordinary consumer wants something at a fair price. They are unwilling to pay a premium. That's the difference between mainstream & enthusiast buyers. The fact that even with a generous \$7,500 tax-credit sales growth has not been achieved is the only other sign needed for trouble ahead. So, there really isn't much of a point of reminding people that guzzling electricity can be a problem too. I did anyway: Notice how the obsession with power diverts attention away from what's actually important? Using electricity to be green is the goal, not to switch guzzling habits from gas to electricity. Some EV systems are very inefficient. Supporters attempt to justify that waste by focusing on want, hoping that desire will make it acceptable.
- 9-09-2017** **Audience.** Making the discussion about themselves is a common undermining technique. It's all about limiting scope. In fact, that's why the antagonists cherry pick. Looking at the big picture reveals weakness. So, they attempt to avoid that any way they can. I don't put up with that nonsense and certainly didn't today: Audience is who the vehicle was designed for, not who's making comment about it. It doesn't matter anyway. Your actions to defend GM, despite the fact that they are avoiding their own customers rather than targeting them as Toyota has, speaks for itself. In other words, GM can only avoid delivering some type of electrified SUV for so long. Meanwhile, there's both RAV4 and C-HR that are plug-ready and Highlander which could ultimately join in too. The efforts to undermine Prime by claiming it is insufficient are weak & desperate... something this audience won't tolerate. Anything that promotes mass acceptance (affordable pricing and not unnecessarily powerful) of plugging in should be acceptable. Put another way, what will mainstream consumers replace their traditional vehicle with?

9-10-2017 **Antagonist Attacks.** It's quite refreshing when a post like this emerges from the chaos of antagonist attacks: *"What hybrid vehicles does Toyota have? Is it just the Prius, Camry and Corolla? Or do they have some others? I would think any serious intentions to move to EV would start by making all the vehicles hybrid."* That provided an opportunity to get the discussion about Toyota's intentions back on track:

30,593 hybrid RAV4. 11,099 hybrid Highlander. 5,338 hybrid RX 400/450. Those are all the hybrid SUV models those attempting to undermine & belittle Toyota carefully avoid every drawing any attention to. Notice how GM offers nothing in the SUV category, which is their most popular type of vehicle.

Notice how well those Toyota numbers from Jan-Aug 2017 sales look here in the United States. In the European market, CH-R is already available as a hybrid. Avalon is another hybrid which is available here. Corolla hybrid is elsewhere. That delivers a strong message of reaching their goal offering hybrid models of all their passenger vehicles by 2020.

Keep in mind how impressive the Toyota hybrid technology has advanced. The 2018 Camry delivers an EPA rating of 52 MPG. That's incredible for a large sedan. We've seen how easily they are able to adapt their system to offer a plug too, without costing a major premium.

This is why we've seen so many desperate attacks on Prime lately. Antagonists are doing everything they can to impede the momentum building, since their preferred automaker simply has no way to compete... specifically GM. Thankfully, we are seeing efforts by Hyundai, Nissan, Ford, and Honda pushing forward with plug-in hybrids of their own. It's really unfortunate GM hasn't expanded their Volt technology into another Chevy vehicle.

9-10-2017 What's The Problem? The rhetoric claiming time has run out, making it too late for some automakers to recover is a load of garbage. It's just more desperate attempts to keep up a good image. This isn't even damage-control anymore. It's plain old recognition of how much the market still has not accepted plugging in. There isn't anything beyond early-adopter buyers still. That's easy to prove too. None of the automakers have used up their tax-credits yet. That means true competition with traditional vehicles has yet to begin. That subsidy is somewhat of a liability at this point. Dependence on it for too long makes that push to the next stage (high-volume production) even harder. Demand simply isn't there yet. Establishing the technology is still the stage we are stuck on. Dealers remain reluctant. Charger use isn't agreed upon. Configurations remain confusing. Prices are all over the place. Basically, it equate to lack of clear purpose. What the heck are those plug-in vehicles attempting to accomplish? You'd be surprised how difficult that question actually is to answer. Anywho, I got fed up with the spin today and jumped on the most obvious antagonist: What legacy automaker is actually committing to high-volume production right away? Notice how GM is curiously silent about increases, despite Volt and Bolt? Nissan is making a valiant effort. Kudos! Hyundai stands potential in a few years. The same can be said for Honda. With Ford, who knows. VW and BMW have plans in the works, but are also years away. In the meantime, Toyota continues to refine their hardware & software with Prime, awaiting the opportunity to exploit the next-gen battery and building plug-in reputation in the meantime. So... what's the problem?

9-10-2017 Fuel-Cell Rants. Another common antagonism technique is to go off on fuel-cell. The antagonist will rant about how wasteful it has been for Toyota to invest, spinning it as a futile endeavor. Facts prove otherwise. Often, they are unwilling to acknowledge them though. So, when their rants get obnoxious and become too much of a distraction, I fight back. Today, it was:

FCEV = Fuel-Cell Electric Vehicle

Advancement in the electrical system is progress for an vehicle using electricity for propulsion & comfort. That dual benefit is so often overlooked by those against fuel-cell development, it's difficult to take what their lack-of-investment claims of investment seriously.

Hyundai, Honda, Daimler, Mercedes, BMW, and GM are all actively pursuing FCEV work too. How come they don't get the same negative criticism as Toyota? It's not like Toyota hasn't invested heavily in lithium use. Both the regular Prius and the Prime have lithium battery-packs.

The heating system for the cabin in Prime is the automotive industries most efficient electric heat-pump, the first of which to take advantage of vapor injection. How come that mutual benefit is so easily dismissed?

Good business includes diversification. Pushing for a single solution simply does not make sense. Yet, that's what many argue for. It's so short-sighted and quite risky. The market needs variety. Think of how profoundly different each vehicle on the road is used. One size does not fit all.

9-11-2017 **Meritless.** Those last few remaining Volt enthusiasts trying to push vastly superior status over Prime sure are getting desperate. The claims being made are without any merit. They just say whatever the heck they want and don't even bother to provide any detail whatsoever. Today, it started with: "*Toyota is far behind comparing technologies...*" My response was a simple list with a half-dozen items. That stirred quite a bit of lashing out. The extreme anger was obvious. So, I came up with the following list and posted it. Unfortunately, the fourth category didn't even occur to me until long after. But rather than post that "*innovation*" design, I figured it may work out better to save that for later. I'll put it hear though. It's ok on the blog to reveal that I'm still holding a wildcard:

Prime technical advantages:

- EV is more efficient
- HV is more efficient
- Heater is more efficient
- Price is more affordable
- Dual-Wave glass
- Carbon-Fiber hatch
- Charge Mode

Prime standard safety features:

- Dynamic Radar Cruise
- Pre-Collision Braking
- Lane-Departure Detect with Assist
- Automatic High-Beams

Prime advanced tech options:

- Predictive Efficient Drive
- Sonar Parking Assist
- Rear-Cross Traffic Alert
- Blind-Spot Monitor
- Vehicle Proximity Notify
- Rain-Sensing Variable Wiper
- Active Grille Shutter
- Color Heads-Up Display
- 11.6-inch Touch-Display
- Charging Cable Lock
- Heated Steering-Wheel

Prime innovation design:

- Directed Heating & Cooling

- 9-11-2017** **Hate.** The irrational behavior of some still in denial about having lost such an extensive battle was summed up with a final insult: "...an arrogant, smug, self-righteous jerk." It was truly remarkable to read that. After having read so many posts about how great Volt would be, it was beyond hypocritical. That's exactly how they sounded. Having so many pages of their own quotes documented in these blogs is vindicating. I have an extensive log of exactly how they behaved. The hate was truly remarkable... something to not be forgotten. Learning from such profound errors is progress. When their hope began to crumble, the response was to lash out at a scapegoat. That's sad. I responded to that ironic situation with: Years of "vastly superior" spin from those here set the precedent for pushing facts and reminding of goals like that. The double-standard has been truly remarkable. It's your choice whether or not to make it personal. The faster & further marketing didn't work out. Time has come to move on. Focus back on the original price & volume targets is essential.
- 9-11-2017** **Stuck.** The fate of Volt is obvious at this point. GM's own customers are not interested and neither is GM itself. So much attention has shifted over to Bolt, there really isn't anything to say about plug-in hybrid expectations. There simply aren't any anymore. Those nasty enthusiasts who feared mainstream acceptance would never come are feeling the sting of being wrong now. They know the tech won't actually die. GM will obviously give in at some point, finally offering a plug for a vehicle the "Who?" will want to buy. Catch is, it won't be vastly superior. It will just be another player on the team... exactly what I wanted all along. We should all be in this together. So what if fulfilling the need isn't exciting. Most mainstream vehicles aren't. I knew that from the start. They were in denial. To sum of the lengthy voyage they took to reach the same destination I was at many years ago, I posted: Sales have always been the ultimate means of measuring progress. Conquest was the first stage, where the new technology is subsidized and often attracts buyers from outside the normal customer base. Cannibalization is what follows. That's when the new technology attracts loyal buyers, convincing them to upgrade rather than replace. Volt is stuck in the first. The faster & further approach simply isn't working anymore. Prime clearly targets that second stage instead. It delivers a wide variety of purchase priorities appealing to mainstream consumers. Reaction to today's post about sales clearly confirm that. Negative votes won't conceal that inconvenient truth.
- 9-11-2017** **Worldwide Sales.** The total count for the year as of July for Prius Prime (known as Prius PHV everywhere but in the United States) was 31,856. That official count is hard to get, since sources aren't readily available. I was able to find the August numbers for here and Japan. They were 1,820 and 1,870 respectively. We also have the September value for here, which was 1,899. What that tells us is there's a trend of at least 3,600 per month which is likely to continue. That means, without any growth or even finding out what the counts are from Europe or Canada, we can still reasonably expect a total of 50,000 sales worldwide for the year. This is why we are seeing signs of panic now. That's quite a debut. Potential for much more once the initial rollout concludes is strong. I wish more than just 1 or 2 available per dealer around here doesn't drag on. Unfortunately, being in the middle of the country means waiting longer. But then again, that doesn't tend to be an impediment of any sort. People await real-world data from the first Winter anyway... and I am well prepared to provide it. That cold season is on the way. My cameras are ready. Meanwhile, a slow but steady growth of sales while we wait would be nice.

- 9-12-2017** **47 Miles EV.** Honda Clarity will be offered as a plug-in hybrid, in addition to EV and Fuel-Cell models. Range has been officially estimated at 47 miles. You can imagine the stir that has caused with Volt enthusiasts. Ugh. I like how it paves the way for a Camry plug-in. Think of what a Prime model would draw for interest? Honda's efficiency rating for hybrid operation is 42 MPG combined. The newest generation Camry hybrid delivers 52 MPG. With a smaller battery-pack, it could be more affordably priced than the expected base of \$35,000 for the Clarity. Note how Toyota strived to deliver a system able to compete directly with its own showroom floor offerings? It's unclear how Honda will actually market this new choice. The expectation is that Clarity plug-in hybrid will become a high-volume seller. That seems reasonable. But then again, there's Hyundai attempting to undercut everyone else on price. Clarity is a full-size vehicle, not cramped like Volt. That lack of compromise is obvious. I'm intrigued. 47 miles of EV is easier to justify with that larger interior, especially when power isn't sacrificed. However, there isn't a to-the-floor approach like with Prime. That will actually start the engine. Hmm? This is a head-scratcher. We'll find out next year when sales begin.
- 9-13-2017** **Undermining Efforts.** Ugh. It's really annoying to have to deal with rhetoric like this: *"Does the battery have a thermal management system?"* It seems reasonable. But in reality, it's a greenwash campaign where some intentionally undermine and others simply spread the misconception without even realizing what they are partaking in. All I can do is play along, but interject some information with the hope of it making some notice what's going on. Sadly, the idea of narratives influencing decisions isn't as wide spread as you would think. There are people who truly don't realize that's even possible. Being naive is dangerous... and we've seen fallout as a result far too many times. Perhaps this though, we can intercept early: The more informative question is what kind is provided for cooling, since there has been quite a bit of confusion between the ACTIVE and PASSIVE types. Nissan chose PASSIVE, which basically means the heat is not dispersed by any forced removal. Toyota chose ACTIVE, which was achieved by pushing cooled air from the cabin through the battery-pack casing. That's a very big difference. Lots of people assume they are the same though, since neither uses a liquid.
- 9-14-2017** **LEV III.** Most people have absolutely no clue what emission ratings are. Of the people advocating green technology for vehicles, few of them understand the categories of "clean" are setup to follow a progress improvement schedule. Every decade or so, the bar is raised, making criteria more stringent for the next stage. We are now approaching the level-3 stage. California establishes the standard. Other states agree to accept & follow. CT, MA, MD, ME, NJ, NM, NY, OR, PA, RI, VT, WA, and DE are those joining in for this round of air-quality improvement. All you need to do is remember there are people like me who bother to read up on detail of the provisions ratified. This is how cheaters, like diesel, get caught. Remember my blogs entries complaining about the suspicious behavior of diesel supporters? Things just didn't add up. How could such a supposedly dramatic level of clean be delivered at so little cost or tradeoff? There's always some type of compromise required. No penalty of any sort made no sense. Study of what is measured and how was what brought about the questioning. We understood the challenges of cleansing emissions and preventing them in the first place.

- 9-15-2017** **Acceptance.** It's not happening for some. This was what a Bolt owner posted about the gen-2 Leaf: *"Besides the very different driving experience, much longer range, better acceleration, faster charge rate, liquid cooling, CCS charging instead of Chademo. all the check marks at a modestly higher price."* I was dumbfounded... and not about to put up with it: \$6,630 is modest? MSRP starts the shopping process. Too high, the customer simply moves on. Reasonably competitive, they take a closer look. The catch is, mainstream interest will focus on creature-comforts & conveniences, not technical design or performance aspects. That shift from enthusiast to mainstream will be painful for some. Accepting the purchase-priority difference won't be easy. But that's what this stage of rollout is all about.
- 9-15-2017** **Chargers.** It's not all bad. There are new opportunities to advance discussions beyond the old rhetoric: *"My wife actually mentioned "what if we get a Bolt when my car needs replacing" while we were talking about putting a 240V circuit into the garage for L2 charging."* I took full advantage of this particular opportunity, knowing that a number of the original Volt owners either just stuck with their factory 120-volt charger or invested in a low-power 240-volt. Neither is enough for Bolt... and they know it. But rather than argue to justify the obsolete position, they are receptive. The reason is simple. The shoe is on the other foot. Irony can be cruel. I don't succumb to it though; instead, I use the change to stir excitement about what's available. In this case, it was with: We just installed 2 JuiceBox chargers with Wi-Fi, each on their own dedicated 40-amp line with individual sub-meters and NEMA 14-50 outlets. That provides extremely convenient usage tracking and time-of-use discounting, as well as capacity for the future. That was the ideal setup... especially with the \$1,000 rebate from our electric provider. 3.6 kW charging for the Primes now. 7.2 kWh potential continuous from both chargers simultaneously.
- 9-16-2017** **Work Trip.** Jumping into an airplane to travel halfway across the country for training isn't a normal experience for me. Work trips simply haven't been necessary. I try my best to achieve all that's needed remotely. In this case though, it couldn't be avoided. The visit for some in-person interaction would be greatly beneficial. So, that's what I'm doing. All things considered, that is the most efficient means of travel. It's certainly faster; though, I do enjoy road trips with the Prius. I'll be away from home for almost a week... no car, no cats, no wife. Fortunately, the online world isn't any further away. It's as if nothing changed in that regard. In fact, I will keep my eyes roaming with the hope of noticing something here on the East Coast that I wouldn't usually encounter in the Midwest.
- 9-17-2017** **Advanced.** It's quite bizarre how some people think having a liquid-cooling system for the battery-pack is advanced design. Requiring a more aggressive heat dissipation system is more expensive, more complex, and more weight. Dealing with that much more makes no sense. Yet, we hear the argument that it is happens all the time. Who are those pushers trying to convince? It seems a step in the wrong direction. The idea of plug-in simplicity is negated by requirements like this. Thankfully, both Nissan & Toyota continued with lithium chemistry development to avoid the need. This is a reason why they have potential for winning over their traditional buyers. That's the type of advancement we require... not some EV supporters telling people that without, they'll suffer terrible consequences with their battery-pack.

- 9-18-2017** **Behind.** How many times have I had to endure the claim of Toyota being behind? The best response was always to push for an explanation of what they thought was still needed. Pretty much every single time, the reply was with respect to EV range. All the enthusiast cared about was battery capacity. Sadly, nothing else mattered... until now. Reality is setting... finally. I'd then point out the benefits of electrification. So much of what gets put into hybrid & fuel-cell vehicles can be reused by a plug-in, you'd think it would be an obvious that those investments were good ones. Instead, they were mocked, belittled, and scorned. So, seeing this emerge from plans GM just revealed has been quite vindicating: *"By 2025, nearly all of GM's brands sold in China – Buick, Cadillac, and Chevrolet – will have an electrified option."* Several years ago, Toyota set a similar goal in the United States... but for 2020... which puts them ahead, way ahead. Hopefully, this news will help end the antagonist posting. Focus on mainstream electrification, rather than faster & further, is long overdue.
- 9-19-2017** **Reasons.** It's getting much easier to see how attitudes differ now. What an ugly past. It's unfortunate we have that mess to deal with still, but acknowledging the problem is progress. This indeed fits: *"What troubles me in reading this article is why this innovation isn't being done in this country. What circumstance, or group of circumstances, makes GM look to China for its future, as opposed to the USA. Is it the EPA, the dealer network, the unions, what?"* I actually got a compliment from a recent foe with this post: Welcome to the world of those who raised concern years ago for listing out the very reasons you now seek. The advice is to not dwell on the problem sources... since you'll get nothing but negative votes. Focus on providing strong solutions instead... something all audiences will embrace. In this case, we really really need GM to announce intent to deliver a Voltec based Equinox or Trax. Offering a SUV with a plug-in option is what will shift the paradigm without upsetting the market.
- 9-19-2017** **Denial.** I didn't even need to respond. He said it well. This was yet another former poster who had countered me on a regular basis. The turn is so nice. True, writing was on then wall for a very long time. They've known Volt was in trouble. I reminded him and several of the others directly, pointing out the gen-2 year-2 situation. There's nothing else to deny. Reasons he provided should have an impact: Are we still in denial about this topic? 1) We are no longer the largest growing economy. 2) We are a debtor nation. 3) There is no consistent "Pro EV" federal policy to encourage investment. 4) Americans (many) are more interested in trucks and willing to take on 8 year loans. 5) High cost US workforce still working through quality control issues.

- 9-19-2017** **Change.** It's dramatic from my perspective. Agreement from antagonists is amazing. Their change is as if it happened overnight. Too bad it actually dragged on for years and years. They'd fight diversification. Asking the "Who?" question all those times eventually got the message through. Volt clearly wasn't designed to appeal to GM's own loyal customers. It was never going to reach mainstream sales levels as a result. That's why conquest was always the focus. They understood the problem, yet refused to acknowledge it. Now, they see how those suggestions for spreading the technology to vehicles like Malibu & Equinox really weren't efforts to undermine or dilute. They really were in the best interest of growth. All that wasn't a twisted way of promoting Toyota. I really was trying to promote plugging in after all. Of course, I'll never get any type of apology. But that's ok. Their steps for change in the right direction is all I wanted anyway. That stupid trophy-mentality had terrible consequences. After 10 years of suffering, no need to drag it on any more. Let's move forward. It will be odd though, knowing Volt will be left behind in the process. But then again, they do now recognize it as a niche. That change is progress. It's not like all the tech will be lost. Reconfiguring it for mass appeal is quite realistic.
- 9-19-2017** **Cold Soak.** It's interesting to throw a term out there to see if any newbies bite? That's the kind of trolling with intent to educate. What a concept! Trying to help people by stimulating the learning process. In this case, it was: "What is maximum cold soak? I only ask because I rarely ever use the timer. What's the advantage of it?" That came about with a random reply on a thread about recharging. I set the hook: That's when you allow the battery-pack to rest as long as possible before the recharge begins. It's for longevity. Toyota conveniently gives you the scheduling feature to make that easy. I have mine set on weekdays for charging to complete by 7 AM in the morning and 4 PM in the afternoon. That makes the process basically brainless. You just plug in and let the car figure out when to start charging and pre-conditioning. To override the schedule, just click the "Charge Now" button when powering down. It's a simple way to get the most out of your investment. Coming out to a car that's warmed or cooled for your departure is rewarding in itself. Knowing it's also taking steps to extend the life of the battery-pack is a great bonus. For those of you who decide to take advantage of time-of-use discounts from your electricity provider, it requires setting the schedule anyway. So, why not?
- 9-20-2017** **Voice of Reality.** This isn't likely to be greeted with enthusiasm: *"If GM keeps building small cars for the US market they are going to be in trouble. We are all screaming for a real SUV/CUV based EREV with AWD, but that falls on deaf ears."* Too many of the Volt enthusiasts were fiercely against anything that would upset the precedent they set in terms of faster & further. That status quo is painfully deafening now. So much was built up to prevent change, they have backed themselves into a terrible corner. This is why so many simply gave up on Volt and directed loyalty toward Bolt instead. It's bizarre to have so much silence now. Unfortunately, that is why the voice of reality gets so much grief. The possibility of getting called out as hypocritical damages their fragile sense of pride. Ugh. Again, the goal is to replace traditional vehicles. Since GM primarily sells SUV/CUV choices, it makes no sense pushing a compact hatchback like Volt. They tried for 7 years. It didn't work. Let it go. Move on to the next. The fact that enthusiasts still don't agree is mind-boggling. They scream, but then go back to Volt support the very next post. There's no substance. It's just empty talk. Without any effort to help promote something supportive of a SUV/CUV offering, how do they expect interest to grow? Remember all the hype they managed for Volt while it was being developed?

- 9-21-2017** **Efficiency Credits.** If they ever do get renewed by the federal government or new ones comes about from some states, it sure would be nice if actual efficiency were taken into account. That importance aspect of measure is currently ignored entirely. All that the big tax-credit focuses on is battery-capacity. It doesn't matter how much electricity the vehicle guzzles, as long as it has a larger size than others. Such a crude perspective of worth made more sense way back in 2008 when the legislation was first drafted. But all these years later, we know understand the importance of using electricity responsibly and should award accordingly. Simply switching from wasteful gas vehicles to wasteful electrics is not enough of a step forward. This is why EV operation with a vapor-injected heat-pump should earn more credit than one with just an old-school resistance heater. One uses far less energy than the other to operate.
- 9-22-2017** **Less Complex.** Being less complex than traditional vehicles has been the selling point for battery vehicles. Cooling the battery with liquid is not a step in that direction. This is why advanced chemistry for cooling with air is a step forward... as well as a cost reduction. Volt enthusiasts absolutely hate hearing this, since GM didn't try that. GM stuck with the overkill approach... which is a carry over from gen-1 design. The hope was drastic cuts for gen-2. In fact, there were some who celebrated that apparent victory far too early. It's a wise move when trying to deliver a robust product that will deliver extremes. But that's not what customers actually want to pay for. There's a balance. That's why those buyers are part of the mainstream. You want more, you pay more. That's what the specialty market is all about. More complex is fine for that audience. Ordinary people are not in that category. They benefit from less complex by not having to pay a premium. Long story short, Nissan & Toyota are well aware of this... hence their efforts to deliver a battery chemistry able to deal with heat better. Higher tolerance that can be cooled with air is far less expensive and less complex. So, with the Honda getting into the game, I was quite curious. Rather than a dedicated liquid cooling system like GM uses, their new Clarity will share coolant with both the engine & battery. One radiator instead of 2 reduces components. Less piping and only 1 pump is less complex. I'm quite curious how the Volt enthusiasts will accept this new approach.

9-22-2017 **Progress.** It's odd to see some still fighting. The world is moving on, overcoming the strange barrier GM erected with Volt... then shifted over to Bolt. What exactly were they trying to accomplish? We see a whole lot of nothing. The technology worked, but their heart didn't seem to be in it. Who was it for? Both plug-in offerings had a very high price and were not targeted at their own loyal customers. Yet, that was always labeled as progress. GM was pushing more than any other automaker. So, even though that didn't actually accomplish much in terms of actual change, it was given recognition as leadership. None of those enthusiasts bother to consider that bad leaders are possible. Heading off quickly seems impressive, but in the wrong direction... Anyway, I'm still a bit irked about so much time & resources having been so poorly used. It's no hopeless though. Progress often includes waste. You try something. It doesn't work. You try something else. Success of Prime isn't what Volt enthusiasts want to hear about. They hold that particular configuration with too much importance. Rather than focus on diversification of the technology to other platforms, it's the compact hatchback or nothing. That's why when Camry hybrid or RAV4 hybrid are brought up as next candidates for getting a plug, they go silent. Needless to say, I couldn't be silent about the situation. So, hopefully this was at least somewhat tactful: Toyota will have increased the population of plug-in vehicle owners this year by 50,000. Rolling out the world's first affordable plug-in hybrid, to several different markets, all at the same time is undeniable progress... especially considering how vital it is to not be dependent on tax-credits. When will GM roll out something similar on that scale?

9-22-2017 **New Ally?** It's rare to have a new ally emerge, especially in the belly of the beast. That daily blog is getting pretty nasty as the end draws near. This stirred that pot: "*GM please give us Volt/Bolt customers a vehicle to grow into, do not squander all of those conquest sales. And just to be clear, throwing a diesel in any vehicle is not an alternative. No plug no sale.*" With the very encouraging news from Nissan and the undeniable conflict GM must resolve, it's difficult to know just how receptive enthusiasts who seem to be losing everything will accept change... especially coming from someone who could say "I told you so". That's why letting someone else do it instead is so interesting. I jumped into that mess with: This audience works hard to hide information that upsets the status quo. It's really sad how much has been squandered as a result of their denial. This time next year, phaseout of tax-credits for GM will be a grim reality. Intent of those subsidies establishing high-volume sales never materialized over the past 7 years of trying. Lack of growth confirms it. Something to appeal to mainstream buyers still isn't offered. What draw will there be for a plug-in SUV that's \$7,500 more when it is finally rolled out to attract GM's own loyal customers? Notice how much of a challenge it has been to grow sales even with the tax-credit?

- 9-22-2017** **Pack Upgrades.** This particular information published today summarized the outlook well: *"In mid-2016, BMW introduced the current 33.84 kWh battery which was an upgrade from the 21.6 kWh battery previously available. That bumped the i3 BEV's 81 mile range to 114 miles per charge. The new battery, which is being introduced sometime later in 2018, is rumored to have a total capacity of 43.2 kWh and offer an EPA range rating of 150 – 155 miles per charge."* At some point, that should become an expectation, rather than a special situation. When Prime was first revealed, I pointed out how the raised floor in back served as a market test to find out if the perception of usable cargo space loss would be more of a deterrent than the increase of capacity mid-cycle would be as an encouragement. Toyota gave itself the option to adapt design without major rework. Increased battery-capacity, due to increased energy-density, could easily be provided. Increased cargo-storage, due to increased energy-density, could easily be provided. It's a choice they don't have to make until mid-cycle. They'd let the market decide which is more important. An interesting twist is that could be an upgrade for existing owners as well. Imagine many years later a buyer of a first model-year plug-in trading in their battery-pack for the newest available, rather than the entire vehicle. There's an interesting profit venue yet to be explored. Why let the aftermarket sellers have exclusive opportunities? Why not the automaker itself? Needless to say, technology for batteries is advancing faster than generational upgrades.
- 9-23-2017** **Selling Points.** That lengthy list of Prime advantages I posted a few weeks ago has turned into the new *"selling points"* document. Just like with previous generations of Prius, identification of standout features of what Toyota delivered will occur. You end up with a list of strengths. That's exactly what I ended up getting out of the antagonists. Their push to exploit what they consider weaknesses will end up exposing the best points to highlight. That's how we sell Prius... letting those who want it to fail most help stir what sells it the most. The ironic backfire is something well worth patiently waiting for... while tolerating the onslaught of attacks. Today though, I got this: *"Where is Toyota's actual, technological leadership?"* That was an unexpected opportunity to share the entire list, rather than draw attention to each point individually. The feedback to it was intense too. Rather than even trying to argument, it was an admission of defeat. He just blew it off entirely. Running away is a dead giveaway. The usual response is to just cherry-pick wasn't attempted. I was thrilled. Knowing the list had been so carefully researched and so thoughtfully assembled, that first test of worth was very encouraging.

9-23-2017

Full Circle. Recognition of the pattern by the antagonist is a very encouraging sign: *"Your protests are awfully convenient to your case, aren't they? We try to hide you with negative votes..."* He didn't understand what was wrong, but knew it looked a little too much in my favor. The problem comes down to realizing there's agreement, but not wanting to admit it. I've seen that before. When I depart, posts will start conveying the very same thing I had been saying all along. Knowing that I'm not there anymore makes it a simple next step. That's why I'm making sure to wrap up everything. The reveal from Nissan brought an end to rhetoric of the past and lost enthusiasts are looking for a new focus. So, I remind them what's important prior to moving on: "NICELY UNDER \$30,000" is the target GM set for Volt. So no amount of hiding my posts or asking alternate questions will change that. It was a goal set for good reason by GM, not me. Traditional vehicles must be replaced quickly. That makes sense. If my reminders of the importance of it is considered a protest, too bad. What difference does opinion make anyway? A goal is a goal. Working to maintain the status quo doesn't accomplish anything. It is just enabling. Protest is a push for change. The reality of sales growth being the measure of progress is just something you'll have to accept... an inconvenient truth. As this discussion points out, competition is expanding. We need high-volume sales not dependent upon tax-credits right away, hence NICELY UNDER \$30,000.

9-24-2017 **Wrap Up.** It took awhile to sort through all the crazy lately, as a result of the impending change, to come up with a fitting analogy. Knowing that it's not an end. Knowing the game is far from over. Knowing that pride often creates barriers. Knowing that taking the next step is hard. Since you've got the upper-hand from having studied and made better choices, it's difficult not to sound condescending. Those struggling simply don't want to listen to you. So, we go through the usual personal attacks and false history. Just like with our president, wild statements are made without providing any detail whatsoever. It's just a vague claim that results in instant gratification. Ugh. The expectation is someone will stand up as a peacemaker, saying whatever it takes for the loser to shut up by addressing the winner suggesting they take a different approach. It's a physiological move that can actually be rather effective. That guy with the upper-hand has to play along though. Thinking about that is how I came up with the game analogy for the wrap up:

Too expensive to compete with traditional vehicles was the message conveyed from Toyota all those years ago, back when Volt was still being developed. Volt enthusiasts didn't want to accept that message, so they changed it to too dangerous instead. It made them feel better. All these years later, there's the same behavior. The upcoming phaseout of tax-credits is really pushing that denial. So, they do what they can to suppress information, rather than accept it.

Rhetoric intensifies the situation when new offerings emerge. Toyota is always a thorn in GM's side, so they don't count. They're just treated as a scapegoat. Panic comes from other automakers. With gen-1 Volt, it was Ford's plug-in hybrid. Wow! It got very intense when C-Max Energi became available. Enthusiasts of Volt would post whatever they could to defend. Despite the lack of substance and obvious desperation, it made them feel better.

Honda's new offering is doing the same thing to gen-2 Volt. There's that same pattern of panic again. It's very easy to see too. Rather than take the situation seriously, the behavior is to use Toyota as a scapegoat and last out at those providing the message of concern. But as difficult as it is to accept defeat of a move, it's just a failed play in a very long game. No need to panic.

GM took a step in the wrong direction. It's not the end of the world. It's just a fumble. The technology is still sound. The configuration doesn't meet consumer requirements though. It's not like adjustments aren't possible. Getting back into play is just a matter of trying something different.

Too expensive continues to be the fundamental barrier for mass acceptance. A compact car like Volt has far too high of a price tag to draw interest in the showroom. Shoppers simply don't want to pay that much. More EV range and more power has proven ineffective for sales growth.

In a game when throwing the ball repeatedly to the same player fails to advance the team, you send in a different player. It's not a big deal. There's no need to panic. With the case of GM, they finally need to call in their most popular player. What are they waiting for? It's long overdue. The appeal of offering a plug-in SUV had long been known. Even before Volt, there was strong interest. Yet, GM hesitated.

We need to hear from GM that they plan to offer a plug-in SUV. Fans of the game (Volt enthusiasts) should be screaming for that at this point, rather than hiding posts and spinning history to pretend all is still ok. Things are obviously quite bad, but the game is not lost. Don't enable GM to continue with the wrong player. Shout out for the favorite to finally get a chance play.

- 9-25-2017 Teaching Moment, part 1.** Attempting to hide posts by negative voting them out of view is bizarre. All you have to do is click on the link to make it visible again. It doesn't actually go away. In fact, the act draws attention to them as a form of highlighting. I couldn't care less, since the goal is simply to get the message across. Posting again achieves the same thing: *"Being less complex than traditional vehicles has been the selling point for battery vehicles. Cooling the battery with liquid is not a step in that direction. This is why advanced chemistry for cooling with air is progress forward... as well as a cost reduction. Explain how such a straight-forward sentiment could cause such an uproar."* The discussion just happened to have drawn attention to teaching moments anyway, so I jumped right in. The point was to get those intentionally trying to mislead about active cooling to finally acknowledge that doesn't mean liquid only. The push to get that misconception to become a major source of disappointment is getting intense. They simply don't care about getting caught. They just repeat the same implication over and over. Passive cooling doesn't exist as far as they're concerned. So, when I point out Prime is active and Leaf is passive, despite but using air, they get very angry. They don't want me to expose their efforts. Finding out there are 2 very different approaches to cooling battery-packs with air can be used will undermine all the worked they've done to create a misconception. Well, too bad.
- 9-25-2017 Teaching Moment, part 2.** Here is what I ended up posting: A teachable moment, in education, is the time at which learning a particular topic or idea becomes possible or easiest. The count of negative votes was a clear indication that not only did the post have everyone's attention, it also was understood well enough to result in a participatory act. It was directly on topic and a relevant response as to which the topic was presented. The reaction though was for Volt enthusiasts to panic. I had pointed out a factor of advancement they were unwilling to acknowledge, providing a reason for which competition could indeed be stronger. There was a major effort to suppress the information, followed by indication of a shift away from plug-in hybrids. That abandonment of Volt in favor of Bolt is not a total surprise. Change on such a scale due to business realignment is a good thing when sales are not as expected. You try something. It doesn't work. You try something else. This is the learning process. Sharing that information is how we are taught.

9-26-2017 **Abandonment.** How it would end was a mystery. I have been witnessing abandonment of Volt. Enthusiasts who pushed "*range anxiety*" concern are now claiming this outcome was inevitable. All those excuses for so much defending has paid off in their minds. It's interesting to witness such damage-control playing out. When pride plays such a major role in their actions, it was quite clear nothing with "*failure*" as would be part of their message. That would make sense if it was just a matter of moving on with a generational upgrade. But that's not the case. Volt is only now starting its third year of sales for gen-2. That's not even mid-cycle year. The product is too new still. There's no diversification either. It would be easy to justify if that long awaited SUV with a plug was finally announced. But there's no sign of any intent from GM and no support whatsoever from enthusiasts. They have simply moved from EREV to EV. The idea of a vehicle with an engine of any kind has abandoned entirely. It's really strange. There isn't a voice for Voltec anymore. The hope of any plug-in hybrid choices from GM is gone. Believe it or not, that's actually a good thing. That terrible group-think from those faster & further pushers was holding back opportunity. With them turning favor to Bolt instead, the ability for GM to finally announce (or even reveal) a Trax or Equinox using an augmented hybrid system is far easier. Barriers of the past are no longer there, now that there's a 60 kWh battery-pack available. An affordable system with a smaller (right sized!) capacity can be offered without loss of pride. Phew! That's long overdue. Want to make a bet that will happen in Detroit early next year?

9-27-2017 **Extreme Variety.** Now that the market barrier Volt created is gone, there's an extreme variety of plug-in hybrids emerging. Those terrible enthusiasts of Volt did indeed become the antagonists we feared. Claiming GM was a leader, when in fact it had become an example of what not to focus. Rather than focus on improvement to emissions & consumption, there was an obsession with faster & further. It was good technology spoiled by foolish management decisions... based primarily on what the enthusiasts were rallying for. They are who I blame. We knew the executives would cater to what they hear from GM supporters. That was how Two-Mode became such a disaster and why I knew Volt would suffer the same fate. That pattern of mistakes was easy to recognize. But every time I brought up the parallel, pointing out how closely the history matched, I was attacked. It was relentless. They took it very personally and tried to humiliate me in response. Their retaliation was an epic fail though. It made no difference. I wasn't impacting sales, they were. Belief that the market would sway in their direction was a fundamental effort. The idea of "*if you build it, they will buy it*" doesn't actually work... since the approach isn't actually that simplistic. They were too naive. They took that literally. Ugh. Oh well. Long story short is that we are now hearing from even the most quiet of automakers, like Skoda. They are even making plans to offer a plug-in hybrid. The catch is, each automaker's offering will be different. The standard Volt enthusiasts hoped would become ubiquitous by now has totally collapsed. In fact, very little of what they tried to push actually survived. The precedent they attempted to establish was far too unrealistic. It's one thing to set an ambitious goals. It's another though to ignore & dismiss evidence as you discover the goal wouldn't work. In fact, that's why a target is so heavily scrutinized. You evaluate milestones along the way to confirm that it can ultimately be reached. What was the point of the goal those Volt enthusiasts were supposedly pursuing? It certainly wasn't sales growth. That failed miserably and left a disastrous mess in its wake... leaving very little for them to work with now... hence others now carrying on as if it was never there.

- 9-28-2017** **Noticed A Pattern.** This statement of closure provided a great sense of vindication: I noticed a pattern with the obsession to hide posts. There are attempts to rewrite the past. Asking why reveals a disturbing revelation. Some are now agreeing with me. The pest who kept providing goal reminders now getting vindicated is terrible. Can't have that. But after 7 years of missed opportunity, what can be said? Other automakers are stepping in to fill the void GM created. The latest is what we all had expected from Voltec advancements, a SUV. The very popular Mitsubishi Outlander PHEV is finally on the way to the United States. \$35,535 is the base price with a 12 kWh battery-pack. Why so much silence from GM still? Who wants to make a bet there will be an announcement at the Detroit autoshow? Who wants to acknowledge it won't be up the standard Volt enthusiasts pushed so hard for, despite knowing that wasn't actually what GM customers were looking for? Spin all you want. It doesn't change the reality that we have new offerings from previously silent automakers. And with the inevitable triggering of phaseout for the GM tax-credits, it doesn't matter what happened in the past anymore. What happens in the next 6 months will be quite significant.
- 9-28-2017** **Missed Opportunity.** You have to wonder what the person knows & thinks when asking this: "*Is it a missed opportunity though?*" With so much change recently and more on the way, it's difficult to recognize what their perspective actually is... especially with what just transpired. So, I went with: Look back at how many trade & conquest posts there were. It was overwhelmingly clear that Volt didn't attract GM's own loyal customers. That's why I gave up on the second model push. Even those cost-reduction was absolutely essential, another model of Volt with a lower sticker price wouldn't appeal to showroom shoppers. Those potential buyers were looking for a high-efficiency SUV... and many of those who opposed me came to realize that same thing. This is where the missed opportunity comes. That plug-in hybrid SUV won't benefit from the tax-credit. It will start sales without ever having that purchase incentive... which will make rollout that much more difficult in a market with a variety of choices at a time when gas is still cheap.
- 9-28-2017** **Too Late.** The time has come! I posted: Some are now in the awkward position of finally coming to the realization that even though I was clearly anti-Volt (large-pack config) that all along I was always pro-GM. The quest was to find an ally in the effort to promote plugging in. What's so difficult about accepting the desire to replace traditional vehicles? This is why I repeatedly kept bringing up Two-Mode. It was that I saw the potential in Volt technology, but understood how easy it would be to fall into the same traps as GM's previous attempt. I was looking for those who also wanted to embrace electrification and had valuable experience to share. Unfortunately, those former lessons learned fell on deaf ears... only to be heard now. It is sad that tax-credits were used in such an unproductive manner. Building up a supportive dealer & salesperson network while educating GM customers didn't happen. Opportunity missed. Now GM has to entice potential SUV plug-in buyers by some other means... which is going to be much more difficult.

9-29-2017 **Prius Problem.** We know that it is truly over because Prius is no longer a problem. Volt enthusiasts were painfully aware that GM sacrificed affordability for the sake of fulfilling want instead of need. That was a repeat of the mistake GM had made with Two-Mode. Making it again with Volt was, in their mind, manageable though. They just figured some effective marketing to emphasize performance instead would be the solution. It wasn't. Ordinary consumers never placed that much importance on acceleration. I knew power wasn't a purchase priority. You can't study mainstream behavior for that many years and not notice it. So basically, the only true way of winning was to wait. Eventually, they too would see it. Toyota's effort to deliver balance would become apparently. Oddly, that wasn't from Volt though. The lesson was ultimately learned about from Bolt. To make it affordable, some sacrifices needed to be made. GM's choice to deliver an interior often described as "*cheap*" and missing some obvious standard appeal features (like dynamic-cruise) exposed shortcomings with the Volt approach. Far more than just better advertising was needed and simply making the vehicle more basic wouldn't be enough. Toyota's approach was correct all along. Agreeing with me wasn't acceptable though; however, hiding what I said would conceal what was actually happening. Admitting the mistake meant swallowing their pride... which is why it never happened. Of course, Prius continues to lead the way regardless. New York just began a new rebate program for plug-in vehicles. 40 percent of the vehicles registered were Prius Prime. Only 10 percent were Volt. We're seeing that not only is the performance acceptable, so is the distance. Selling a vehicle based on the desire for faster & further isn't working with non-early-adopters. It should have been obvious that all the low-hanging fruit had already been picked. To reach the next audience would be considerably harder than just flaunting specifications. Now they know what "*vastly superior*" actually means.

9-30-2017 **Progress.** There are some winners. There are some losers. Seeing them emerge is how you know progress is being made. Advancement of technology shakes out the better choices and leaves behind what couldn't compete. I summed it up this way: It's unfortunate some are still trying to rewrite history. Details about what was actually said and when are well preserved in the blogs, so there's no need to rehash or clarify. What is undeniable is the fact that Two-Mode had a plug-in prototype of a SUV. All those years ago... and we are still waiting. Looking forward, there is a growing expectation of that long awaited plug-in SUV from GM to come as Volt reaches the end of its product-cycle. Hope is that this will come much sooner... especially since we see a variety of plug-in SUV offerings on the way from other automakers. In the meantime, the Volt enthusiasts can say whatever the heck they want. Spin about Toyota having been against lithium is an outright lie. The word from way back when Volt was first being developed was that it was TOO EXPENSIVE to compete. And sure enough, even in 2017 with tax-credit subsidies, there is still a struggle to grow sales beyond niche. We are seeing progress in terms production-volume increasing. Toyota is using lithium in both the Prius and Camry hybrids, as well as in Prime. First year sales of Prime look to easily be in excess of 50,000 worldwide. That's a great start for such an AFFORDABLE plug-in. Let's hope other automakers are able to jump into the game with their own priced low enough to actually compete directly with traditional vehicles.

9-30-2017 **Camry Hybrid.** Speaking of hiding things to pretend they don't exist... that was the strategy of Volt enthusiasts that is no falling apart... finally! Ever notice how they kept focus exclusively on Prius, never acknowledging the existence of other hybrids? That's because Prius placed more of an emphasis on efficiency than power. To get more, you have to pay more. That made Camry hybrid a bit too much of a tradeoff... until now. The new one offers that next step without a MPG penalty. Toyota did an amazing job of making that affordable. My wife and I took one for a test-drive the other day. What a great experience. There's a clear distinction of approach. Yet, you still get great performance... that one aspect of argument the Volt enthusiasts can no longer exploit. It's over. This next-generation upgrade truly delivers. Remember the "*too little, too slowly*" concern? Those antagonists claimed Toyota was resting on its laurels, only to discover the opposite was true. Toyota wasn't. It was actually their own GM who got caught up in misplaced priorities. That's why this fallout from Prime success and the very likely success of Leaf is becoming so apparent. They are now stuck in a hypocritical situation. Watch for the spin. That's an inevitable outcome. They hope to confuse readers enough to protect their damaged pride. Ugh. Why not just focus on goals instead of letting ego get in the way? Remember, it's all about replacing traditional vehicles. That makes GM's own offerings on Chevy showroom floors the competition, not what Toyota offers. When will they get a clue? Perhaps Camry will provide some perspective. It's not Volt verses Prius!

10-01-2017 **Simply Not Worth It.** Attempts to mislead & undermine aren't working anymore. The come off as desperate. For example: "*The awful 0-60 times of the PP also qualify it as sub-par. But, it's the small battery that really makes it a joke. Especially given that it's their second attempt to make a PHEV.*" Remember how Prius owners were supposedly smug? That role is exclusive to a few Volt owners doing everything they possibly can to hold back the advancement of Prime. Knowing sales results for September will be out soon, and they are anticipated to heavily swing favor in Toyota's direction, this childish behavior is to be expected. It's the enthusiasts perspective taken to an irresponsible level. There's nothing at all wrong with having an appreciation for performance. Misrepresenting it though is an entirely different matter. I'm not going to put up with it either: Same thing every time. A few are so focused on faster & further that they completely overlook the market as a whole... and end up laughing alone. It's somewhat of a surprise at this point that the "*vastly superior*" attitude continues with a few. Everyone else has seen the importance of sales. Growth is essential. Catering to a small audience by highlighting power & performance is a waste. Mainstream buyers are unwilling to sacrifice their purchase priorities for that. Toyota nailed it with the balance of price & features. Ordinary consumers have taken notice. The motor & battery are right-sized for the price, allowing them to get a nice assortment of standard safety & comfort features too. For them, the extra power & capacity is unnecessary, simply not worth the tradeoff.

- 10-01-2017** **If You Build It.** Just how naive some supporters were about dealer & salesperson interest is becoming quite apparent. They were beyond clueless. Assuming that if the automaker would build a plug-in vehicle, the customer would buy it is far from reality. It's far more complex of a situation. Enthusiasts shunned & ridiculed me for being what they thought was pessimistic. Turns out, I was being realistic. Simple, it is not. Reading a financial article about GM dealership support for Volt & Bolt, the findings were glum. It was summed up with: "*No interest and no demand.*" How much did you encounter from GM about their plug-in hybrid over the past 7 years? There's no message of support, no message of direction, no message of intent. They are just a "*halo*" vehicles. Isn't that ironic? Knowing GM's history, that fate is well deserved. It's unfortunate though, since this could have been prevented. Watch what Toyota does as the worldwide rollout of Prime takes hold. Having targeted ordinary people, its far easy to get dealers to take interest. That sets the stage for salesperson interest... if inventory is ordered. With a MSRP of just \$27,100 and Prime not skimping on standard features, it is realistic to see sales not requiring much initiative. That should be enough to attract a customer with a basic understanding of plug-in benefits. This is very much like how hybrids were first marketed. There was just enough awareness prior to shopping to draw attention to them. The same should for plugging in too... far more than just building it... but not difficult if you properly identify audience.
- 10-01-2017** **Mini Countryman Plug-In.** 7.6 kWh battery. 221 horsepower. 12 mile range. Those specifications sound promising for the market supposedly targeted. But the fine print says the electric-motor will the car up to speeds of 55 mph. That isn't encouraging. Then it turns to true discouragement when you see 27 MPG after depletion. Who will this appeal to? With a sticker-price of \$37,650 in the United States, it seems like a very small audience. Potential buyers can't be plentiful in any regard. Remember how we had relentless spin from Volt enthusiasts who did everything they could to paint a rosy picture for GM? Is there anyone to speak up for this? Mini doesn't sell that many vehicles anyway. But with such an expensive and strangely configured choice, it shows the market is all over the place now. The old days of "*more is better*" are long gone. Whether it be plug-in hybrid or electric-only, the preferences for buyers is far from clear cut. Configurations can be anything at this point. Makes you wonder what automakers will try next. Makes you really wonder how consumers will respond. Thank goodness its easy to see how Prime is a natural progress from the regular model Prius. Adding battery & plug is a next step that's very easy to understand.

10-02-2017 **Arbitrary Divisions.** People are drawing lines without any rhyme or reason: "*With a minimum AER rage of 40+ miles for PHEVs, none of these 20 mile PHEVs.*" Seeing an arbitrary division intentionally being made without any clear explanation of why that particular value was chosen is a dead giveaway of trouble to come. When they just choose a number that sounds sensible, but has no merit based on any obvious measure, it is clearly a defensive maneuver. In this case, it's the result of California making a consideration of banning the combustion engine at some point. That puts plug-in hybrids in an awkward position... for Volt enthusiasts, anyway. That AER value is coming back to haunt them. Now that Prime drives "*all electric*" just like Volt, the only argument remaining is to claim that more capacity is necessary. They know that isn't true. But there's nothing else to argue. I'm doing my best to expose that weakness too: Establishing a plug infrastructure at home is the goal. Any size battery-pack will achieve that. To plug in, you require a dedicated line in your garage. Most can find an outlet to use. Delivering electricity for a second vehicle is no where near as easy though. Notice how everyone is focusing entirely on the low-hanging fruit (only 1 plug-in) and overlooking that dilemma? It's a very big problem for most households, since they typically have at least 2 vehicles. With my household, there are 2 Primes. Each has its own 40-amp line, complete with L2 chargers and individual time-of-use meters. That wasn't a cheap upgrade, but it was totally worth the investment. The first 1,000 miles of travel with my most recent tank only used 3 gallons of gas. So the "*rage*" about AER (funny typo!) doesn't have much merit. You can achieve outstanding MPG even with a smaller battery-pack and it forces owners to start the upgrade process at home. That is a very real step toward banning traditional vehicle sales.

10-02-2017 **It Begins, Again.** Right on schedule. Exactly what we've seen in the past. When 3 year begins, GM makes an announcement of something new on the way... Two-Mode, Volt gen-1, Volt gen-2, each having predictable & recognizable turning points. The pattern is undeniable. I bet there will be quite a bit of denial though. It will start with the usual vague & ambiguous nature of the announcement. GM states there would be 20 new "*all electric*" vehicles delivered by 2023. For the past 7 years, we've been hearing that Volt is an "*all electric*" system with an engine for when the battery-pack is depleted. In fact, that's what all the AER hype was about. The "*AE*" stood for "*All Electric*". Remember the thousands of posts claiming Prius PHV had only 6-miles of All-Electric-Range officially, but that the AER rating should actually be zero since you couldn't accelerate onto a 70 mph highway using only electricity? And now that the upgrade to Prius Prime can, they changed the argument to a required "*40 mile*" minimum AER instead? I can't imagine the spin that will emerge from this. But then again, that should be easy to foresee. The nature of GM announcements are that way to stir online posting and contribute to hype. We've seen this so many times in the past, how can anyone deny it isn't beginning again?

- 10-02-2017** **Instant Tension.** Reaction was immediate. Volt is getting pushing into the plug-in hybrid category by EV supporters. It should have been obvious to them that anything with an engine would not be welcome. All that enthusiast fighting against Prime, only to find out they are looked upon as the same. Heck, just a few hours ago I posted how the two plug-in hybrids yield similar results in real-world driving. Hype of further range doesn't mean better MPG in return. It all depends upon how the technology is actually used. That's a very hard lesson learned, now especially. This isn't a sucker-punch to all the enthusiasts though. Some changed loyalties recently, jumping ship when they saw sale results. In fact, this is why the announcement was made today. We'll be getting September counts tomorrow. The expectation is that Volt's struggle is getting worse. GM targetted a niche audience, which is now totally saturated. Opportunity has shifted to mainstream buyers... which Prime is configured to directly appeal too. It's much lower price and generous collection of safety & comfort features make it much more appealing. Who is the market for Volt? Watch the tension build as that question becomes painfully obvious of a problem. Volt is suffering an identity crisis now. It's not an "*all electric*" vehicle as previously hyped and enthusiasts have been dead set against ever calling it a plug-in hybrid. Why?
- 10-02-2017** **The Trap.** It's amazing how gullible some people can be. My guess is it's a combination of not paying close enough attention combined with a blind hope of enthusiast dreams coming true. Whatever the case, I'm seeing the pattern and posted about it: Notice how the "*at least 20 new all-electric vehicles that will launch by 2023*" follows the GM reputation for ambiguous statements? It's so vague, interpretation will be all over the place. That's what GM did countless times in the past. It generates hype without obligation. No actual quantitative measures are provided with respect to production. There's an obvious absence of detail. People easily fall into the trap anyway. As a result, the same old rhetoric starts up, yet again. And sure enough, that's exactly what we are seeing. Watch how dealers react. Will the potential for greater variety help with their lack of interest shown for Volt and Bolt? If so, when and how?
- 10-02-2017** **The End.** Rhetoric ramped up remarkably fast. Fortunately, most of it was obvious trolling. Antagonists found their bait didn't work well anymore. Reaching the masses means fulfilling needs they don't find appealing. Their focus on want was clearly misplaced. I'm delighted how much of a mess the situation has become. Lack of any message on their part makes consumer confusion far less of an issue. You cannot undermine when there is no direction to mislead. Put another way, this new twist of having vaguely announced a variety of "*all electric*" vehicles wrecks the faster & further mantra. There's no way to push a one-size-fits-all approach when there's variety. It really is that simple. Where do you draw the line of acceptability? I brought the day's nonsense from spin to chapter closing with: In the end, it boils down to the argument about leadership. Some firmly believed it was all about breaking new ground, rather than getting ordinary people to change. Now, they're discovering the ground is already broken and the work to appeal to mainstream consumers is a much bigger effort than they imagined.

10-02-2017 **Changing Definitions.** That is a clear indication of having moved on. This new chapter in history is odd. There's outright denial of the past, which is recognizable. The part that's missing is having a goal. What the heck is it? Claims that "*all electric*" wasn't used differently ends up just being a red herring or a moot point, depending upon who responds. There are some frequent posters that will end up feeling lost... especially when a supposed newbie like me chimes in on websites they previously had strong control over. Disruption to the stability they had enjoyed is difficult to accept. Seemingly simple things like the changing of definitions shake up expectations. I come from outside with lots of information about how things were viewed and acted upon elsewhere. Their instinct is to dismiss, assuming my claims are knowledge limited to personal experience... not well researched material collected over the past 17 years. It's a shake up they are ill prepared for. The abrupt alteration of posting content is quite a shock. So... they change definitions to help deal with a new set of circumstances. Hopefully, most of this won't become yet another episode of moving goal-posts. Sometimes, their outright dismissal makes moving on easy. We'll see.

10-02-2017 **Innovator's Dilemma.** Typing up and posting this sure was an intriguing outcome of the crazy chapter that just started in vehicle efficiency history:

Ironically, some of what innovator's dilemma highlights is why you and I have been clashing.

My focus is entirely about the masses, those mainstream consumers are who the first-generation plug-in offerings were not able to reach. I couldn't care less what enthusiasts have to say at this stage about the past. It's all about looking forward to grow the market. A significant increase of sales quickly is essential. That requires change.

Those potential buyers have very different purchase priorities. Some of what had been a compelling draw to early-adopters may have little to no impact for this new audience. The failure to appeal the same way is harsh reality to deal with. Unexpected new problems emerge as a result and former strong players end up struggling to adapt.

Think about how welcome a disruptive technology is when it first enters the market. Those willing to embrace it readily accept change. That most definitely isn't how you'd describe an ordinary customer shopping for a replacement vehicle. Somehow, the new technology must be made available in an entirely different manner than it had been introduced.

Are you ready to take on this next stage, willing to accept an approach necessary to rollout on the grand scale with little reward in return? Successful ubiquitous implementation is a thankless job. Few will recognize how much was truly accomplished, simply dismissing it as an "obvious" next step... even though you know that is anything but the true situation.

10-03-2017 Overnight Chaos. I went to bed having the knowledge that GM's announcement to introduce "*at least 20 new all-electric vehicles that will launch by 2023*" was already a confusing mess. It left so much to assumption that even former allies were now foes, simply because their interpretation of what had actually been said was different. Personally, I wanted to find out what "*all-electric*" actually means and what the production intent was. That makes sense and seems reasonable; yet, there was backlash anyway. The attitude was quite surprising, in fact. Well, overnight, things went from uncertain to chaos with this: "*GM Will Go All Electric, Will Ditch Gas And Diesel*". That was the title of the article. It opened with this sentence: "*General Motors plans to go 100 percent electric, the Detroit automaker announced Monday.*" Where did all that come from? Needless to say, I recognize the pattern. We've seen this so many times before, there's no surprise anymore. My blogging has become a chronicle of announcements gone wild. Ugh. What's most interesting is not that there's an complete absence of any timeline or volume expectation, it's the fact that GM's plan for the future clearly included fuel-cell vehicles. That really upsets those who I rubbed the wrong way in the past, saying FCV will co-exist with EV. The one-solution-for-all has completely fallen apart. They cannot deal with multiple outcomes. For me, that's been the foresight all along. A quick study of real-world driving is all it takes to realize there's a wide variety of need. Wanting one particular thing simply doesn't work. Anywho, the uncertainty of what "*all-electric*" is telling us has really made a mess of things. There is an element of certainty though. Later today when September sales get revealed, expect the situation to get worse. I anticipate a number of Volt enthusiasts looking for a scapegoat, doing whatever they can to feel better about the lack of sales growth.

10-03-2017 September Sales. As anticipated, Volt is stuck at a low with 1,453 for the month. Remember how we saw gen-1 sales between 1,600 and 1,700 for nearly two full years? The rollout of gen-2 was supposed to usher in a growth boom. That didn't happen... not even close. In fact, sales are struggling so much, few have wanted to talk about Volt. There are too many other plug-in hybrid choices emerging... none from GM though. We have arrived at a turning point. There is no denying the paradigm shift taking place. With sales of Prime at 1,899 for the month, there are encouraging signs of strong growth potential. My dealer only had a single model in stock. Others locally are very limited too. But with such an appealing price and an array of draw factors, discussions are stirring. That's exciting. I can't wait until inventory does finally get built up. In the meantime, we're stuck with focus on GM rather than Toyota. I'm working to change that though: Volt needs more than just a price reduction to be competitive. Remember, there's serious competition on the showroom floor. The sales numbers for Equinox, Malibu, Cruze, Traverse, and Trax are all harsh reminders of what GM has placed Bolt & Volt against. Toyota worked really hard to get in front of the entire industry to deliver an affordable plug-in hybrid that also offers a variety of other appeal factors. This list highlights some of those potential draws to deal with the pressure from all parts of the market.

- 10-04-2017** **Poorly.** That new blogging website I have been frequently posting on recently has quite a few of the same problems that Volt blog had: "*That's the only way I can imagine someone who frequents this site not understanding how poorly Toyota has done with EVs & PHEVs.*" It was the assumption that I worked for Toyota. How could I possibly have an interest in the well-being of many automakers, with a focus on plugging in instead? It's absurd that a website supposedly trying to promote EVs would not have an attitude of cooperation. Unfortunately, we're seeing a quite a bit of bickering based upon battery-capacity. Everything from charging speed to blocking charger spaces comes up routinely. The supposed problems with small are quite an issue for them... hence the "*poorly*" attitude. They are very much of the "*more is better*" perspective. That's sad. I fired back: Coming to that conclusion requires a disregard for profit and a dependence on tax-credits. Anyone can slap in a larger battery-pack for good show. Making real change though requires an effort to actually target the masses, instead of just trying to please those who frequent this site. True leadership is often difficult to understand, especially when economics must take precedent to engineering.
- 10-04-2017** **Other Perspectives.** Pushing the belief that I must work for Toyota is mindboggling: "*It's the only way I can wrap my head around someone advocating a sub-par PHEV in an EV enthusiast forum.*" You'd think at this point in internet history, the realization that motive beyond being paid exists. I want to contribute something to make our world a better place. What a concept! Ugh. I finally replied to the nonsense with: I'm a customer representing ORDINARY CONSUMERS, which is why the enthusiast opinion make little difference. You can "*sub-par*" until the cows come home. It won't make any difference. Mainstream buyers just plain don't care. Enjoy your niche. That's perfectly fine, but is in no way representative of what someone shopping the showroom floor is looking for.
- 10-04-2017** **Who?** For crying out loud! He still either didn't understand or didn't want to accept that I could just be motivated by a desire to help. Why is there such a blindness to anything other than financial gain? I tried to provide more information: I wasn't dodging the question either. I was stunned to find out that this ENTHUSIAST venue showed such little interest in the mass market. KNOW YOUR AUDIENCE. Mainstream consumers are much more difficult to reach. The faster & further is great, but lacks balance. There are many other issues to address still.

- 10-04-2017** **Too Late.** Waiting is truly a terrible choice. Yet, that is the preferred approach: *"We'll deal with the post-credit prices when we reach that point."* Over and over again, we have witnessed reaction following something prove to be a great loss. Remember the dramatic price reduction for Volt when inventory pile-up became a huge problem? After the initial surge of sales faded, owners were discovering the value of their vehicle had plummeted. So, on top of having to pay more in the first place, they now had a vehicle worth much less. Ugh. Unintended consequences come from not planning ahead. Being proactive is always the better choice. How many times has the "rested on their laurels" comment come up lately about Toyota, yet that's exactly what enthusiasts are advocating for GM. Again, ugh. Annoyed, I posted: Waiting to react is too late. Getting caught mid-cycle without a plan already in place is costly mistake. Think about how close the GM is to triggering phaseout. If price can be lowered without serious profit loss, great... no change in price won't help at all though. Growth needs to be promoted somehow. Notice the struggle Volt is already having? Be proactive. Don't wait.
- 10-05-2017** **The Push, ironic.** Celebration about Bolt says with no regard to what that does for Volt is really getting big. That hypocritical response amazes me. They don't care. As long as there is some type of victory to celebrate. Ugh. I started my push on the Volt enthusiasts with: Isn't it ironic that *"too little, too slowly"* ended up being competition from within? Concern about showroom shoppers should have never have been dismissed. Bolt cannibalizing Volt sales... So much for *"range anxiety"*.
- 10-05-2017** **The Push, bickering.** Choice of response to my push was: *"Did you happen to notice that the RAV4h outsold the Prius this month? Dealers steering buyers from 52mpg to a 32mpg?"* What do they hope to accomplish with bickering like that? It doesn't achieve anything. It does make them feel better though. I wasn't about to put up with it: Toyota adapted to the market favor for SUV. GM still hasn't. What's your point? Toyota also upgraded Prius to Prime, another planned adaptation without mid-cycle interruption. Tit-For-Tat all you want. The point is progress forward and the enthusiast here fought against the very move GM has made. That's incredibly hypocritical. All the *"range anxiety"* hype, for what?

- 10-05-2017 The Push, diversion.** Hope is that diversion of attention will somehow make the situation better: *"Did you happen to notice that the RAV4h outsold the Prius this month? Dealers steering buyers from 52mpg to a 32mpg?"* I know that isn't the case, having got confirmation of it directly from my local dealer. People looking to purchase a RAV4 anyway end up seriously considering the hybrid model. A surprising number of them end up getting one too. So, the claim of switching from Prius is a stretch, at best. I pushed back with: How many of the potential RAV4 hybrid buyers will look at the 52 MPG rating for the sporty new Camry hybrid and give pause? I could understand GM seeking a balance with Bolt and Volt, offering diversity for their customers. In fact, that makes a whole lot of sense. Unfortunately, that isn't the message being conveyed. Instead, it's abandonment. Volt is struggling due to lack of attention being given. Neither GM nor enthusiasts are showing interest anymore. This time next year, the expectation is for tax-credit to have dropped to \$3,750. How is that going to help Volt, which is stuck with gradually falling sales already? My point is GM and enthusiasts better get their act together quickly. Come up with a concise marketing message. Wasting precious time (too little, too slowly) on pointless tit-for-tat arguments is an incredibly poor choice. Though, ironically, that same behavior actually favors Toyota. More attention given to its array of complimentary offerings is beneficial. The day of reckoning has arrived. How will you proceed?
- 10-05-2017 The Push, message.** Timing is interesting. Kickoff of the autoshow season usually is. I continued my push using some of that new information just released: Speaking of the message GM is sending, notice their eAssist plans for 2018 pickups just announced? 15 kW electric motor. \$1,125 for an upgrade providing what? 123 kW (front) and 50 kW (rear) electric motors from the current generation of Highlander hybrid. The next generation should deliver a decent upgrade and will be built in the United States. GM history & experience with Two-Mode should put them on course for delivering much more. Why is there no push for that? Why is the eAssist plan considered good enough?
- 10-05-2017 The Push, serious.** It continued: If GM is at all serious about pushing Bolt sales, the tax-credit eligibility tally will hit 200,000 phaseout in the first half of 2018. If sales are slower, by the end of third quarter. Either way, this time next year it will be reduced by 50%. Why squander those precious few tax-credit opportunities on spin with pointless misquoting? What a waste. Notice how vague that *"all-electric"* talk was the other day? What did that really tell us? We need a concise message of intent now.
- 10-05-2017 The Push, waste.** I was accused of wasting their time. Ironically, the push is to get an opposite outcome... to get them to finally shake the "good enough" attitude. It's so frustrating to watch the goal-posts get pushed every time monthly results are posted. Each effort to excuse lack of progress is pointless. Yet, that's what gets applause anyway. Praise is given for technical achievement, regardless of whether or not it actually advances mainstream penetration. Ugh. Oh well, that's why the push is so important. I punched back: Yet, I end up with reams of information as a result. The feedback here is fantastic! Replacing traditional vehicles quickly is the goal. Having to put up with spin & rhetoric is totally worth figuring out how to effectively do that. What would you like to see happen with Bolt and Volt over the next 12 months?

- 10-05-2017 The Push, behind.** Watching the tortoise and the hare play out is fascinating. Simply being ahead at this point is reason to celebrate a victory? The race has barely begun and enthusiasts are calling it already. Wow! I kept pushing for perspective, hoping to prevent a Two-Mode abandonment... though, it doesn't look promising: Behind what? The economics don't support your claim. GM squandered credits by not using them wisely. They were wasted on conquest, rather than trying to lure in their own customers with a sustainable product. Toyota adapted, saving credits until they had a product capable of high-volume profitable sales. That makes the credits available a tool for mainstream penetration, rather than just proving a technology. In the meantime, Toyota also rolled out a platform in 4 different bodies capable of supporting a plug. Each can deliver a full EV driving experience. Each is establishing a reputation ahead of that market. The architecture is already in place. All that's needed is more cells to make the battery-pack larger. Claims of behind have no merit.
- 10-05-2017 The Push, overlook.** The heart of the problem comes from living in the now, only seeing what's happening at the moment. It's a "*worry about it when necessary*" attitude. Rather than plan ahead and prepare for the next stage, it's all about enjoying the moment. That can be a horribly costly mistake. But when dealing with someone who clearly never took an economics class, it doesn't matter. They have no idea what you are talking about. I do keep trying though: You have completely overlooked the phaseout period. During that time, there is no sales quantity limitation. Vehicles experiencing strong growth could exploit the opportunity. To achieve this, demand must already be established. For GM with Volt, we're seeing a decline. Interest is fading, since conquest sales are over and no plan for EREV advancement has been proposed. Instead, focus is shifting over to EV. For Toyota, the preparation for ramped up production is obvious. They are clearly working to attract their own loyal customers to a plug-in hybrid purchase. Dismiss all the evidence. Spin lots of excuses. Do whatever you want. It's just wasting time... the very thing Toyota has carefully planned to take advantage of.
- 10-05-2017 The Push, production.** With judgment of progress clouded to an extreme, it's easy to see how audience is misunderstood. Over and over and over, I remind about the ultimate goal of replacing traditional vehicles... since getting lost in sales is far too easy. Each month it's the same thing, enthusiasts will cherry-pick data. In other words, they isolate counts to just that of the plug-in market. Completely ignoring the market as a whole is the only way to stay positive. Ironically, there's always complaints about how slow Toyota is supposedly moving, yet GM isn't going any faster. In fact, it was from the GM crowd we've had to endure the "*just be patient*" posts, yet they won't heed their own advice. We all know GM will announce, then proceed painfully slow... hence the "*too little, too slowly*". It's becoming increasingly difficult to say the same about Toyota. We see the Prius, Camry, RAV4, C-HR potential already... hence all the denial lately and my push. Anywho, I was somewhat surprised the spin is still going on about conquest sales being all that matter: That goal is about changing vehicle PRODUCTION, reducing the number of traditional vehicles being PRODUCED. If 0% of the customer base doesn't change and all those "*lure*" vehicles represent are new customers, the outcome is only compliance sales. Selling the same original count of traditional vehicles means no progress... no replacement yet. GM electrification "*plans*" don't actually tell us anything.

10-06-2017 The Push, journey. Providing a positive outlook for those who only see hate really doesn't accomplish much. It may not be futile, but it seems like just a waste of time. In reality, attempts to summarize do help if some type of "*what's next*" is included. What good is a push if you don't supply expectation? Remember how the hate originated. There was a resentment for Prius being so far ahead and so popular. Toyota had research need so well, you couldn't do anything but follow. The formula for success had already been proven. GM certainly tried. Two-Mode was a disaster though, so bad the next step wasn't acknowledged until that too had failed. It was Volt. Their ambition was to deliver a series hybrid with a plug so efficient, the death of Prius would be painfully quick. Instead, the design ending up being a series-parallel similar to Prius, but no where near as efficient. In fact, Volt efficiency in HV mode was so bad, enthusiasts shifted focus entirely over to EV mode operation. That could have worked too, if battery-capacity had been higher and cost significant lower. Unfortunately, that isn't even realistic now, a decade later. To make matters even worse, the next-generation Volt was only a minor upgrade. That really hurts when you look at Prime and see how significant that upgrade became. Dramatic cost reduction with a undeniable class-leading efficiency. HV is so impressive, there's nothing to say. EV is only now getting recognized with a "*we're in trouble*" realization. That's why whenever any type of design discussion starts, it ends with a Volt enthusiast angry due to the approach resembling something Toyota has already delivered. This is why the GM announcement for "*all electric*" vehicles on the way came about... right on schedule too. Literally, it was the first day of the third year. Talking about being predictable! Needless to say, I was happy to bring this chapter to a conclusion. This has been a wild journey: It does seem reasonable of an expectation. We've had quite a journey getting there though... Two-Mode = start. Volt gen-1 = upgrade. Volt gen-2 = refine. Bolt = almost. Each of those steps had peril, but not an end. It's really too bad so much conflict came along the way. Missing important milestones is a problem, but you learn from that and move on. The finish line is mainstream acceptance. Measure of that has never changed. Sales of 5,000 per month (the ordinary type, not subsidized) is a clear indication of having achieved that goal.

10-06-2017 The Push, Why? The senseless waste continued on until this was posted: "*After years of FUD against all plugins that aren't branded Toyota, you've painted yourself in a corner, and no one wants to listen your nonsense.*" That abruptly brought it all to an end:

I can put up with the false claims of my past. Distorting position by exaggeration and mixing up when things happened is tolerable. The internet is filled with incorrect information and having a good laugh (even at my expense) is useful to keep discussions going. But there's no escaping this. You crossed the line.

Everyone knows I've been active in our local plug-in owners group for years. My push for lithium battery use in plug-in cars was well known. Even with that small pack in the Prius PHV, an outspoken endorsement was obvious & undeniable. 5 full years of real-world data, including detailed video. Then I upgraded to a Prime Prime... larger lithium battery-pack along with an upgrade to 240-volt charging and Time-Of-Use discount meters at home for 2 cars at the same time.

Everyone knows how much I worked with the other owners of other plug-in vehicles. They know how much I've enjoyed the car gatherings and was able to develop friendships, despite our different plug-in vehicles. Lots of stories have been shared. We've had lots of good times. It was all an effort to find genuine solutions for ordinary people, figuring out the next step beyond early adopters.

What are you trying to accomplish? All the "*late*" claims without explanation are bizarre. Now this. Why?

10-08-2017 **Being Observant.** Yesterday, we got back home from a trip up north. After unloading the Prime (which holds far more cargo than the raised floor leads you to assume), I plugged in. It had been a whole week with only that single original charge, which I used sparingly while away. There was no place to recharge. Yet, overall efficiency for the 618 miles of driving was an amazing 61.8 MPG. That's especially impressive when you realize the temperature varied between 47°F and 65°F, which meant no more warm-season engine startups and running the heater. We had to deal with rain a few times too. Anywho, after a little bit of plugging in. I grabbed my phone to check on charger status. Nothing. Huh? Turns out, I needed to reset the extender for my Wi-Fi. No signal. For some reason, the channel for the garage was out. After that quick fix, the charger displayed status. I took a quick print-screen, not realizing the significance of that moment I just captured. An hour later, I got a notify that charging had finished. Again, I wasn't paying close attention, but took print-screens. After all, I had gone an entire week without recharging. My desire for a full battery-pack had peaked. It was especially interesting, since that was the first time my wife had actually plugged in to recharge at the very same time. We installed 2 independent 40-amp lines for that benefit, why not take advantage? That full recharge (5.8 kWh) only took 1 hour and 17 minutes to complete! How could it take so much less time? It usually requires about 30 minutes longer and my history log clearly confirmed that. Nothing looked out of the ordinary. I routinely see a sustained charge-rate of 3.6 kW. Faster didn't make sense. So, I shared all the information I had online. Our guess is that I uncovered a bug in the software for the charger. It pays to be observant. I wonder how many others have run into odd sets of circumstances like that? Writing software myself, the experience doesn't surprise me. There are many unknowns that are difficult to predict. It's nice knowing the fail-safe worked. Despite the signal loss, the charger worked anyway. I wonder if the newer model would have worked differently or if the addition of a Wi-Fi signal indicator was the solution. After all, that's ultimately what you want fixed, since the charger has no control over that.

10-09-2017 **New Chapter.** Remember what got repeated relentlessly when antagonists were attempting to portray Toyota as lost and going in the wrong direction? They certainly don't... yet their posts are so abundant, it's effortless to find. The mantra they kept pushing was fuel-cells. Rather than them being a complimentary electric-propulsion technology that would co-exist with electric-only vehicles, it was claimed to be a complete waste of resources. All that time. All that money. Poor Toyota. They wouldn't acknowledge any of my facts posted about GM's fuel-cell past and their on-going effort to advance development of fuel-cell vehicles. Each time, I was attacked. Each time something praising Toyota came up in the news; sure enough, someone would start a rant about fuel-cells. It all changed abruptly with that announcement a week ago. It's amazing how that has all been forgotten. None of that ever happened... Ugh. This is how the 7 years of trouble from Volt sales struggle will be looked upon too. I can see it slipping into discussions already. Volt was simply a "*stop gap*" only intended to serve as a temporary bridge to electric-only vehicles. The fact that interest faded so dramatically mid-cycle is something that GM planned all along. Ugh. It is well documented that wasn't the case. Of course, evidence of this change being unexpected isn't necessary. Economics of a premiere product don't support it. Remember how Volt was to lead to a paradigm-shift, where Voltec would be spread among the fleet to be profitable & abundant? They don't. It's so hypocritical, but in no way a surprise. This is why Toyota is now being portrayed as "*late*" with electric-only vehicles. It comes down to pride. They don't want to admit having misunderstood the market. They don't want to admit that it is actually more difficult to build a plug-in hybrid than it is an electric-only vehicle. Both are obvious huge challenges financially, but technically not having to integrate a combustion-engine is obviously harder. In other words, Toyota already had an electric-only vehicle. When I accelerate onto a highway at 70 mph and know I can accelerating all the way to 84 mph, what else is there to prove. That requires far more energy than simply maintaining that speed afterward, which Prime easily does. GM failed at their attempt to replace traditional vehicles, again. But rather than do what can be done to learn from the mistake, there's an effort to pretend this was the plan all along. This is how mistakes are repeated. We have no idea what the plan is now. All we know is a new chapter has begun. GM, their supporters, and their enthusiasts all see forward now. Whatever happened in the past is in the past and doesn't matter. Ugh.

10-09-2017 The Last Word. After the hell they put me through, a harsh reminder was of what's important is appropriate. You don't just say whatever you want for 7 years of sales, they walk away without giving thought to the loss... pretending none of it ever happened. These blogs extensively document the mistakes they made... as well as the ways they came up with to torture the messenger... the one who stood true to purpose. I ended it with:

Remember that "*5,000 per month*" goal ?

Look at annual sales of Volt, excluding 2011 due to rollout and ramp-up inventory limitations:

2012 = 23,461

2013 = 23,094

2014 = 18,805

2015 = 15,393

2016 = 24,739

2017 = 19,848 (15,348 thru Sept 2017 plus 4,500)

That lack of growth, despite all the years of hype from enthusiasts with blinders on unwilling to see the facts, is the real problem. No amount of hiding posts or ignoring the messenger changes that. They were who set the precedent. They were the ones who smugly claim "*vastly superior*" status.

Now the tables have turned and reality of the economics is becoming undeniable. That mainstream minimum value was set as a goal to ensure the technology could not only sustain itself, but follow a course for significant growth.

That didn't happen. New choices from other automakers filling the void Volt did not are getting attention. This is why focus has shifted over to Bolt instead. This is also why there is such intense resentment for the reminder of goals.

Like it or not, that's the way things turned out.

10-09-2017 **Looking Back.** That crazy thread was about Bolt sales. They didn't take off as hoped. In fact, they lagged in the shadows of Tesla all year. Rather than being that runaway hit that revolutionized the industry, interest was tepid. Breaking the 200-mile distance milestone didn't end up stirring much interest. Supporters are learning the hard way that there's much more than faster & further when it comes to sales. Range-Anxiety wasn't the biggest hurdle to overcome after all. That's what made my favorite quote from the so-called discussion so meaningful: *"Hybrids? Why are you talking about old technology? We are talking about replacing these vehicles with plug-ins, not more gassers. This is the problem with Toyota, innovator's dilemma, thus: too little too late."* It confirmed a complete lack of understanding of how Prime actually works. I had wondered if the hate had grown so intense that there was no intellectual exchange anymore. Toyota's brilliant next step of adding a clutch to allow the 2 motors to operate together to provide additional electric propulsion-power basically meant nothing. It was a innovation so subtle, providing such a great return, that there was no real notice. It was assumed just a gimmick... rather than a stroke of genius... since it was a remarkably inexpensive upgrade. That's exactly what the industry needed. GM wasn't able to deliver that \$10,000 cost-reduction the enthusiasts had boasted about for years. They counted their eggs far too soon. Clichés are often convey a profound teachable moment. This was it. Cutting corners on Volt to make its price competitive turned into an epic fail. Meanwhile, Toyota was able to improve Prius to make Prime bay enhancing the existing design. In other words, they started with an affordable platform. Looking back, that's what I said would be advantageous right from the start... hence the enthusiast hate. My study of the industry took far more than just engineering into consideration. Having a background in marketing, accounting, and economics really paid off. Who knew a computer science bachelor's degree with a minor in business would be so beneficial in this. I understood far more factors were at play and correctly assessed their impact. I guess that means all that study in system design made difference. College was really fun. I got more out of it than I ever realized. Anywho, my prediction of Toyota being right on time with the right approach looks very promising. Cautious consumers will take notice; ironically, they'll notice the subtle those terrible troublemakers did not.

10-10-2017 **New Attacks.** They were expected. It's an unfortunate reality. The rapid fade away of Volt is stirring new discussion on the other forums. Prime is getting much more attention now. Fortunately, I'm fairly well prepared for it too. Dealing with stuff like this would be a challenge otherwise: *"Cherry picked list. Where is all the performance metric? That is right. You ignored it. You started to sound like a Toyota sales person."* It was in response to me posting that extensive list of Prime strengths. I know the antagonist was looking for acceleration speed... since that's all I had left out and all that he cared out. The first two items listed were about efficiency. He doesn't count that as *"performance"* though. He only cares about power... which is why I kept my response to him short. His opinion doesn't matter. He's clearly not representing the interests of mainstream consumers. So, it was just: That's called understanding audience. In this case showroom shoppers.

10-11-2017 **New Anger.** Whoa! Seeing that the Volt enthusiasts are now playing a hypocritical game of double-standards and moving goal-posts, there's quite a bit of new anger to deal with. They are claiming Toyota was caught totally off guard and without anything prepared. It's an effort to create a narrative that just plain doesn't work. Yet, they try anyway by claiming none of the hybrid advancement contributes to the delivery of an EV. Then in the very next post, we get a long story of how GM had used their own hybrid technology to deliver an electric-only vehicle. It's an act of desperation to portray past history in a different way, knowing evidence to the contrary is so easy to find. Why in the world would GM work so hard to deliver a second-generation plug-in hybrid with an expectation of it being replaced just 2 years later? That makes no sense in itself. Claiming that was the plan all along for GM, but a long-term strategy from Toyota along a similar path but without such massive sacrifice, is just so obviously wrong. Ugh. Oh well. It presented me with an opportunity to point out the true situation, via reply to a post comparing Equinox to Prius sales within that crazy thread:

RAV4 >> RAV4 hybrid >> Camry hybrid

Prius >> Prius Prime

Why anyone would compare a SUV to a hatchback? It makes no sense. The natural progression from traditional to hybrid to plug should be obvious. Each model will get an upgrade, though the path may differ though based on market.

C-HR >> CH-R hybrid >> CH-R ev

China will be getting that EV upgrade. Here in the United States, hope is C-HR will get a Prime upgrade to start with. The first EV model for here may be a dedicated electric-only platform, rather than an upgrade.

10-12-2017 **Cheese Emergency.** Gasp! We didn't have any parmesan cheese. Since the grocery store is just a little over a half-mile from the house, I saw no reason not to dash over there with the Prime. After all, the chargers are nice front spots that are usually available. For someone like me, that's easy to understand why. The entire visit, which included parking, plugging in, walking to get the cheese, wait in line at the register, paying for it, then unplugging took a total of 5 minutes and 28 seconds. That was enough to provide 1.7 miles of electricity. In that seemingly short amount of time, I had recharged enough to drive triple the distance required to get home. Just think what could have been possible with the Japan-only option of CHAdeMO charging for Prime. That connection delivers electricity in DC format, rather than AC. It's quite a bit faster as a result. Normal shopping takes 20 to 25 minutes. Imagine how incredibly convenient a visit would be then. After all, most visits won't be an emergency. A simple 10 minute stop for coffee could really make a difference for some people with longer commutes... who would be getting a morning coffee anyway. The grocery store hopes you'll also pick up a donut or something for lunch, as long as you are there. That sounds like a viable business plan to attract plug-in drivers.

- 10-13-2017** **Dead?** I asked the question: Volt is dead in favor of Bolt? That was met by an obvious act to spin history: *"That was the plan, Stan. All along. Volt has been described here and elsewhere as a gateway drug."* Knowing there are literally thousands of posts easy to find contradicting that claim, I was a bit taken aback. Knowing there would never be an admission of how hard GM fought against EV on so many fronts, it seems pointless to argue. Remember all that *"range anxiety"* campaigning? That rhetoric of how superior EREV was to all PHEV and EV offerings was intense. They had been so hostility in the past to defend Volt, it makes total sense how they'd try to distance themselves from that past as much as possible. After all, this is why the supporters vanished. They wanted no part of the terrible things enthusiasts were doing. Now, the enthusiasts don't either. Pretending this was the outcome hoped for all along reveals a different story though... since the actions don't make financial sense at all. So, I provided a brief and difficult to argue reply: That plan was for it to struggle with sales growth in gen-2, then die off mid-cycle as the tax-credit phased out! No.
- 10-13-2017** **Behind.** Spin about Toyota being far behind is the only recourse available to those still trying to portray GM as being far ahead. With the fallout of Volt becoming so difficult to conceal at this point, that makes sense. What else could they say? So, we get this: *"However, Toyota will be so far behind they will need to go to full third-party supply or buy drive trains from a competitor."* Reading that brings a huge sense of relief. Those few antagonists have nothing left, certainly no enthusiasm for Volt. It's too bad things came to this. Hope of diversity fell apart. Too much was sacrificed for faster & further. Oh well. I'll keep pointing out what Toyota did right and ask questions: Huh? RAV4-EV and Mirai already have electric-only drive trains produced by Toyota. Prime reuses much of that technology, including the high-end EV stuff... like the vapor-injected heat pump. Camry hybrid delivers the latest & greatest for their higher horsepower affordable electric-motor. And the lithium cells are being used in a variety of hybrids now. What is missing?
- 10-13-2017** **Other Reasons.** Trying to see from the perspective of an antagonist is odd. There is nothing else beyond just faster & further. From their point of view, what else is needed? They simply don't see the value in other vehicle traits or features or even price. Remember how with hybrids there was no value given to reduction of smog-related emissions? That was annoying. But to dismiss so much more, that's entirely different. It's all about being *"vastly superior"* still. That's really sad. At least they don't actually say *"vastly superior"* anymore. In the past, the smug really was that blatant. Toning it down is good, but in no way an improvement when it comes to sales growth. In fact, accepting the decline of Volt demand is far from a reality. That means there is very real potential for mistakes to be repeated, yet again. Oh well. I keep focusing on strengths. That's how you draw interest. This is how I handled the situation today: Think about all the plug-in shows I participate in with other owners of other types a battery vehicles. Do you honestly believe those checking out the cars are focused that much on acceleration and handling? Answer is no. Instead they ask about the very things I listed... the other reasons to buy a vehicle.

10-14-2017 **Audience.** We're getting back to basics. When a newbie posts this, you've got confirmation of that next chapter being well underway: *"I think you're fighting a losing battle. You should drive the Volt and find out how much better it is over the Prius..."* He had no idea I have and was not impressed. The reason why is simple, my criteria for *"better"* is much different. Mine is a close reflection of what mainstream buyers see as a priority. How could he not see that? It's another example of the *"other reasons"* problem. Obsession with faster & further blinds them from see the obvious. You'd think with so many years of struggling to grow sales based on that approach, they'd finally figure out what wrong. But then again, even though the enthusiast mindset is shared, the experience is not. This is how mistakes are repeated. Again, oh well: Convincing enthusiasts that ordinary consumers are not interested in paying a premium for *"better"* is a losing battle, but they do a great job of validating that point. 7 years of sales failed to attract GM's own showroom shoppers. Conquest wasn't enough. That's why they've moved on, from Volt to Bolt. That list represents aspects of Volt not addressed which that bigger audience would find of interest. It's a matter of growing sales now, not appealing to early adopters.

10-14-2017 **That's Reality.** The ironic nature of this posts left me beside myself: "*The reality is, in a market that only has a 1% share of the entire auto sector, GM is the sales leader. You need to compare plug-in sales among their peers to gauge success.*" This antagonist has been harassing Toyota with claims that they are stuck in an innovator's dilemma situation; yet, he's forcing that very perspective to make GM appear to have the upper hand. My definition of leadership requires breaking out beyond the 1%. He's doing everything possible to ignore the 99%. That's overwhelming confirmation of being stuck. When someone says we need to consider the forest and you insist only the tree directly in view is all that matters, that's a big red flag. You've become the problem. He still doesn't see it though. So, I climbed up on the soapbox:

Volt gen-1 was highly specialized, targeting enthusiasts directly... the 1%. Gen-2 wasn't able to overcome that barrier. Rather than reach a larger market, it remains trapped within a very small group of potential buyers. In other words, it's an innovator's dilemma situation.

Struggling to move beyond initial audience is a difficult problem to address. Toyota recognized the situation, which is why their gen-1 model was not rolled out beyond the initial 15 states and stopped production well over a year before revealing to gen-2. Figuring out how to configure a plug-in vehicle to appeal to a wide consumer base became meant patience. Change took time.

Signs of success from that gen-2 are emerging already. Beside the forecast of 50,000 to be sold the first year in 3 major markets, there's disapproval from enthusiasts. They don't like how it draws ordinary customer interest for ordinary customer reasons. Rather than a focus on faster & further, there's a nice balance of purchase priorities.

The other 99% don't need your approval... or even your opinion. Wanting to purchase a Toyota means an indifference to whatever GM is doing anyway. Those loyal customers are looking to replace their aging Camry, Corolla, Prius, or Scion with a new car. Prime will become a serious consideration for that audience.

That's reality.

10-14-2017 Shutdown. We're seeing an inventory pile up again. The slowdown of Volt sales has become so bad, there's a 4-month supply now available. Production will be reduced next week, then after a month of that, shutdown entirely for a month. Imagine that with Prime? Right now, my dealer only has 1 in stock. What a drastic difference! Think about who the customer for Volt actually is. It's the dealers, not mainstream consumers. GM must make their vehicle enticing enough to dealers to order them. If they are difficult to sell, the dealer won't. What consume limited lot space with a car that will sit there for months... especially if it's a challenge to get salespeople interested in showing it. What's the incentive? Selling an expensive car returning a very small profit means a very small commission. Why bother? Think about all the extra work it requires to explain charging. The larger battery-pack doesn't share the simplicity of Prime. Rather than 5.5 hours using 120-volts, which is no big deal overnight, Volt takes 13 hours. Do you really think a salesperson wants to bring up the purchase & installation of a 240-volt charger? Needless to say, the shutdown of production is no surprise. In fact, it was very predictable. Volt is a small hatchback. GM likes to build SUVs. GM customers like to buy SUVs. GM dealers like to sell SUVs.

10-15-2017 Continued Attacks. He's just making stuff at this point. What do you do when someone is so desperate they turn dishonest? His lack of understanding basic business principle combined with a desperate need not to be proven wrong is a recipe for endless posts. He just keeps attacking me. It's bizarre. Everyone else sees what's going on. You'd think he'd back down at some point. My next step is to make it personal. That's how you let everyone else know they are not part of it. You don't want to accidentally make the situation any bigger. State the situation with the hopes of ending it, then move on:

That isn't at all what I've been saying. You're making up stuff yet again. Fortunately, it is a great confirmation of status... more feedback I couldn't get from any other source.

The tax-credits are only for the sake of introduction, that 1% market you're still so hung up on. To exceed that, the technology must not have a dependency on subsidies. This is why the design has to be profitable. This is also why it must sell in high-volume.

As for Toyota losing money on each, there is nothing to support such a wild claim and an large collection of evidence to the contrary. In fact, even some here have repeatedly stated Toyota went "cheap" by leveraging the regular Prius to make Prime. That's exactly how profit is achieved.

With respect to not understanding either economics or accounting, that's your problem. There's no reason I have to even bother explaining why sales must grow to that mainstream minimum, especially after 7 years of Volt's struggle to grow. It's a basic business principle for the sale of a sustaining product.

- 10-16-2017** **Acceptance.** It's finally beginning to happen: *"This news is like the death of a good friend. Pretty hard to take, but we all could see the handwriting on the wall."* The reality of Volt's sales struggle leading to its demise was foretold. Accepting that wasn't easy though. Wow! The enthusiasts fought me with everything they could. It didn't work though... since I wasn't the enemy, nor was I the customer. They knew mainstream consumers should have been the target, but didn't want to accept a niche status. It didn't matter anyway. This is why I kept mentioning the showroom floor. To attract potential customers there, the dealer would have already had to buy into the idea. The dealer's purchase of inventory to sell is what made them the true buyer. Not understanding the actual business is why these engineers fighting me were doomed. They were fighting the wrong battle... and only now see the losses. It's too bad. Of course, Toyota will gladly enjoy the spoils. No more market confusion is a huge barrier removed. Yeah! This is what I had to say about it: Who is the market for Volt? I asked that question literally hundreds of times, trying to get it through to this group that those here are not at all representative of what's needed. GM catered to enthusiasts to prove the technology. It was a good audience, very receptive, very vocal. Unfortunately, moving on to that stage beyond early adopter is easy to misunderstand. Mainstream consumers are very different. Requirements were not correct. Sales didn't materialize as a result. Gen-2 should have had a very different configuration to make it appeal to such a different audience. This is where the hate emanated for Toyota. They targeted mainstream consumers from the start, skipping the *"early adopter"* stage with the plug-in Prius... since the technology was essentially proven already by the hybrid. Instead, a mid-cycle rollout to just 15 states was used to study the target market closer. It worked too. We see Prius Prime much closer aligned to ordinary customer appeal. Who cares about enthusiasts at this stage? Faster & Further isn't a strong selling point... as gen-2 Volt has clearly confirmed.
- 10-16-2017** **Cold Weather.** We're starting to see the first signs of Summer becoming a distant memory. Reports of morning frost have become a reality. That's messing up some data logging owners have been doing: *"What's going to do that list in is the ICE going on while I'm defrosting. Just starting to see temps in the 30's around here."* We haven't discussed Winter yet. That's an entirely new topic for the big Prius forum. Prime rollout didn't happen in the northern states until Spring arrived. I only saw a very brief snow fall with mine. Cold weather driving opportunity simply wasn't possible. Warming has already begun. I do have experience from the PHV though. That's a good background to leverage from. We can at least start posting thoughts. Real-World data will come in just a few weeks. Here's my contribution: Have you actually found the need to use that defroster (the dedicated physical button)? Choosing the blower option for the windshield with the electric-heat instead is all you should require with temperatures that warm. Even here in Minnesota, I don't expect to use that forced ICE option unless the car has been sitting outside in much colder conditions for hours without the ability to grid pre-condition. btw, it is interesting to see that Toyota selected an aggressive strategy with the ICE warm-up. The result is a net gain with the EV range as a result of it running to generate heat.

- 10-16-2017** **Spinning History.** Giving Toyota credit for planning a strategy consisting of a series of small steps with limited risk and the potential for huge gain won't ever happen. Instead, we'll get stuff like this: *"I guess battery technology has now advanced to the needed level. Amazingly, overnight, now that Toyota plans an EV."* The problem originates from the cultural difference. Continuous improvement has been a part of Japanese business since things were established after World War II. That's at least 3 generations with the mindset of no step forward is too small. Every advancement is progress. We don't think that way here. We analyze return and decide whether or not the effort is worth it. That's missed opportunity. Not seeing that does indeed make success look sudden. When the competition finally takes notice, quite a bit has already taken place. Oh well. All I can do is point out what hasn't been noticed and what's to come as a result: Is that like the *"overnight"* success of an artist who has been working hard for the past 20 years? Prius Prime offers EV driving up to 84 mph, complete with a high-efficiency electric heater and CHAdeMO charging. That sets the stage nicely for taking the next step. Looking closer at the new C-HR, you can see why it is expected to become their first BEV offering for China in 2019. In other words, that carefully planned progression is amazing... but in no way overnight. We have witnessed battery improvement from each hybrid upgrade leading to this point.
- 10-16-2017** **Looking Forward.** I don't expect this to be well received, but that isn't the point. You post something like this solicit feedback. Anything in return is confirmation of having read it. That's the point. So, I posted: We're starting to agree. Gasp! Looking forward, there's concern about getting households upgraded to handle that type of demand. How does a home with multiple vehicles? How do they even pay for the upgrades. For that matter, how do we educate people about what upgrades are needed and what the process is? This is why I place far less priority on faster & further and simply want to get plug-in decisions going. We have to start somewhere. Waiting for the ideal capacity, size, speed, etc is wasted time.
- 10-17-2017** **Inevitable Outburst.** I got my confirmation: *"That your posts are pathetic..."* Clearly, he got the message. Too bad there are some who refuse to simply be part of a team. Why must Volt be vastly superior? Why can't it just be a player helping to win the game? It's that homerun thinking. Rather than small advances for the chance of scoring a single, there's the hope of gaining a lot from just one hit. This is why there is so much mocking & belittling. Our culture teaches us to always fight, that winning is more important than just being part of the game. Ugh. There's so much waste with that approach. You don't place the entire game on just the fate of one hitter. Being a team means having a variety to "cover all the bases". It's really unfortunate that I have to interact with people online who don't notice the world around them. It doesn't require formal education in business practices or even that much study. They just have to observe what works and what doesn't, then make changes accordingly. Oh well. It's their loss. Meanwhile, I just keep providing my observations: Is being correct about Volt sales that difficult to accept? It's not like the technology itself was ever a sales concern. It was always the choice of configuration. For mainstream sales, a small hatchback with that much battery was doomed to struggle. It simply didn't match GM's consumer base. You made that sustain worse by supporting the decision for so long. Glad you're now seeing the technology would be a better fit used another way. Diversity support is long overdue.

- 10-17-2017** **Baseball Analogy.** It's quite remarkable having to deal with someone who just plain doesn't care. You are wrong. He is right. Period. Even with overwhelming evidence to the contrary, there is no compromise, no meeting in the middle. That stubborn attitude is a very real problem. If the person is unwilling to budge under any circumstance, what do you do? The advice I was given is to keep replies simple and use analogies. The response back will be an analogy that doesn't apply to the situation, but that doesn't matter. Everyone else will see that it doesn't apply and how desperate that person has become. It's sad that principle blinds some. Most people do tend to become set in their ways, far less open to change than when they were younger. It usually isn't a barrier to progress though. It only limits choice. In this case though, it's causing him to be left behind... hence all the "behind" references. That's the textbook reflection response I keep getting. Anywho, I did keep it simple with this analogy: GM keeps trying to hit homeruns. Toyota continues to hit singles to fill bases. The game isn't over, but the score is adding up.
- 10-18-2017** **Market Expectations.** We are still very much in the "early adopter" stage. It ends when the tax-credits end. In other words, when people are willing to pay full price, you know a true milestone has been reached. Meanwhile, we are getting into the gen-2 rollouts. That will create a nice used market for those looking for a bargain on a plug-in vehicle. That gives early adopters an excuse to upgrade. I'm obviously one of them. Of course, I sold my old plug-in to a friend, so that didn't contribute to the used market at all. However, it does still serve to influence more people. That's a new audience getting exposed to the benefits of being able to recharge at home, instead of a gas station. For the new market, we have lots of work to do still. Think of all the garages without level-2 support. Being able to take advantage of level-1 in the short-term is great, but ultimately upgrading from that ordinary household 120-volt outlet to a charger with a dedicated 240-volt line is a big improvement. There's also the complexity of households typically having 2 vehicles. How will those be accommodated? It's education about the technology, combined with cost-reduction, required to get growth to happen in the next stage. Whatever we can do now will help make it easier later. Right now, there's the basics to address still. We aren't even far enough along to set decent expectations. What should happen at public charging-stations? That seemingly simple question doesn't have any simple answers. So, even when we overcome the sales aspect, there is that to deal with too.
- 10-19-2017** **Wasted Space.** An owner pulled apart the back cargo-area of their Prime. I was surprised to find out how long it took for a thread of that nature to finally be started. I had my battery-pack exposed within hours of purchase. Of course, I needed that information to confirm I wasn't going to interfere with any of the sensors by taking so much apart to install that receiver-hitch. Anywho, this ended up as a comment posted: *"Before you say it's for cooling, there are TWO substantial blowers there for that purpose, ducted from the left and right rear passenger seat-backs."* He was talking about the unexpected void underneath. Like most, the expectation was that the battery-pack was consuming that entire area. It isn't. There's about 4 inches of empty space. Naturally, many theories are being shared about why that is. This was my contribution to the discussion: Air is an isolator. Radiant heat from asphalt and extreme cold are battery enemies. Having an extremely lightweight layer of protection like that makes a lot of sense.

10-19-2017 **Prius v Gen-2.** Toyota doesn't like to rollout too many new vehicles all at the same time. There's nothing to gain and lots of extra overhead doing too much at once. So, we get staggered introductions. The new Prius and RAV4 hybrid was enough, last year. This year, it's C-HR and Camry-Hybrid. Between those with staggered distribution was Prius Prime. Back in last 2011 thru early 2012, we had the rollouts of Prius v, then Prius c, then Prius PHV. Understanding why, it's easy to see how the very first spy photos of the next-gen Prius v are only now emerging. Toyota kept silent, hiding its development until just yesterday. We hadn't heard a peep. Nothing at all, even rumor. With a vehicle style so popular within the service industry and a strong choice for families not interested in an SUV or minivan, you'd hope there would be an upgrade of some sort. It now looks like there is one on the way. The snapshot of the camouflaged vehicle is clearly a large Prius. It doesn't look wagon-shaped anymore. The style appears to have taken on some aspects of being a CUV, but without anything resembling heavy-duty suspension or all-wheel drive. That would seem an excellent design for our changing market, especially if it were to get the hybrid system of Camry hybrid. The added power, while still delivering outstanding efficiency, is what Toyota needs to keep the product-line strong. That sets up their customer-base for an easier transition to plugs. Dealers & Salespeople will especially like that. My guess is that we'll have detail by the Detroit autoshow early next year. Perhaps, we could get a little bit of teaser information in the meantime. Whatever the situation, news of this first sighting spread like wildfire across the internet. I was able to find several instances of the photos attached to articles in other languages. And with the power of Google Translate, reading them was a snap. Like all things Prius related, patience is required. For now though, let the rumors spread. That helps raise awareness. I'm sure there are many who were not aware that a wagon model of Prius was even offered.

10-20-2017 **Reality Check.** When I bring up having a Prius Prime in a random audience, even when in context, the response is typically some type of "wow" and nothing else. That happened this week in a class I was attending. It was about process improvement. Our education was an in depth look at how. General Electric and Toyota are industry leaders in this, each with an extensive list of success stories. Naturally, the dialog came around to a topic related to Prius itself. So, that was an excellent opportunity to share my own real-world experience and how it related to exactly what Toyota had strived to deliver. Anywho, I only had them captive for a few minutes. Like most people, they weren't interested in much detail because they were not shopping for a new vehicle. I see that trait a lot. Consumers don't research unless they are in the market to purchase. So, there isn't anything to gain by providing that detail. You offer a few well thought out basics, share what they express interest in, then move on. That usually last anywhere from 30 seconds to 2 minutes. Rarely will I even get asked anything beyond the basics. We simply aren't at that next stage yet. Early adoption is pretty much just a phase which you raise awareness. Teaching more isn't realistic until the market has advanced. Fortunately, Toyota is making a lot of small steps. It will be easier to draw attention when lots of hybrids have already replaced traditional vehicles. It makes the step to a plug that much smaller. For now though, patience.

- 10-23-2017** **Priorities.** Some people don't understand how to deal with complex issues: "*They were shoe-horning a big battery into a car not designed for it so they just threw it in the trunk.*" Part of it is the internet culture. Taking the time to analyze all the points rarely happens. The venue isn't supportive of that. You cannot convey complex information into a simple post. I keep trying though: You can't do it all in a single upgrade and we know there are more to come. Toyota chose to deliver a robust battery for an affordable cost, at the tradeoff of it not fitting as well. The result was an impressively efficient vehicle so competitive, it makes you wonder how likely a next-gen model without a plug will be. Successful business requires a balance of priorities. As much as the engineers here would like more, it simply doesn't make sense after you come to realize the actual customers are dealers. Think about it. What incentive is there for a dealer to purchase and stock Prime on their lot? It won't return much of a profit and their staff must do more to prep & sell the vehicle. Battery design doesn't even come into play. Dealers are much better off simply selling guzzlers. Why spend extra resources knowing you'll get less in return? People here need to step back and look at the bigger picture.
- 10-23-2017** **Nope.** I liked reading this: "*Except actual customers are required, and therefore they need to actually consider the packaging...*" It was easy to say "no" to: I just finished taking a class on business process (six sigma) where we analyzed the how's and why's of large-scale success. We learned about seemingly sensible conclusions like that having cost some companies billions in losses. Toyota was brought up on a regular basis with unexpected examples of success. Who is buying vehicles from the automaker? It is dealers, not the people who will end up driving the vehicle. Lego is an example of having failed to understand that, suffering from an entire decade of serious financial trouble. They also thought their customers were the people that used the product. Turns out they were wrong, very wrong. It was the retailer. When places like Target & Walmart didn't get what they wanted from Lego, they chose to fill their shelves with something else instead. That was a painful lesson learned. Ordinary showroom shoppers want a well-balanced vehicle at a reasonable price that's very reliable. It doesn't have to be perfect. In fact, the expectation is that in years to come that next offering will be better. They want to have a selection of them available for immediate purchase. That only happens if you have a dealer pleased to carry them. Business is not as simple as it seems.

- 10-24-2017** **Continuous Improvement.** I said it was always the plan, as is cost containment. That was confirmed correct. Our official Toyota representative posted the following about the generation design of Prius Prime: *"The two main options to reduce the gap - either redesigning the traction battery to fit in a different space, or using a separate under-floor assembly unique to the Prime - both would drive up the cost of the vehicle pretty significantly. It was a difficult tradeoff, but we stand behind the decision that we ultimately made on this version of the vehicle."* That priority of keeping cost in-check, to ensure affordability, rings through as strong now as ever. That was always essential with each generation of Prius. Sure, they could enhance performance, but the cost increase wasn't ever worth it. That's not how you design a vehicle for the masses. Instead, you provide continuous improvement. That's why each generation is so much better. You deliver what makes sense for that time. This has proven a very effective approach for Toyota. Unfortunately, the bottom-up mentality makes for great ridicule material. The top-down pushers love to mock & belittle that opposing method. They don't see their smug either. The view of *"vastly superior"* is something I know all too well.
- 10-25-2017** **Solid-State Batteries.** Elimination of the electrolyte in lithium batteries would allow for both greater energy-storage density and faster recharging. It's what Toyota has stated they are working toward for their next-generation plug-in vehicles, including their first EV for the masses. It's a challenge for the battery industry which many battery-powered devices will benefit from. Think about how great it would be to replenish the battery in your phone with just a few minutes of charging. Technology leaps forward like that are what we need to stir interest for plug-in vehicles. What we have now proves they are worthy of consideration, but the need for improvement is obvious. At least it sets the stage for realistic expectations. This isn't a miracle. It's a matter of getting the chemistry refined for mass-production. There's enough potential for serious development work to deliver a paradigm-shifting return. In the meantime, platforms are being proven for this upgrade.
- 10-26-2017** **Gen-2 Leaf.** Since early September in Japan & Europe, there have been 9,000 orders & sales. That's a great start, very encouraging. It will be exciting to see what happens here in the United States. Production isn't even expected to begin until early next year. That's a little later than expected, but no surprise. Toyota took a multi-market approach with Prime for first-year rollout too. That resulted in understandable, though annoying, delay. Hitting a wide variety of customers right away makes planning for production ramp-up more accurate. That challenge can be risky, since profit-margins are razor thin still. Getting a better idea of true demand really helps, especially when you know supply will be thin for quite awhile. However it plays out, this serves as the rude awakening GM enthusiasts have needed. With all of their promises being proven false hope, we can finally get down to addressing what the business truly needs. Their want obsession has caused far too much delay. Nissan deserves a kudos for the push forward. The rut Volt got stuck in was getting rather ugly.

- 10-27-2017** **New History.** We get a lot of history rewrite attempts. But now things are changing. The upcoming plug-in hybrids open new questions. Today's came about from this: *"60 hp electric motor? Sounds like it'll behave more like the first-gen plug-in prius where the engine really is necessary for almost every trip unless you plan on holding up traffic."* I stated, then asked: Prius PHV didn't actually work like that. Basic merges onto the highway didn't trigger the engine. Though, it wouldn't have mattered anyway, since the design was for it to optimize blending, not to act as an EV. Prius Prime has a different purpose. It was indeed designed to act like an EV, so you can drop the pedal and do an high-demand merge without need for the engine. You can switch to EV-Auto mode for additional power, but owners say that pretty much never triggers the engine. The new clutch that allows both electric-motors to provide enough power. With my Prime, I'm always in EV mode. The only time I ever switch to HV is for saving EV when on long highway trips. (Of course, I have taken advantage of Charge-Mode a few times on trips.) I'm just about to 10,000 miles and a need for EV-Auto still hasn't come up yet. Something to keep in mind about new plug-in hybrid market entries is heating. There are a variety of electric heaters, some more efficient than others. That obviously impacts the range available for EV driving. When an electric heater is drawing load from the battery, will that cause the engine to start sooner? So, this begs the question... does Kia even have an electric-heating option?
- 10-27-2017** **Troll Attacks.** Enablers like to call you out as a *"troll"* when you post anything that doesn't support their narrative. It's really annoying; however, the emergence of *"enabler"* as the term to identify their activity is redeeming. They can't just cry wolf anymore. That rebuttal label is quite effective. I dealt with today's related situation this way, saving the label for later: To be a troll, posts are off-topic and have the intent of stirring emotional response. Quite a number of Volt enthusiasts attempted trolling with me. Most of their bait was entirely wasted. I kept my broken-record approach staying on-topic and polite with posts about goals. It made them crazy. That's called irony. Their own posts stirred emotion in them, not the person they were provoking. Anywho, one of the die-hard Volt enthusiasts abandoned Volt in favor of Bolt. The hypocrisy of being so anti-EV, then buying one. Ugh. Despite his focus now entirely on electric-only driving, he's been attacking Tesla supporters. It's really caused quite a bit of anger... even within the Volt forum. A thread was started to point out his activity and it went on for 52 posts before getting locked. It a case of just wanting to fight, without any interest in a common cause. That's why I had so much trouble. The idea of cooperation was never acceptable.
- 10-27-2017** **Dropping Temperatures.** It has begun. Snow fell today. That was the first for the cold season. Temperatures for the morning commute had been in the low 50's. Yesterday, after driving 19.7 miles in EV with the electric-heat set to 65, there were 10.8 miles of estimated EV remaining. That was 36% of the overall EV capacity available. It represents a clear impact to overall range; however, that reduction from the dropping temperatures clearly isn't so much that it would cause range below 25 miles. Delivering that distance in all be extreme cold conditions says a lot for the approach. Keeping the design affordable by trading off battery-pack fit clearly didn't mean sacrifice to overall efficiency. Yeah!

- 10-27-2017 Freezing Point.** It's 32°F here in Minnesota now. We've been getting very wet snow here all day. Just a few minutes ago, I was at the grocery store giving the remote-climate feature a test for the first time using the "Max Heat" setting. Plugged in, I wanted to see how much electricity could be used to recharge the battery-pack with that much demand from the heat-pump. Knowing that max uses far more electricity than just at setting of 65°F with ECO, having to wait so long for this test was a big deal. Way back in 2010 when Toyota provided me with a prototype plug-in Prius to play with, it was August and the decision had been to not include a heat-pump. Anywho, in the 12 minutes I was away from the car, the charger provide 0.64 kWh of electricity (at a steady rate of 3.16 kW). That resulted in only an estimated 1.3 miles of electricity being added to EV range, but the interior of the Prime was toasty. Sweet! And yes, interior heating takes quite a bit more electricity than cooling. Fortunately, we get a high-efficiency heater... a vapor-injected heat-pump, which better than both the regular type of heat-pump and quite a bit better than the resistance type.
- 10-27-2017 Still Not Getting It.** That problem Bolt owner is drawing a lot of attention now. A comparison was made to me, sighting the narrative that all my posts were only about blind loyalty to Toyota and Prius. That portrayal of exclusivity was a diversionary tactic to draw attention to the problems I was pointing out about GM... and the sensible suggestions I was providing. Knowing that and not wanted to bite that bait, but wanting to join the discussion, I chose this to respond to: *"Just like john1701a, --- is illogical and irrational in his Tesla bashing and partisan boasting."* Until that point, I had remained silent. The invitation from being specifically called out was too good to resist: I was correct about GM's approach. The concern about *"too little, too slowly"* that I echoed from the bankruptcy recovery plan was right on the money. Volt struggled for 7 years and 2 generations without achieving the goal of high-volume profitable sales. The promise of a plug-in SUV never happened. Hope for diversification has faded away. GM delivered an expensive system in a small package that was neither an efficient EV nor an efficient HV. It was the worst of 3 worlds. But since it performed so well in terms of power, supposedly that factor alone would be how sales growth was to be achieved. That failed and enthusiasts have moved on to Bolt. Nothing about that is illogical or irrational. Pointing out the opportunities GM continues to miss is not bashing, it's constructive. Just think if one of those suggestions had been followed. Rather than Volt becoming a forgotten chapter in the early years of plug-in history, the potential could have been exploited. Instead, the problem of *"range anxiety"* now has a different solution.
- 10-28-2017 Winter Conditions.** 82°F back in June, the 7.5 mile drive to the coffeeshop took 19% capacity. 34°F a few minutes ago, that same 7.5 mile drive to the coffeeshop took 29% capacity. Increased resistance from outside air, reduced efficiency from the battery, combined with the electric-heater set to 65°F in ECO revealed the harsh effects of Winter. For me, that means my 19 miles of commute each way should remain in EV. The catch is that drive-time can be dramatically longer in on snowy days. Fortunately, those don't actually happen often. It's mostly just continuous sub-freezing temperatures for many weeks in a row. Obviously on those days when it dips down near 0°F and below, running the engine will be a welcome addition to heat provision. Regardless of Winter conditions, the resulting MPG will be outstanding. Also having the benefit of pre-conditioning the interior using electricity directly from the grid will be a very nice bonus.

- 10-28-2017** **Outright Lies.** Having a president who says anything he wants, then doubles down when it is proven untrue, it's no surprise people online feel comfortable posting outright lies. Despite knowing that, I was flabbergasted seeing this today: "*If you search for Volts online, you will find only black ones! Does this tell you anything?*" It's so easy to disprove, why would anyone take such desperate measures? Oh well. I let him have it: Yes, it tells me you can say anything you want on the internet. That doesn't make it true though. Using cars.com search, I found 5,933 Volts available for sale. All were new. All were not black. 2,713 of them were last year's model. That tells me GM is in a world of hurt. Having that many still in stock the last week of October is a very real problem. Over supply is a costly mistake for an automaker. Dealers get upset with that much old inventory to still sell when shipments of the new continue to fill precious limited lot space. Here's the color counts I found... Beige (6) Black (1,165) Blue (651) Brown (1) Gray (1,222) Green (89) Red (379) Silver (724) White (1,515) Other (181).
- 10-28-2017** **Claiming Superiority.** That Volt enthusiast so desperate to undermine Prime, we're getting stuff like this: "*GM is too far ahead of consumer comprehension of Voltec Superiority, as you fully well know.*" I remember dealing with posts like that when there was little data to back up the unrealistic expectations. But now that those events have come to past and we now have proof, it's rather bizarre to still be seeing them. Oh well, again. I followed through with: That claim of superiority has proven meaningless, since it didn't result in needed sales. In other words, the extra work GM did attempting to hit a homerun didn't result in a homerun. All they did was get a runner on base. That's it. As for your on-going attempts to somehow make this about Toyota and Prius, stockholders couldn't care less and neither could Volt supporters. Both hoped for high-volume profitable sales... which didn't happen after 7 years of trying and unsold inventory is now piling up. To make matters worse, that \$7,500 tax-credit GM relied so heavily upon will trigger phaseout next year. With sales of Volt well below mainstream level and slowly dropping, achieving the significant growth that's needed looks quite unrealistic. This is why most interest from enthusiasts and attention from GM has shifted over to Bolt instead.
- 10-28-2017** **Not Paying Attention?** You have to ask yourself that after reading this: "*I suspect that TOYOTA will join the push for pure EVs rather than much further development of the Hybrid concept, though almost certainly they'll keep PRIUS going for at least another generation.*" It could also be that people posting comments like that have no engineering background. It's easy to see how assumptions could be made about design. You'd think that motor & battery would be recognized as transferrable. Perhaps not. But with Prius and Prius Prime co-existing, you'd think they'd recognize the situation. I pointed out: They already have. Prime is a full EV in every respect. Efficiency, Power, Heating, Cooling, Charging... Now they are heading down the path of lowering cost and increasing capacity on a larger scale. Solid-State battery technology is the solution they're investing heavily in. That level of EV advancement is what the entire industry yearns for. None have anything resembling such a paradigm shift... yet. In the meantime, continued improvement with the EV technology deployed in Prime and Mirai helps advance the overall electrification effort.

10-29-2017 **Heat Power Usage.** We're getting questions now that reflect more than just basic interest: "*Any sense of how much power the seat and steering-wheel heaters use?*" That's how we get newbies to stay in discussions. They wonder & ask. We do our best to figure out how to get answers. Early on like this, there isn't much to work with still. At least I had this to contribute, related to the use of the heater to pre-condition the car for you prior to driving: Nothing for seat or steering, but I measured one full cycle of remote climate on MAX HEAT. It uses 0.37 kWh.

10-29-2017 **Runaway!** I found this hysterically amusing: ">>>> *EVERYONE PREPARE TO ABANDON THREAD* <<<<" The hypocrisy has become so bad, all they can do is runaway now. There is literally nothing left to say that won't be called out as contradictory with past statements. History has exposed their mistakes and they don't want to be reminded. I remind them anyway:

Ironically, there is no "*everyone*" here to direct that statement to anymore. This explains the extreme measures taken to keep what remains going. Notice how there aren't any topics about Volt now on this Volt blog? Virtually all focus has shifted to Bolt, the very antithesis of Volt.

Remember all the "*range anxiety*" propaganda? It was the solution to fear of running out of electricity and becoming stranded. Volt was far too complicated though, making it unable to compete with the traditional vehicles it was intended to replace. Bolt is quite simplistic in comparison... still too expensive, but better for long-term investment.

This is why when discussions are entirely about GM, some Volt enthusiast will ultimately end up shifting attention to Toyota... the automaker who actually figured out how to deliver an affordable plug-in hybrid. Resentment of having succeeded reminds us of the original definition of trump: to outrank or defeat someone or something, often in a highly public way.

Moving to Bolt is a welcome improvement. Ever since the concept reveal of Volt, far too much emphasis was placed on making a statement... rather than actually changing the market. At least with this attempt to deliver something offering a plug, there is focus on a larger audience. The cramped rear seating for Volt never made any sense and was made worse with gen-2.

Sadly, the typical GM customer still won't be interested. Bolt does nothing to appeal to SUV buyers, the dominant market for GM. Those shoppers have literally nothing green to choose from still. Equinox & Trax are only available as traditional vehicles. No plug. No hybrid. Nothing. That lack of electrification progress continues to be the concern.

- 10-30-2017** **For Example.** The Volt enthusiast didn't like reading this at all: "*A sale is a sale, but automakers historically dislike it when one product in the portfolio cannibalizes demand from another, because it can erode profit margins and frustrate marketers and production planners.*" All along, I kept pointing out how conquest sales were a terrible means of advancing a technology. True, it proves worth, but there's no long-term gain if you all you do is attract non-loyal customers. They just take advantage of low lease-rates and tax-credits, then move on to the next bargain. There's no interest in purchasing another GM product. We've seen that play out too. They don't become loyal supporters. In fact, many couldn't care less. It's a waste. I called it out as squandering subsidies, an obvious missed opportunity. Now, we see Bolt taking interest away from Volt almost entirely. Are any of those sales attracting loyal GM customers? This is how I stated it today, upon providing that example article link confirming what I had been saying all along: My supposed bashing was about GM's continued terrible business decisions. At times, there can be a reference to Toyota's formula for success, but focus is still very much on GM. After a decade of claiming high-volume sales and 7 years of attempts falling well short, what do you expect? GM executives admitted the Volt's biggest hurdle for many of its seven years on the market was an inability by the automaker and its dealers to effectively convey how the technology worked.
- 10-30-2017** **FULL!!!** It was a sweet sight today. For the first time ever, I got to see all 6 charging stations used at the ramp where I park for work. 2 Prime, 2 Leaf, 1 Volt and 1 e-Golf were all plugged in. That's great. Someday though, I won't have a place to recharge. Gasp! Imagine that as a problem. It will help support the plans for offering more plug-in spots in the future. We have to start somewhere. The population of vehicles able to take advantage of the opportunity is painfully small still. You spot a handful of them on the road each time you go for a drive. That gives the impression of progress... until you realize just how many guzzlers were also seen. It goes to prove how early in the transition to electrification we are still. There's a long way to go still. Any claim of "*late*" is totally inaccurate, an obvious attempt to not take the situation seriously. Traditional vehicles totally overwhelm still. 6 plug-in vehicle seems great... until you realize just how much non-plug-in vehicle fits on the 8 levels of parking there.
- 10-31-2017** **Charging Prices.** There are a lot of napkin calculations taking place now. We are far from any type of pricing pattern or consistent message. There's lot of variety out there and the prior generation of plug-in vehicles certainly didn't establish any type of expectation. I jumped into a discussion about that when this came up: "*Guess 240VAC public charger (rate of \$1/hr)*". Hopefully, it will help stir interest: Keep in mind that public-charger pricing varies dramatically. The ones just a few blocks down the road from me are free. The ones further off at the park have a flat per-use fee along with a per-hour rate. The ones at the mall are per-kWh. The ones at work are for an 8-hour span with a single price, but there's a fee if you exceed the time. Electricity rates will vary dramatically too. I pay 0.0710 per kWh (tax included) for overnight charging. During the day (non-peak, tax included) the price is 0.1204 per kWh. For the after dinner hours (peak, tax included), the rate jumps to 0.4180 per kWh. If you want to take advantage of pre-conditioning, rather than getting into a cold car, that electricity must be accounted for. However, that is a luxury feature many would be willing to pay a premium for. Running MAX-HEAT on the 10-minute remote climate cycle will consume 0.37 kWh.

- 10-31-2017** **Spinning History.** You've got to like this: "*This was the plan all along.*" That quote emerging out of the shift from Volt to Bolt is most telling. When reality of the situation first became apparent, reaction was to suppress information to that affect as quickly as possible. It was a state of panic. Enthusiasts were about to be exposed as hypocritical for now supporting the very thing they had for years fought so hard against. To change perception, they instead claim that was the plan all along. Clearly, it was not. It is heavily documented in these blogs, confirming otherwise. There isn't any need to look backward though. Knowing that past isn't necessary. Just look at what's happening now. 3,053 available 2018 models in inventory waiting for the 2,614 remaining 2017 models to be cleared out speaks for itself. Clearance time should have been over in August. Dealers don't like getting stuck with so many unsold vehicles, especially the ones that are low-volume. Claiming that was the plan all along requires disregard of some important factors. Looking forward makes the claim even more difficult. Production of Volt has been shutdown and won't resume until early next year. What will expectations be for dealer interest? Why would anyone believe the waning interest will encourage ordering more? With the upcoming phaseout of tax-credits, it is reasonable to see Volt becoming a sold-order vehicle rather than keeping them in stock. In other words, we're seeing a shift of priorities. This topic of labor practices is undeniable evidence of that. The days of "*vastly superior*" engineering focus are over. Business is taking precedence. That's good in regard to support, but it reveals much about what GM still must address to make Bolt a success.
- 11-01-2017** **Oversimplification.** Certain names pop up from time to time. They are the antagonists. Their intent is to undermine in any way they can. Today, it was the subtle approach: "*There are no free power conversions. So, using gas to charge the battery will always be less efficient than using gas to drive the wheels directly.*" This would seem reasonable... to the uniformed. That means direct confrontation would halt the assault, but leave those newbies confused or misled. That meant I had to be subtle in return: Oversimplifying efficiency equations is a common problem. It's very easy to overlook the opportunities the power-split system exploits. Using an aftermarket gauge, watch RPM of the 3 components at play all at the same time: gas-engine, traction-motor, generator-motor. You'll see the flow of power being redirected several times per minute. That's because roads aren't really ever flat or straight; traffic isn't constant either. Those tiny variations are losses. The hybrid system takes advantage of them, reducing their impact. The result is an efficiency gain. Each opportunity adds up to a noticeable overall MPG boost.

- 11-01-2017 Targeting.** It's interesting to read comments on the new venue, one for plug-in supporters of all types. There, the well rehearsed debate material can be presented to a new audience. Results are dramatically different than that of the Volt blog prior to 2017: There's a fundamental misunderstanding of market still at play. Who is GM targeting? Looking back to the beginning of the plug-in hybrid offerings, the most common trade-in for getting a Volt was indeed Prius. But with those Prius at high miles and with GM leases so cheap, who wouldn't choose that? Volt never appealed to the masses, only early adopters. It was low-hanging fruit though, now all picked. When the leases expired, they moved on. Fast forwarding to the gen-2 rollout, we found out that GM decided to leave the rear seating cramped and only modestly improve HV efficiency. That left Volt in a difficult position with the "*range anxiety*" sales strategy. Why not just buy a Bolt instead? After all, most Volt owners did everything they could to avoid having the engine start. We now see Toyota & Hyundai/Kia targeting the void GM was never able to fill, offering an affordable plug-in hybrid for the masses. Prius Prime is loaded with safety features standard and is more efficient in both EV and HV modes. MSRP is so low, the phaseout of tax-credits won't even be an issue. Volt's is far too high still. Success of Bolt is great, but it does leave you wondering if GM plans to compete in the plug-in hybrid market.
- 11-01-2017 History Exposition.** It's difficult to slip in details about the past on that new venue, since the response is quite unpredictable. You have to try though: Prius PHV never remotely shared the same purpose as Volt. Toyota rolled out a mid-cycle upgrade to 15 states, testing the waters with real-world market research before going mainstream. Watching GM struggle made the decision to postpone expansion until the next full-cycle easy. That meant not having to deal with gen-1 differences at all in 35 states. The gen-2 model would be new to dealers, mechanics, salespeople, and customers. Prime is what ended up being the first with mainstream intent, with a worldwide rollout all in the first year. The total sales for 2017 will end up exceeding 50,000. Growth is absolutely essential. We are no longer dealing with early adopters. Appealing to ordinary consumers is very different. Toyota was well aware of that situation. GM clearly was not.
- 11-02-2017 Grow Sales.** Reminders of what's important need to be provided too: AFFORDABILITY was always a top priority for me and no amount of Volt enthusiast rhetoric could break that priority. It was a very real concern that sales would struggle from high prices, even with heavy dependency on tax-credits. APPEAL to mainstream consumers was the key and still is. If you can catch the interest of someone casually shopping the showroom floor, you have a product able to please consumer & business need. Volt never could achieve that, despite all the faster & further hype. REALITY is crashing down with an onslaught of guzzler support. We don't want to lose momentum on plug-in vehicle acceptance. That means making hard decisions and acknowledgement of a changed market. Let go of the past... otherwise, I'll just remind you of my concerns having been validated. Look forward. What do we do now to grow sales?

- 11-02-2017** **Enthusiast Obsession.** Sometimes the blindness from faster & further makes even the basic understanding of how ordinary customers approach the process for selecting a new vehicle impossible to see. They simply have no clue others don't share their priorities. For example: *"Are you suggesting that 'showroom shoppers' look for Dualwave glass, Predictive Efficient Drive, and Directed Heating & Cooling? Sounds like a bunch of buzzwords to me to detract from less electric range, less seating, fewer airbags, less horsepower, slower 0-60, etc."* A mainstream consumer wouldn't even encounter that information until it is stumbled across right there on sight. Ugh. All I can do is point out their oversight... which I don't expect to do any good: Not understanding the "buzzwords" will do that. This is why the in-person experience plays such a vital role. Also, use of "less" and "fewer" and "slower" is an indication of not properly recognizing mainstream audience. As much as people like to believe the marketing of those traits is the bulk of what buyers actually buy, it simply isn't true. The masses go for balance and don't obsess about wants like early adopters. None of those standard safety features listed draw in customers from whatever they may stumble across prior to going to the dealer. But once they are there looking at what's on the window-sticker, things like Dynamics-Radar-Cruise pop out as a strong want. As for the dual-wave glass, in-person compliments are plentiful. Most people say "Whoa!" when they see it, then start asking questions... which is exactly the type of showroom reaction salespeople want. Know your audience.
- 11-02-2017** **Halo Effect.** Each month, slipping sales brings out rhetoric so effective, the people spreading it are clueless as to what they are actually saying: *"Brings people into the showroom so they at least consider Chevy."* Remember how that used to be a bad thing? Now, the misdirection is thought of as a normal part of the purchase experience. Sadly, that's the perspective I have come to expect from the Volt enthusiasts. They simply don't care about actually replacing traditional vehicles. It's a matter of pride now, protecting reputation by putting up a good show. That's such a disappointment... and such a waste. Oh well. I keep providing those reminders: When a person is shopping the showroom, we want them to actually purchase the vehicle that catches their attention. Having a "halo" vehicle instead is in no way what I posted. As for the rest of what you posted, it indicates being a "niche" vehicle. That is a problem too. We want to sell lots of the vehicle, not use it as a technology showcase. Sales in high-volume is a necessity for the automotive business. Simply selling lots of guzzlers instead, like Equinox (25,722) and Malibu (14,647) and Traverse (11,098) in October, is not the outcome we want. And with the possible abrupt end to tax-credits, it's going to be even more difficult to sell Volt... and for that matter, Bolt. Think about the anti-plug movement that's growing. Search the internet. You'll find articles stirring FUD about batteries. The best defense against that is getting more plug-in vehicles on the road as quickly as possible.

11-02-2017 **Continued Attacks.** This is all you need to get an idea of what I encounter routinely still: *"...are admitting the weak position of the Toyota Plug-in entry? What a flake car."* That smug attitude of being *"vastly superior"* from some enthusiasts is alive & well still. The difference now though is their voice is beginning to get drowned out by other plug-in owners. There's power in numbers. The voice of ordinary consumers can be rather loud too. This is very much a welcome change. I jumped in with: Production capacity is key to making prices competitive with the fierce challenges of overcoming guzzler appeal. Toyota is looking to deliver 50,000 worldwide this year. That's a very clear push toward sustainable high-volume sales. How is that a weak position? This is what I pushed for Volt, hoping gen-2 would take on an affordable design approach. But rather than doing what was necessary to achieve that much lower cost, GM stuck with the *"strong"* position and ended up delivering a vehicle only appealing to early adopters. Face the reality that the ability to appeal to mainstream buyers requires more than just delivering faster & further design. GM has a very real challenge approaching with the loss of tax-credits and much lower MSRP choices from other automakers on the way. Are you really going to waste time posting stuff like that, rather than providing constructive suggestion? Bolt had a strong sales month. What are you going to do to help promote it to sustain that success?

11-03-2017 **Being Warned.** What can you say to this: *"Did no one believe us when we warned everybody that this would happen?????"* You spend years showing concern. They spin it to make those posts appear to be attacks. Anything a Toyota owner says must be an effort to undermine GM. They were too ignorant to believe an partnership among plug-in owners would be possible. That has cost them dearly. Mistrust is such a waste. What did they have to lose? Was it really that much of a risk to not even try? Ugh. Oh well. Turns out, they lost far more than ever imagined. All I can do now is remind them of those mistakes to help prevent them from repeating... yet again: Sadly, no, it was quite the opposite. When I brought the topic up, there was an enormous amount of effort expended to assure people this wasn't anything to be concerned about, that I was just spreading FUD. So now, it's long overdue to acknowledge the reality and come up with suggestions about how to proceed. My suggestion was originally to offer a second model of Volt with a smaller battery-pack, which would make it both more affordable and more efficient. Upon the realization of how misaligned gen-2 was with needed audience, the suggestion became a switch to just focusing entirely on getting a plug-in choice for GM's primary buyers... SUV shoppers. In other words, find a solution that doesn't require tax-credit help ever. Make sure the initial rollout MSRP is relatively competitive with other GM offerings. Set a target premium. For example, design a Chevy Trax to deliver a plug with a price no higher than \$5,000 above the median traditional package price.

11-03-2017 **Flag Waving.** Knowing how much of Bolt is from Korea, reading statements like this is annoying: "*Only change i would make is, STOP giving american taxpayers rebates to FOREIGN car companies.*" The irony is rather redeeming though. They blindly wave the flag without bothering to actually do any research. The fact is, we see LG supplying GM with battery cells, the completed pack, the management system, the power electronics, the traction motor, and the transmission. That's a major portion of the vehicle. What non-foreign components make it worthy of stopping subsidies? We benefit from reduced oil-dependency and cleaner air regardless of where the business headquarters are. Manufacturing of vital components is clearly not in America. Annoyed, I posted: There are many clichés to describe the unintended consequences of such a decision. Instead, define a clear purpose. With a precise goal, it's much harder to take away. In this case, there was no obvious intent. Was it to prove the technology? Was it to attract mainstream buyers? Was it to help establish infrastructure? Was it to get automakers to try something new? Fundamental clarity is essential. Notice how we still have no idea what purpose public chargers are intended for? There is no agreement of any sort about who should use them, for how long of a duration, and for what price. It's so confusing ever to us. What message does that send to those considering a plug-in vehicle. Heck, we don't even know how to deal with a ICE'd charging spot. It's time to step back and ask what's really important. Disagreement about petty things, like battery-pack size, have been a massive waste of resources... our own brains about how to effectively entice new customers to buy.

11-03-2017 **Leadership.** Refusal to acknowledge facts leads to cherry-picking so well accepted, you don't even notice the altered perspective of reality: "*...awards those manufactures who have taken the risks and are now established as the leaders.*" Leading people in the wrong direction is not good! This is why stating goals has always been vital. Yet, many absolutely refused to. Volt turned into a disastrous waste as a result. Delivering a great product to for such a small audience was a terrible plan. They endorsed it though, assuming the leaders knew that path was the correct one. Clearly, it was not. Now, there's a mess to deal with. Thankfully, we're still in the early stages. So, despite the disaster, it's not a total loss. The situation remains a matter of stating goals. This is what will put GM back them back on the right path. Unfortunately, it points them in the direction of Nissan & Toyota, who already have sizeable head starts. Their pride will likely make the next step harder as a result. But any step forward in the right direction, even a small one, is progress. My words this time were: Leadership in the early-adopter phase (defined as gen-1 offerings dependent upon tax-credit subsidies) is very different from leadership in the next. The struggle to overcome this new barrier is known as innovator's dilemma. To be a successful in the mainstream phase (defined as high-volume profitable sales able to compete directly with traditional offerings) requires cost to be low enough for competitive pricing. In other words, no manufacturer is actually an established leader yet.

11-04-2017 Denial. Encouragement isn't always welcome. The barrier of pride is difficult to overcome. These words of mine prompted yet another head-in-the-sand reaction: *"In other words, find a solution that doesn't require tax-credit help ever. Make sure the initial rollout MSRP is relatively competitive with other GM offerings. Set a target premium. For example, design a Chevy Trax to deliver a plug with a price no higher than \$5,000 above the median traditional package price."* It never ceases to amaze me how attempts to ignore a problem are the most common reaction. How does running away from the issue help resolve it? I ended up following that with:

Lots of negative votes from that post. Why?

There has been a lot of spin & rhetoric from me having pointed out the importance of understanding audience on a regular basis. But it was for good reason... we'd see the end of tax-credits after the early-adopters used them all up. Ordinary consumers would have nothing as an incentive as a result.

The original plan from GM was to reach mainstream minimum sales volume by the end of year 2 for the first-generation offering. That's 60,000 per year... which meant there was an expectation of sustainable sale without subsidies prior to second-generation rollout. It was a strategy with the intent to make the technology as high-volume offering.

Is everyone here just going to abandon the idea of GM offering any type of plug-in hybrid in favor of only EV choices?

There seems to be no interest anymore, when attention should be the highest. Volt worldwide sales through September for 2017 only come to a total of 19,748. The month-to-month decrease in sales and the continued build up of unsold inventory is a clear indication that a significant decision must be made. This new concern of federal incentive loss highlights the vital nature of timing even more.

More pressure is about to be added too. Hyundai will soon be rolling out an plug-in hybrid sedan with an emphasis on affordability. Kia will be doing something similar with a SUV. From Chrysler, we already see a boom in sales for their plug-in hybrid minivan. And of course, there's Toyota with Prius Prime already at 39,369 sales worldwide for the year, as of September.

What should GM's plan be for plug-in hybrids?

11-05-2017 **Extreme Reaction.** That post wasn't well received, as this simple reply clearly conveyed: "*Are you high?*" I fired right back at that:

No, I'm pointing out what was hoped for and supported to happen... not the reality of the situation. The who, when, and how much details often get distorted when looking back. This is definitely the case. For example, what exactly does "quickly" actually represent?

People with sound business & engineering background were constantly fighting those who saw the situation as only needing a simplistic "if we build it, they will buy it" approach. Spin started right after the reveal, claiming the "*40-mile, 50 mpg, nicely under \$30,000*" delivery criteria for late 2010 was totally realistic. Any mention of "vaporware" was met with hostility. Yet to this day, 10 years and 2 generation later, that criteria still has not been achieved.

Failure to deliver can be argued away by addressing market change. That's acceptable; however, an alternative must be viable then. It is not. Bolt replacing Volt doesn't actually achieve the overall goal of offering a competitive choice for the masses. GM's other vehicles are far more appealing to their loyal customers.

This is why enthusiasts of Volt continue to drag Toyota into discussions, attempting to make it look like I did. They see how Toyota designed Prime with that loyal customer audience in mind. The configuration has been given a balance of price & features with the intention of swaying over their traditional buyers without the need for a paradigm shift.

We all knew GM wasn't using federal incentives for the purpose they were intended. Conquest sales wouldn't change their own loyal customers' purchase behavior. The term GM had coined for the modern version of "bait & switch" to insult Toyota with had become GM's own business practice. Talking about self-fulfilling prophecy. Saying "*halo vehicle*" for so many years made it their own reality.

Tax-Credit phaseout was supposed to occur at a point which high-volume sales had become established and sustainable profit without the subsidy would be realistic. That wasn't going to happen even with the anticipated time-table. GM's abandonment of Volt being a range-anxiety solution to Bolt leaves Volt in a world of hurt mid-cycle. Will that supposedly "*vastly superior*" technology just die as a result?

- 11-05-2017** **Top Speed.** It's nice when questions come about from discussions trying to uncover technical detail. I provided an answer for that today: Top-speed of electric-only driving is based upon kW draw. If demand exceeds capacity, the engine will simply start up to provide that additional power. This is why you get a wide variety of answers when asking about maximums. People make anecdotal observations rather than use an aftermarket gauge to figure out what's really happening. Long ago, it was a 10 kW draw. That would allow a decent amount of power up to 25 mph. Faster, power dropped off significantly until the max of 46 mph. But with the larger battery for PHV, despite also being a gen-3, max was increased to 62 mph (that's 38 kW or 51 hp). With the gen-4 Prius, you can see even faster electric-only speed. That is also dependent upon power demand, but is a little more squishy than the hard limitations we saw with prior generations. Basically, the engine will shut on & off during the course of ordinary driving. It's among the methods used to deliver outstanding efficiency without plugging in. With Prime, you've got the much larger battery along with the clutch to include the second motor for quite a bit more overall power... enough to accelerate all the way to 84 mph (that's 68 kW or 91 hp) using only electricity.
- 11-06-2017** **Climate Change.** It's a bizarre situation when political stance on the environment takes such a drastic viewpoint, one blatantly contradictory to what scientific data shows. The administration doesn't like it, so they don't accept it. They just plain don't care. Despite a long report released today overwhelmingly proving we are having a direct impact on climate change and must take immediate action to prevent worsening damage, there's just an outright dismissal. It's not even an effort to discredit. The evidence is simply ignored. Treating it as unimportant is what we see now. When it is brought up, they just move on to the next topic or bring up a diversion. The disregard as if it isn't even an issue is so odd. You wouldn't think that level of complacency would even be attempted, since it would be so obvious. Yet, that's what we are seeing anyway. This level of selfishness, to preserve the status quo, is truly amazing. Greed is a powerful motivator and there's lots of money to be made when the effects of climate change are not taken into consideration. Pretend it's not a problem...
- 11-07-2017** **Why?** Clearly, purpose of the federal subsidy was not understood: "*Maybe having the credit extended would encourage GM to continue offering the Volt, which is an AMAZING car. I'd like THAT!*" Of course, most people posting nowadays don't have any knowledge of the history. Not being aware of the past makes a difference. I wonder if my injection of information will: Remember the tax-credit for hybrids? That \$3,150 for the first 60,000 purchased was intended for market growth, since the technology had already been established. Toyota triggered phaseout in just 9 months too. Goal achieved. The \$7,500 for the first 200,000 was far more generous, yet had much lower expectations. Why should such an offering be continued? Volt is still a small hatchback, the type of vehicle GM customers simply aren't interested in. Subsidizing that doesn't make any sense, especially when it took so much longer to reach the trigger volume. In other words, what should the goal be now? With the technology so well proven now, there must be some type of timeline & quantity requirement. Why reward any automaker not committed to rapid & significant growth?

- 11-08-2017** **Tank Refill.** The act of going to the gas station to refill the tank is becoming so rare, I have a hard time remembering when it last happened. Typically, it's due to an upcoming road trip where I'll need to do some long-distance highway driving. Otherwise, I'd likely see a pattern of every 6 weeks or so. That's around 2,000 miles per tank. It's an interesting statistic I hadn't considered. The assumption was being closer to the much celebrated 1,000 miles per tank we heard GM so often promote for Volt. Perhaps it will and my driving circumstances just happen to be ideal. But then again, I expected the frequent trips to be out of the ordinary. Whatever the case, it has been interesting to watch the overall MPG average continue to climb. I suspect it will plateau around the upcoming holidays. Approach of the new year often brings a bunch of unplanned running around in extreme cold conditions... which can be quite significant, here in Minnesota. We'll see what happens. I'm certainly looking forward to the experience, even if it does send me to the gas station more often.
- 11-09-2017** **4K Video.** I've filmed a few videos, capturing my commute to & from work, using the new camera. But all that footage was in HD still. The setup up to 4K resolution requires a new approach. Even though I had worked really hard in the past to refine the rigging, simplification was still needed. It took too long to get everything in place and there was no guarantee of consistency. So, I began my experimentation today. No more anti-glare blanket. That was a pain to get in place... too many soft & firm pieces to assemble. The camera mount itself was still presenting challenges as well. How could I get a quick & easy process in place to deliver even higher quality than in the past? Today was my effort to give it a try. Hopefully, this first drive will deliver some obvious improvements. I'm willing take apart what I had in the past to see if a new approach will work. After all, anything I can figure out now... prior to the arrival of the extreme Winter weather... will be a welcome change. Wish me luck.
- 11-10-2017** **C-Max Energi.** It was rolled out in October of 2012. Today we found out, 5 years later, production came to an end last month. Ford delivered 40,690 of that plug-in hybrid. That was between 7 and 8 thousand per year, which wasn't much. Odd configuration of the battery-pack may have contributed quite a bit to the disinterest. It's hard to tell. That protrusion into the cargo area was much more than the floor lift we see in Prime; however, that is a factor to keep in mind. Though, we could see Toyota finding a way to condense stack density to make it smaller for lower placement in back. So, it could end up a non-issue anyway. Efficiency wasn't as good as Prius. Lower MPG for HV makes sales harder. People expect hybrid performance after depletion. There was that scandal too. Whatever the case, it wasn't a SUV and that's what Ford shoppers would like. We know there's one on the way. So, this discontinuation isn't a big deal. Of course, it draws even more attention to audience targeting.

11-11-2017 Closure. Summarizing the chaos and hostility over the years isn't all that difficult. Volt failed to attract GM's own loyal customers. With Toyota striving to draw in their own loyal customers using Prime, the reaction certainly has been intriguing. Antagonists see the potential and try their best to spin away the position outlook. It's not working though. I stated why:

The point of all of this was to draw attention to the bigger market, to finally look beyond the initial audience. It's obvious this group does not want to, that they are not ready to take the next step. So, I'll simply end by restating points of a nicely balanced offering and why we will see those sales grow...

\$27,100 for a high MPG hybrid that also offers 25 miles of EV along with:

- Dynamic Radar Cruise
- Pre-Collision Braking
- Lane-Departure Detect with Assist
- Automatic High-Beams

That describes a well thought out vehicle appealing to a very wide base of consumers.

11-11-2017 Reaction. Going down without a fight isn't acceptable. Some absolutely insist on getting the last word in. That gives me the opportunity to continue stating purpose... as well as point out observations: The desperate reaction of participants on this thread to spin & suppress information is amazing. They see that year 8 of Volt is off to a terrible start. Inventory is currently at 5,800 unsold. That's an undeniably bad sign, especially knowing Bolt will be the source of conflict to come. Adding to the growing pressure is the reality that there are a number of plug-in hybrids on the way, all with tax-credits still. The crutch Volt depended on will vanish in the meantime. Negative vote posts to make them disappear. Sticking your head in the sand won't fix the problem though. It's too bad those who dismissed it didn't take the situation seriously. That concern of "*too little, too slowly*" has been validated.

11-11-2017 Waste & Avoidance. The perspective of someone refusing to accept defeat brings out interesting comments: *"I find it odd that you consider GM developing several different plugins architectures, and selling 160,000 of them, as a waste... and I bet Toyota is kicking themselves. Now they have to play catch-up."* They simply never see the bigger picture. Acknowledgement of the market as a whole doesn't seem important to them. That's a vital mistake, but the effort to justify poor decisions of the past is even worse. It's avoidance to the extreme, as I pointed out:

Shortsighted perspectives will do that. 160,000 is the typical sales expectation of a core-product mainstream vehicle for just a single year. That's right on par for GM's base... Malibu, Cruze, Equinox, Trax, etc. Use of tax-credits to not support a technology to replace them, but to rather be a niche offering primarily for conquest sales, is certainly not what they were intended for.

Call the missed opportunity anything you want. I will call the *"behind"* narrative a waste, knowing the affordable configuration Toyota delivered is what was needed to appeal to their own customers. GM can continue with their *"halo"* vehicle. It's just more time wasted if it doesn't get their traditional buyers to switch over to something with a plug.

Continued spin that this is really not about GM, that it is somehow a defense of Toyota, has no merit. EV efficiency delivered in Prime is among the top. 4.7 kWh with the heater running makes it a very worthy contender. 60 MPG averages on the highway (and even higher on suburb roads) is among the top too. Claiming Toyota is kicking themselves and having to catch up simply makes no sense.

7 years later, there still isn't a Voltec offering available that appeals to the typical GM shopper. Even with the generous \$7,500 tax-credit, Volt struggles to draw interest. It's too expensive and doesn't come close to appealing to GM shoppers who favor SUV choices. Opportunity missed is waste.

We all saw the writing on the wall. GM would shift efforts from Volt to Bolt... because what they delivered for a plug-in hybrid wasn't enough to appeal to their own loyal customers.

11-11-2017 **Goals.** The denial runs quite deep when you actually have to ask, after all those prior exchanges: *"Why would someone shopping for a Prius go with a PP when they can save \$3000 by buying a regular Prius that comes with those same features, and they get 5 seats instead of 4? How is Toyota going to attract its own customers with a more-expensive vehicle that offers less?"* Oh well. That's how you go about closing a chapter:

About a decade ago, Toyota set out to deliver a plug-in hybrid based upon the premium their customers would be willing to pay. The price targeted was \$3,000 to \$5,000... which is exactly what ended up being delivered. They stayed true to the goal that was set.

As for offering less, the loss of a squished middle seat doesn't ever come up as an issue anywhere except in arguments online. If you truly need it, you'll just end up buying another plug-in later. Prime is only the first model to be offered... and it won't take over 7 years for the next.

That \$3,000 buys the customer roughly 25 miles of EV along with the plug-in benefit of pre-conditioning. The result is absolutely outstanding MPG combined with a comfortable smooth & quiet drive. Whether or not the quad-led highlights or the dual-wave carbon-fiber hatch come into play is just a bonus. They are getting quite bargain on the efficiency boost.

Appeal isn't just directed to those shopping for a Prius. Think about those considering purchase of a traditional Camry. There are many models more expensive, including the hybrid. Excitement from the EV experience Prime delivers on a test-drive can be a powerful draw. No special equipment needed for an overnight recharge either, just an ordinary household outlet. It's a simple, affordable choice.

11-12-2017 **Serious Change.** The message from Toyota is beginning to emerge as a significant investment in hybrids... without anything being said about electric-only vehicles. It's the typical short-sightedness combined with a big dose of forgetfulness. Toyota already stated plans to move away from traditional vehicles with an "all hybrid" plan. We have also heard about the EV intentions. But since those are focused on 2020, there's that absurd panic to deal with in the meantime. It's the same old spin that started when PHV was halted and we heard nothing about Prime. Looking back at long-term strategy that had been shared didn't happen. People just jumped to conclusions based on only the information available to them at that very moment. Ugh. I tried to provide the voice of reality:

- Camry
- Avalon
- RAV4
- Highlander
- Corolla
- C-HR

All are vehicles we recognize as common choices here in the United States. All are offered as hybrids somewhere in the world. Other models not known here, like Estima (small AWD minivan), are available to other markets as hybrids too.

The point is that Toyota is striving to end production of traditional vehicles by pushing all those non-trucks into the hybrid category. The next step of adding a plug for the masses will come easy then, with the majority of vehicles on the lot already having a battery-pack.

None of the other non-luxury legacy automakers are pushing for such change. Only Toyota is looking to alter a large portion of their fleet in the not-too-distant future. That grand-scale thinking should not be so easily dismissed.

Think of the message it sends to both customers & dealers. That is serious commitment to change, not a token or uncertain effort as we see from others. It's an effort to reach beyond the barriers all automakers must face to end their own traditional production.

11-12-2017 Quick. The antagonist posts were shift & plentiful. None actually addressed the "*quick*" reality though. As if overnight, with no resistance at all, the automakers will magically shift over to EV offering. No challenges, issues, or concerns from dealer or consumer. It is obvious. It is painless. It is about to happen. Ugh. What it really is can be stated with one word: "*unrealistic*". It's like when a politician promises quick restoration after a natural disaster. Again, ugh. Oh well. All you can do is provide "*I told you so*" information, since they won't bother to listen to reason until it's too late: Why don't believe in a phased approach? That has been overwhelmingly successful in the past. Are you really expecting the other automakers to drop all traditional vehicles and go straight to BEV as quickly and on the same scale as Toyota with hybrids? Our infrastructure can handle a rapid next step from hybrid to plug-in hybrid, which would dramatically reduce emissions & consumption. How will BEV be handled? Think about where & how people park at home. Setting that up for overnight charging to support large battery-packs for 10's of millions of vehicles quickly is not realistic. In other words, emergence of a wave of anti-PHEV sentiment is going to faced a harsh reality. What is the true goal for the next decade... dramatic improvement or elimination? I don't see legacy automakers stepping up to high-volume, multi-model BEV offerings that quickly and the thought of allowing new non-hybrids to continue to populate our roads is very upsetting.

11-12-2017 Too Late. The rhetoric that Toyota is hopelessly behind and will never catch up is an act of pure desperation, since statements like this aren't followed by any reasons why: "*By the time they realize EVs are the future, it will be too late for Toyota.*" They just chant that mantra over and over and over. Lack of anything to support the claim should be a red flag. Unfortunately, the internet is filled with enablers. They want to believe it, so they validate by agreeing. Those enablers do a great deal of damage. It's really unfortunate. But then again, the support of true supporters can fall victim to being naive enough to believe that doesn't ever happen. It's makes for a seemingly hopeless situation... hence the success at conveying a "too late" message. You see no obvious reason to question the claim and reputable data is difficult to find. I try to share the knowledge. Though, it is challenging. Today it was: Using the identifier of "*PHEV fan*" but not actually understanding how a Plugin-Hybrid-Electric-Vehicle actually works is rather ironic, especially when making comment about Prime. That offering from Toyota provides a full electric drive experience. Everything operates using electricity. The smaller battery-pack is all that really sets it apart. That combustion-engine is not necessary. There's 2 electric-motors for propulsion and a heat-pump for warming & cooling the cabin. A claim of "*too late*" doesn't make any sense. Too late for what? Toyota will have invested heavily in high-volume production of battery-cells, traction-motors, controllers, and heat-pumps. Isn't that exactly what you need to build an EV? Nothing is missing. What is the supposed problem? Think about the economy-of-scale benefit. Think about the massive build up of easy-upgrade customers. Think about the reputation for abandoning tradition vehicles across the fleet.

11-12-2017 Past & Future. Closure gets weird. Witnessing the end of such a troublesome failure can make it even stranger. You sometimes end up with distorted history and strange perspectives. Oddly, it wasn't that way this time. It was nothing but a spin attempt to make the first Volt appear to have been a complete success and Prius a terrible failure: *"What's your, I mean Toyota's, excuse for the Prius Plug-in vs Gen 1 Volt?"* That's just plain old damage control, nothing special. Things are sounding like it is indeed over. So, I jumped in with:

Toyota designed gen-1 Prius PHV to deliver a significant MPG boost to the hybrid system. Exactly what they intended is what they rolled out. The message to consumers was obvious too.

GM stated intentions for gen-1 Volt to deliver series-hybrid operation, a full electric experience without ever using direct-drive for propulsion. That most definitely is **NOT** what they rolled out. People had no clue what in was and still to this day are uncertain of purpose and how it operates.

Neither had the potential for high-volume profitable sales. So, looking back doesn't serve much purpose. However...

Toyota had the good sense to restrict availability to just 15 states, so real-world data could continue to be collected without influence to the rest of the national market. Consequently, they don't need to re-educate the untouched locations. Gen-2 would be the first, a design modified specifically for mainstream buyers based upon real-world data findings. They took the time to analyze the market. Measure twice, cut once.

GM simply dove in head first, using their precious limited supply of tax-credits and muddling up their own customer base. Gen-1 was a disaster with respect to market acceptance. Too expensive. Too small. GM shoppers simply weren't interested. Many buyers ended up being those lured from other automakers by incredible lease offers. Why not take advantage of such low payments for a vehicle you only had to commit 3 years to? Gen-2 improved range & power while delivering a modest price reduction... no where near enough to stir demand. GM shoppers still aren't interested.

2018 brings about new plug-in hybrid choices from other automakers, in addition to triggering the tax-credit phaseout for GM. Along with so much emphasis now being focused on Bolt instead, demand for Volt will continue to drop. Will the idea of a plug-in hybrid from GM just fade away as a result?

11-12-2017 **It Happened.** Hints in the past became a full blown declaration: "*Volt has been replaced by Bolt.*" Exactly as what had been feared about the past repeating happened again. GM rolled out diesel and made a mess of the market, almost killing it entirely. GM did the same thing again with plug-in hybrids. They messed up so bad, their sales struggle just about destroyed the possibility of any other automaker successfully rolling out their own. It was nasty. For 7 years, nothing could be said about anything from Toyota without a direct comparison to GM. That wouldn't have been a problem if Volt actually sold in high-volume. It didn't though. Interest never grew beyond niche. That meant a mainstream offering like Prius PHV was doomed to have to deal with Volt fallout. It would be held back by hype. The idea of "*better*" soured potential. That's the trademark "*over promise, under deliver*" problem GM still has yet to overcome! They mess up everyone in the process. Fortunately, they move on from failure rather quickly. Remember how the Two-Mode disaster was quickly pushed aside in favor of Volt? We now have the same thing happening with Bolt... which is what I stated would happen when the name was first revealed. The confusion would make the transition easy. I joined in to help the process along: Do you think GM will actually send that message of intent? Lack of clarity has been a fundamental issue since even before Volt was rolled out. It would be nice for all involved to understand purpose & goals.

11-13-2017 **Really?** The dramatic change having taken place seems to have gone unnoticed. It's so extreme; yet, there's no acknowledgement or even a sense of awareness. The hypocritical nature of such contradictory behavior seems good reason not to bother even addressing it. They won't hear the message anyway. That would be enablement though. You don't want to provide a silent vote of acceptance. So, pushback is required. Point out the change, drawing attention to it anyway you can: The group **WAS** strong opposed to EV. That fact is written in stone with the words: *RANGE ANXIETY*. Remember that campaign and all the pushing against Tesla & Nissan? Seeing Volt abandoned in favor of Bolt is quite paradigm shift. We could see this coming. Volt owners would go to extremes to avoid using any gas. Simply making the battery-pack larger eliminates the need for such a system. That's why there was so much upset when BMW ended up delivering what GM originally intended.

11-13-2017 **Video: Cold Morning.** The thought was that conditions would be much colder here in Minnesota later, so simply giving the new 4K camera a basic shakeout before would be good practice... so I didn't bother to clean the windshield or setup any anti-glare material. Little did I know how great the clouds would look on that blustery cold day at 10X speed. I pre-conditioned the Prime just before leaving and had the heater set at 65 ECO with driver priority. So, this drive gives you a pretty good idea of what an ordinary commute is like when temperature drop below freezing, but conditions are still tolerable. Watch the various gauges as I drive. Note the speed, the traffic, and the conditions while enjoying my first 4K footage of the Prime. See it here... [Cold Morning Commute](#)

- 11-14-2017** **Video: Accident Delay.** It is interesting to hear someone cry "*troll*" even though the posts are on topic and clear attempts to stick to business goals. Meanwhile, I have to deal rhetoric chants and blatantly false information with no data to actually back any of it up. Fortunately, I now have video conveying real-world data to help counter the greenwash efforts. I can remind them of the goal to promote widespread adoption of affordable plug-in choices while pushing their nonsense out of the way. Sharing of owner experiences is very powerful. In my case, I do that by filming drives. This one was intended to just be more test footage, but the unexpected circumstance of getting trapped in an accident delay made it as keeper. It was an opportunity to be in stop & slow traffic with the electric heater (vapor-injected heat-pump) running, just like I'll be doing in the winter... but not actually having to deal with the mess fresh snow makes. Fortunately, the congestion experience wasn't too bad. The lighting during sunset made for interesting video to work with. And of course, there was still enough electricity available to stay warm and drive entirely in EV mode. Watch what I saw, in 4K resolution... [Accident Delay](#)
- 11-14-2017** **In Your Head.** The denial is so extreme, it boggles the mind that you'd ever have to deal with such nonsense. Yet, there it is, post after post. That was claimed to be "*in my head*" though. None of the rhetoric exists according to them. All of the spin is just an illusion, not any basis in reality. Ugh. Fortunately, it is easy enough to provide proof to the contrary: Avoiding detail and evading goals is what you do, not me. GM needed to achieve sales at a minimum of 60,000 per year (5,000 per month) prior to tax-credit phaseout for Volt to become a sustainable & profitable vehicle. That failed to happen with gen-1. This is what the "*too little, too slowly*" concern was all about. Excuses were given. Delay was accepted. Gen-2 rolled out. Sales were even worse. They have been successively dropping, rather than achieving growth as needed. Spin whatever you want. Blame whomever you want. It doesn't matter. The result is support has moved to Bolt instead.
- 11-15-2017** **Too Bad.** It didn't go over well. To that, I thought "*too bad*" and posted this follow up: Nicely under \$30,000. The business reasons why that goal was set by GM for Volt were sound. Enough sustainable demand would be needed prior to tax-credit expiration to ensure strong sales (5,000 per month minimum) could be profitable. Your obvious disregard for that yesterday, spinning posts as an endorsement for Toyota, didn't hold up. Nissan & Hyundai also share that same goal. The importance of price was repeated by others several times in that thread. GM must deliver something nicely under \$30,000 without tax-credits. Too bad if you don't like that. Too bad if you feel it dilutes the market. Too bad if it makes the vehicle ordinary. You've know for years that diversity was essential for growth... hence the too little, too slowly. An affordable choice must be offered.

- 11-15-2017** **Magic.** Here's yet another "same dance, but different song" situation: *"You can't hide the battery cost, there's no magic wand that Toyota waves to eliminate the cost of the EV drivetrain."* That's the no-free-lunch argument. Rather than acknowledging worth, they eliminate any possibility of success through outright dismissal. Seeing no value in change is key. Pretend there isn't anything to gain in return. If magic isn't used, there's no reason to consider it realistic. That's the kind of nonsense I have to deal with. Day in, day out, it's the same stance being taken. No magic beans, no gold egg. Ugh, yet again. I responded to that waste-of-time with: That has never been necessary for any hybrid or any plug-in. For the past 20 years, the goal has always been to offset cost. You can spend more upfront on the vehicle because it will save you money in fuel & maintenance later. That still holds true today. It is a matter of how much is that worth? People do put value on reduction of emissions & consumption. Switching from oil to electricity has clear, easy to understand benefits.
- 11-18-2017** **Too Late.** A few days later, I am now playing offense: *"Remember that discussion covered price-points, confirming \$30K was the proper target for when the tax-credit expired."* He tried to spin the situation as if was brand new, never having been addressed before. It's a common tactic. You are basically just pressing a reset button, taking the discussion back to the starting point... rather than address the points that had already been brought up. We see this routinely in politics. People know they have limited cards to use, so they forcing only the games to be played which show them favorable. It's like choosing which game will be played after the dealing. That's not even cheating. It's a way of winning by betting on the horse after the race has been run. That's manipulation. Anywho, he sounded off with: *"No. You just made that up now."* It's not even worth looking up posts of the past, though I was tempted to point out the hypocritical move. Instead, I posted: Discussions of price-point have been brought up on a regular basis. Rather than just negative voting, try actually reading what's posted. Of course, it doesn't matter anymore. Too late is now a reality for Volt. The price for Honda's plug-in hybrid was just announced. \$80 more for a vehicle with vastly superior seating is a no-brainer. It makes you wonder what GM's position on Volt really was. Could price have been reduced to make it competitive? Or was Volt basically just abandoned in favor of Bolt?
- 11-18-2017** **Not Yet.** How to respond to this: *"Toyota still doesn't think electric cars are ready for mass consumption."* The short-sighted and poorly informed usually are the one making comments like that one posted today. So, not much of a chance to influence their thinking. Those without a business background likely won't understand the elements at play, but not being expensive does draw attention. Perhaps there is a possibility for them: Electric clearly isn't affordable yet. That's a harsh reality to accept for those who don't understand the masses. This is why Toyota is pushing so hard to phaseout traditional vehicles. Already having that well underway positions them better for when that next-gen battery does become realistic. Potential from solid-state chemistry will allow greater energy-density and faster recharging. Getting someone to upgrade to from a hybrid or plug-in hybrid is much easier than going straight from a guzzler. Don't forget that the primary customer is the DEALER, not person who actually purchases the vehicle. That's a difficult perspective to acknowledge... until you try shopping for a plug-in. Most dealers simply aren't interested yet... because they aren't affordable yet.

11-19-2017 **It's Over.** Attempting to spin what I said by making it seem like I'm the one posting spin: *"I see you have now pivoted to Honda... more EV range, which is the most important stat when you are talking about EVs."* I was not assumed, nor did it matter. I know it's over. He knows it's over. We're done. Honda is helping to make that happen. It really burns Volt enthusiasts when the subject of opposition isn't Toyota. They don't know how to fight that fight. The precedent was established & reinforced for beating Prius... not some new unknown. Anywho, I fired back with: The obsession with faster & further has blinded you from seeing how vital low MSRP actually is. After all this time, that reason for Volt's struggle to achieve sales growth should be obvious... especially with the rapidly approaching tax-credit phaseout about to be triggered. Nicely under \$30,000 is still the price-point for vehicles in the compact/midsize category for very high-volume profitable sales... the "bread & butter" product for automakers... seen as a ubiquitous choice, since they are so common & affordable. The category of *"somewhat over \$30,000"* is for the midsize category often looked upon as the larger no-compromise family vehicles... Accord, Camry, Fusion, Malibu. Ford's sales have been strong, despite the limited EV range. Honda is about to take that on directly. Seeing a model of Camry hybrid offering a plug from Toyota on the way is quite realistic. Clearly we can see that Volt is now misplaced, unable to attract sales with such a high MSRP in a such a small body. In other words... no pivot, I simply see what's happening with the market.

11-19-2017 **Home Charging.** The first new illustrated document I have created for Prius Prime owners is now complete. It's presented as stand-alone information all about home charging. But in reality, this is really just a chapter in the upcoming User-Guide. Writing each section for such a large resource to share takes quite awhile. Simply due to the effect of seasonal changes, there's no way to deliver something comprehensive until you've experienced a full year firsthand. So much is based upon observation, that you need to witness quite a bit, then share what was learned with others to find out what's anecdotal and what's really a pattern. The goal is to set realistic expectations. I take lots of notes & photos. Over time, what's important begins to stand out. That's what refine into a collection of need-to-know facts. In this case, it's all about charging at home. You get a 120-volt charger with the purchase of Prius Prime. That included hardware works fine. If it is all you ever use, no big deal. It obviously will do the job. That's all I ever used at home for my 5 years of ownership with Prius PHV. But having moved to a new house and got married, it was time to setup a home for 2 high-speed chargers. So, I documented my experience in detail about the setup required to take advantage of 240-volt recharging. There's a wide variety of equipment to choose from. You will likely have the option of selecting a discount program from your electricity provider too. Knowing what's available is key. Hopefully the examples I share will be a good basis for owners to begin their research. After all, once you get use to plugging in every evening, the idea of not having a vehicle that uses electricity seems bizarre. Why wouldn't you? It's especially rewarding when finding out how basic the process is. Not knowing where to start is often a big barrier. This new document will hopefully make that much easier... [Home Charging](#)

- 11-20-2017** **Album 207.** My time is beginning to free up. Phew! I finally have the opportunity to start sharing some of the photos I've taken. On this new webpage, there are several. Having completed research, it's exciting to start sharing what was learned. That's something I immensely look forward to with each new generation of Prius. I'm starting with some photos to show how I captured the video. That question gets asked each time I publish something. So, taking some nice photos to convey that information is a good idea. In this case, I got really lucky with the timing. Those photos require soft lighting. I just happened to time it with the color of a Fall sunset. That makes sharing what I do even more exciting. There's also a nice collection of photos included in the Home Charging document. Time-Of-Use meters setup for each of our Level-2 chargers is likely something most people haven't ever seen before. After all, most people rarely even think about what a 240-volt line can be used for. The idea of setting one up to take advantage of price discounts is definitely a new concept for most. I took a variety of photos of the screen in Prime related to charging. It's a nice sampling for those who don't even know where to start. Look for them here... [Photo Album 207](#)
- 11-21-2017** **Album 208.** With the exception of the yet-to-be published collection of photos taken while on vacation, not a lot were taken. Much of my available time was taken by other ordinary non-transportation needs. So, finally being able share the other odds & ends that I do have is nice. There are several random photos, in nice weather, before the crazy cold & messy conditions that will soon become the norm. I stopped for coffee, at a location where I could plug in. Parked next to me was a BMW i3. Little did I know that when I mentioned charging inside that the owner would be standing next to me. I enjoyed that exchange of information... and got a memorable photo from it. My wife and I carpool as much as possible, but that doesn't always work out. We have events that take us elsewhere some evenings. So, driving separately happens from time to time. I have captured that in a few photos too. After all, 2 shiny new Prime parked side-by-side at the chargers isn't something you see everyone. We do have that setup at home too, each with our own charger. Naturally, I captured some of that setup to share as well. You'll find them all on this particular page... [Photo Album 208](#)
- 11-21-2017** **Reality.** An early adopter coming to terms with the reality of mainstream priorities... Now, I've seen it all. There's not much else to say. The goal all along was to make the perspective of ordinary people know. That wasteful trophy-mentality has been so costly. What a terrible experience. The opportunity lost is mind-boggling. Who would have ever imagined the idea of a plug-in hybrid could be messed up so bad. Paying little regard to the importance of cost was huge mistake. It was a gamble that ramping up production would result in massive drops very quickly. Turns out, with little demand, there's no way to make those price reductions a reality. Instead, you've got the reality of an unprofitable vehicle dealers express no interest in. The vehicle called "Volt" was an object of praise by enthusiasts and a source of nightmare by executives. GM rolled out a mess that never got any better. It's too bad advice about what to try next was never tried. Just think if Tesla stuck with an idea of trying to make Model S more popular, rather than starting fresh with Model 3 based upon what had been learned from Model S. There shouldn't be any stigma from moving on. If a plug-in hybrid model of Trax was extremely well received, so what if the Volt remains a niche or fades away. That's progress, not a problem to be concerned about. Ugh. That goodness we're finally getting the message through to some early adopters. That next stage should be embraced, welcomed, accepted...

- 11-21-2017** **Hasn't Happened.** It's interesting to read this post from a die-hard Volt supporter: *"Given the number of Prius owners, my prediction was the Prime would easily outsell the Volt. The fact this hasn't happened is a bit of a surprise to me."* That comes from not actually paying close attention. Seeing the craziness & uncertainty emerge from growing Model 3 & Leaf interest, combined with the soft sales of Bolt, the fact that Toyota kept Prime deliveries limited to both coasts shouldn't have been a surprise. The timing didn't make sense. Why would you ship new vehicles right when the model-year is coming to a close? That's clearance time for 2017. Dealers barely make any profit on sales like that. Some end up losing money. So, shipping to new territory is a problem easily avoided. It sends a misleading message to those not paying close enough attention. But the dealers appreciate it. They are a customer after all. You don't make them happy, they won't order more to sell. It's not rocket science. Not upsetting them by sending vehicles that won't deliver upon their usual expectations isn't worth it. Wait until the 2018 models are ready. That makes far more sense.
- 11-22-2017** **Single Minded.** We see that pattern. It's so obvious to everyone but the person posting: *"So, when my 198 beats up your 120 mpg, you start to divert the conversation by making up some numbers to advocate your case."* Only an early adopter would focus on a single trait as the selling point for a vehicle. Mainstream buyers don't do that. For that matter, neither do the people filling inventory at dealers. It's amazing how the single-mindedness plays out online. Avoiding well-rounded, dynamic conversations is easy when posts in a discussion thread are limited to a day or two and individual messages can easily be lost in the crowd. Someone just cheers out a talking point and everyone diverts to it. You'll get accused of leading that effort simply by adding comment to it. People just plain don't pay attention or even care for any of it to matter. That's why the focus on MPG persisted for so long... and continues to be the distraction. Attempting to move on to the next item of appeal puts the spotlight on you for changing the subject... when all you are doing is trying to get each priority some recognition. It's the obsession with just one trait that causes so much issue. Imagine actually making a major decision of any sort based upon a solitary qualification. Unfortunately, there are many people who think that way... and pay the consequences later.
- 11-22-2017** **Video: No Highway.** My latest & greatest had an "oops" situation. The commute to work yesterday did quite get captured as planned, but it still left me with some cold weather driving data to share. Lesson learned was to plug in the USB cord if you are pushing it with the battery... or just don't broadcast live video via Wi-Fi the entire duration. Duh! Oh well. The quality of the dash video has clearly improved, despite the minimal setup now. This particular drive was to avoid the highway entirely, taking the longer & slower route. It's a pleasant drive and the preferred alternate when traffic gets crazy. That can actually take less travel time when the weather is really bad, since it doesn't get congested with lots of stop & slow driving. My goal was capture real-world data of sub-freezing drives before the extremes of winter arrive. 19.1 miles were driven using electric-heat set to 65 ECO with driver priority. 4.4 miles of EV were estimated remaining. Average temperature outside was 27°F. The Prime was parked inside the garage overnight plugged-in with pre-conditioning set on the timer, hence the warmer reading upon initial departure. The gas engine never started throughout that entire commute drive. Watch it here... [No Highway Commute](#)

- 11-22-2017 Holding On.** The past is sometimes very difficult to let go... They needed to hear it, since clearly that message has not got through yet: Most of us recognize that Volt is on year-3 of gen-2 with tax-credit phaseout being triggered mid-2018. Sales rate is slowed and inventory piled up, to the extent of halting production. In other words, the early adopter phase has come to a end. Preparation for the next should be well underway... a very different audience. That's where Prime comes in. It's low MSRP, well-rounded collection of standard features, and simplistic approach will appeal to ordinary shoppers. Some here recognize that, seeing the market shift necessary for growth and how well Toyota targeted their plug-in hybrid for that. What does Volt do to attract buyers who aren't willing to spend a premium for plugging in?
- 11-22-2017 Neither Does Prime.** It's gets tiring to here such nonsense repeated over and over. That is a good sign though. The "*neither does Prime*" claim today especially stood out. Rather than leadership, it was an acknowledgement of trouble concealed by an attempt to divert attention. I got things right back on track: Why would anyone care about such rhetoric? \$27,100 base price is what draws interest. Recharging is inexpensive too. It's a simple approach. Asked for detail, I point out that pay just 7.1 cents per kWh to recharge my Prime here in Minnesota. That gives me anywhere from 23 to 35 miles of EV (depending upon temperature) on my usual drives around town and the commute to work... for just 44 cents. There's no HOV access available here. It's just doing our part to reduce emissions and dependency on oil. It's easy be disappointed about Volt not being able to deliver a similar draw. That's no reason to mislead about Prime potential though.
- 11-22-2017 The Message.** I'll keep repeating the message of affordability over and over again. My version of supposed rhetoric is to get choices for ordinary people. Without something for mainstream buyers to buy, what's the point? So, I'll keep reminding that \$27,100 delivers a solid 25 miles of EV. All those attempts to divert attention away from MSRP are very telling. They negative vote to hide the information related to cost too. It's obvious that is a sensitive point. Not attracting the masses should be a concern. That audience doesn't just change because they should. Heck, they don't even change when the better choice only takes a small amount of research. Sticking with the status quo is easier. They will stick with what they know. This is what the enthusiasts just plain don't understand. After all this time, they still believe it will be a matter of getting price to a reasonable point. Too bad they don't take the time to do a small amount of research. Some of those original misconceptions for hybrids apply to plug-in vehicles too. We'll never get to deal with those though, until that affordable level is reached. This is complicated. Refusing to acknowledge the barriers doesn't help.

11-23-2017 Volt vs Prime, part 1. The speculation articles continue to emerge on forums throughout the plug-in world. With the virtual tie last month, there's lots to discuss. Some stand firm with old beliefs though: *"I still think they would prefer to sell them in carb states, because they are not profitable."* Since that showed up on the big Prius forum, I went all out with my response:

That's an anecdotal observation. Looking at the bigger picture, it's easy to see there's more involved.

Stepping back to consider everything at play, which many posting comments do not, is the fact that Toyota is rolling out Prime worldwide all at once. Seeing Japan, Europe, and North America get first delivery all in the same year is quite an challenge to take on. They are all very, very, very different major markets. Having a new product take on so much, so quickly deserves recognition.

Zooming into to consider just the United States, we can see very distinct regions. Their differences are vast. Toyota has learned that rollout during the cold season has consequences. With the heat-pump in Prime, that effect from Winter will have quite a pronounced impact. So, it makes sense that final 2017 inventory was focused on the coasts instead. Middle America will have to wait until the thaw.

Another ***MAJOR*** issue overlooked by virtually everyone is the fact that dealers are the primary customer, not who actually ends up driving the vehicle. That's a business fundamental most people have a very difficult time accepting. Why wouldn't the vehicle owner be most important in the rollout process?

Look at it this way, if the dealer isn't interested in selling the vehicle, there isn't a choice available for the consumer. Toyota has chosen a phased rollout for this reason. It does seem odd to have ample inventory at some places, especially with \$1,000 cash back offers, when there are shortages elsewhere. But from the perspective of keeping dealers happy and providing incentive for salespeople to actually want to try to sell the vehicle, it makes a lot of sense.

The business is quite complex. Things worldwide need to settle down first. Seeing that Toyota is on target for selling 50,000 Prime this year is a really big deal. We'll see 2018 models all over... eventually.

11-24-2017 **Volt vs Prime, part 2.** I continued the next day with the rest of the information needed for consideration:

The previous post only addressed internal considerations, those factors of influence only pertaining to the perspective of the automaker and related resources. Stepping back even further, that biggest picture complicates matters to a degree most people don't properly recognize: failure fallout.

Not every attempt will succeed to attract mainstream consumers. The design or approach will get trapped in a problem called "innovator's dilemma". Just because the first-generation of a product strongly appeals to early adopters is no guarantee that the second-generation offering will. It's a easy trap to fall into. The manufacturer will focus too much on traits that made it popular... only to discover the wider audience unwilling to pay a premium for that.

This is exactly the problem gen-2 Volt is struggling with now. GM focused on faster & further. They enhanced the configuration to be even more specialized, rather than shifting emphasis to other appeal factors to make it a more balanced offering. So as well as it works, it's trapped in a niche. Ordinary shoppers just plain are not interested.

This is what some are so hard on Prime, failing to recognize how much Toyota strived to avoid that same trap. That de-emphasis on faster & further allowed resources to be placed on keeping the configuration affordable, while included draws like dynamic-cruise and lane-departure standard. This makes Prime easier for dealers to consider and for salespeople to sell.

It deeply upsets some to watch the true signs of progress play out. When a chapter closes, it reveals some winners and some losers. In this case, it will be the end of the "early adopter" phase, which is clearly marked by the phaseout trigger of tax-credits. The expectation is for this Volt to be too expensive to survive. The next product-cycle may bring about a design that is competitive. But gen-2 as it is now, is an extremely difficult sell.

Prime's much lower sticker-price, combined with the nice variety of features and simple approach, targets it at that harder-to-sway but much wider audience. So, even with the loss of tax-credits, it stands a reasonable chance of attracting a large number of buyers.

Also, don't forget that Toyota is cultivating new potential at the same time. We see the Camry, RAV4, and C-HR hybrids all being positioned to deliver a plug option later.

11-24-2017 **Endless Attacks.** It has been fascinating to witness the desperation play out: "*You usually mention the PP in your first post no matter what the topic. Even when you don't, you just set a trap hoping someone else will.*" The fade away of Volt is difficult for him to accept. He needs to feel better by finding something to belittle. It's quite adolescent. I have found it an excellent example of closure, ensuring every possible aspect of fallout has been addressed. Why did this happen? What was learned? How will it be fixed? When should we expect change? Who will be the new leader? I submitted: It has been confirmed that you don't actually read what I post, so no sense in pointing out that's false. Many here drop bait for me, but aren't labeled as trolls since they supposedly support Volt. In reality, they are politely stirring the pot to draw attention to the formula for success Toyota has followed... implicitly implying GM should try something similar so the technology in Volt isn't lost as Volt itself fades from consumer interest. How can the progress of Prime not be brought up in these discussions? Being on target for selling 50,000 the first year of availability is what GM had always dreamed of. No one is saying it's not possible for GM, they are just pointing out gen-2 Volt is not the vehicle to achieve that... especially when the second year of availability is coming to a close. As for calling the business need to replace traditional vehicles with high-volume profitable alternatives a trap, you've lost touch with reality. That is a normal requirement for all automakers. They must advance or die. How they approach the problem is what we address. Toyota is clearly on the right path. GM is at a point where trying something else is necessary.

- 11-25-2017** **Lame.** The adolescent behavior continued. He simply dismissed the business logic as lame. Ugh. It's been the same since long before even the first generation was just an idea. I was happy to provide a reminder: Being held accountable for "*over promise, under deliver*" can be called whatever you want. This group fiercely defended the plans to make Volt a mainstream vehicle, selling so well it would become a common choice among GM customers. There's simply no way to summarize the outcome without being given a label of "*troll*" despite 7 full years of having been confirmed that concerns were indeed justified. That's why everyone else has stop participating. I'm not afraid to ask for lessons learned. That's how the next step stands a better chance to actually succeed. After all, GM's reputation has come from repeating the same mistakes over and over again. Helping callout issues to prevent falling into the same trap yet again is what someone needs to do. Saying that is "lame" certainly isn't constructive. Sales has always been and will continue to be the measure of progress. More traditional vehicles offset by plug-in choices is necessary. Simply growing the consumer base by adding conquest sales dependent upon tax-credit subsidies was an idea that did not lead to traditional replacement. Loyal GM customers replaced their old SUV with a newer model. They simply weren't interested in Volt. They were promised a SUV with a plug. Here's a wake-up call about how long GM customers have been waiting, the opening statements from an article published December 5, 2006: "*Last week General Motors (GM) gave a boost to plug-in hybrid vehicles. It announced a new gas-saving technology that could transform transportation and make renewable sources of electricity, such as wind and sun, more feasible. At the Greater Los Angeles Auto Show, the automaker committed to manufacturing versions of its hybrid Saturn Vue SUV with a much larger battery pack that can be charged via an ordinary household socket. The increased size of the battery pack makes it possible to rely more on electric drive than current hybrid vehicles do, thereby saving much more gasoline. The actual rollout date will depend on the development of suitable battery technology, according to GM chairman and CEO Rick Wagoner.*"
- 11-25-2017** **Noise.** The vague & ambiguous claims never cease: "*Umm, have you not been following all the things GM is doing?*" There was nothing whatsoever provided to support that. It was nothing but an empty statement. I get so tired of that crap from our president. Baseless messages of disdain are so tiring. What a waste having to deal with such nonsense. I keep up the good fight though: It's what GM is not doing that everyone should take notice of. You in particular are especially vulnerable to distraction. Squirrel! This year, yes... within the next few weeks... Mitsubishi is expected to roll out their plug-in hybrid Outlander. \$34,595 for their system with two 60-kW motors and a 2.0 liter engine, delivering 197 combined horsepower. The battery-pack will have a capacity of 12 kWh. Sometime for 2019, a similar type plug-in hybrid is expected from Ford. Knowing that Toyota's RAV4 hybrid has been selling so well, that Nissan just rolled out Rogue hybrid, and that Honda is planning a CR-V hybrid, you have to ask why we haven't heard a peep from GM. You don't though. It's just a bunch of rhetoric claiming "*too late*", even though GM is the one without any efficiency SUV plans. Think about how simple of a next step it is for Toyota to offer a plug-in model of RAV4 hybrid. For Prius, it was essentially just adding a one-way clutch and a larger battery-pack. The silence from GM is deafening. Is that why you are making so much noise about me?

11-25-2017 **Irony.** Watching someone use a term incorrectly over and over again is fascinating. I've seen it some many times now. They don't bother to actually research what's being claimed. It is just assumed. Most recently, it has been: "*Innovator's dilemma, can't get out of the past.*" Using that to establish a narrative of Toyota falling behind is remarkable. Each generation of the hybrid system is clear progress. The new Camry hybrid is amazing. Prime is a great example of the potential to come. There's a growing audience with each step. That is progress forward. GM's supposed leadership isn't actually changing their own base. How is that progress? Notice how many of the RAV4 sales are now the hybrid model? That's clear advancement away from traditional vehicles for Toyota. From GM, there is still nothing... unless you consider the new diesel Equinox progress. Ugh. There is literally nothing clean & efficient for those SUV shoppers still. GM didn't adapt. They got stuck in the trap of catering to their original base, rather than reaching out to the general population. Oh well. It's interesting to watch this history in the making, posting commentary along the way: The ironic use of that term is what keeps me coming back. GM couldn't figure out how to make Volt appeal to an audience other than early adopters. Volt's focus on more power and more capacity isn't what ordinary GM customers were interested in... which is why the first 2 years of sales for gen-2 didn't result in market growth. In fact, the opposite happened. Sales are lower now than they were for gen-1... which is undeniable evidence of innovator's dilemma. The new larger audience wasn't interested in the upgraded offering. GM messed up with gen-2. Focus on making Volt go faster & further was clearly a mistake. That's what early adopters wanted, not mainstream consumers. Focus should have been on making it more affordable and more efficient instead.

11-26-2017 **Vastly Superior.** Owners proud of their purchase attack post-early-adopter articles with their vastly superior rhetoric: "*The Volt is a much better car and designed to be an EV first (more than double the AE and much better performance/handling), unlike the Prime, which is designed to be a hybrid first.*" It's becoming a real problem. They troll by posting claims without substance, just a clear effort to retain the status quo. Moving on beyond the early-adopter phase isn't something they are prepared to do. The idea of Prime winning the popular vote through sales is sickening. From a mindset where performance is what matters most, they'll never understand the balance mainstream consumers want. So... my reply is to address their performance claims with detail exposing their attempt to mislead: Volt's supposed "*designed to be an EV first*" claim doesn't hold much merit... simply based on the fact that it isn't as efficient for electric-only travel. It takes 31 kWh for Volt to travel 100 miles. It takes 25 kWh for Prime to travel 100 miles. Also, how do you explain Prime's vapor-injected heat-pump? That's far more advanced of an electric-heating approach than Volt's resistant type heater. There's the option of CHAdeMO charging available in Prime's domestic market too. Volt doesn't offer any type of high-speed charging option anywhere.

11-26-2017 Psychological Issues. We see it daily from our president. The same thing plays out online... WHAT ABOUT... PARROT... REFLECTION... CHANTING. It's all so agonizing to have to deal with. Also facing the reality of dishonesty makes the situation nearly impossible to address. It's nothing but a series of avoidance techniques being used, day in, day out. It never ends. The protectionists just keep pushing the effort to delay & distract. Ugh. I'm looking forward to what Honda (Clarity) and Mitsubishi (Outlander) will bring to the table soon. In January, I suspect we'll hear from Ford (Escape) about their plans. Chrysler (Pacifica) is ramping up production. Hyundai (Ioniq) will be rolling out early next year. All those plug-in hybrids, in addition to Toyota, yet nothing upcoming from GM. All those promises about Volt technology went no where. I wrapped up the 2-week long argumentative thread with a person clearly desperate to protect reputation by posting: GM must still deliver something affordable that their own customers will buy. No amount of spin, distraction, or rhetoric will change that. It must happen. Volt was rolled out with the intent of achieving mainstream sales volume by the end of the second year of availability. Now, beginning the third year of the second generation, we clearly that still will not happen. That justifies asking the questions of what to expect next. What will be that affordable choice and how much longer must GM customers wait?

11-26-2017 Closing Thoughts. Chrysler Pacifica... Mitsubishi Outlander... Honda Clarity... Toyota Prime... Ford Fusion... Hyundai Ioniq. Each was created with the purpose of targeting their own respective customers. Not any different from how front-wheel drive, fuel-injection, anti-lock brakes, or airbags were introduced, shoppers will simply see it as a new standard. The expectation is that technology will be spread throughout the entire fleet. Not having anything spread in GM, despite 7 years of Volt availability, leaves customers wondering what happened. Isn't GM interested in offering plug-in hybrid choices? Hope has been to replace traditional vehicles and Volt was to champion that effort. Instead, it just fizzled. Why shouldn't we push GM to join the rest of the automakers?

- 11-27-2017** **Hypocrites.** When the antagonist starts posting repeats of what you posted years ago, but presents it as if they shared that same stance all along, you know things have changed. The attitude of enthusiasts back then was to discredit anyone who shared information that did not support their position. Now, they pretend that history never took place. This is an excellent example of that: *"They often mention how a lot of the engineering that went into the EV1 was used for the Volt. Many of the same engineers even. That's how engineering works. It's an iterative process."* When Volt was rolled out, enthusiasts claimed it was *"all new"* and nothing from the past efforts (EV1 & Two-Mode) was carried over. This *"please be patient"* excuse was used repeatedly for years. With that quote, that particular individual used it on a regular basis. I got negative votes routinely from pointing out that very history. He simply didn't care. Those preferring his narrative didn't either. They needed an excuse to justify the *"too little, too slowly"*. Now, they need credibility, so taking the opposite stance is embraced. That's quite hypocritical. I could point out that contradictory posts, but it just plain is not worth it. They don't care. So, I won't. The information will only be shared here. I know what happened. I know they did the same thing to portray Prius progress differently by excluding what they didn't like about that too... like pretending Camry hybrid didn't exist and omitting the fact that PHV wasn't available nationwide. They just cherry-pick what they like to convey the message they like. Addressing the big picture and focusing on goals is simply not acceptable. It's like how they quote price with the tax-credit already subtracted while claiming their is no tax-credit dependency. Fortunately, like always, sales tell the true story. That's why each month-end the excuses ramp up. Fortunately, the upcoming overtake of Volt by Prime will help silence some of the obvious misleading. The rest will come from the hypocrites who now contradict their own statements from the past.
- 11-28-2017** **Legacy Automakers.** Online posts are filled with short-sighted, narrow-view perspectives. They simply don't see beyond what's happening at the moment. To exacerbate the situation, they lack the business or engineering background to even try having in-depth discussions about the matter. It's often a hopeless extreme, where you stand no chance of getting the message through. I keep trying though: Tesla is not a legacy automaker. Anyone taking a serious look at the market as a whole will notice EV sales now are still just low-hanging fruit, dependent upon early-adopters and tax-credits. Being competitive with traditional vehicles isn't realistic yet. Innovations, like the potential solid-state batteries present, should change that. They are a number of years away though. Convincing ordinary consumers to even consider the purchase of an EV will remain a challenge even when price drops. Just finding a way to recharge one EV can expensive. Adding a second EV to that same garage can introduce problems people here participating in discussions like this rarely want to address. They pretend adding a 40-amp line is no big deal, a trivial effort for anyone interested. Think about how straight-forward of an upgrade path Toyota is establishing for their own loyal customers who could be interested in an EV later. Prius Prime will usher in other Prime models. Adding a one-way clutch and larger battery-pack to the Camry, RAV4, and CH-R hybrids provides an easy to understand benefit, using an affordable approach. What will other legacy automakers do?

11-29-2017 **Goodbye Volt.** This offering from GM is rapidly becoming a footnote in history. With the start of the Auto Show in Los Angeles, we have already had a flurry of announcements. Most focus on what will be coming in the 3 to 5 years. That's creating a very big opportunity for the affordable plug-in hybrids. Turns out, the 25 to 30 miles of EV range is perfect for that category. You get your plug-in without having to tradeoff much. Basically, just some storage space is reduced. The spin, nonsense, rhetoric, excuses, and delay we've heard from enthusiasts falls completely on deaf ears. No one cares anymore... which is clearly reflected in online posting activity. It's amazing how things have died down to almost a deafening silence over the past 3 weeks. This new audience is very, very different... not at all interested in the games they play. I knew this would happen, simply based on experience. You cannot witness the transformation of Prius firsthand like that without noticing the patterns. Gen-2 was the introduced here to mainstream potential. (Gen-1 was far too rare to even be recognized as what a "hybrid" had to offer. In fact, most people didn't even hear about it until Gen-2 was rolled out.) It established the potential for change. Gen-3 is what actually brought it about. The reason was simple. It matched mainstream purchase priorities so well, there was nothing to debate anymore. Appealing to ordinary consumers is absolutely essential. Whether it is the draw of size & ruggedness from the SUV or the smooth & silent from Luxury, there must be something matching the current status quo. That's how paradigm shifts are triggered. Everyone just naturally advances forward. The delivered interest presents itself as an obvious choice. Squeezing into a ordinary-equipped compact with the price of a nicely-loaded midsize is a strategy doomed to fail. Volt couldn't possibly succeed beyond niche. This market is far too fickle to accept that. It's why the road being paved by Prime offers so much more potential. It's so easy to see a Camry hybrid with a plug. The same goes for RAV hybrid. (Since we don't have CH-R hybrid in this market, that will come later.) No big deal. It's an logical next step. The same potential exists with the upcoming Kia Niro too. Some people will want a bulkier vehicle than Prius Prime, but don't care for a SUV. Having the choice is key. This is where the "*too little, too slowly*" came from with GM. That opportunity for GM to offer a plug-in hybrid SUV of their own was missed. Time is up. Too late. This is why saying goodbye to Volt is the topic now. It's collateral damage. Nothing going forward has consequences. People see GM isn't interested in offering plug-in hybrids. They see a shift to expensive electric-only vehicles instead.

11-30-2017 Hello Niro. With GM sales being so heavy in favor of SUVs, the fact that there was never any effort or even interest to deliver one with a plug was highly suspicious. Why not? This was how the endless questioning of audience came about. Who was the market for Volt? It simply never made any sense. Needless to say, the market doesn't care anymore. Interest has shifted to other automakers to deliver instead. In this case, it will be from Kia. Their upcoming plug-in SUV was revealed today and will be available for purchase before the end of this year. Yes, within the next month. This is why there was a relentless push for acknowledge of the "*too little, too slowly*" concern. The denial ran so deep, those enthusiasts saying everything was fine really didn't have a clue. They weren't paying attention to any of the information being conveyed. It was nothing by blind hope that things would work out. Instead, there's a wide-array of choices on the way... none from GM. In fact, this is why I withheld comment about Kia. Each of the other new offerings needed attention first... since Niro would be the final nail in the coffin. As well as Volt worked, it was a disastrous business venture. What a massive waste of opportunity. GM had the technology, but didn't actually capitalize on it. Those precious tax-credits were used for conquest sales, rather than actually changing GM's own customers. Thank goodness Kia isn't doing the same thing. It's quite obvious they are appealing to their own shoppers. The 26-mile EV range will keep price affordable... giving it the potential for high-volume profitable sales. It's nice to be able to welcome a new choice with so much potential.

11-30-2017 Shortages. Here's an interesting thought to ponder: A now obvious advantage of sticking with smaller packs during the introductory stage allows more plug-ins to join the population while working to lower costs at the same time. People are rarely ever aware of the impact shortages can have on business. Do you remember the LCD shortages when that technology first became viable? The computer industry struggled for years with the shift over to them for laptops as a mass replacement for desktops and as an alternative to the large monitors. Yields of flawless quality (who wants a dead pixel?) were a big problem. It was costly to achieve and warranty coverage was a big unknown. Sound familiar? That's the same type of thing we are seeing with batteries now. Demand is rapidly growing and supply simply isn't there. How common do you think those highly desired "*300 mile*" range packs will be? That's quite a few cells being packed into a single vehicle. Think about how much more impact to the market they'd have spread among a group of plug-in hybrids instead. A dozen with 25-mile ranges could be offered instead. That's a far more effective way to change the market... and deal with shortages in the meantime.

- 11-30-2017** **Enthusiast Magazines.** Ugh. There's simply no getting through to some people. Fans of certain things seek out praise, disregarding source for the sake of feeling good. We have seen that from Volt enthusiasts for years. They absolutely refuse to acknowledge audience. The reality of it being a niche never made any difference. Scope was just reduced to a scale where it looked impressive. Those trying to be objective call that cherry-picking. You can't just eliminate the data you don't like. That's not the slightest bit realistic. It gives a distorted view of reality. Of course, some people are fine living in their own world... hence: "*2017 Chevrolet Volt Premier vs. 2017 Toyota Prius Prime Advanced - Comparison Test.*" Using that article from what had been known as a "*muscle*" or "*sport*" magazine of the past is very much cherry-picking. Look through back issues? Find any praise for the most popular vehicles... like Camry or Corolla? Despite such high sales numbers, mention is almost non-existent. That's not who they write the articles for, which is perfectly fine if you understand that. But if you use it for greenwash material, to intentionally misrepresent, that's an entirely different matter. In the topic of discussion on that recent article, I posted this in the comments: Ordinary shoppers just plain will not care. They aren't enthusiasts. They're just normal consumers looking for the same formula Toyota has always delivered.
- 11-30-2017** **Late?** It never ceases to amaze me how often the claim of "*late*" is used to support GM's supposed leadership without providing any reason other than EV range. No concern is given for cost or audience. It has always been that. GM delivers on promises and their announcement about upcoming reveals is all they need to justify their continued stance. Ignoring the fact that there's significant dependence on tax-credits, the reality that Volt sales are shrinking, and that Bolt in no way targets GM shoppers isn't an issue for them. All is going well. Ugh. Fortunately, I that rhetoric isn't getting as much attention as of recent. With so many other automakers revealing their own plans for electrification, the missing opportunity GM had is quite obvious. No need to rehash any of that now. I just keep it simple... and get likes in return... the sentiment has most definitely changed: We're just getting started. The early-adopter phase hasn't even ended yet. This new batch of plug-ins is for that next audience, those closer to ordinary mainstream buyers.

- 12-01-2017** **Not Enough.** Open discussion on venues not just for Volt offer far more diverse comment. And since Volt no longer dominates the media, those venues actually have a chance of finally be heard. Remember the concern of the past was that GM would impede progress by promising something that wasn't actually realistic, resulting in a stalled industry... which is exactly what happened. They did the same in the past with fuel-efficiency decades ago. Rather than pursue the problem constructively, they ended up stalling advancement with the diesel debacle... which never really recovered. Only VW made any supposed recovery... but that ended up being a purposeful deception. True, we know GM's focus now has been on halo, but at least that's out in the open... due in part by other automakers stepping up: *"Clarity PHEV looks interesting, but only 42 miles rated EV range. That's not enough range to do much more than to drive to work and back for most people. 2011 Chevy Volt was introduced in December 2010."* That posted comments was mistaken with the 42, which is actually 47. Nonetheless, the point was understood. We all see the changing market. People are becoming receptive to the idea of plugging in. Problem is, there are Volt enthusiasts who still have a superiority complex. They choose to belittle still. It's really annoying. Fortunately, I have real-world data to help counter their impeding efforts: 232 MPG was my average for November, with *"only"* an EV range of 25 miles. Calling that *"not enough"* doesn't mean much when real-world results show such a massive efficiency boost.
- 12-01-2017** **Cross Shopping.** Comments online from the prior chapter (early-adopter phase) often obscure progress forward. It's too easy to slip into the trap of looking backward, rather than keeping attention the goal... moving forward. The biggest problem with that is understanding who. In the past, there were only a handful of choices available. You had no option available. It was either consider the purchase from an automaker you really had no preference for or settle for a traditional vehicle. The selection of plug-in vehicles were far too few. But now with this new chapter bringing about a choice from each automaker, there's no reason for cross shopping anymore. You can see investment in the future taking place. The expectation of multiple models coming is quite realistic. It has become a matter of when, not if. That's why a reminder is necessary from time to time. Today, it was with the plug-in owners group: Know your audience. Wanting more is perfectly fine, but it makes you an enthusiast, not a mainstream consumer. Think about who shops from automaker to automaker.

- 12-01-2017** **Not Good.** The positive sales spin started right away. Prime pulled ahead in the year-to-date tally compared to Volt, so that was to be expected. If you create enough of a diversion, no one will hopefully notice: *"And the Volt moved up to 1702 deliveries, which is down from last year but a nice move up from last month's 1362 deliveries. Not bad."* I was delighted to provide some perspective on that narrative: There's always a year-end rush to take advantage of tax-credits. Adding to that surge in demand is the possibility of those tax-credits not being available come January 1st. An important aspect of demand not to be overlooked is supply. As of this post, there are 2,118 new 2017 Volts listed as available still. That's not a good sign going into December, especially when there are 2,929 of the 2018 models listed too. That brings some perspective to the *"not bad"* assessment, basically changing it to *"not good"*. In fact, this is part of the reason why production was temporarily halted. To really drive the point home, think about how much harder sales will be the second half of next year when the tax-credit phaseout has been triggered. That higher MSRP will really make Volt a challenging sell, especially against Bolt.
- 12-01-2017** **Hindsight.** Reading this on the big Prius forum sure caused me to flinch: *"In hindsight, it is obvious GM wasn't planning on the Volt itself in becoming wide appealing. It is a C-segment car after all."* It came from a well-known antagonists, a person who prides himself in being the ultimate devil's advocate... which works fine when looking forward. But when you look backward, that reverse perspective becomes an attempt to rewrite history. These blogs here are written to prevent that, by documenting what happened when it happened. I wasn't about to let him mislead with such blatant misrepresentation: No one's going to believe that greenwash. Even before it was rolled out, some of us were screaming from the rafters that it was going to be a niche vehicle. With those performance specs, it was clearly not aimed at the mainstream audience. Concerns of *"trophy mentality"* clouding direction emerged right from the very start. The design was unrealistic for mass appeal. There isn't basis for a hindsight claim. There is an abundance of evidence confirming Gen-1 would be stuck as a specialty offering. Gen-2 made that bad situation even worse. GM knew all along it could exploit the opportunity of tax-credits for reputation building, rather than actually delivering something for ordinary consumers... their own loyal customers simply looking for a green option to replace their aging GM vehicle.

12-02-2017 **Change.** It can be quite painful for some. The Volt enthusiasts inflicted an endless stream of hostile posts on me. Listening to the voice of experience, with a reasonable goal of helping all who wanted to promote plugging in, should have been welcomed. Instead, it was fight, fight, fight. Volt was "*vastly superior*" and nothing else mattered. They were wrong, wrong, wrong. What a waste. Now, there is a collection of choices growing, all defying the nonsense their rhetoric claimed was necessary. Now, it's time for me to provide some pain... by pulling off the bandage from their own self-inflicted wound. That's the best way to deal with the problem remaining. Get over it! Then we can finally focus on that reasonable goal. Ugh. Needless to say, I enjoyed posting this... with the hope of it being the very last on that terrible daily blog, which had such a negative influence on market change:

Too little, too slowly was the concern brought up well before the rollout of Volt. It was expressed due to the need to make sure sales were strong enough to allow the technology it used to be spread quickly in a profitable manner.

That never happened. There was so much missed opportunity, it became a business model of what not to follow... a modern example of how good engineering advancements can be seriously undermined by poor management decisions.

- * 1.6-liter 4-cylinder engine
- * 8.9 kWh lithium-polymer battery
- * 60 horsepower (44.5 kW) electric motor
- * combined output of 139 horsepower
- * 48 city, 44 hwy, 46 combined MPG

Those are specifications of the recently revealed Kia Niro, which will be available for purchase in the next few weeks. It's the plug-in hybrid SUV which had been long expected from GM, but never delivered. The belief is it will be affordable too, around \$30k.

The claim of industry leadership from GM has proven false. So many other automakers have stepped up to fill the void everyone had anticipated GM would fill, there's simply no attention being focused on Volt anymore. Those days of carefree rhetoric are over. Enthusiasts have some humble apple pie to eat now. It was not *vastly superior*. Lack of sales growth overwhelmingly confirms it.

The question now is: Will a spirit of cooperation finally emerge? Remember, the original purpose of participation on this blog was to find an ally in the quest to conquer the reign of traditional vehicles with plug-in choices.

- 12-03-2017** **No Jacket.** Reading this was interesting: *"This is the energy drawn from the garage outlet during a TESLA 30 minute pre-heat. It amounts to 1.64 kWh of electricity obtained from the house, instead of the car's battery."* I asked why 30 minutes. That's excessive in regard to any garaged vehicle. 10 easily removes the edge. Then I asked if he was driving without a jacket on. Turns out, he was. Imagine allowing yourself to run the car so long before driving that it's toasting warm inside. Regardless of fuel used, I couldn't imagine that level of waste. Never would it even cross my mind to do that. Wearing a jacket is a perfectly normal thing to do. Even if I could afford one of the nice models of Tesla, using so much electricity is wasteful. That's roughly 8 miles of EV driving distance in warmer conditions. With my recent Winter driving, it would be about 6 miles. The 10-minute pre-condition (warming before you leave) when set on MAX only uses 0.37 kWh. I have mine scheduled to use the 65 ECO setting instead, which uses quite a bit less. How anyone could use so much more without considering the energy involved is troublesome to think about. We don't want to just shift our wasteful habits from one fuel to another.
- 12-04-2017** **Tit-For-Tat.** Those final voices of the past aren't able to get much attention anymore. They certainly try though: *"Take your Volt blinders OFF. The Prime is in the same category as the Volt. The article was comparing the GM EV sales to the GM PHEV sales so I was referring to EV/PHEV sales..."* Knowing they lost and that it is over, there's nothing to lose, so they think anyway. Turns out, they can actually make a bad situation worse: It is all about sales of TRADITIONAL vehicles verses PLUG-INS now. With the end of tax-credits in sight and each automaker soon offering some type of vehicle with a plug, the early-adopter phase has come to a close. It's over. Though, if you do still want to tit-for-tat, I could point how that Prime offers a much more advanced electric-heater. The efficiency from its vapor-injected heat-pump is a step above what GM offers in both Volt and Bolt. So, I suggest we drop any of the debate and simply call it a wash at this point.
- 12-05-2017** **Attacking Niro.** It has begun. Some of the same old antagonists are fighting the new battle. Since Prime's presence is growing more and more of a challenge to overcome, they are trying for weaker prey. It's the same thing that happened with Leaf. Those nasty Volt antagonists attacked it relentlessly. It was an EV. That was Volt's supposedly enemy. When they couldn't defeat that foe, they pretended it never was the target and went after Prius PHV instead. Ugh. Fortunately, I have real-world data from back then which will be helpful to Kia's new plug-in hybrid now: Claims of more power being needed, but no actual data to support it... That complete absence of detail is a dead giveaway the situation portrayed doesn't have any merit. Lack of supporting material is just rhetoric. Knowing the 51 HP from the gen-1 plug-in Prius was often enough to merge onto the highway without starting the engine confirms the 60 HP will do the job for Niro. So what if the engine starts? It only runs for a short time anyway and on the highway you tend to want to save EV capacity for when you get off later. Of course, you don't need that much HP to maintain a cruise at 70 mph. So, what exactly is the problem?

- 12-06-2017 Real-World Data.** It took 1 hours 4 minutes travel 16.7 miles. That was the first Winter commute with a heat-pump. It is rather noisy, but moving so much air made that a realistic expectation. Of course, with all the ice crunching, I couldn't really hear it except when stopped. It's still an extremely efficient way to travel, as clean as possible too. The mission of Prius remains intact. I'll be seeing the ups & downs of each passing season just like in the past with the older generations. The benefit is obvious... and still quite pronounced. With a guzzler, you don't notice as much. No screen and such poor efficiency all the time, you suffer all year long... but have grown accustom to the sacrifice. Between the screen and plugging in, you can't miss it. Real-World data is what proves worth. The approach of much colder temperatures will do that too. For now though, it's just a peaceful (so to speak) drive in crazy traffic with all the guzzlers.
- 12-07-2017 Video: Messy Winter.** My commute 3 days ago was that opportunity I had long awaited. Winter finally arrived. It was an abrupt transition from rain to snow though, which left the roads a lumpy & wet mess. Travel was slower due to it being so slippery, but was otherwise uneventful. You can see how the electric-only operation for propulsion & heating worked just fine throughout the entire morning commute. Note that the "Climate Prep" option was part of my scheduled recharge at home, while plugged in at home in the garage. So, you'll see the temperature gauge reading warmer than the outside temperature at first. The footage turned out great. The 4K makes it especially nice. This is a video I'm very happy to share... [Messy Winter Commute](#)
- 12-08-2017 Model 3.** Guess who got to see one today. Me! At our plug-in owners groups, a person from within Tesla corporation was able to take delivery. So, we got to see it at today's meeting. That sure was a nice looking car. The reality really does meet expectations. It is a great EV. We're still facing the paradigm-shift required for something like that to become common. Plug-In Hybrids will bridge that divide. Between cost & infrastructure, the hope of fast simply isn't realistic. This is why so much hope had been placed on Volt, but time proved it wasn't up to the chore. So, we look to automakers pushing the production up front... like Tesla... and those pushing from behind... like Toyota... to make it all happen. With the generational cycle of vehicles typically 6 years and ownership over 10 years, there's much to consider. We'll make electrification happen, but pounding out issues... like cost & production... is quite challenging. That doesn't even address what it takes to get dealers on board. Upgrading homes for high-capacity charging will be a challenge too. Fortunately, we get confirmations from time to time about how well worth the effort is. That Model 3 today most definitely confirmed we should keep pushing.

12-08-2017 **Range Estimates.** How does a plug-in vehicle with just 0.1 kWh more battery-capacity earn 4 more miles of EV estimate? That's what EPA rating supposedly just awarded to Hyundai's new Ioniq. Thinking since it's a smaller car, weighing less could possibly provide that advantage. Perhaps it is a more efficient system too. After all, both hardware & software can make quite a difference. No, that wasn't it. In fact, the story doesn't make any sense. Prius is rated at 25 kWh/100mi. Ioniq is rather at 28 kWh/100mi. How can the vehicle with a more efficient rating get fewer miles? That doesn't make any sense. The only plausible theory is that it utilizes more of the capacity. That's really hard on a battery though. You want upper & lower buffers for longevity. Sacrificing that for the sake of a better rating is a terrible idea. Is that what actually happened?

12-09-2017 **Melting Snow.** People ask about the curved glass. No wiper gives the impression you'll have snow build up in back. Turns out, that's not the case. Wind from driving gets funneled. That amplification causes a clearing effect. Great... if you're driving already. But what if you aren't? This evening, I got to find out. It snowed while I was inside shopping. When I got out to the Prime, there was a thick layer of fluffy snow covering the hatch. I wondered how long it would take to melt off. So, I didn't bother sweeping it off with a brush. Instead, I got in and pushed the rear-heating button right before driving away. Before I even got to the stoplight just outside of the shopping complex one block away, most of it had already melted away. Whoa! That was impressively fast. I hadn't crossed my mind that Toyota would use powerful heating-elements to ensure the window would stay clear.

12-09-2017 Engine Started. Posts have been going on for weeks... to the point of that owner with the "*engine started*" problem ended up purchasing a video camera to document what was happening. In short, he wasn't getting an all-electric drive experience. For some reason, the EV was disrupted. Here is the conclusion drawn by that owner after all of our discussion on the topic, followed by mine:

"It seems to be my consensus that driving immediately, accelerating to a speed of 35 MPH while engaging the cruise control. It has been 9 days since ICE came on. The only thing I'm doing different is NOT engaging Cruise control. Accelerating quickly to 35 MPH does not necessarily cause ICE to kick in. Also the criteria is car is left outside overnight and only unplugged when I leave for my trip and the temperature is below 50°F"

It was obvious you were doing something outside of the "*predictable*" use cases. We've encountered that a number of times over the years, where some critical bit of information was unknowingly omitted.

My all-time favorite was from a Prius owner who complained about the car rolling forward unexpectedly. It took weeks for us to figure out that this owner, who had been driving for over 50 years, had never been behind the wheel of a vehicle with an automatic transmission. It never dawned on any of us that natural forward-creep behavior was something he hadn't ever encountered over all those decades. That doesn't exist with manual transmissions. It sure was a learning experience for us.

Another big "*problem*" of the past was the lock-up at start-up. Some owners were reporting the dashboard lighting up like a Christmas tree and the Prius never getting to Ready mode. It would lock the transmission, not allowing you to shift the selector. Eventually, they'd figure out how to force the system off. The next time they'd try, it would work every time. Our debugging efforts took forever. Turns out, when we asked if they were pressing the brake first (as instructed), before pushing the Start button, they actually weren't doing that. Not being attentive enough to notice the timing was key. If you were slightly ahead with the button... only a fraction of a second... the self-inflicted problem arose.

One other story was the "*brake pause*" issue. When you've been driving for that many miles and there's a claim of the system having a dangerous flaw, yet never experienced it yourself... despite trying to replicate the claimed situation... it makes you wonder. After weeks of posts, we finally got our answer. You had to be braking aggressively, then smack into a substantial road-hazard, at the peak of deceleration. I rarely ever brake that hard. Hitting a pot-hole or train-track at that exact right moment was quite a bit less likely. Finally putting those pieces of the puzzle together brought a much better understanding. Toyota did indeed tweak the parameters of the brakes to better deal with that rare situation too.

Will they do anything for those choosing to use cruise-control in low-speed driving with cold battery? Most likely not. The "*predicable*" use of the car is to plug it in overnight. That's an expectation for a plug-in vehicle, especially since it has a battery-warmer. Not doing that defeats the overall purpose of getting owners to equip their overnight parking location with a permanent charging option. That's how they'll get you

to upgrade your current plug-in with one offering a larger capacity in the future. Doing less means getting less.

It was yet another interesting learning experience for all of us.

12-09-2017 **Slow-Speed Cruise.** It appears to be that was indeed the trigger we've been looking for. Using it for suburb driving was not something any of us had anticipated. It's like those who disregarded the audio & visual warnings to inform you that fuel is getting low, then having the engine stall because it ran out of gas. Not telling us the warning part, yet complaining about having been stuck on the side of the road, leaves out an vital component to the story. We need to know every little detail. Patterns are easy to overlook. Someone who routinely used the cruise for their commute, despite not being on the highway, didn't think about how uncommon that was of a thing to do. With the radar for the dynamic-cruise, that isn't as much of a surprise. But nonetheless, it certainly wasn't predictable behavior. That was definitely a new one for us. I summed this situation up with: Cruise was the unexpected element in the equation. Normally, it is used for highway driving. With just a 25-mile EV capacity and a high probability of soon driving faster, engagement of that mode is instructing the system to be ready for more power to be demanded. So, it fires up the engine in preparation for that. It's another easy-to-explain situation that took us a great deal of time to insolate detail for. That's what we do as first-year owners.

12-09-2017 **Archival Note, part 1.** The final lashing out happened. I knew we were close. It was labeled "*Archival Note*" to mark this point in history, when we look back later at how things actually played out. It's good to document events in-the-now like that. I certainly have benefitted from taking the time to note thoughts & feelings at the moment. Anyone, this particular individual was a troublemaker who lost quite a bit. Several of his hopes & predictions feel apart. He was looking for some to blame. I was unwilling to oblige, making note of his particular frustration with the voting there: Voting has been a source of sabotage for years. Rather than any other venue that provides a means of conveying likes & dislikes, it allows you to hide anything you don't want to see... enabling it to become just a fanboy website, rather than a constructive place for discussion. Voting isn't even a tally, it's nothing but a simple up & down. So, anyone can take influence what is seen, calling ON-TOPIC discussion trolling while hiding the actual content to portray a different narrative. There's no accountability whatsoever. Just image if those providing the multiple negative votes took the time to respond to the topic instead of dropping bait and spinning rhetoric. You reap what you sow... Turning a blind-eye to problems is troublesome, but being an enabler is quite a bit worse. Why are blatantly false statements misrepresenting Volt to make it look favorable not called out? In other words, you should be trying to fix the true issue, not just look for a way of concealing it.

12-09-2017 **Archival Note, part 2.** My punch back at the lashing out was to provide a detailed summary of the situation:

The target of an annual sales rate of 60,000 was set for the end of year-2. This group had high hopes of Volt achieving that mainstream vehicle milestone. It was the technology to crush Toyota, as they often reminded everyone using "*vastly superior*" proclamations. With total disregard for how costly the design would be, they proceeded on with great enthusiasm.

It wasn't realistic. Price was far too high, even with the generous \$7,500 tax-credit, to draw interest from anyone beyond enthusiasts. GM shoppers simply didn't care anyway. Their preference for SUVs and large cars wasn't a good match for the small hatchback. Promotion of Volt becoming a high-volume, profitable offering fell apart.

Those who remained loyal turned a blind-eye to shortcomings, unwilling to acknowledge lack of an audience for the design they had endorsed and put so much effort into promoting. Over time, more abandoned hope and moved on... to the point where all who remained were just die-hard fans unwilling to recognize goals missed.

This topic about Kia Niro marks the end of their rhetoric... since the ultimate goal of Volt was to spread its technology to GM vehicles that their own customers would be drawn to. Very specifically, that meant seeing Voltec offered in a SUV, either Trax or Equinox. Despite the concern of "*too little, too slowly*" being continuously dismissed, it never became a reality.

GM's leadership didn't result in a mainstream product. Instead, we see Kia about to offer the first plug-in SUV (Niro) in this market, and it will be affordable (est \$30,000). Though more expensive (est \$34,500), we will also see a larger SUV plug-in (Outlander) offering from Mitsubishi shortly following that. The first deliveries of Honda's new plug-in hybrid sedan (Clarity) has already taken place too. With a \$33,400 base price, there's little to stir interest in Volt anymore.

Watch the variety of plug-in hybrid choices result in the market growth GM continues to struggle to achieve. It is absolutely essential to appeal to loyal customers. When someone comes in to replace their aging GM vehicle, what will they purchase from the GM dealer?

12-10-2017 **Competition.** Knowing what's going on in the larger scale is vital. Most people don't, as this clearly drew out in discussions: *"Toyota chairman says electric cars are not ready for mass production just yet due to long charging times and expense."* Comments came from enthusiasts, of course. Nonetheless, it still provided an opportunity to point out a few things... most notably, who the competition actually is: Notice how many EV announcements from other automakers are also given *"not ready"* status by stating they will rolled out in 3 to 5 years? Notice how none actually state the intended volume for those rollouts or their potential for profitability? Toyota is being up front, setting realistic expectations. Others are being vague to stir hype. There's a big difference most don't seem to notice. Remember all the *"over promise, under deliver"* we got from GM. Pointing that out isn't anti-GM. It's simply an attempt to get others to be realistic. In other words, this is a matter of acknowledging challenges still faced from the true competition: TRADITIONAL VEHICLES

12-10-2017 **Too Late.** Over and over, we keep hearing it's too late for Toyota: *"Even if solid-state will be THE final brick in the wall it will be too late for toyota who will be dead last in experience with electric cars by then."* They just keep repeating that brain-dead mantra. It's like they don't have any clue what a hybrid actually is. The manufacturing of parts for electric propulsion is already well established. Think about the motor used for Camry hybrid. Put that larger electric-propulsion component into the smaller body of Prius, you have a what you need for a EV with more power than Prime... exactly what they are spinning Toyota still won't have for years. Why don't they recognize that? Or do they, but their intent is to undermine by convincing people none of anything needed for EV has even been designed yet? Whatever the case, my intent is to circumvent theirs with video. That will be very visual rebuttal difficult to deny. But while I'm busy capturing a collection to share, it's still mostly words: That's comes from not understanding how Prime actually works. It's remarkably efficient... more so then some currents EV offerings. That's a big deal when moving up to dealing with cost issues from very large battery-packs. Did you know Prime uses a vapor-injected heat-pump for cabin warming? That is the industry's leading technology for electric heating. It's an advancement most people are totally unaware of. Toyota is far from the claimed last in production feasibility too. They are prepping their hybrid offerings to include plug-in options. Camry, RAV4, C-HR, and that replacement for the Prius wagon are all being positioned for that. Think about spreading cost and the benefit from high-volume interest. Who else in the industry is taking those measures already?

12-10-2017 **Stupid?** It's getting to the point that the question needs to be answered: "*No matter how you look at it Toyota are behind and are a part of the problem rather than the solution.*" After reading that, what do you think? It goes beyond just be clueless. But then again, we have a person now in the highest office of the country who doesn't know a number of the things he comments about. It's so bizarre to hear such blatant errors, things so easy to fact-check, being spewed on a regular basis. Hearing that there makes the nonsense here very easy to accept. It's like posting help-info 15 years ago. The internet of that time didn't have many who would do that simply to be helpful. Why would anyone do that without getting paid? It was a reasonable question to ask. Now, all this time later, it seems almost absurd to even consider that. People reach out to other people online just for the good of making humanity a little better. That's rewarding, even if it costs the provided time & money. It's what many do now. So, hearing people outright lie to defend their beliefs... knowing it is so easy to disprove what they claim... isn't so far fetched. It is weird though. Why would you do that? Are they so desperate they are already at the "*nothing left to lose*" stage? Needless to say, it is rather baffling. Fortunately, I persist through all of it still: Are you unaware of what it took to make Prius into Prime? That hybrid to plug-in transformation was basically just adding a one-way clutch and increasing the size of the battery-pack. Having other models of hybrid at the ready for the same thing puts them in an excellent position to offer affordable plug-ins for the masses. What other automaker is preparing to provide a wide variety of choice in the near future like that?

12-10-2017 **Innovative!** Turns out, those enthusiasts really are just stupid: "*...they just stopped innovating! They still haven't equaled what the Volt offered in 2010, never mind offering an EV of their own.*" So desperate to defend GM from Toyota, none are bothering to do any type of study anymore. It doesn't take more than just a few minutes of research to find out Toyota is far from the only automaker pushing GM out of the picture. This is why I stated the "*too little, too slowly*" concern so often. Rather than actually paying attention to the words, they took it as an insult. It's like yelling "*watch out*" and them brushing it off as a joke. You tell them what's wrong and what to do about it, but the advice is outright dismissed. Ugh. Oh well. It's not like I didn't try. They're in for quite a reality shock next year. In the meantime: \$27,100 MSRP is not being innovative? Not able to see that the challenge of making the plug-in choice affordable is a problem Toyota has taken quite seriously. Despite the use of carbon-fiber for the back hatch for weight reduction and waved glass for aerodynamic improvement, they delivered. It's a remarkable efficient vehicle, in addition to being affordable. That's innovation.

- 12-11-2017** **Failure.** You'd think they would finally see it. Apparently, that's asking too much. How anyone thought GM could blow away Tesla with conquest sales is mind-boggling. Who of the early-adopters shopping for an EV would take that comparison seriously? Bolt has a price higher than Model 3. It simply makes no sense choosing a small wagon over an elegant sedan from an audience beyond a very small niche. Sure, you'll get some people unwilling to wait and those desiring a more practical shape. But the comments of Bolt looking & feeling cheap inside puts much of that consideration to rest. It's a small audience, period. You don't build mass-market expectations on such a small prospect. That isn't realistic. In disbelief that I actually had to post this, it happened: GM is not seeing SUV owners express interest for Volt or Bolt. Small hatchbacks & wagons do not appeal to them. Their priorities are quite different. This is why the "*it's worth it*" approach failed for GM and simply doesn't apply to Tesla. Know your audience.
- 12-11-2017** **Wake-Up Call.** Reading post after post with smug remarks. They were so insulting, intended to offend & harm. It has been quite amazing. Prius is slow. Prius is ugly. Prius is short. So much attitude toward blind hope. Volt was supposedly "*vastly superior*". Their market was tiny though, just niche. No one cared beyond their own group. Those Volt enthusiasts were terrible. Closing of this year will bring their failure-to-grow vehicle to an end. Ordinary consumers will simply brush it off the same way they still do with Prius now. We see it coming. Signs are obvious. This attention that will come from the affordable plug-in hybrids is why Volt will die. Who knows what GM may do with the technology itself. The barrier it caused will be gone. I posted: "*It's a wake-up call for many who assumed people like you and I were the customers. All along, it has been the dealerships who the automakers must appeal to.*" This was the vital mistake, a catastrophic oversight. This is what held back growth. This is why Volt failed. Those terrible troublemakers slewing all those insults didn't realize their efforts were for the wrong group. Prius supporters weren't who mattered. If you cannot get a dealer to support more than just a few token vehicles, there won't be much for sales. No inventory was a problem they took seriously. Salespeople won't bother with a vehicle that's difficult to sell and won't earn them much commission either. This was missed opportunity. So much could have been done, but wasn't. All those attacks were a huge waste. They didn't pay attention. They didn't learn.

- 12-11-2017 Reality Check.** The clueless nature of some people is truly amazing. They make assumptions and never bother to verify. That fundamental mistake leads to countless errors being made. Even after that, they still don't take the time to check original sources. They continue to assume incorrectly. That level ignorance is very difficult to overcome. Not having any awareness of the problem allows it to persist pretty much indefinitely... as we have seen play out. It may change as some point though, as I eluded to today: Reality check isn't necessary. We already know there will be problems, but those are easy to address... once the vehicles are carried in inventory. This is how the "Prime" models will demonstrate a strong approach for penetrating dealerships. Much like the popularity growth of RAV4 hybrid, it will simply be a model available to choose from. In other words, the dealer will have to do little to stock them and the salesperson little to promote them. It will just fit into the existing process... but also have a plug. When I went on a test-drive of Prius Prime, it wasn't charged. Go figure. That was no big deal though. No plug required. For the first part of the drive, we put it in CHARGE mode. That aggressively charges the battery-pack using the gas-engine (at a faster rate than you can pull from the grid, in fact, an 80% recharge in roughly 40 minutes). This allowed the return trip to the dealer to be entirely in EV mode.
- 12-09-2017 Video: Ordinary Winter.** "Just Drive It" was the approach with this video. Again, I was able to deliver 4K resolution. Winter cold had finally come to stay, here in Minnesota, so I captured my morning to commute to share detail of that all-electric experience. It was a non-event, an ordinary commute for me in the winter... hence the name. I got to the charger at the ramp with electricity to spare, despite the need for running the heater very close to the heat-pump threshold. A few more degrees colder, the engine would start to supplement warmth. It was nice enough though to avoid that. So, you see the maximum 199.9 MPG displayed on the screen was the outcome. Results like that are what others in a less hostile state will see routinely, all throughout the cold season. I'll see that often, but there will be cold-snaps later where that won't be realistic. I can't wait to see what the results are then, when the plug-supplied electricity is used less often, since the engine will cycle from time to time. The threshold for that is 14°F. In the meantime, temperatures slightly above are all with EV driving... [Ordinary Winter Commute](#)
- 12-12-2017 BRAKE!** That certainly was impressive. Off in the distance, the Prime detected stopped traffic and recognized I hadn't done anything to decelerate yet. Having your foot still on the accelerator-pedal indicated there was no acknowledgement of the danger being approached. So, the system buzzed an audio & visual warning. That was sweet! I hadn't realized just how far ahead it was scanning or how active the response would be upon recognition of a problem. This is why Toyota's choice to include collision-avoidance in virtually all their passenger vehicles is such a great investment. That's quite a number of years ahead of the auto-braking mandate (2023 model-year, I believe). To see it in action like that was a great demonstration of worth. Thankfully, I responded to the bright red "BRAKE!" message on the screen, rather than the Prime having to do it for me. That advanced warning of an imminent could be really helpful. Another new standard technology included is auto-high-beams. Those sure are nice and surprisingly quick. Handy improvements like that make the driving experience much less stressful, as well as safer for everyone.

12-13-2017 **Soon.** I could feel it coming. An end to the absurdly long problem call "Volt" was approaching. The car itself was actually rather nice, but in no way realistic for mainstream buyers. Being so small and expensive never made any sense. In fact, it was as if GM has sabotaged gen-2 for the sake of moving on to EV instead. After all, it's not like they didn't do that already in the past anyway. They say it didn't work and move on. In a manner of speaking, it really didn't work. The catch is, some of us saw that with the approach back when Volt was still being designed. The specification simply made it too expensive. It was a very risky "top down" strategy. Both the price of gas and the price of batteries needed to remain expensive. Turns out, neither did. That hurt Volt so bad, it was doomed years ago. Some simply didn't want to acknowledge the facts placed before them. Some still don't: *"Really? In the same thread you have two opposing views? Everything should be plug-ins, but, they don't compete with each other? Yikes."* I was happy to address the denial: Still not understanding that each automaker must address their own customers is indeed a major problem. No opposition. No contraction. No competition. "Who is the market for Volt?" was asked literally hundreds of times to point out that GM's own production for GM's own loyal customers is what must change. When a shopper goes into a GM dealer to purchase a GM vehicle, they couldn't care less what the other automakers are offering. That's how it has been for decades. Like other new technologies of the past PLUG-IN will be just another step forward... a big step... but nonetheless, seen as the expectation for each automaker to replace old technology. No amount of short-term spin will change that. We see the need for a plug-in SUV from GM for GM shoppers. Period.

12-13-2017 **Not Enough.** I found this an absolutely wonderful way to wrap of the rhetoric: *"But 22 miles of pure EV range is just not enough today."* That claim had no merit, nothing whatsoever to back it. I knew it would hit hard. There's simply no way to respond. All their efforts provided practice for me, allowing an opportunity to refine responses prior to it actually mattering. No one really cared much until now. Early adopter opinions are meaningless to mainstream consumers. This is why knowing your audience is vital. A common about someone passionate about performance is just a waste of time to someone looking for an affordable choice. They just plain don't care about extremes. They just want to get from point A to point B without ever any trouble. It's that simple. That makes selling the benefits of plugging in a monumental challenge. Anywho, I made it quite clear their enthusiast opinion didn't matter: Not enough for what? SUV is not a single-occupant commute vehicle. That usage never made any sense, nor could it be realistically justified. In other words, wasting electricity isn't acceptable either. Simply switching from gas isn't enough. The vehicle should be used for the purpose it was actually designed. Running around town with the kids or to do some shopping is a realistic use. 22 miles fulfills that for a large number of potential buyers. You can do those weekends trips towing the boat to a fishing hole too. In other words, without solid reasoning, any distance qualification is arbitrary.

12-13-2017 **Goodbye.** The ultimate death-blow to the Volt enthusiasts came from Mitsubishi. With the news of Kia's small plug-in hybrid SUV and Honda's large plug-in hybrid sedan, they couldn't take anymore. It was clear the discussion-topic on it today would bring about an undisputable end to their avoidance. So much else going in the industry left them without anything of merit. It was literally down to just spewing rhetoric. Evading the inevitable wasn't going to work. They faced a day of reckoning. I was pleased to sum it up for them:

The extreme reaction here today, defending the "*too little, too slowly*" situation with gross over-generalizations and hiding posts, is more than enough proof to confirm the problem is finally a serious concern.

IT'S ABOUT TIME !!!

To be told over and over and over that GM had this amazing technology which would take the market by storm, yet not actually do that after 7 years and 2 generation, was terrible to have to deal with. The "*over promise, under deliver*" denial became a major barrier to progress.

NOW, WE MOVE ON.

Seeing Volt enthusiasts shift support from EREV to EV is quite the hypocritical thing to witness; nonetheless, the act of pointing that out is acceptance of it. Volt has been abandoned in favor vehicles with no engine at all.

REALITY HURTS.

The sting of financial burdens will become all too apparent for this group of die-hards here. GM will succeed in carving out a niche, but the challenge of appealing to the masses is an entirely different effort. Overcoming their apprehension to change is far more difficult. Unwillingness of the market to adapt will take a great deal of time & money... far more than many want to admit.

BOTTOM UP.

The approach of top down isn't providing viable for legacy automakers. The idea of building an expensive vehicle, then convincing consumers it is worth the money, simply doesn't work for them. Far too much of the existing system already in place needs to change. That's only realistic for a business starting from scratch.

GOOD LUCK.

You're going to need it. Today's topic makes that all too clear.

12-14-2017 **It Happened.** This was the outcome of my post: "*The technology has taken the market by storm. Plug-ins sales are increasing month over month. Even today's articles is about the #1 selling plug-in in Europe. Even Toyota finally joined in. Hybrids are old technology, no matter how much you try to say otherwise. Plug-ins are the future.*" I was quite surprised to see such a drastic measure being taken. The expectation was a quiet fade away, not a parallel to what we see in the Oval Office. But then again, he got into this position by the same means. So, I sounded off one last time with:

Wow! I haven't said otherwise. In fact, what you posted goes well beyond desperation. It is a last ditch effort to paint a rosy picture with distortion & misrepresentation before the inevitable end.

You know all too well that sales of Volt have been dropping. The much hoped for second-generation was not able to achieve growth. Watching Prime take its place as the vehicle that was able to appeal to mainstream consumers is simply too much to accept. Making the situation worse is hearing that Mitsubishi, Honda, Kia, Hyundai, and Chrysler all have new offerings to fill in the gap GM wasn't able to. Each strives to appeal to their own customers.

It wasn't supposed to play out like this. The technology used for Volt worked fine. Problem was, the capacity was overkill. That much didn't result in taking the market by storm; instead, it just dragged along for years using up precious tax-credits on nothing but conquest. I was correct. Reducing the battery-pack is the key to sale growth. Combine that with a vehicle type appealing to GM customers, you've got a winner. Only problem, pride gets in the way.

So, we see this final attempt to conceal the true story. Go ahead. Say whatever you want. I'm done. We can see the end coming. This chapter is over.

12-15-2017 **Tortoise.** The same old nonsense continues, only with new voices now. On the blogs dedicated to EV advancement, there's quite a bit of smug emerging. They're measuring leadership the same way. The bigger the battery-pack, the further along the automaker supposedly is. It's so naive of a perspective, taking the posts seriously is a debate. Should you? They obviously don't have a business background, so any comment posted in regard to market behavior is just blown off as blind loyalty. The very idea of affordability or diversity is outright dismissed. Some have already made up their mind that it is over. The race has been won and Toyota lost. Ugh. It's so bad, I won't even waste including a quote this time. You can easily guess what was stated. I responded to the growing rhetoric with: For that narrative to work, one must pretend the newest hybrids being rolled out aren't plug-ready. We already know that isn't the case. Prius is now available as a Prime model by having added a one-way clutch, increasing battery-pack size, and upgrading the heat-pump. Those are all cost-effective modifications. The rest of the system is already designed to handle the EV driving. It's pretty difficult to argue the new Camry hybrid isn't the same way. And now from this discussion topic, we've been told the Corolla hybrid is too. Think about RAV4 hybrid, CH-R hybrid, and the upcoming replacement for Prius v. There's an Avalon hybrid too. We also know there's a next-gen Highlander hybrid on the way. That means a lot of denial is required to see that Toyota isn't taking the goal of phasing out traditional vehicle production seriously. They are clearly positioning to offer a number of plug-in models. Attracting that audience is far more difficult than the early-adopter (tax-credit incentivized) sales so far. That progress is how the race is won, not by position in the first stage.

12-16-2017 **Analogy Attack.** There is one particular individual on the EV forum who feels threatened from the rise of Prime. He's been doing everything he can to undermine that progress. That most obvious is spinning an analogy of doom. Yesterday, someone chimed into that narrative: *"A better comparison would be Nokia or Blackberry, both of which delayed going to keyboard free for far too long and then messed up the transition when they eventually went. Toyota are at the first stage obviously."* Drawing someone else into the narrative to impede is a problem. Can't let that happen: That analogy falls apart when it's pointed out that neither Nokia nor Blackberry had decent software to support a touch-interface. That most definitely isn't the case for Toyota. They are already delivering the full EV drive with Prime. Toyota already has a ton of experience producing a variety of electric-motors and battery-packs. Prius Prime includes a heat-pump and optional CHAdeMO charging to build upon that foundation the analogy overlooks. Claims of delay don't have a merit; there simply isn't anything to support that. When the next-gen batteries become available (higher density with faster recharging), Toyota will have a vehicle shaped to pack in lots of those cells. Everything else is already established. Think about how far along Toyota is with reliability and cost-reduction. They even have an extremely efficient electric-drive system already, both hardware & software. The analogy doesn't apply.

12-16-2017 Both Are. The rhetoric has really ramped up lately. It is obviously a final desperate act to save reputation. We are watching Volt's failure to grow sales come to an end. It didn't achieve the necessary goal. So much was invested in a poor configuration choice. Management made the decision not to take their engineering advancement to mainstream consumers. Volt was designated a niche and was doomed to stay that way. Gen-2 made that overwhelmingly clear. Trouble was. Few wanted to admit it. Acknowledging sabotage isn't easy. But it isn't hard to see the cramped seating and lack of advertising as anything other than disinterest. Rather than deliver something for the masses, focus remained on faster & further. Giving it more power & range than the previous generation was exactly the wrong thing to do. The size of motor & battery should have either remained the same or been made smaller. That's how cost-reduction is achieved. Increasing specifications is the opposite of what was needed. Anywho, I've been witnessing the resulting mess play out to its inevitable conclusion... denial: You seem to be suffering from a chicken/egg situation. GM is focusing on the chassis, hence rumors of the Bolt platform being offered as a SUV in the future. Toyota is focusing on mindshare and reputation, hence replacing their existing production with hybrids & plug-in hybrids. Both are pursuing the same goal. Both are refining production of components within to reduce cost. Both are improving hardware & software operation. Yet, you claim that GM has a *"huge head start"* and Toyota has *"squandered its leadership"* even though evidence proves that's not the case.

12-17-2017 Few Years? The denial continued: *"It's a safe bet the tax credits for Tesla, GM, and Nissan will run out within the next few years."* I was rather surprised to see that, so must so I posted the following... making sure there was lots of detail to ensure it was overwhelming clear that the loss of subsidies would come sooner:

Few years? GM is already at 158K. With the year-end scramble to take advantage of tax-credits, it's easy to see that count climbing to 163K. Assuming no growth in demand or supply, a Bolt/Volt sales rate of 4K per month would mean the phaseout would get triggered at the end of Q3.

That would mean the last quarter of 2017 and the first of 2018 would offer the tax-credit at 50%. The following two quarters would be at 25%. The final tax-credit opportunity would be September 30, 2019... which is not a few years. That's less than 2.

Volt is already struggling with sales, primarily from being too small and too expensive. Even with a miracle price-drop from battery-tech improvements, it wouldn't be anywhere near enough to offset the \$7,500 tax-credit loss. From \$200 per kWh to \$100 is only a saving of less than \$2,000.

GM's supposed leadership cannot just settle for sales well below mainstream levels for Bolt and barely niche levels for Volt. The loss of the tax-credit will make that situation even worse. This is exactly what the *"too little, too slowly"* concern was all about.

Remember, both Tesla & Nissan are planning for much higher sales volume and neither has a tax-credit dependency as part of their plan. Model 3 is competitive at \$35,000 as a low-end luxury offering and Leaf has a base price of \$30,000.

- 12-17-2017 Winter Charging.** A strange new topic emerged today. Some random newbie posted a random question: *"So I guess what I'm saying is, should I give up charging in the winter? Am I still saving money when I'm charging every 3 days?"* That's as random as you can get. I certainly didn't see that coming. My assumption was the benefit of plugging in would be obvious, even when the depths of winter arrive. Apparently, that's not the case. I wonder why. Hmm? There's lots to learn from owners new to plugging in... hence, the intentional limited rollout of Toyota. Keeping the markets limited made study of usage behavior somewhat easier. With so many variables at play, it's quite a challenge to identify patterns and pinpoint bottlenecks. We're all trying though. From an owner to owner perspective, I shared: Any electricity you use will provide a greater benefit to the gas used. That has been overwhelmingly confirmed by those who drove their Prius PHV in the winter, leaving home with full charges every morning. When the engine runs, that heated coolant will circulate to provide warmth for quite awhile, allowing the EV drive to be taken advantage in the meantime. MPG clearly shows the resulting gain. Electricity use will also help reduce pollution, which is worse during the winter. So whether it saves money or not, there's still a win in return. Leaving Prime plugged in will take advantage of the battery-warmer too, which reduces impact from the cold. Have you looked into time-of-use discounts from your electricity provider? I had a sub-meter installed. That dropped my price paid for overnight charging to 6.74 cents per kWh.
- 12-17-2017 Spreading Misinformation.** Figuring out how to respond to something like this can be quite a challenge: *"I found it strange that Toyota's very first PHEV, a Prius Plug-in with quite minimal EV-only range, had two separate battery packs, but both were lithium!"* Where exactly did that information originate and what is the intent of spreading it? Fortunately, I don't encounter stuff that misleading too often. Simply being that vague makes it less likely to go anywhere. But nonetheless, we do get comments about having read it from some source in the past... making you wonder if this was an effort to supply exactly that, hoping someone else will pass it along without questioning its reliability. Needless to say, I jumped on that right away, pleased I had some supporting video to help back up my claim: That very first was just a prototype, used for testing the system prior to the production pack. I got to drive one for a few days back in August 2010. That was very different from the actual rollout model, which I purchased in May 2012 and drove until I replaced it with a Prime in April. Prius PHV most definitely only had a single pack, shared for both EV & HV operation. Here's one of many videos I filmed proving that... [Prius PHV - Commute Work \(Deplete EV\)](#)
- 12-17-2017 Misinformation Harm.** When someone reads the misinformation, they base assumptions upon it... contributing their part to making the problem worse. For example: *"Since they had two separate battery packs in the car, and since (as I understand it) the car operated most of the time in parallel hybrid mode, just like an older non-plug-in Prius..."* See how easily the situation gets blown out of proportion. How would you go about correcting that, knowing the person spreading misinformation may not be the slightest bit receptive to what you have to say. Why would they? Who are you? How could you know more than some unknown on the internet? Ugh. That happens all the time. It's amazing how much damage is caused as a result. There are misconceptions that emerge which can live for decades. You can't stop understanding issues. You can work to prevent them from starting though. I certainly try: Neither the prototype, nor the PHV model, operated like that. As the video clearly reveals, you could drive the entire EV capacity without the engine starting. In that example, it was 14.1 miles.

12-18-2017 **Known Plans.** Remember how FUD works? It's the spread of Fear, Uncertainty, and Doubt. That's used to undermine progress. We see this coming on a regular basis from Volt enthusiasts, the very same individuals that will take GM vague announcements at face-value as a solid promise. Yet, when it comes to Toyota they pretend nothing is ever told, that intent is a total mystery. When confronted with detail, they just brush it off. The hypocritical nature of their behavior is what I key into. That's what I use as confirmation that nothing has been overlooked. Since the upcoming new year will bring an end to certain debates, it's good to have researched each of the topics as thoroughly as possible. This was my response to their latest FUD attempt:

We have known about the plans for quite awhile. The entire passenger fleet being offered as hybrids is a positioning maneuver to make the plug-in option an easy next step... at low cost...

- Corolla hybrid
- Camry hybrid
- RAV4 hybrid
- C-HR hybrid

Each of those await the opportunity to exploit the "*Prime*" update similar to what was delivered for Prius.

Being simple & affordable is key and the HSD design makes that realistic.

12-19-2017 **Know Your Audience.** No matter how much I share that message of importance, certain people just plain don't get it... or don't care. They keep the blinders on, concentrating exclusively on what they prefer rather than what is necessary. It's the problem of want. Some don't understand the difference. Anywho, it has been interesting to witness the person having brought up "*innovator's dilemma*" not understand what it actually means. Ironically, he's suffering from that very issue. This is where psychological behavior of reflection originates. You see what's wrong, but don't realize you are the one experiencing it. I posted this about it today:

It's quite clear that the majority here don't recognize how vital that advice is.

Applying the early-adopter perspective to a mass-market audience doesn't work in many situations. The problem is called "*innovator's dilemma*". It's when the formula for success in the initial stage of rollout is assumed to be what's needed for the stage to follow.

In this case, we see how GM's upgrade of Volt to gen-2 focused on enhancement of the same traits which drew sales for gen-1. That clearly didn't result in the much hoped for sales growth; instead, the opposite happened. We've been witnessing sales shrink.

The reason why should be obvious. GM listened to the same audience that jumped on tax-credit savings and low-lease opportunities for Volt, who have since moved on to Bolt... because it was the next step in electrification: large-capacity batteries.

Abandoning everyday consumers for the pursuit of the latest & greatest is perfectly fine, when your purpose is pushing the leading edge forward. That is a horrible mistake though, if you are trying to deliver a product for the masses.

This group clearly isn't interested in that audience. They prefer support of the innovation, the push. That's ok, but mainstream consumers still need their "*ordinary*" choice to purchase... which is exactly what Toyota seeks to deliver.

PHV/Prime models of Toyota other hybrids are on the way. We see the impressive upgrade to larger and more powerful, yet still remarkably efficient, from the new Camry hybrid. The upgrade to deliver a plug is the obvious next step for mainstream consumers.

Too bad if you find it dull or boring, that's how the bulk of the automotive business makes sustainable profit. Know the buyers.

12-20-2017 **Insight Gen-3.** Rumor or Sneak-Peak? It was hard to tell. The impression given from an image being circulated on the internet today was that Honda will be revealing a gen-3 version of Insight at the Detroit autoshow. It looks a little bigger than Civic, squeezed in between it and Accord for size. That would be an interesting twist. With the newer two-motor hybrid system, that approach does make sense. Why not? After all, the offering for vehicles in the future will be some type of hybrid. Since plug-in models won't work for everyone, that's definitely a wise option to offer. The question is, when will it be rolled out? With the Kia/Hyundai offerings entering the market, there's new competition to deal with for the usual initial round of conquest sales. Then once things settle down, the plug-in hybrids will be established. 2018 certainly is shaping up to be interesting.

- 12-21-2017** **Clarity Attacks.** One the wide-audience blogs for plug-ins, we're seeing a lot of attacks on Honda's upcoming new offering already. The Clarity is getting the "*vastly superior*" treatment from... you guessed it... the Volt enthusiasts. They sure are a pain. It's the same old "*leapfrog*" nonsense all over again. This is no surprise, of course. They've been all-bark-and-no-bite for so long, they've lost touch with goals. Sales growth clearly doesn't matter to them anymore. All that seem to care about is showing some type of dominance. It's like the alpha parading around expecting everyone else to provide praise. Who cares if all you are doing is an exhibition. Actions speak far more than words. Yet, we're not seeing it from GM. But we are already from Honda. That's impressive. The initial round of reviews are demonstrating ability worthy of attention. Enthusiasts are more worried than ever about losing their spotlight. Well, too bad. This is what the "*too little, too slowly*" was all about. You can't just rest on laurels like that. Now, they have good reason to panic.
- 12-22-2017** **Refusal To Accept.** Some just plain don't want to. The pattern of who is blaringly obvious... Volt enthusiasts. This is why I blogged so much about them. I could see the pattern from prior generations of Prius. When change is necessary, you must adapt. They refuse to. That's a major problem which will inevitably play out in a bad way. Rumor of Volt's impending death are becoming common. No message of intent from GM is what's bringing this about. In the past, they were fed ambiguous & vague announcements which provided the meritless hope they thrived on. Having nothing whatsoever to support their claims didn't matter. It was all about having a clear direction, not a realistic means of getting there. Now, there's nothing. It's creating a sense of loss. They have no idea what to do... other than the usual... place blame and make excuses. I push back every time they do, like today: Toyota will be offering a BEV, in addition to the HV, PHEV, and FCV offerings. What's wrong with diversifying to cover a variety of markets? After all, much of the hardware & software can be shared. Take a deep look into Prius Prime. It takes advantage of the existing cell-stack design in its battery-pack. The tradeoff is physical size, but what you get in return is an robust & affordable offering. The new Camry hybrid is amazing. 52 MPG from a larger, more powerful vehicle than Prius should really catch people's attention... but won't. The design is so subtle, it will just be part of the fleet. A model offering a plug will likely have the same "*ordinary*" appeal. In other words, the short-sighted hype we encounter within online discussions don't necessary reflect what mainstream customers will actually encounter.
- 12-22-2017** **Bizarre Behavior.** This blew me away: "*I tried unplugging, plugging, unplugging very fast and plugging back in, unplugging from socket wall with charger still in car port, nothing works.*" It was a truly bizarre behavior to read about. What in the world would give a person the impression that faster is better? Imagine pulling the power-source on a device out quickly, just moments after it detected power and began to start up. Halting it mid-cycle makes no sense whatsoever. Needless to say, I was quite curious. Sadly, the person never did reply to my post. That often happens. Someone will post an odd experience, then vanish. I certainly tried to bring some clarity to the situation though: That's exactly what you shouldn't do. Fast could cause a fault. You likely need to reset your CFCI outlet, service-panel breaker, or the charger itself. What does the status light indicate?

- 12-23-2017** **Dropping Bait.** Despite not fitting the definition of *"troll"*, since I make sure posts are on-topic and within context of the discussion, that's what I get labeled as anyway on that old Volt blog. They do that with the hope of concealing the reality that they are actually the trolls dropping bait. When I don't participate, there's little activity. Most days just fizzle without any type of opposition. That's what happens on a venue where everyone blindly agrees. Just a bunch of followers makes for a very boring setting. So, they attempt to provoke. This time, it was: *"Today's post is about Toyota going fully electric and not a single comment from our dear 'friend'."* I waited until there was no more posting, late in the evening with the knowledge of it being past their time of interest, then bit the bait with: \$27,100 MSRP for Prius Prime. Disregard toward the importance of that has set a precedent of disregard for affordability. There's simply no point discussing matters of price when there isn't any concern for it. Toyota continues to deliver, keeping price a major priority. \$27,900 MSRP for Niro PHEV. That shows us that Kia also has price as a major priority. GM does not yet. We are still waiting... too little, too slowly.
- 12-24-2017** **Really Cold.** It was -2°F two nights ago. Cruising at 80 mph with a nasty headwind resulted in the usual much-lower efficiency, but heat stayed quite comfortable after getting off the highway. I switched to EV and took advantage of the battery for the rest of the drive. No matter how cold it gets, you'll have the opportunity to use heated coolant to stay warm for awhile while the engine is off. It just cycles from time to time to generate more heat to circulate after it shuts back off. With an aftermarket gauge, you can see the temperature thresholds. I haven't tried that yet with the Prime, since being below 14°F for me to carefully observe the cycling hasn't happened yet. Following holidays, I know there will be plenty of opportunity. Back in Minnesota, the cold doesn't go away for quite some time.
- 12-25-2017** **All Day, No Plug.** We got there early in the morning and didn't leave until last in the evening. My Prime sat outside all day, exposed to the extreme cold of that Wyoming open prairie, while we were inside celebrating Christmas with family. It was the ultimate test of not plugging in. Just how long would it take to warm up for the drive afterward? Being so far below the freezing-point, somewhere in the negatives, I didn't care to find out. That would be a rare occasion where I did what everyone else does... start the engine and let it run for a few minutes. That works out when you have to sweep off the fresh snow and load up the car anyway. Turns out, there was a decent warmth coming from the heater after just a short span. I was even able to get a few photos on the way back to the hotel of Charge-Mode in action. That's nice proof of it working just fine in extremes.

- 12-26-2017** **\$24,950 Ionic PHEV.** That base price revealed today is amazing. As expected, it's missing some of the standard safety features which come on the base model of Prime. So, there really isn't a lower price. They basically work out to the same. The catch is, Prime offers more power and electric heating. So, the well-informed will have to carefully consider their options. Hyundai's Ionic isn't quite as large as Prius either with respect to visibility out the rear. It's quite obvious too. But then again, the plug-in model of Ionic has noticeably more cargo space available. I like this. It's more of a rivalry than competition... as it should be. Remember, we are looking for adversaries, not enemies. Too bad the GM people never understood the difference. We're supposed to be fighting together to end the reign of guzzlers, not to battle each other. Ugh. Anywho, the price Hyundai delivered is impressive. Kudos to them for making low-cost such a high priority. That most definitely is nicely under \$30,000.
- 12-27-2017** **Extreme Cold.** Our road trip to Wyoming was our first encounter with extreme cold in the Prime. It sat outside all day without plugging in, then got an decent warm-up with the engine prior to leaving. Prior to reaching the 80 mph highway, I switched over to charge-mode so we'd have an ample supply of electricity for driving through the Christmas Light display. All went extremely well... though, I am really looking forward to the return of warmer weather. -5°F is far from ideal. The photo my wife took at 81 mph show 9.7 miles traveled resulting in a 28.4 MPG average. Not bad, considering such drastic conditions and recharging the battery-pack at the same time. Looking back to the photo taken prior to getting on the highway is what really caught my interest. While at 43 mph, the screen showed 23.5 MPG at 4.7 miles. Seeing the efficiency go up like that was an unexpected outcome. Of course, it's simply a surprise to most that Prime runs so well under that extreme. To watch it push efficiency too, that's sweet. Turns out, we got most of the way through the long drive in the park while in EV. Sitting there at the start of the illuminated tunnel and while at the most elaborate display (one synced up with a radio broadcast) caused the engine to cycle shortly for cabin heat. We had a good time. I really enjoyed it... and quite thankfully was pleasantly warm.

12-28-2017 **Avoidance, struggle.** Discussion of Volt's demise is rapidly growing. Year-End sales results combined with the inevitable loss of subsidies is a very real problem enthusiasts don't want to address. Today's blog post drew attention to the struggle Volt is having. I provided context:

January 6, 2007 is when GM revealed Volt to the world. Struggle to sell Two-Mode hybrids made it the next logical step. The automaker would refine their system to use a dedicated platform optimized for EV driving. Following depletion, it would also deliver incredible hybrid-efficiency.

40 EV miles. 50 MPG depleted. Nicely under \$30,000. Those were the targets set for the end of 2010. It seemed too good to be true though. How could so much be delivered so quickly?

By 2009, concern of "*too little, too slowly*" became a very real issue. The automotive task-force assigned to oversee bankruptcy recovery explicitly stated this as needing serious attention. We were assured over and over again, there was no reason for concern. Technology in Volt was "*vastly superior*", allowing it to achieve mainstream sales volume by the end of the second year.

That didn't happen. Volt was far more expensive than anticipated and no where near as efficient. All 3 targets had fallen came up well short of expectations. We were told to be patient. Design of the second-generation Volt would address those shortcomings. No need for concern.

That didn't happen either. EV range target was achieved, but hybrid-efficiency and production-cost prevented it from reaching ordinary consumers. Sales were flat, rather than being the much hyped big boom. Now on the third year of that upgrade, sales decline is undeniable.

The rapidly approaching phaseout trigger for the \$7,500 tax-credit raises concern of attracting GM buyers to Volt a serious problem. GM simply cannot afford conquest sales (drawing customers from other automakers) anymore and cannibalization (losing sales of Volt by choosing Bolt) hurts dealers & salespeople. Replacement of traditional offerings clearly isn't going well.

It doesn't matter what other automakers are doing at this point. Time is rapidly running out. GM has backed itself into its own corner. GM shoppers don't want a small hatchback or a small wagon. The fact that both Volt and Bolt are so expensive to produce & sell negates any supposed benefit the design offers. People don't want that tradeoff.

We all know offering an affordably designed plug-in hybrid system in a small SUV, like Trax, is what GM desperately needs. We also know that the moment it is announced, demand for their traditional SUV offerings will see an immediate negative impact. That corner GM is trapped in has become quite obvious.

Choose how to reply to this carefully.

Think about posts of the past.

What's different now?

- 12-28-2017** **Avoidance, distract.** Within just 7 minutes of my post, I was attacked. It was impressive. You could imagine he was so angry, he could barely type fast enough. I saw that play out by repeatedly refreshing the webpage. Post content changed several times within those next few minutes to follow, adding personal insults to help make sure the problem could be avoided. It's truly amazing how some will lash out, doing everything they possibly can to not actually deal with an issue. They place blame and make excuses, rather than just face reality. It's so predictable and undermines their own desire to make progress. Goals are impeded by pride. I kept my response to such an obvious antagonist, who was desperate to distract, as brief as possible: GM has a SUV-centric approach. Offering a small hatchback and a small wagon with plugs doesn't address the problem. You didn't either.
- 12-28-2017** **Avoidance, topic.** Research from observation & participation was usually kept quiet. I'd find a subject worthy of intense discussion, they identify the theme associated with it. That's how you know there's rhetoric at play. Stepping back to acknowledge the bigger picture is absolutely vital. Enthusiasts don't... hence their failure to know audience. They stay too focused on just the immediate discussion. So, I blog about their actions & mistakes. Things took an odd turn this time though. Knowing the year-end sales results will bring about the 2-year judgment... and that a status of "failed" is inevitable... there's nothing else to study in terms of expectations. It's over. At an end. Done. So, I revealed the theme this time: "*Avoidance*" is the latest blog series topic. It describes how GM enthusiasts do everything possible to avoid dealing with GM problems. Several examples were contributed today. GM has an audience primarily of SUV shoppers. That's what they want to buy, not a small hatchback like Volt. We've been told by those here that GM was the market leader; yet, tax-credit expiration draws near without any plug-in hybrid SUV to purchase. To make matters worse, Volt and Bolt fundamentally contradict each other, making the message of intent even more difficult to understand. But rather than supporters helping out, they avoid the problem entirely. GM still does not have a path toward electrification. We see the inevitable struggle to deal with the loss of subsidies coming; yet, there is no clear next step. What was the point of all the "*range anxiety*" promotion and plug-in hybrid development? All that money invested, then abandoned, in favor of an EV instead?

- 12-29-2017** **Avoidance, approach.** My observations continued with this interjection: TOP-DOWN was the approach that led to GM getting trapped... which this thread never addresses... hence the avoidance... that difference now from in the past. Starting from the top and working your way down can work. It takes an entirely new platform, then alters & expands it to achieve cost-reduction. It requires a major commitment though. The resulting investment (production, education, advertising, incentives to dealers, etc) will drive costs down and demand up. GM didn't do that for Volt, as countless people here in the past complained about. That approach is quite risky. People here made fun of Toyota for taking the approach that was less risky. BOTTOM-UP still requires major commitment though and it must be altered & expanded. The primary difference is you are building upon, rather than starting from an end-configuration. Toyota's approach worked too. Observing how Prius became a Prime model, knowing Corolla hybrid is scheduled for the same, and seeing the potential for the other hybrids not only reduces risk, it also sends a clear message of intent to both dealer & consumer. That clear path to electrification is what GM still lacks.
- 12-29-2017** **Avoidance, diversification.** The study of avoidance continued: Since long before gen-2 Volt was rolled out, my push was for diversification. The technology GM had designed could not reach mainstream volume or buyers without expansion. That's where the "*too little, too slowly*" came from. More was needed and the wait kept getting longer. Now reading others say the very same thing... that a second lower-range model of Volt and a CUV/SUV model should be offered... confirms those claims of being anti-GM were unjust. I was indeed watching out for the business, suggesting viable next steps to help GM be successful. All along, it has been an effort to promote plug-in offerings from all automakers. Whatever issue you have with Toyota should not be reflected on me, since I'm in favor of all realistic choices... like the plug-in SUV just rolled out by Mitsubishi... the very thing I stated repeatedly that GM should also offer. So what if Volt failed to catch on. It's not like a configuration appealing to GM shoppers can't still be delivered. It's not too late. It certainly is taking far longer than expected though.
- 12-29-2017** **Mutiny.** Seeing the winning formula emerge... being affordable ...their are a number of former Volt enthusiasts sounding off. They words are an echo of what I was saying years ago: "*Make less expensive versions with about 25 mile range (sub \$30k) and maybe more expensive versions with 50+ mile range that are also larger and better equipped vehicles.*" Sound familiar? I was delighted to read that and others being posted, on the dedicated member-only Volt forum. On the open blog, there's a scramble to hide any evidence of mutiny. It's quite amusing to witness that. Basically, the time has come to abandon ship. The quotes kept coming too: "*It is a hard sell to sell a \$35-\$40k MSRP vehicle that is a compact car, doesn't come standard with safety features like ACC, AEB, LKAS, no power seats.*" All that faster & further rhetoric is falling apart. They see the end coming, when sales results are revealed for 2017. Things haven't gone well. Declining demand confirms failure, ushering expectations of change. Volt didn't work. 7 years and 2 generations is enough. Time to move on.

12-29-2017 Deep Discharging. Whoa! We found out today how Hyundai was able to squeeze out 4 more miles of EV range from a battery-pack only 0.1 kWh larger than the one Toyota uses. It simply didn't make sense. $28 \text{ kWh}/100\text{mi} = 29 \text{ miles EV}$ for Ioniq. That's nowhere near as efficient as $25 \text{ kWh}/100\text{mi} = 25 \text{ miles EV}$ for Prime. Turns out, Hyundai made the decision to utilize more of the overall capacity available. That capacity is usually used as a longevity buffer. If the system doesn't ever deep discharge, the battery-pack should retain capacity longer. Only 9% was programmed to remain untouched though. (That's 8.1 of 8.9 kWh.) Again, whoa! It's so much less than the 28% that is reserved as a buffer in Prime (that's 6.3 of 8.8 kWh), it makes you wonder what magic chemistry or poor management influenced such a decision. This seems a terrible idea. Just like with the stories from diesel supporters, something doesn't add up. Do we really have all the correct information? What happens many years from now when EV range drops considerably due to diminished capacity? Maybe that's just part of the design. People will just trade-up for a new battery-pack years from now. That would be an interesting new business-model. After all, vehicles with electric-motors providing propulsion should last considerably longer. Maybe Hyundai sees the opportunity to capitalize on their own post-upgrade sales, rather than letting aftermarket providers reap the benefit.

12-29-2017 Prime Availability. With the end of the year quickly approaching, there's lots of talk about demand. Perception of it is derived from sales. Consideration of supply is almost always overlooked. We've seen that countless times over the generation rollouts. People simply view purchase counts as the indicator of interest. I know all too well that you cannot buy a vehicle if it isn't available. For Prime, that's been a big issue. 2017 model rollout was awkward. With production challenges of the new technology (carbon-fiber hatch and dual-wave glass) adding to the usual challenges of physical delivery to several very different markets all in the same year, it's no surprise that penetration wasn't going to be comprehensive. Some dealers wouldn't get supply until the following year, regardless of demand. To draw attention to limited supply, I did some quick research and posted what it revealed: Doing a search within 500 miles of Kansas City, MO for Prime, only 15 are found. That's an inventory count so low, it basically can't be considered available. Sliding east over 650 miles to Columbus, OH and repeating the 500-mile search for Prime, there were 1,046 found. That pocket of the country actually has choices. Going down 570 miles to Atlanta, GA and searching 500 miles again, there are only 13 found... another large area without any. In other words, the wait for 2018 models is necessary. We simply didn't see 2017 on a large number of dealer's lots. Demand cannot be properly gauged until then. Fortunately, even with limited availability, Prime still ended up with decent sales counts for the year here. Worldwide, it looks like total sales will end up hitting the 50,000 mark. That's pretty good for a start.

12-30-2017 **More EV.** The belief of more being better is very effective marketing. We've been brainwashed into thinking it is necessary, that less simply won't work. With things like medications & foods, the size of doses & portions have grown ever larger. Cutting back isn't easy. People mix up want & need so frequently, many don't even recognize the difference anymore. That's really sad. Think about how often we hear that 5 seats are necessary, even though there is rarely ever more than 2 people in the vehicle. Remember how the reasoning for 5 instead of 4 eventually fell apart? Volt enthusiasts forgot and have consequently become hypocrites for contradicting their own past statements... but that's another story. This one is about more EV. Supposedly, range in the 20's isn't enough. I ask: "*Enough for what?*" Every response I get is a want, not a need. No one has been able to state necessity. That's because the purpose of a plug-in hybrid is to take advantage of having an engine from time to time. If it wasn't, everyone would just purchase an EV instead. Needs vary. Neither enthusiast, nor antagonist, understand that though. It is the problem of knowing audience. They don't... or they don't care. Either way, it's a problem we have to deal with when promoting plug-in hybrid choices. Today, I dealt with the "*more*" claim this way: There is no need for bigger. The system will blend, still taking advantage of electricity... just not as much in extreme cold. My commute yesterday was in the single digits. 18.5 miles at 6°F in my Prime delivered a 64.1 MPG result. That's amazing overall efficiency at such a low outside temperature. So what if the engine runs. Between the heater delivering warmth via engine coolant and use of the heated seat, I was quite comfortable. The windshield stayed clear too. What more do you actually need for such an affordable price?

12-30-2017 **Avoidance, facts.** Attempts to discredit totally fall apart: "*You keep trying to push your narrative, but the facts don't agree.*" It's what happens when the discussion continues for too long. They run out of material and their transparent efforts to misleading become exposed. You need something to actually support claims. People need proof. No merit means no progress. Even enthusiasts want something to work with. Empty chants falls apart. Facts can be manipulated to mislead. They know that. So, not having anything at all to work with makes it a dead issue... nothing to argue about. I gladly pointed that out:

Facts don't agree... which is why you avoid actually posting them. Omitting that detail is the spin.

Mainstream volume is the most avoided fact, the statistic which angered you most. It was very specifically sales at a rate of 5,000 per month. That's an annual production of 60,000 vehicles, here in this market. The target date for that was the end of the second year of sales... which was 2012... that's 5 years ago.

The reason for that target was obvious. It was what GM needed to put Volt on the path to profitability, so sales could continue on with dependency on the tax-credit and expansion to other vehicles could take place. All of that fell apart though. Sales fell well below that target... and continue to, despite so much time passing and a second-generation upgrade.

That fact is especially difficult to accept with the knowledge of Toyota not having made the same mistakes... hence the constant insults... "*laggard*"... "*lame product*"... "*obsolete*"... "*too little, too late*". You know quite well they have a clear path to electrification. Their hatchback already demonstrates how easy & affordable it is to go from hybrid to plug-in hybrid. Now, the rest of the hybrid fleet awaits the same upgrade opportunity.

The ultimate though is this quote, since spin about the past doesn't matter: "*We've ALL been saying this since day one, 10 years ago. We want Voltec everything.*" Fact is, you are omitting detail about who "*we*" actually is. A large portion of Volt supporters from the past don't want that anymore. They have turned to saying Volt was just a bridge to Bolt. Now that "*range anxiety*" has been resolved with a larger battery-pack, they see no need for a plug-in hybrid.

Take your own advice. Pay attention. That is why I use "*notice*" so often in my replies. You clearly are not. So many former Volt enthusiasts have abandoned ship, there are only a handful left. They either switched over to Bolt or left GM entirely. The count is remarkable. In the past, when those amazing Volt leases expired, those owners moved on to purchase a Ford Energi (plug-in hybrid). Now, we see many planning to switch to a Chrysler Pacifica or a Honda Clarity.

In other words, we already see trouble brewing for GM. Phaseout trigger for the tax-credit is only 9 months away and Volt sales are declining. Adding to the struggle is the rollout of the Kia & Hyundai plug-in hybrids. Both are nicely under \$30,000... the other goal GM still has not achieved.

Avoid this supposed narrative all you want. Negative vote to hide the facts. That won't

change the path GM is on though, which you enable by avoiding acknowledgement of the bigger picture.

Vague claims of "*We want Voltec everything.*" doesn't actually tell us anything. Total absence of detail, no specifications whatsoever, leaves people wondering what you really mean. This is why stating goals was requested over and over and over again. Instead, that is still being avoided. After 10 years, you'd think that lesson would have been learned.

12-30-2017 Avoidance, stating goals. That was by far the biggest problem, right from the start too. The first attempt was immediately called out. Those goals were so unrealistic, the label of "*vaporware*" quickly became an expectation for Volt. That infuriated enthusiasts. They had nothing to support their blind hope either. Making that bad situation worse was me... armed with lots of real-world data pointing out their oversights. The fighting never ended. I kept pushing for goals. But rather than stating specifics anymore, it turned to mindless propaganda... hence the "*vastly superior*" nonsense. Eventually, that settled down, becoming "*no plug, no sale*" instead. Being so horribly vague though, it didn't actually help. Needless to say, my push continues by exposure their efforts to avoid:

STATE THE GOALS NOW... FINALLY... AFTER 10 YEARS OF AVOIDANCE...

- **Nicely under \$30,000 MSRP**
- **Real-World average of 100 MPG**

IS IT REALLY THAT DIFFICULT TO ACKNOWLEDGE SHARED GOALS?

12-30-2017 **Avoidance, missed opportunity.** Enthusiasts would spin excuses, place blame, and make assurances... all to cover up missed opportunities. Volt was the only choice. GM was offering unbelievably low leases. Gas prices were expensive. Early adopters were eager. Think about how many aging Prius being replaced by the first of the plug-ins to be offered. That was when something else should have happened, when the momentum was still strong. Instead, it fizzled. Posts become an effort to defend GM and offend everyone else attempting to deliver on those same goals. Now, all these years later, we see several contenders striving to fill in the void GM left behind. What a waste. Those enthusiasts know it too. That's why so many disappeared. The only few left are so desperate now, then have no idea what to do. Is there any opportunity remaining? Their propaganda about "All Electric Range" has been annihilated by Bolt, leaving Volt completely without a purpose now. I knew their goal was to crush the competition... which they believed was other plug-in vehicles. They were wrong, very wrong. It was a mistake so profound, the enthusiasts were able to convince GM of that purpose. This is why gen-2 was so poorly configured to face direct competition with traditional vehicles. The design had focused on other plug-in hybrids instead. Oops! Really big oops!!! What a terrible missed opportunity. Of course, the other automakers actually listened to their own shoppers looking for a plug-in hybrid, not early adopters who already owned one. That's why focus was on affordability instead, a priority GM didn't think was important due to the influence online posts had. This is why I documented so much of their propaganda and there's so much effort now trying to conceal the mistakes they made.

12-30-2017 **Avoidance, next year.** We've reached that tipping point where Volt is no longer an impediment. GM dangled a carrot in front of the entire industry, setting a precedent of supporting unrealistic expectations... to the point of them being normalized. If the plug-in hybrid wasn't at least as good as what was delivered in late 2010 by GM, it was unworthy of consideration. The market damage that caused is truly remarkable... exactly what people who witnessed the GM diesel fiasco of the 70's feared would happen again. And it did! The vehicle of praise was unprofitable, so production in high-volume simply couldn't ever happen. That hampered the entire industry, holding back consumer acceptance. Enthusiasts set the bar so high, failure was inevitable... which is the state Volt is at now. In a few days, sales results for year-2 of gen-2 will be revealed. Rather than the significant growth the upgraded Volt was to deliver, we'll see an undeniable decline. Demand isn't there. They built it, but enough people didn't buy it. True to form, GM will follow the timing pattern we recognize all too well. This point in history has repeated itself several times already. They will make an amazing new vehicle announcement to conceal the problem with Volt. A new hope will be revealed, at the Detroit autoshow. Knowing that Honda, Kia, Hyundai, BMW, Chrysler, Mitsubishi, Toyota, VW, and Ford are all actively going after the plug-in hybrid market GM could not reach, it makes sense that GM will move on just focusing on pure electric vehicles instead. Bolt doesn't stand a chance of competing directly with Tesla though. No one is going to compare a small wagon to the sleek sedan and consider it a toss up. GM must finally turn to its own customers... the SUV buyer. Offering one that reuses the Bolt platform is a sound next step. Putting a small SUV body on that motor & battery configuration makes sense, especially since they would be able to justify the higher price. Remember, the \$7,500 tax-credit for GM is expected to only last 9 more months. Then, it drops to \$3,750 for the following 6 months. After that, it drops to \$1,875 for 6 more months. In short, the challenge of growing sales will become quite a bit more difficult next year. Time is running out. Change is necessary.

12-31-2017 **Avoidance, conclusion.** It took nearly a day to finally get a response. Such an extreme delay (with obvious multi-downvoting still taking place in the meantime) but no posted reply, is an clear sign of having correctly identified a major shortcoming. Since the usual turn-around is only a matter of minutes, that's a pretty solid confirm. He posted a series of attacks. All were antagonist nonsense, intended to divert attention. There was nothing of any substance, just vague ramblings about Toyota. That's was key... and I knew it. That was a lesson learned from the past. Enthusiasts established a concise definition for what "Volt" would be. But when the final production model was revealed, that "Volt" didn't fit the vary criteria they had preached so much about. Specifically, it wasn't a SERIES hybrid. It turned out to be a PARALLEL, similar to Prius. That was a painful error to accept... and that was before finding out how expensive & inefficient their pre-praised plug-in hybrid actually was. That's how EREV came about. If you don't like an existing definition, make up a new label with a definition to fit... a key to avoidance. Making matters worse. 2 years later when Ford rolled out their plug-in hybrid, it fit the EREV definition. Ack! They got burned again. 2 years following that, when BMW rolled out their plug-in hybrid, it all became a chaotic mess. Not only had BMW actually met the specifications those enthusiasts has so desperately manipulated, BMW has grossly exceed this... by a very significant amount. This is how the attacks on Toyota became so intense. GM could not compete with those other traditional automakers, so enthusiasts look for seemingly weaker prey. Little did they understand though that there's power in numbers. Prius has won many battles in the past by overwhelming opposition. Enthusiasts see the modest goals as a joke, something to be mocked & belittled. Mainstream shoppers see them as an automaker's effort to deliver an affordable choice. That fundamental difference ties back to the key... being concise. Needless to say, I found the response quite vindicating. He did precisely what I had anticipated, to provide the ideal conclusion to such a senseless waste of time... so much missed opportunity due to pride getting in the way... some just play the game... which is why I point it out: Avoid. Avoid. Avoid. That continues to be the theme. Do every but actually step up and accept some responsibility. If you don't actually commit to anything, there's no accountability.

12-31-2017 **Avoidance, goodbye.** I got a response from another Volt enthusiast, one who got burned so bad by gen-1, he still holds a grudge after all these years. It was captivating: "*Look for more in 2018.*" I took that as more rhetoric... which will be quite a surprise for him. There's no reason to participate on the fanboy website anymore. They made it overwhelmingly clear it is only for cheerleading, that anything of a constructive nature which could be construed as negative is not welcome. Their hate was always fascinating. For some much to be sacrificed for so little in return. They got nothing but a sense of righteousness from attacking me. It did nothing to actually advance their cause. Pride was more important than progress. Ugh. I was delighted to finally say goodbye. Toughing it out had been a test of character. Learning from other leaders I look up to provided a common suggestion... participate in groups that don't share your perspective. It makes sense, but isn't easy. It sure is worth it though. That taught me far more than just simply going along with the mantra they were spewing out. I still had to fire back one last time though: More what? Being vague is key to avoiding responsibility. That's why GM is routinely so ambiguous with announcements. We only get basic information, lacking any quantitative value. Yet, those here embrace that anyway. They get played and are too naïve to realize the problem. Asking to state goals is a raising of awareness to the problem. If you want to defend the subterfuge, that's your choice. I'm choosing to draw attention to it, even if I get labeled as a troll for not accepting the status quo.

12-31-2017 **Video: Extreme Cold.** 6°F is the coldest temperature many Prius Prime owners will ever encounter, so this particular commute home provided a great opportunity to capture & share. Being below the 14°F threshold for the electric heat-pump meant the gas-engine would need to cycle to provide warmth inside. Electric-Only driving would still be available, but from time to time rather than continuously. No plug was used. That meant the battery-warmer could not be taken advantage and a recharge would not occur. The car just sat there in the cold all day while I was busy at work. 18.5 miles of driving through traffic dealing with fresh fallen snow resulted in an overall average of 64 MPG. That's quite remarkable for what was basically treated as an ordinary winter commute here in Minnesota. Here's the video, as I asked the question... [What happens in extreme cold?](#)

- 1-01-2018** **New Audience.** Having left that enthusiast website behind means participation elsewhere. In the case today, it was on the big EV blog. That gets lots of posting activity from a wide variety of electrification supporters, many of whom barely know anything about plug-in Prius operation. The mindset there was one of no interest for years. They all just assumed Prius would never be part of it. For that matter, anything not pure EV was questionable as being market leadership. Basically, if it had an engine and you were supporting it, your priorities were no acceptable. There was no sense of unwelcome, it was more of a *"don't waste our time"* type mentality. Seeing Prime success and anticipating other automakers also striving to make the affordable plug-in hybrid category popular, there has been an obvious attitude change. They still don't understand what it means though. There's a bit of smug due to lack of background: *"Are you suggesting that the gas engine kicks on, even when the car is in EV mode? LOL huh?"* He went on to say: *"This has been my experience in Prius plug-ins as well as some Fords."* To what was he actually referring? We know Volt acts that way at times during Winter. I took it as being poorly informed, a good opportunity to provide some exposition: Prius PHV (2012-2015), yes that was the case. Much of the driving could still be EV exclusively, but a hard acceleration caused the engine to temporarily join in for additional power. Prius Prime (2017-), most definitely not. While in EV mode (not EV-Auto), the engine stays off under all driving circumstances... hard-acceleration, driving at 80 mph, running the A/C. Only when the system temperature drops below 14°F, the engine will cycle on & off in place to provide cabin-warmth. In sub-freezing temperatures higher than that, the electric heat-pump works fine for keeping the engine off. In short, Prime offers more EV power due to the addition of a one-way clutch to allow the second motor to be used, so much of the previous generation's history simply doesn't apply.
- 1-01-2018** **Honda Clarity.** The sponsorship of this year's RoseBowl parade was Honda. The featured vehicle was Clarity. It was great. The background banners had images of the new plug-in hybrid. The car itself made a reveal during the performance. And while the parade took a commercial break, there was a full 60-second television commercial aired. It was an excellent way to debut a new offering. They had quite a number of opportunities for product-placement and product-mention. It made me wonder how much people were paying attention. Would that make enough of an impression for some to be curious enough to take a next step? If nothing else, it was a really good attempt to raise awareness. I bet we'll see it again in 1 month, during the SuperBowl... which is here this year, in Minneapolis. I wonder what how that will play out. The following month, we'll have our big autoshow. There will be a room for the plug-in vehicles again. Sure hope Honda will be present. Clarity looks really nice. I know of 1 couple here locally who have already purchased one. It's happening. The plug-in hybrid market is expanding. Yeah!

- 1-01-2018** **Change.** Remember what Toyota said about their audience changing... Prius owners who shopped for a growing family back then, now handing the car down to a child and looking to Prime as a vehicle for their new found freedom? That was the question I asked. This was the answer I got back: "*That's me, but I would still like a full hatch.*" I was intrigued where this new twist on an old discussion topic would take us: That's the older generation. That isn't necessarily what the newer generation deems a priority. Toyota is trying to avoid falling into the same "*generation*" trap that GM did, finding their formerly-popular product now something only appealing to a rapidly shrinking audience. Keeping an offering aligned to match up with middle-market, where high-volume sales are dependable, requires adaptation... changes over time... the kind some former buyers may not be interested in. Regular Prius clearly focuses on the younger crowd, those seeking to have a standout look. Remember, there is no longer Scion choices available to serve that purpose anymore. Plug-In Prius has moved up, where the unlikely-to-be-needed middle seat was abandoned in favor of taking on the layout found in higher end vehicles. In fact, that's exactly the reason why such a large display is offered. That is why also having lots of height in the cargo area isn't a priority. Dropping the seats for hauling lots of cargo is no big deal for this audience. Don't forget how many other "*Prime*" hybrid upgrades could be offered in the not-too-distant future. They have their own audience too. A full hatch would be a priority in that upcoming new larger model of Prius.
- 1-02-2018** **Dual-Wave Glass.** The self-clearing nature of that glass on the back hatch cannot be understated. Having driven in snow and through the message that follows, the trait is now quite obvious. After hearing so many comments about how terrible it would be to not have a wiper, it is really nice getting confirmation that Toyota thoughtfully researched the situation. Eliminating the need, while also improving both aerodynamics and visual appeal, is a very big step forward... so much so, most people won't have a clue... even after taking ownership. You tend to not notice things that aren't a problem. Air getting funneled into that dip creates a pushing effect. The 2 waves get cleared of water & snow right away and the rest slides down the middle. It's quite remarkable to witness.
- 1-03-2018** **Achievement.** Year-End sales being posted had brought about a tsunami of attacks. The antagonists are spinning wildly, in desperate attempts to undermine. It's quite subtle though. They know trouble is on the way. So, we get stuff like this: "*What's holding Toyota sales back is the New Leaf, and the Model 3.*" How they respond to my reply is key. It confirms their stance. They try everything they possibly can to evade. Not acknowledging the fact presented is a dead giveaway. I've seen that pattern countless times in the past. Each time plays out the same way. I sure it will again with this: That's an anecdotal conclusion, not what is actually happening. First year sales were hampered by striving to reach 3 distinct major markets all at once (North America, Europe, and Japan). The result was extremely limited availability in many areas of the US, but the total production was still an impressive 50,000. Initial rollout sales of those 50,000... especially when it includes new tech (dual-wave glass and carbon-fiber hatch) ...is certainly a noteworthy achievement.

- 1-03-2018** **Great Insight.** That was the reply posted about this retrospective I posted: GM configured Volt gen-1 to appeal to enthusiasts, which was a bit risky even back in 2010. But without any other choices on the market yet, there was time to explore what gen-2 would need to attract a wider audience. Supporters were convinced that was an acceptable strategy. It became a huge a big mistake though. GM fell into the innovation's dilemma trap of making the successor even more appealing to that same group. Those changes needed to adapt Volt for ordinary consumers didn't happen. The obvious priority of reducing early-adopter features to make the design more affordable were totally disregarded. The range & power were fine already. Increasing them was exactly the wrong thing to do... which is now very obvious into the third year of gen-2 sales. So much opportunity has been missed. Toyota used their own gen-1 to research the market too, only they made the decision to make affordable a very high priority... which is paying off already. Even with inventory basically non-existent in big chunks of the United States, the first year of sales beat Volt... despite the \$3,000 tax-credit advantage. We see Hyundai & Kia working to also capture the affordable market, targeting the same mainstream shoppers as Toyota. Things will get interesting as production & inventory ramps up. In the meantime, it seems GM is just abandoning the plug-in hybrid market in favor of EV sales. Oh well. It's yet another "*over promise, under deliver*" story.
- 1-04-2018** **More Retrospective.** I stayed up on that soapbox and continued with my observations of the past, providing more insight about how we got to this state: 2018 is looking great for growth potential of plug-in hybrid sales. Major impediment to the plug-in hybrid market is finally subsiding: Volt. It was promoted as a EREV all throughout gen-1 development. But when rollout finally happened, Volt turned out to be a PHEV instead. Enthusiasts refused to accept that though, claiming otherwise... which created a great deal of market confusion. A few years later when BMW rolled out i3, it became clear what Volt actually was... or more accurately, wasn't. That confusing message to the market should have ended then; instead, we ended up getting new rhetoric from enthusiasts about what gen-2 would deliver. That turned into an expectation disaster too. Rather than tuning down the impressive performance traits so it would attract ordinary consumers, they were increased. It was a complete disregard for the priority of reducing price to grow sales and compensate for the upcoming loss of tax-credits. Now, we see the competition stepping in to fill the void GM is clearly shying away from. It's odd to see such abandonment of an entire market segment, especially after such bold promises. But that's what we have witnessed for plug-in hybrid efforts from GM.

- 1-05-2018** **Hate.** The end really did come. It has been a bitter pill for them to swallow too. Those few remaining enthusiasts were so let down by the news of Prime sales having exceeded Volt, despite the limited supply, it was too much to acknowledge why. I did some more searches online. Knowing that the Los Angeles and Boston areas had ample inventory readily available, where else could Prime be purchased? The results shouldn't have changed much from a week ago. But curiosity got me. I also wanted more documented for reference later on. Portland, Denver, Minneapolis, Kansas City, Phoenix, Dallas, Atlanta, Orlando... none had more than just a token few available within 500-mile radiuses. Toyota basically just concentrated on the initial markets for Prime, just like they did for PHV. This time though, we know more are on the way. Holding off on 2017 models makes a lot of sense, even more so now. They knew the market would be a confusing mess in the second-half of the year... and it was. Rollout of Leaf & Model 3 put Bolt in a position of struggle. The race for long-range EV attention left Volt without purpose anymore, abandoned. All those mixed messages from GM finally sunk in. My concern was confirmed correct. They hate me as a result... which the posts on the thread I refrained from participating on clearly reflected. A scapegoat to tell their excuses to was desperately needed. Refusing to state goals has consequences. They know that all too well now. My push was an effort to recognize what was truly important. They chose to focus on faster & further instead. It was a terrible decision.
- 1-06-2018** **Video: Single-Digit.** Starting from a garage warm, the first few blocks of driving were with electric-heat. Watch the temperature drop. The engine then cycles on & off, allowing for heat from the coolant while driving with only electricity. All gas & electric vehicles pay a penalty for having to deal with the more dense air of winter and having to provide heat for the cabin. The end result with my Prime from that 18.7 miles of driving was 67.1 MPG. That's quite impressive when the temperature drops all the way to just 1°F. Here is a link to that video, available for viewing education & pleasure in 4K... [Single-Digit Winter Commute](#)
- 1-06-2018** **Heat-Pump Threshold.** I have been watching temperature closely. The 14°F cutoff is actually a little squishy. It can be a little bit colder outside before the engine will start-up to produce heat for the cabin. And even then, the heat-pump will continue trying to produce as much warmth as possible. In the meantime, while the coolant is warming but still hasn't collected enough heat yet, you can see electricity from the battery-pack being sent to the heat-pump. I hadn't thought of checking the energy display until the moment came. And there it was, confirmation of a smooth transition. It's a nicely thought out approach. This is similar to the value stated for EV capacity remaining. In the extreme cold, it will leave a few percentage of a buffer for the transition. Toyota simply understates to set realistic expectations. Far too many early adopters are completely clueless about what the mainstream perspective is. Moving from the initial rollout stage to one with a much wider audience means looking at more than just faster & further. You'd think they would catch on after a few years. Not yet, but hearing from a more diverse set of first-time owners should help a lot. No more Volt rhetoric means progress can finally be made. The unfortunate holdback GM caused and enthusiasts greatly contributed to sure made education more difficult. Oh well, we seem to finally be stirring constructive discussion.

1-06-2018 **Big Picture Refusal.** Attacks on Toyota are almost all the same. Either has been the "*faster & further*" obsession or the "*fuel cell*" distraction. Now, it seems to be changing to just: "*I think BEV's will be fine.*" In other words, the enthusiasts are giving up. Neither attack approach is getting much attention anymore. Affordability of plug-in hybrids is becoming realistic, which negates any draw for standing out. And the complexities of actually dealing with energy transfer simply confuse discussions to the point being repellent. It's a good note to finishing closing things down on then. So, I posted this reminder that the situation is much more complex: That vague of a response is considered dodging the issue, especially since it diverts discussion from storage to vehicle. Electricity must be stored somehow. The grid can only temporarily hold it. Storage overnight or longer needs something to contain it. Batteries can handle a sizeable portion, but the quantity needed is enormous... and takes away from the supply for vehicles. Hydrogen, whether used directly or converted back to DC for charging, is a means of supplementing that need. In other words, I used your response to draw attention to the bigger picture. Far too many don't notice there's more at play than just vehicles. That's a fundamental oversight. Storage is a huge consideration which must be addressed.

1-06-2018 **More Than The Vehicle.** There's much more. Unfortunately, most people don't even see the entire picture for the vehicle itself. So, expecting them to be aware of everything else at play with respect to electrification is quite unrealistic. Most simply have no idea. That means posting exposition from time to time, with at least the hope someone will notice that there is more. Today, I shared: Our local plug-in owners group strives to draw attention to needs of the entire transportation sector. Much of that focus lately has been on infrastructure, to the extent of us working with the local power-companies & equipment-providers to address issues and raise awareness. Electricity required to power our plug-in vehicles is a necessity; otherwise, usefulness of the vehicle is severely degraded... not a good selling point. Using things like battery-banks to offset dirty peak generators is one of many factors often not known, rare for anyone to even be aware of. Have you ever seen the duck curve? Also, think about how large recharging areas will be able to supply a spike of electricity demand. The 21st Century equivalent of a gas station may need to have an assortment of electricity sources to be able to keep up. Imagine 350 kW charging speeds. That's what people are expecting. Supply from power-lines may not be enough. Do you really want to have an unpredictable recharge time that varies significantly? A supplemental supply source is needed. In short, there's more to our plug-in vehicles than just the plug-in vehicles.

- 1-07-2018** **That Button.** Sometimes, it is really difficult to figure out what the person actually knows and why they are asking. In this case, I got the impression it was simply a newbie wanting to learn more: *"Isn't there a "mode" that forces running the ICE to charge the traction battery?"* Sometimes, that isn't the case. I've had quite a number of antagonists who cause trouble by resetting the discussion. They do that to prevent conclusions from being drawn, posting that question to make it appear as though they are genuinely curious. In reality, it's a distraction. You can tell by watching for that to repeat. The pattern becomes obvious... until the next generation is rolled out. Then you have to deal with the unknown all over again. Anywho, I hoped for the best this time and provided some information about that button: It's the HV/EV button. You just push it to toggle modes. This is how you save EV for use later. That also helps shorten the wait-for-warm-up situation. It makes the engine start, which results in a small addition to the EV range. Holding it for more than 3 seconds will engage CHARGE mode. So, if there's an opportunity of engine running for sake of EV benefit later, you have that option too.
- 1-08-2018** **Purpose?** It's nice to see this getting asked: *"...now it raises the question of what purpose the plug-in hybrid Volt serves. What does it offer?"* With Bolt being presented as the solution to range-anxiety now, that message of Volt is lost. Why spend so much for so little? It's a very real problem... which is the reason GM abandoned promotion for it. They simply saw no reason to pursue any type of advertising or education for such an awkward product. Someday, if a SUV is offered as a plug-in hybrid, it would be reasonable to expect some type of re-introduction. But for now, it makes no sense. Based on the comments still being posted, ending its presence would be a good idea now. I'm still seeing a surprising number of posts from people absolutely insisting Volt is a series hybrid. They truly believe the engine is only used for generating electricity. After 7.5 years of knowing that isn't what GM designed, it's rather amazing with have that type of misinformation to deal with. Such a fundamental misunderstanding of what GM actually delivered reveals a lot about how poorly it was marketed... which brings us back to the question. What purpose does Volt serve?

1-09-2018 **Sad.** The idea of leadership coming from a vehicle offering less range makes no sense to the simple-minded. They obsess. More is better. Ugh. Having to endure that while getting insulted is so smug, you're left scratching your head wondering what comes next. Volt failed to achieve sales growth. Whether or not Prime is successful has absolutely nothing to do with GM's struggle. The glory of conquest blinded enthusiasts from the next challenge... attracting GM's loyal buyers. The need to get those customers currently owning a GM vehicle to replace it with other GM vehicle offering some type of clean & efficient choice is vital. That hasn't worked; yet, Toyota's effort to offers hybrids with a transition to plug-in hybrids is labeled as "*sad*". That new Camry hybrid is amazing. Just think of what that would be like with a Prime enhancement. It's reasonable to expect the next-generation battery... a battery offering higher energy-density from a smaller physical size... as a realistic upgrade. Nothing else is needed. The upgrade of Prius to Prius Prime clearly confirms it. Heck, just think of what a mid-cycle upgrade to Prius Prime would be like with that same enhancement. Anywho, I was annoyed and posted this as my reply: Desperate enough to distract the **COST** benefit Prime offers? The resulting much lower MSRP will play a major roll in mass-market appeal. In the meantime, we patiently wait for first year ownership to draw to a close for the initial buyers. Their real-world endorsements will play a vital role in reaching the audience Volt never could. It's all about growing beyond early-adopter interest. Achieving high-volume sales requires far more than just "*sad*" insults. Real leaders find a way to attract ordinary people to their product.

1-09-2018 **Poorly Informed.** Looking past the spin and the rhetoric, I've noticed a pattern. Some don't know how Prime actually works either. There are assumptions being made, leading to incorrect conclusions. This is a major reason why Toyota spread first-year rollout to multiple markets. Education takes awhile and GM caused a lot of collateral damage with Volt confusion... hence their own enthusiasts not understanding how Volt works. It's unfortunate that exists and is now having a noticeable impact on Prime. You'd think the best informed would come in the big Prius forum would be able to squash resulting misconceptions. That hasn't been the case though. There is a glimmer of hope emerging though. Overlooking plug-in hybrids was clearly a missed opportunity that the consequences of are starting to be recognized. That audience GM didn't care about is now being targeted by the other automakers. Toyota is one, well positioned to take advantage of the situation. The poor information must be overcome still. That's the key to success. Resources like the videos I share are an effective means of delivering that education. It empowers those who take the time to watch detail. Hopefully, they'll become agents of change as a result. Each person contributing a small nod of acceptance is all it takes to reduce the momentum guzzlers built up. Think of how much influence mainstream sales of affordable plug-in hybrids like Prime could have. After all, learning from observation is the first-year owners begin their influence of others.

- 1-09-2018** **Cold Impact.** I remember the fanboy attacks from Volt enthusiasts back in 2009 when bringing up this very topic. They exclaimed heresy for even suggesting such a thing. Their denial that cold temperatures could have such an impact ran quite deep. They didn't want to accept such an oversight. After all those years of hype, finding out they made such a fundamental mistakes was too much to accept. It was nasty. I knew I was correct... since I had real-world data not only confirming it, but also providing a realistic expectation. The numbers hurt bad. They hated me even more when finding out for themselves that I was being honest all along. I wasn't attacking Volt. My claims were not an effort to undermine. I was being constructive. Admitting that was too much to accept though... so much so, there are a few who still resent me. Oh well. That's their loss. Too bad they wasted so much effort fighting a hopeless cause. They were wrong. Everyone knows it now too. We no longer have to deal with the denial. It sure is nice to finally have objective analysis & discussion of the matter. Of course, real-world data is still scarce. The few articles & posts available are still quite vague and make far too many generalizations. But at least they draw attention to the impact of cold.
- 1-10-2018** **Video: When you use up the electricity.** I'm especially excited to share this particular new video. It shows an easy to follow set of circumstances to observe what happens then... Heater & High-Speed use of the electricity faster than less demanding conditions. That can make the winter commute uncertain... until you get familiar with how the plug-in hybrid system works. Watch this video closely. Notice how heat to keep you warm comes from the battery for the first 2/3 of the drive. Then when plug-supplied electricity is used up, the engine starts. That's RPM value displayed. While the engine runs to provide propulsion, it is also warming up coolant to circulate later while the system returns back to EV driving. That's when the RPM value returns back to 0 (zero). Notice how the electric heater (called a heat-pump) runs both while in EV mode and later while the engine is warming up coolant. When the coolant temperature reaches the requested heat level, it will trigger the engine to shut off. At that point, you will drive in EV using up whatever electricity had been generated while the engine was running. Once the warmth from the coolant is exhausted, the engine will restart. See what all that does to the MPG value? Despite the engine running, it remains at 199.9 MPG. The reason for that is simple. My commute only consumes a tiny amount of gas when I take that longer & faster route home in the winter... a value above the 199.9 MPG maximum the screen will display: [When you use up the electricity.](#)
- 1-11-2018** **Sighting.** Yesterday's surprise at the parking ramp sure was unexpected. I certainly didn't think an encounter with Honda's new plug-in hybrid would happen so quickly. It made me wonder if that wasn't actually a coincidence, someone who just happened to be downtown for something special. The guy who own's the Leaf had been plugging in their for years. Could it be that he was ready to become an early adopter again? Trading in his EV for a PHEV certainly would be an interesting twist. It looks like a very nice car. The larger size will be a devastating blow against Volt... especially when GM's tax-credit limit is reached late this year. Imagine how easy it will be for people to consider so much larger of a vehicle, with only 6 miles less EV capacity, for almost the same price. Clarity potential is very promising based on that first look I got... which makes me wonder even more if that will be the only time, or will it be routine now. Hmm?

- 1-12-2018** **Huh?** This was so bizarre, I was befuddled how to answer: "*The reason that Prius PHV was priced at \$28K is to sell only at a lower volume. And Hyundai has done the same with Ioniq-EV and Ioniq-PHV. This is a tactic all automakers do to keep the sales of plug-ins lower.*" You price something very high to impede sales. Making it affordable will do just the opposite. To have logic so backward and be arguing it fiercely is bizarre. What would even make a people convince themselves that lower would somehow scare people away from a purchase? That actual number of Prime sold makes the situation more confused. Was this an antagonists hell-bent on undermining to the extent of post blatant lies and not worrying about getting called out? Our president is that stupid. There's no other way to state that either. It goes beyond desperation when you know the claimed fact can easily be confirmed as false. I ended up responding to that insanity this way: 50,000 sales worldwide is hardly low-volume, especially for the first year. As for pricing, that's an indication of high-volume intent when tied to production-cost... which was designed to be profitable at that low MSRP. Remember, the introduction of carbon-fiber and the new glass slowed production ramp-up too. First year rollout is typically hampered by dealer training and customer awareness anyway.
- 1-12-2018** **Underperformed?** The claim that Prime "*underperformed*" is what Volt enthusiasts seem to have agreed upon as their message of retained superiority. How do you deal with people who disregard facts entirely now? In the past, they would mislead. Now, they just use vague claims to portray a false reality. The days of posting outdated information and cherry-picking data are over. They just avoid facts all together. I kept my response to that rhetoric short. There's no sense trying to provide any type of perspective anymore. Those few in denial still just plain don't care. So, it was this for my post: No. Rollout to three major markets all at the same time was a huge undertaking. Japan, Europe, and North America for the first year was a big accomplishment, especially at a volume of 50,000.
- 1-12-2018** **Video: Snowy, No Recharge.** The expectation of snow and a challenging commute home turned out to be a great opportunity to capture a lot more ODB-II data from my Prime. So... I took advantage of that situation. There's lots engine cycling to witness. Watch the coolant temperature and demand for power. There's quite a bit of EV activity, despite running out of plug-supplied electricity at the start of the drive. This is the description I published along with that video: Winter storm conditions were on the way. Precipitation followed by a rapid temperature drop was the forecast. Exposing the Prime to that for the sake of plugging in wasn't worth it. So, I parked within protection of the ramp with hope of filming the drive using a depleted battery-pack was the plan for my commute home from work. Starting that snowy drive behind a police-escorted filming crew was a rather odd start. But it certainly was an interesting way to use up that last bit of electricity remaining from the morning commute. The electric-heater and electric-drive quickly used it up too. Watch the ENGINE value showing RPM. As temperature of the COOLANT value rises enough for cabin warming, the engine will stop running. The system will use up as much heat from that supply as possible before turning the engine back on. It's a remarkably efficient process. 58.3 MPG overall from the 18.4 miles of driving was great, especially considering how cold it was and how little electricity was available... [Snowy, No Recharge](#)

1-13-2018 **Labels.** This particular climb up on the soapbox shouldn't have been necessary: Labeling a suggested enhancement as a "*defect*" won't get you too far... especially with Toyota, who uses a business-model of continuous improvement. Take a close look at Tesla's success, who also follows that same approach. The design is what they specified for requirements. Since nothing is actually broken or not working as intended, hence no defect. Instead, you should have submitted it as an improvement idea. Looking at the other plug-in hybrids, like Hyundai/Kia and Honda, we see differences that completely mess up the rhetoric Volt enthusiasts have been spewing for years. Their mantra falls apart when the business aspect of design is taken into consideration, especially now with those new choices. Then ask why did Toyota make specific choices for this particular release. It comes down to how expectations are set. "*Know your audience*" does indeed go both ways. We've witnessed that in the past with Toyota being receptive to owner feedback. For the topic of dynamic-cruise, there was no expectation set for cruising in the suburbs. That's new, a use no one ever mentioned that prior to its availability. Driving with cruise-control anywhere except on the highway was simply unheard of. And since that's what consumes EV the fastest, the expectations was that the engine would be used then anyway. With the next iteration of design from Toyota, we could the requirement change. Note how Tesla calls those changes to existing vehicles an update. That works great... for them, as a new player exclusive to the EV world. With legacy operation... such as the big traditional vehicle manufacturers, like Toyota... changes after the sale are given a "*recall*" stigma. So, take into serious consideration about how changes are presented. Business is much more than just great engineering of hardware & software. Labels make a difference.

1-14-2018

Suggestions. Why do some people feel they can be more effective by pushing rather than leading? I had a friend start a stir by labeling an upgrade opportunity as a defect. It was strange that his stance was not changed after pointing out that nothing was actually broken. You find something that can be improved, you provide a suggestion. It's not a difficult to understand approach. After all, that has been a fundamental strength for Tesla. Owners thrive on the upgrades, especially since those are delivered over the air, into your garage overnight. Anywho, others chimed in to defend the old-school mentality to push: *"If it cannot run the advertised distance in EV, it is really just a plain ol' hybrid."* The vague nature of that is a red flag. It had little to do with the issue at hand too, but it did present the stage for a perspective response: Advertised? Sounds just like complaints of the past from people who didn't actually read what the window-sticker said. We're set on educating people. Doing things like provide video-clips for them to observe system operation, just like we witness but take for granted, is a mixed blessing. Think about how many people don't have a clue how their old ICE vehicle actually works. The raising of awareness contributes to a wide variety of "issues" to deal with. Take a look at ERDTT for Volt. After all these years, that so-called "problem" still exists. Ask why? That condition of *"Engine Running Due To Temperature"* is a reality, whether you like it or not. GM takes advantage of having an engine available. It's a tradeoff. Providing heat at the low extreme is very expensive, hence the more complex warming system in Bolt. I don't see plain ol' hybrids offering outstanding MPG in the warmer months for only a small MSRP less. Watch my most recent video and show proof that the tradeoffs Toyota decided upon are not worth it. The behavior to make sure the engine is pre-warmed when using cruise below a certain temperature could easily be a safety aspect. You're not paying as close attention when using cruise as when operating the pedal, so the windshield must be guaranteed clear. Calling that a "defect" or a "bug" is refusal to acknowledge the possibility of it being a conscious choice. As a software engineer, I'd see the complaint ticket and reply back that the system is working exactly as designed. The defect ticket would then be closed, since there's nothing broken. There would be a suggestion for future improvement, since that's what upgrades are for.

1-15-2018

Calm Before. Denial runs deep. Some are doing everything they can to prevent the following message from getting attention, but finding it a struggle with no other news to distract with: The variety of choices on the way causing a sales plateau was a very reasonable expectation. In fact, that serves as a gauge to indicate change. As mentioned, RAV4 hybrid, Camry hybrid, and Prime all had an impact. There's a lot of "wait & see" anticipation to acknowledge too, namely how Model 3 and the new Leaf will stir the market. We'll see the ramp-up & distribution of Prime contributing more to the shift. It's an approach that can yield a good return for dealers & salespeople, which is vital for the advancement of green tech. They don't need to do much to sell Prime. The low MSRP and easy recharging basically speaks for itself. Simplicity was the key to Prius sales. We see Prime following that same path. 20 years later, having a plug become standard is a logical next step. It's not going to happen overnight though. Owners sharing their real-world experiences takes a year or two for the word of confidence to emerge. Being one of the earlier owners, I haven't even reached the first-year anniversary yet. Two trips over 1,700 miles each and a few in the 400-mile range, combined with daily electric-only commutes, sure is providing nice experience to share... especially with the extreme cold we are currently experiencing here in Minnesota. Consider this moment, the calm before the storm. The technology works and is very affordable, an excellent match for mainstream consumers.

1-15-2018 **GM Promises.** The reason GM gets featuring so often in my blogs is the ever-changing stories are an endless source of insight. That reputation for "*over promise, under deliver*" gets renewed over and over again. A product gets hyped to an extreme, rolls out with disappoint, then they move on to the next. It's a continuous cycle, with the new chapter starting today... at the Detroit autoshow. It began today, upon an obvious death of Volt. That compact car never made any sense. For that matter, neither did the EREV marketing... since it very directly contradicted any possible intent toward EV support. To embrace Bolt, they must discard Volt. The original hunch has been confirmed, they were indeed given similar names for the sake of obscuring the transition. GM wasn't able to deliver an affordable plug-in hybrid platform. That reality has been overwhelmingly confirmed today with the announcement of the newest promise... to make money on all-electric cars by 2021. Claims by antagonists have indeed been confirmed as false. GM is in no position to be rolling out at mainstream volume yet; instead, they are making a serious investment in the future... abandoning any hope of competing with Toyota in the process. This is the very thing Volt enthusiasts feared the most. GM has become a player on the team, not a stand-out leader. It's really unfortunate pride became such a barrier to progress. They succumbed to faster & further, rather than supporting something for ordinary people. Oh well.

1-16-2018 **Market Growth.** The effort to dismiss obvious efforts to move away from traditional vehicles are ramping up. Failure of Volt to capture the market was indeed the tipping point. GM was a legacy giant who would lead the way. We heard about the supposed leadership for years. But then when it came to measure of actual progress, there was hostility & denial. My efforts to document the unfortunate history playing out provides a great deal of satisfaction. We now have a resource pointing out problems as they were formulating, rather than looking back long afterward. The blogs contain speculation & detail you can't get any other way. They also highlight the denial, all those attempts to conceal truths about what was actually happening. Ugh. All I can say to that is "*oh well*", since comments just like this fall on deaf ears: Camry and RAV4 hybrids are becoming the dominant choices here. Corolla and C-HR hybrids are available elsewhere already, with the opportunity to be brought here later. Seeing those everyday choices taking over for Prius, while watching Prius itself take on a standout look is part of the diversity effort toward hybrid market growth. In the meantime, we are watching Prime introduce the plug-in option. This is a very realistic plan for phasing out traditional vehicles. Disruption to dealer, salespeople, and mechanics is minimized. The transition is a clear cut one for consumers too.

1-16-2018 Leadership. The hate for Toyota, especially when it comes to Prime, can be quite intense from a few certain individuals. By no coincidence, all were Volt enthusiasts turned antagonist. Frustrating by the growing sales struggle and complete absense of support from GM, they feel let down. The result is to make sure others are not successful where they failed. I find it quite remarkable how they never want to surrender to a spirit of cooperation. So, they spin circumstances any way they can. The most effective... in their mind, anyway... is portraying the image of leadership as a measure of capacity: *more is better*. Apparently lacking knowledge of how business actually works, their brainless banter just continuously spews out that same weak message. Rebuttal in any form is just brushed aside, since they simply don't care... or understand. So, I don't bother addressing those attempting to gain satisfaction. Instead, I post detail why sighting why their claim is meritless, as I did today... This sure looks like leadership:

- \$27,100 MSRP
- 25 kWh/100mi EV
- 54 mpg HV
- Vapor-Injected heat-pump
- Dual-Wave glass
- Carbon-Fiber hatch
- *standard*: Dynamic Radar Cruise
- *standard*: Pre-Collision Braking
- *standard*: Lane-Departure Detect with Assist
- *standard*: Automatic High-Beams

1-16-2018 Clueless. When you come to the realization that the person you've been debating with doesn't have a clue, what do you do? I posted the following to find out: *"25 kWh/100mi means Prime will consume 25 kWh of electricity to travel 100 miles. 31 kWh/100mi means that vehicle requires 6 kWh more to travel the same distance. This is the EV equivalent of MPG ratings, depicting the efficiency for electricity consumption."* The response was amazing. He had absolutely no idea what I was talking about. He kept forcing the perspective of range & capacity, with no regard whatsoever to efficiency. The fact that Volt is a guzzler of electricity clearly hasn't ever come to his attention. It was always a lashing out about the other choices offering far less. That level of uncare & unaware is dangerous. He is clueless, but has a group of followers unequally clueless to drown out posts of logic. I remember years ago, how facts would be down-voted until they became hidden. I always thought that was an effort to conceal evidence pointing out their blatant mistakes. Now, it really looks like they were just dismissing what they didn't understand. That borders on basic stupidity, where you cause problems for yourself by not taking the time to figure out what's going on. Not actually knowing what the situation is, yet arguing about it anyway, is why I called their spin nonsense... since, it didn't make sense. Finding out they didn't recognize something as simple as how EV efficiency is quantified, is amazing. It would have been a massive waste of time, had those exchanges not provided some insight to what they believed... since perception was clearly altering their reality. The measure of *"kWh per miles"* is a basic concept. That's how you determine electricity use. Just like gasoline use, there's a number. For MPG, higher is better. For EV, lower is better.

1-17-2018 **Range Matters.** That one last post, playing offense now rather than defense, provided the opportunity to feedback... with the hope of change. Nope, it didn't happen. The same old rhetoric of range mattering was spewed out. It was nothing but meritless hope. The antagonists want that to be true, so they keep repeating the mantra with the belief it will push away evidence to the contrary. Their ignorance is costly. You can only disregard & dismiss for so long. That's why I am no longer in a defensive position. They lost the ball. I turned and ran with it too: It does not, as the effort to hide those other traits clearly confirmed. There would be no reason to suppress that information otherwise. In fact, the opposite should happen. You'd want to point out those as shortcomings... rather than validating them as strengths. Sales decline of gen-2 Volt also reinforces the finding that range does not matter. The increase from gen-1 made no difference. Instead of achieving the much hoped for growth that upgrade was intended to deliver, demand dropped. 199.9 MPG is what shows on the dashboard when the engine starts in Prime. In the summer, you can drive up to 50 miles before overall trip average drops below that maximum display value. It's that efficiency result, not always having the engine off. That's why people purchase a plug-in hybrid rather than an electric-only vehicle. This is also why so many other automakers didn't follow GM's supposed lead. They saw other priorities and focused on them instead. Range proved not to be most important. It's like a wage increase for some professions. It isn't an incentive for careers that involve problem-solving challenges. Once you reach a certain level, other aspects of the job are more important.

1-17-2018 **Video: Heat-Pump with Engine.** As outside temperature approaches single digits, the effectiveness of the electric heat-pump drops. So, the engine starts up to heat coolant, which is then used as supplemental heat to warm the interior. Watch as the engine cycles on & off. Notice how much electricity is still used for propulsion in the meantime. Overall, this is more efficient than using just electricity alone in extreme cold. The cutoff is around 14°F, but the heat-pump will still run until engine warm-up is complete. When the temperature is above 14°F, the system will run entirely with just electricity. It's a very efficient process, taking advantage of having an engine available but only using it in an optimized manner... [Heat-Pump with Engine](#)

1-18-2018 **Plug-In Owners.** Our group meeting this time was very crowded. The number of people attending has increased significantly. Pacifica, Clarity, Outlander, and Model 3 were all present. Those days of limited choices are a quickly fading memory. 2018 is off to a very good start. It had bit of a solemn feel though. We know how poorly informed those not there are. Understanding how much everyone else doesn't know by sharing what we do brings about that not-so-optimistic outlook. We are realistic though. We are well aware how much work it will take to even just stir interest. That's why there's such an investment toward the upcoming autoshow here in Minneapolis. To have a very large crowd expectation is great. Last year's dedicated room for plug-in vehicles was extremely popular. With more to see this year, that venue is a solid target for reaching out to the wider audience. It's very exciting. In the meantime, we are discussing infrastructure, solar recharging, and at-home storage. This particular meeting had local electricity providers sharing time-of-use discount information. Mine discussed the upcoming pilot rollout of smart meters. Enabling people to see their own consumption, via the internet measured every 15 minutes, is quite empowering. It's like the screen in Prius. Going from summary bills to a breakdown to tiny intervals will teach far more effectively than anything they have ever imagined. That simply act of real-time observation is priceless. Like any feedback, you make discoveries. We hear stories routinely about encounters with people asking about our plug-in experiences who don't have any idea how the vehicle actually operates. Too bad more groups like ours don't exist yet.

1-19-2018 **Halo Benefit.** Is there one? An article published today attempted to point out a flaw in the tax-credit approach by labeling those not already pursuing EV production as "*laggards*". There was nothing to actually quantify the effort though. In other words, the exploit of that money is getting support. The mindset is focused only on what they can see directly... that usual shallow analysis of the market simply by making anecdotal observation. That's really unfortunate. Efforts to reward automakers working toward profitable plug-in vehicles that don't guzzle electricity are not recognized. The tax-credits can be squandered, wasted on vehicles clearly not intended for mainstream buyers, then beg for more afterward. Wise spending to help ordinary consumers isn't addressed. As a result, there's no concern about when or how. The idea of significant sales growth has been abandoned entirely. This is clear evidence of change... the market approaching saturation with no plan what to do about it. There's just talk about when the credits expire. By the way, that expiration timeline includes a quarter (3-month) buffer, pushing the trigger expectation to this time next year, rather than in the fall. Remember all that hope for high-volume? These expense designs forego any of that. Inability to achieve profit, combined with the disincentive from dealers, is stalling progress. That leaves us with nothing but a "*halo*" benefit from most of the automaker. Autoshow reveals at Detroit confirmed it too. Everything coming from it reset the clock to the early 20's. This generation is basically abandoned by all by Nissan, Toyota, and Hyundai/Kia. Nothing is expected from the Detroit automakers. It was strangely quiet. They clearly aren't ready. They just plan to appear green by making bold announcements for years from now, rather than actually delivering anything soon.

1-20-2018 **Laggards.** That concern of "*too little, too slowly*" is dead. GM failed to deliver, despite on the assurances this would never happen. It's so bad, there are green apologists emerging. It would be nice if they were realists instead, but lack of any concise message cancels that out. You need a plan. No goals means no expectations. That's a very real problem... hence the original concern. Anywho, we now have the new label of "*laggard*" to deal with. Rhetoric to support that spin is rapidly growing too. That's what happens when hope falls about. I posted this on the topic: Taking the viewpoint of "*laggard*" requires turning a blind-eye to the original intent of the tax-credit, which was to bring about a profit high-volume product prior to it expiring. Those automakers who squandered that time, available on their own timeline, are now beginning to complain that their niche is too expensive. Why the heck didn't they design the vehicle for the wider audience like they were supposed to in the first place. For example, Chevy Volt is a compact hatchback with an emphasis on range & power. Who was that vehicle for? GM shoppers overwhelmingly prefer SUV choices. As a result, the GM tax-credits were wasted on conquest sales, rather than actually getting their own base to change. Meanwhile, we can still Toyota shifting battery offerings in their hybrids from NiMH to Lithium and the first of the plug-in hybrid choices rolled out worldwide. So even though there is a clear effort to reach a wide group of consumers by adapting their profitable platform to offer a plug, they are labeled as "*laggard*". That disregard for purpose & intent is harmful to the effort of electrification. You can't just dismiss the approach you don't like and not expect a backlash. Think about the negative impact expiring tax-credits could have on production volume for those automakers without a profitable offering available.

1-20-2018 **Looking Back.** Another obvious sign of having progressed to the next chapter are posts reflecting upon that past. Making calls about a choice following its completion is rarely ever objective. Looking back makes it easy to forget about all the factors of influence, especially when outcome was so uncertain. I attempted to point that out: It's easy to say that long afterward. Deviation from original intent has been a problem for years. Making excuses now doesn't help. Labeling some as "*laggards*" only makes the problem worse. There's no way to establish the next round of incentives without any clear focus of what should be achieved by them. Why is there still no focus on qualitative measure? We don't want to just shift the guzzler problem from gas to electricity, since it doesn't take into account emissions concern. Notice how there is a disagreement about how charging-stations should be used. Not addressing fundamental issues like that is how disagreement about subsidies come about. What are they trying to achieve? Consider what "*fallen behind*" actually means. That shouldn't have anything whatsoever to do with battery-pack size. Dealer support and salesperson interest focus on entirely different priorities. Aren't they customers from the automaker perspective? Think about the success of Prius. Just a tiny about of EV driving made for a compelling draw, one that resulted in millions of sales. Setting an arbitrary level on capacity and shunning those who choose to deliver less is counter to move toward electrification.

1-20-2018 **Purpose.** All I got was an ambiguous response to the "*halo*" observation, a complete absence of detail about how the "*product*" is perceived. He didn't see that providing an explanation of the situation without including an opinion or suggestion is being an enabler. I called that out as giving excuses. In general, that naive nature of just going-with-the-flow is quite harmful. This is how a paradigm-shift takes place. So many embrace change, the entire culture is altered. That's not a bad thing if you want it to happen. But when it goes unnoticed and there are consequences, undoing the damage can be extremely difficult. For example, out shift from car to truck. Back in the mid-90's when people starting calling their SUV a car, no acknowledgement of that obvious incorrect labeling contributed heavily to its normalization. Why would anyone use a large, bulky, guzzler designed for off-road driving and towing large loads to commute to work? It never made sense. Yet, people now absolutely insist the SUV is essential for their commute. Lack of detail. Unwillingness to be objective. Misrepresented Purpose. Remember the claims of being safer? All that got out of hand, leading to the mess we have to deal with today. Now, we have the same type of approach happening with plug-in vehicles. There is no operational clarity, no unified message, no agreement of intent. Some plain just don't care though, as the lack of a response to this confirmed: In the past, the intent was to deliver a plug-in vehicle competitive with traditional offerings. That made cost & price obvious. Changing it now, after the failure to deliver, is moving the goal-posts. That "*product*" has become so vague, propose has been lost.

1-21-2018 **Smug.** The ironic nature of some makes leaving them behind quite easy: "*I'm never going back to a Prius. I've been there and done that. I'm driving something better now.*" When they accuse you of acting that way, then do it themselves, using their own label seems so fitting. Ugh. In response, I simply pointed out the big picture: The competition is traditional vehicles, not other plug-in vehicles. Power, handling, and sound in Prime are all improved over the generation of Prius you once drove. For that matter, so is the efficiency, range, lights, screens, and safety features. Toyota shoppers are looking for competitively priced green choices. \$27,100 for a base Prime that's nicely loaded will draw their attention. Despite limited distribution of Prime in 2017 (basically no inventory available in roughly half of the country), we still saw stronger demand than that for Volt. A total of 50,000 Prime produced & sold in North America, Japan, and Europe is a very good first-year rollout. Again, the competition is traditional vehicles, not other plug-in vehicles. Toyota is striving to attract their Prius, Corolla, and Camry shoppers with Prime. GM has all but abandoned Volt, as the heavy endorsement for SUVs and Pickups continues to confirm. So, what you drive doesn't matter. You're an early-adopter drawn by conquest allure, enjoying the opportunity.

- 1-21-2018** **Actual Data.** Constructive discussion requires data from real-world driving. In the past, that was nearly impossible to obtain. Volt enthusiasts simply didn't want to share detail. It was quite annoying and very counter-productive. Today, I got this: "*I have averaged 4.4 miles/kWh... more efficient*" Unfortunately, the tone was condescending. The tendency to dismiss is usually what follows, when you supply actual data for Prius. They don't like to see better numbers... which I was all too happy to provide: That doesn't work either. Real-World results from Prime are also higher than the rating. 4.6 = April; 5.0 = May; 5.1 = June; 4.8 = July; 4.9 = Aug; 4.9 = Sept; 4.4 = Oct; 3.9 = Nov; 3.7 = Dec. Being in Minnesota makes the extreme low temperature operation especially noteworthy. The point is, we are looking for well-rounded solutions. Balance of price & performance is vital for any vehicle to be able to capture interest of the masses. Replacement of traditional vehicles with plug-in choices is the goal. That means offering a profitable vehicle in high volume.
- 1-22-2018** **Truck Intensive.** This year's Detroit blitz was summed up as: "*...the most truck intensive North American International Auto Show, ever.*" GM is rolling out a lighter & longer Silverado to compete with the success of Ford's newest F-150 and Dodge is attempting to up the ante with RAM 1500. Talk of plug-in vehicles or even just hybrids is barely a mention. That's not what the audience there is interested in. This is why I asked the "*Who?*" question for all those years. Volt never made any sense. Developing a small hatchback for those interested in truck was a colossal waste. Proof of this is overwhelming now. Those enthusiasts were fooling themselves. It's sad that they held on to a hope of that catching on, rather than just facing reality to find a way of getting Two-Mode in its original form resurrected. Oh well. It's not like I did tell them literally hundreds of times what to look out for and what to expect.
- 1-23-2018** **Insulting & Dishonest.** At this point, hearing this from former Volt enthusiast turned antagonist was a bit of a surprise: "*So, if the U.S needs a great award-winning hybrid sedan, it has the Ford Fusion Hybrid. We don't need any *stinking Prius*!*" There's nothing to gain at this point. Volt lost. Neither generation was able to achieve sustainable sales and now the more affordable choices are moving in to take its place. Besides all the insults, he was dishonest. That's what really stood out. That quote was from the end of a very long post where he attempted to wave the flag and claim superiority, adding: "*BTW, any Toyota lovers here? I bet over \$10,000 that if any Prius had its weight increased to 4,300 pounds (with the driver) and driven against a Fusion Hybrid under identical conditions, it will NEVER ever reach 44 MPG!!*" Repeating mention of a vehicle only rated 42 MPG (that's 43 city, 41 hwy) highlighted how much he no longer cared. He could say whatever he wanted, since there was nothing else to lose. I fired back with a link showing his numbers were incorrect, then added: 2018 Ford Fusion Hybrid = 42 MPG. 2018 Toyota Camry Hybrid = 52 MPG. The attempt to greenwash by pretending choices other than Prius don't exist has been exposed. Intentional misleading, just like that, has been what created so many problems with progress forward. You cannot exclude what you don't like.

1-24-2018

Avoiding What's Important. There was an article published today. Its purpose was obvious... to save Volt. The title was: "*Toyota's New Prius Prime Needs More Battery.*" We were then presented with the flurry of beaten-to-death rhetoric about how Volt was vastly superior. In the last sentence before the summary paragraph, price was finally mentioned: "*It does start at about \$6,000 less than the Volt (\$28,000 versus \$34,000), but that difference is negated somewhat by the \$4,500 federal tax credit versus the Volt's \$7,500, so the real difference in cost, barring options, is only \$3,000.*" I was very annoyed at that point. After claiming Volt had 5 seats and Prime only 4, my hope of anything constructive was lost. But that complete disregard for what each actually delivers (remember all the standard features Prime offers but Volt does not) along with the reality that tax-credits expire is too much of an avoidance. Good journalism doesn't exclude important information like the business itself. We know GM will offer very few Volt due to the approach of the tax-credit phaseout trigger, especially now that it's clear Bolt is GM's preferred plug-in. If there will be very few to actually purchase, what is the point of the article? Oh, that's right... to save Volt... or at least its reputation. I saw that in the comments too. My favorite was someone begging from kindness toward Volt efficiency since it was GM's first hybrid. Ugh. Not being aware of Two-Mode, BAS, or eAssist tells us the real story. Like many, their introduction to GM efficiency started with Volt. That means not having any history whatsoever to look upon for insight upon for business approach... something to reveal intent. Seeing it as a first attempt makes it look far more optimistic. Coming to realize GM actually had all that experience already, combined with EV1, you discover a lot of disinterest... which explains how Volt was never really had any purpose to grow beyond the niche it was. All that misleading about becoming mainstream was a farce. That's why I asked "*Who?*" all those hundreds of times. Needless to say, you have to avoid that detail to get the impression of Volt sharing the same intent as Prime. It doesn't. Toyota configured Prime to be competitive with traditional vehicles. That meant serious decisions about cost were required. No dependency on tax-credits. No omission of standard features. No disregard for audience. Think about what's important.

1-25-2018 Tax-Credit Reality. With the total sales count at 168,183 for GM, there's a growing stir about what will happen when the 200,000 limit is triggered. That expectation is for that to happen prior to the end of this year. No surprise, I had much to say about the situation: The fundamental problem with that tax-credit approach was no clear goal had been defined. Leaving it too open-ended resulted in an unintended consequence of GM delivering a vehicle that was a terrible fit for their own customers. GM's potential for getting their own loyal buyers to switch from SUV to small hatchback was very limited. To make matters worse, GM's design for Volt was neither efficient nor profitable. The upgrade to gen-2 should have reduced electricity-consumption and reduced production-cost to levels making it competitive with traditional vehicles. That hasn't happened so far, and won't before the 200,000 mark is reached. Toyota has delivered Prime, a vehicle compelling to Prius, Corolla, and Camry shoppers. It is a realistic design for profitability too, which can easily be spread to their other hybrid offerings. Prime sales of 50,000 (combined in North America, Europe, and Japan) the first year demonstrates a push to reach that wide audience with a highly efficient choice able to compete directly without tax-credit help. Whether you like it or think it's just rhetoric spew, that is the situation. The fact that Toyota didn't squander tax-credits on a design unable to compete will provide a nice incentive to accelerate mainstream acceptance... exactly what the subsidy was intended to provide. GM's decision to waste their opportunity should not be reinforced by simply extending count limits. Criteria defining useful goals must be added.

1-27-2018 Failed Incentives. We're seeing attention shift over to tax-credits. They will end this year for GM. That's a very real problem. It will prevent too much of a production ramp-up in the meantime... to milk the publicity for all it's worth... and will also pretty much guarantee mainstream acceptance gets delayed until after phaseout ends. See, the fade away of that \$7,500 incentive makes an already uncompetitive MSRP even harder to deal with. Think about the cash-on-hood deals already. Volt is struggling and Bolt is limping along, bracing for a sales hit once Leaf gen-2 arrives here. It's an ugly situation, one that could have been prevented. Oh well. It's not like we didn't all see this coming. I expressed that inevitability this way: Failed incentives come from overly simplistic criteria. kWh capacity as the only qualifier to meet presents the opportunity to exploit based on size alone. Why bother designing for efficiency when you can just slap in a bigger battery to compensate for that shortcoming? How come no one ever brings up charging-speed as something worthy of subsidy money? Having a collection of plug-ins put on the road that are "*fast ready*" would go quite the distance for promoting infrastructure investment. Then there's the issue of volume. Shouldn't there be some type of incentive to help dealers push the new product? After all, they are market consumers too. If they buy more to sell more, that is a win for everyone involved. In other words, all that chest-pounding about needing large range didn't accomplish the goal of profitable high-volume sales. So, it makes no sense to continue down that path.

1-28-2018 **Anti-Smug.** Things are suddenly getting weird. Some who had been incredibly smug, have abruptly changed their stance. Joining the effort to fight the very thing they were recently guilty of is usually a hypocritical move; however, they acknowledge it. Such open recognition of position switching is bizarre. In fact, I'm wondering what exactly just happened to trigger it. Perhaps the tax-credit situation hadn't actually been taken seriously until just now. After all, many antagonists just blow off what you post. As a matter of fact, that's exactly what that nasty daily blog for Volt has been doing for quite some time. Anything I post is just immediately negative voted until the content is hidden. They don't even try to be constructive anymore. Things have soured so bad for them, only good news is welcomed. That makes being constructive impossible. They don't want to acknowledge anything which could potential cast a bad light. Those rose-colored glasses of their's have been on so long, they have forgotten what the world actually looks like. That's a surprisingly common problem. People lose touch all the time. The catch is, that group didn't care if it happened. This group now speaking out against them do care though. They've had it with the "*vastly superior*" nonsense. They've seen that criticism can be a useful tool. This is the main reason I participate on hostile forum. Within that unfriendly territory is how you can the best feedback.

1-29-2018 **Already In Place.** Toyota's approach has been remarkably effective. They strive to deliver more than what's necessary. We've seen this many times now, where the design of Prime seems to under-utilize the actual operational parameters that are possible. Normally, you'd call this over-engineering. We've seen that from GM with Volt. There's a difference with this though. Having that extra capacity in Prius doesn't cost extra. The ability is an inherent part of the design. So, there is no sacrifice. You aren't paying more for something you likely won't ever use. That seems odd until you look at it from a production perspective. That's how cost is reduced. You refine design ahead of time. Having that already in place saves money both up front and later on. It's a win-win situation. In this case, it would be great to see the payoff. Planning for the potential of a mid-cycle upgrade is very forward thinking. Whether or not it is ever exploited or even given recognition doesn't matter. The point is there was an obvious effort to deliver above and beyond what was necessary. I posted this with the hopes of someone reading it and having one of those "*Huh?*" moments: It's really only a matter of waiting for the next-gen battery. Heck, just imagine what that higher-density, faster-charging pack would deliver in the current Prius Prime. All the building blocks are already in place, so refinements to the system... like the heat-pump... and the carbon-fiber... and the aero-glass... are showing up in the affordable category. It's easy for the early-adopters here to make the snide remarks, but it is an entirely different matter getting ordinary consumers to buy into their priorities. Think about how Prius became widely accepted.

- 1-30-2018 Truly Desperate.** The level of discord is so high now, I wonder when something will break. Volt enthusiasts are starting to freak. 2017 sales were a slap in the face. It was bad enough seeing gen-2 flounder. Struggling to maintain sales was far less than they had hoped for. The expectation was a big jump, for growth to boom like gen-2 Prius had experienced. Instead, Prime took the lead. Being dethroned is difficult to accept when being "*vastly superior*" was supposed to make sales so easy. They were wrong, very wrong. Now, some are lashing out, trying to hurt Prius & Toyota anyway they can. Today, it was this attack: "*you keep saying carbon-fiber this and aero-glass that, but these comments are just lipstick on a pig. The Prius is so dated and yet Toyota is trying to put little fixes in...*" I was amazed to see that level of desperation. Usually, they'll just try to change the subject. But rather than divert attention elsewhere, what I had posted was actually directly addressed. Gasp! Knowing January sales results will make this bad situation worse, I kept my response to that brief: Calling weight-reduction and aerodynamic-improvement efforts "*lipstick*" shows just how misplaced some priorities are.
- 1-30-2018 It Didn't Go Well.** My response to the lipstick attack resulted in this: "*Toyota builds cars for soccer mom's and beta males.*" I was amused. It was inevitable that the discussion would shift from addressing design to personal insults. The speed at which it happened is key. That reply was so fast, there's no denying the state of panic. He clearly didn't think about what he had just posted. It got me really excited. The very thing he attempted to offend Toyota supporters with applied to GM supporters too. That's a really big oops. He shot himself in the foot. GM has been gloating about doing exactly that. It was the topic most emphasized at the Detroit autoshow and this desperate Volt enthusiast tried to use it as a source of insult. That's why they call it spin. Sometimes things get so mixed up, you don't know what the truth actually is. Of course, I was delighted to point it out: Ironically, weight-reduction and aerodynamic-improvement is exactly what GM just announced as major upgrades for their large pickups.
- 1-30-2018 Pride.** This is my summary of the web of emotion Volt enthusiasts got themselves tangled into: Pride has been a very difficult challenge for GM supporters to overcome. Voltec progress has been impeded by the "*vastly superior*" mindset, where speed & range were given higher priority than bring affordable & profitable. Too many tradeoffs were made to sustain that. The consequence of which are now becoming all too clear. GM has a product without an audience. The early adopters have moved on and ordinary GM shoppers simply aren't interested. Volt has become a leading example of what happens when customer needs are not recognized... mistakes to be avoided, not the type of leadership supporters were looking for. Toyota already has a platform that's profitable and upgrade-ready. A new battery-pack, one offering higher energy-density, can simply be exchanged. No next-gen rollout necessary. Buyers get the choice. That flexibility is a big cost-saving opportunity. This is the same approach BMW, Nissan, and Hyundai have all embraced. We'll see if GM is able to adopt Voltec for something similar... if they can overcome the pride.

1-31-2018 **Sales.** My prediction is that tomorrow things will get ugly. Sales of Prime are anyone's guess. There's ample 2017 inventory in regions that rollout took place in. For regions like where I am, here in Minnesota, we're waiting for 2018 models to be delivered. So, there's nothing to purchase here but decent selections in areas peppered along both coasts. Volt gen-2 is piled up everywhere. The rush to take advantage of tax-credit opportunity ended on December 31. Any purchase after that meant waiting an entire year before collecting that generous \$7,500 incentive. So, why bother? January is a terrible month for sales anyway. Why purchase a new vehicle in the dead of Winter? That being said, the prediction is a very low count... quite noticeably lower than Prime. How many won't be a mystery for long. I expect to get results early tomorrow. The thing going for Prime is real-world data. Owners sharing their driving experiences in wintry conditions provides a huge endorsement. It has worked exceptionally well with each generation. So, there's no reason to think it won't with this one too. We always see a bump in sales following that unknown related to cold endurance. Being here in Minnesota, armed with a 4K camera, I see the potential. There has been excitement each time I publish a new video. Yeah! Anywho, stay tuned. I'm quite curious how this will play out.

2-01-2018 **Motivation.** I asked: "*There simply isn't incentive for GM to deliver a lot. What's the motivation?*" The first reply was an outright lie. Rhetoric clearly doesn't work anymore. The antagonists simply don't care about being honest or being confronted with facts. The state of desperation is so drastic, an end is obviously drawing near. Shoppers are looking elsewhere. The only draw was to conquest buyers. GM's own customers simply have not been interested. I summed the situation up with: Volt sales that low, in year-3 of gen-2 with a \$7,500 tax-credit, makes being profitable a moot point. As for making a claim of Prime not being profitable, without providing an proof whatsoever, is clearly an attempt to change the topic. Augmentation of Prius to add a plug and larger battery-pack for that MSRP is feasible. There's no reason to believe the FUD. Toyota's first year for Prime resulted in over 50,000 worldwide sales, despite a large chunk of the United States not having any inventory. The second should show strong growth as rollout expands to reach more potential customers.

- 2-01-2018** **Imminent Death.** It's so blatant that GM has no where else to turn with Volt. Something is going to happen. My guess is silence, a deafening absence of any stance. It will just fade away like Two-Mode did. That's really unfortunate. The technology itself offered potential. Neither management, nor enthusiasts, wanted diversity though. Any effort to broaden appeal to attract mainstream consumers would sour interest for enthusiasts. It was a problem of mutually exclusivity, a disaster in slow motion caused by conflicting purpose. Who is the market for Volt? We got the answer to that much asked question. It was early-adopters. Ironically, the very problem the biggest antagonist tried to pin on Toyota, ended up being the very reason GM's struggle has been lost. Listening to those early-adopters about how to make gen-2 better was a fundamental mistake. Asking the wrong audience was such a dumb move, it made you wonder if the motive was to aim the technology into its corner... letting it kill itself, so they don't get blamed. They'll blame the market for disinterest. Trouble is, people like me noticed the obsession for large, powerful vehicles. The showing at Detroit this year confirmed it. Nothing came from GM with respect to plugging in. It was all about new Pickup & SUV offerings instead. That's why this particular post from one of the GM supporters trying to be constructive didn't get much pushback. They silently acknowledged what he said, without argument: *"Amen. These fanbois are in denial. The Prime is number one like I predicted year ago. RIP Volt."*
- 2-02-2018** **Too Late.** I know reading this really hurt the enthusiasts: *"GM is wasting the goodwill and conquest customers they gained with the Volt."* That's all too true. Opportunity has been missed. When leases began expiring, those conquest buyers jumped ship... distancing themselves from GM as quickly as possible, never looking back. I watched early-adopter after early-adopter choose a non-GM replacement. They were drawn to incredible lease pricing, not any sort of loyalty or true support. GM's own customers, those who have driven GM vehicles for years, never expressed interest. That's why I got attacked whenever I asked the *"Who?"* question. They'd get more and more angry each time... knowing I was correct, since each asking meant more calendar has been used up. Years of listening to me express the *"too little, too slowly"* concern has built a solid argument of being too late. This is now the 3rd year of gen-2 being offered. Sales reveal a vehicle struggling for survival. Then when you consider it is all with a \$7,500 dependency, hope fades away entirely. Upcoming phaseout of the tax-credit means making a decision soon, prior to clearance time. It's approach directs the spotlight over to Bolt. Why attempt to save Volt when so much pressure is also building from Nissan & Tesla? Knowing Toyota, Hyundai, and Honda will dominate plug-in hybrid sales anyway, all you can really say now is: Too late.

2-03-2018 Reality. I searched through my old blogs. The want was to find when it all started, how the efforts to be constructive turned sour. I found that specific entry, the one where I first brought up the topic of diversification. Toyota was expanding their hybrid choices, delivering a minivan, a SUV, and a sedan, in addition to a hatchback. Their newest (the third-generation Prius) demonstrated the potential for further electrification. It was really only a matter of readying to take advantage of battery advancements. Once cost dropped and energy-density increased, adding a plug would become realistic. GM was attempting to race ahead, to "*leapfrog*" those efforts. That failed terribly. We are not seeing the aftermath of a number of poor management decisions. I was happy to point them out:

Why not offer a second model?

September 5, 2009 that question was first asked. The lead up to it was: "*...it simply doesn't make any sense to not offer consumers a choice of battery capacity. That would lower the price quite a bit, appealing to a much wider market. 16 kWh means low-volume production & sales for many, many years to come.*"

That was prior to the rollout of gen-1 Volt about what strategy GM should take. It was constructive. It was agreed up. It made sense. Unfortunately, things took a turn in the opposite direction shortly afterward, when the topic of winter efficiency was brought up. Reality of how much battery-capacity would be consumed by cabin heating revealed the "*40 mile*" goal to be unrealistic. That loss of hope created a series of conflicts to come.

News emerged that Volt wasn't actually a series hybrid as expected, that the system would deliver power directly to the wheels at times. Then came the "*Freedom Drive*" publicity stunt, where a pre-production Volt was driven 1,776 miles. The very information most wanted from that was withheld; GM absolutely refused to share that real-world data. Worst though was when price was finally announced. Volt would be far more expensive than supporters ever imagined.

Fear of product dilution from offering a choice of smaller, yet much more affordable, battery-pack overwhelmed supporters, creating a rift of those who were unwilling to compromise... the enthusiasts. They felt the tradeoff was far too much to sacrifice. They told us all to be positive. They claimed we only had to be patient. Concerns of "*too little, too slowly*" emerged. What if the one-size-fits-all approach fails? We now know the consequences of being unwilling to diversify.

GM will trigger tax-credit phaseout without having established a profitable, high-volume, plug-in hybrid offering. The opportunity to shift their customer-base was wasted on conquest. Rather than delivering what GM shoppers would be interested in, there is nothing... no choice of affordable compact plug-in hybrid... no choice of a modest-range SUV plug-in hybrid... no clear message of intent... nothing.

Now, we await what from GM? All those vague & ambiguous statements of the past resulted in meritless hope, where enthusiasts never saw any value in supportive facts. There was always mindless cheering and the belief management would make the right decision. Enthusiasts refused to take a stance and demand change; instead, they attacked voices challenging the status quo.

We see Honda, Hyundai/Kia, Chrysler, Mitsubishi, and Toyota all striving to fill the void GM left behind, the market Volt enthusiasts absolutely insisted GM could capture.

2-03-2018 **Video: One-Degree with Drive-Thru.** Getting food on the way to work is something I hadn't ever captured on video. People routinely use the drive-thru as part of their daily commute. So, why not share some real-world data for that too? Choosing a day where we were experiencing extreme cold made it especially noteworthy. The temperature was too low for exclusive use of electricity. The engine would need to provide some supplemental heat. What does having it cycle on & off do to the over efficiency? Watch the MPG value in relation to the ODB-II data, those 2 meters added to the video. One shows temperature of the coolant, the other RPM of the engine. Both play a key role in keeping you warm, while at the same time striving to deliver optimal overall efficiency... [One-Degree with Drive-Thru](#)

2-04-2018 **Doesn't Compete.** Yup, you know it's getting ugly when comments like this are posted: *"I have had it with PHEV nonsense..... If they can have a real electric vehicle for under 40k with over 200 mile range, they want it and prefer it..... With affordable EVs around, PHEV become niche. A Volt for 34k doesn't compete with a long range Leaf or Tesla."* There wasn't much of an argument in response either. I piled on with: It's very easy to be tired of the games GM played with Volt, a niche vehicle marketed as if it was designed to appeal to the masses. The situation has recently changed though. Very different choices are emerging. \$24,950 base MSRP for Hyundai Ioniq PHEV. \$27,100 base MSRP for Prius Prime, which is nicely loaded. Both are newcomers striving to reach ordinary consumers, those who don't want to spend a lot on a vehicle and may not in a position to recharge at home with 240 volts. Toyota was able to deliver & sell 51,000 of the new Prius Prime last year, despite including carbon-fiber & aero-glass. Both those weight & drag reduction technologies, combined with a significant improvement upon their popular hybrid technology, are a winning formula for affordable & profitable choices. PHEV are the clear next step for mainstream shoppers and represent little risk for dealer & salesperson. Battery capacity is enough for daily commutes and simple recharging. There's an engine available for longer distant travel too. Like it or not, they are key to EV acceptance.

- 2-04-2018 Reality.** I kept firing, to make sure the reality of this situation is overwhelmingly clear: Dealers are the true customers, not ordinary mainstream buyers or even early adopters. So, data before the other automakers got on board doesn't apply to the emerging market we see in 2018. Neither EV nor PHEV have appealed to dealers. They were simply too expensive, too much of a challenge to explain to shoppers, and offer too little in return. That's changing. Toyota delivered 218,600 of the regular model Prius last year. All but the rare ECO model used lithium battery-packs. The plug-in model basically just includes more of the same. That's an approach easy to get dealers to buy into, since they are already quite familiar with the product and MSRP doesn't increase much. As you point out, the current bottleneck is cell capacity. Production in high-volume is a major problem. Prius Prime doesn't offer a huge capacity increase, but those cells are put to good use. Rather than just 1 vehicle using up 60 kWh of cells, you can have almost 7. Hyundai & Honda are finding themselves in the same predicament. They aren't about to follow the failed path GM took, where dealers weren't interested in an expensive niche... regardless of how much early-adopter praise Volt was given.
- 2-04-2018 Market Observations.** It's easy to feel the momentum of change now. I'm giving it a shove too, doing all I can to make sure those few still in denial see what's been happening: Sadly, our market isn't interested in minivans. GM and Ford completely abandoned them. In fact, GM is now abandoning cars... 26,405 = Equinox. 11,627 = Traverse. 10,858 = Cruze. 7,553 = Malibu. 6,106 = Trax. 3,150 = Impala. That's a very big warning sign for those who think Volt or Bolt stand a chance. GM simply isn't interested in the smaller vehicles. We see them pushing the US market more and more to SUV purchases... very non-green choices. The only saving grace we have is that cramming battery-capacity into them is easier than cars. Toyota's effort to get RAV4 hybrid into the mainstream and redesigning Prius v to become a CUV strategically positions them to deliver an affordable & profitable plug-in choice. So, that opportunity won't be missed. They can take advantage of that demand here for the larger, yet efficient, vehicles.
- 2-05-2018 Guilt Free.** As long as electricity is being consumed for transportation, it's ok. That mindset of trading gas guzzling for electricity guzzling has been the backbone of arguments in favor of Volt since before it was rolled out. That fundamental argument has persisted throughout the years. Enthusiasts just plain did not care about waste. Electricity = Good. Gas = Bad. They were that braindead. Consideration of how the electricity would be generated, transported, or stored didn't matter. That's why we keep getting comments like this: *"While most plug-in hybrids can manage roughly 10 to 20 miles of electric-only range, the Volt can eke out 53 miles..."* Which are always followed with something like this: *"...this car's most important standard feature: 53 miles of guilt-free driving on electricity alone."* All that matter was range, nothing else. Cost of that larger battery or how much it would take in terms of time for recharging didn't matter. All that mattered was range. They had no guilt about it either. In their minds, it was all about avoiding gas consumption. Ironically, that has become the cause of their own death. Repeating that mantra over and over and over again for Volt is how they created loyal supporters of Bolt. I always found that self-deprecating behavior fascinating. How could they not realize they would contribute so heavily to their own demise?

- 2-06-2018** **Hypocrite.** Nothing happened this morning. The daily blog didn't have an update. So, the discussion still active on yesterday's thread continued. It took an interesting turn too. They started discussing discussions. This emerged: "*When someone says credible facts against you, your only recourse is to attack their character.*" It came from... you guessed it... the person who routinely did exactly that. He'd often parrot what you say and posts reflective thoughts. That reveals his own shortcomings; yet, he still doesn't recognize them. It's the ironic nature of the whole situation with Volt. The enthusiasts are guilty of the very thing they despise the most. I saw the same mistakes being repeated over and over again. They really don't learn. That comes from not taking the time to actually research. Why bother to study the market? Assumptions are good enough. Ugh. Needless to say, I was amused to see that ironic quote. Pride being more important than integrity says it all. They don't want to be constructive, period. It's all about hiding, evading, and attacking what you don't like.
- 2-07-2018** **Subaru.** We got a surprise announcement from Toyota today. Remember the sharing & licensing of previous Prius technology with other automakers? Toyota did that with several in the past. It worked out well. There was a mutual benefit. An automaker unable to fulfill a mandate on their own in a timely fashion or simply wanting to measure market demand with reduced risk took advantage of the opportunity. Now, we hear that Subaru will be doing that. Parts of the system from Prius Prime will be offered in a Subaru to be rolled out late this year. No detail was revealed... other than there being an expectation for it to be AWD. Since there is already a model of Prius in Japan available which features all-wheel-drive, the idea is realistic for this plug-in hybrid to share the approach. We likely won't find out what model or size of the battery for awhile; nonetheless, it puts even more pressure on GM to finally give their own customers something to look forward too. Bringing an AWD offering to market is a step toward getting traditional buyers to finally take notice of plug-in hybrid potential.
- 2-08-2018** **Not Interested.** The end has come. Exactly as expected, year-2 of gen-2 for Volt was so bad, even the daily hypocrites have fallen silent. It was much easier when there was uncertainty. But now with the year-3 underway and the problem such a high MSRP looming, they have given up. There is literally nothing left to spin. I hadn't expected such an obvious cease of the rhetoric. It just died abruptly. I'm not interested in starting anything new with that group. The negative feedback was priceless back when they had blind hope. But there's value in any of their enablement anymore. That group-think doesn't provide any value when the next step is actually being taken. It was a great insight to learning about audience. That's done. Time to move on. So, I chimed in to be part of the acknowledgement of finality with: Too little, too slowly was the pointing out of opportunity being missed. It simply never made any sense wasting good tech like that, especially with so many sharing words of praise for the potential. GM management wasn't interested in reaching out to the larger market.

- 2-08-2018** **Temperature Adjustment.** I am approaching my first-year anniversary for Prime ownership. That means I will have had a full year to study the system, to observe the changes from each season. It's time to begin thinking about all the stuff that needs to be documented for the User-Guide. There's quite a bit for this generation of Prius. Simple things go a long way too. You'd be amazed at some of the complaints that come about from owners who assume. They aren't rewarded like the ones who enjoy exploring. A good example of this came today from: "*I don't think the Prius Prime has temperature adjustment buttons on the steering wheel...*" That comment came about from a complaint an owner had about the placement of the dedicated buttons for temperature on the dashboard. He somehow keeps slipping, accidentally pushing the button below it that starts the engine for "power" defrost mode. It never crossed his mind that it would be an option on the screen... despite all the promotion of having buttons on the steering-wheel, to prevent having to reach over to push something on the dashboard. Ugh. Needless to say, there is. In fact, there's an entire section that allows you to make creature-comfort adjustments simply by moving your thumb. That's good stuff to put in the new document!
- 2-09-2018** **Video: Charge-Mode in Winter.** Hybrids achieve high efficiency by seeking out opportunity. That gain can be boosted even further the choice of how & when is carefully considered & control. Charge-Mode provides that benefit... if used wisely. Gas engines waste quite a bit of energy. A source of that waste comes from not carrying much load. The combustion process is most efficient when the engine is being utilized more, closer to its full potential. Charge-mode allows you to take advantage of that. In this example, I active Charge-Mode on 3 different occasions. This running of the engine more than needed results in electricity being generated to recharge the battery... which I take advantage of afterward. Watch before & after I get on the highway. Also watch as I cruise along the back country road as I get close to the end of my commute home. Since this demonstration took place in the winter, I also took advantage of the other wasted energy from the gas engine: heat. When I shut off Charge-Mode, the system switches back to EV mode. So, rather than using electricity to provide heat while driving with the engine off, the cabin warming is provided by heated engine coolant. Used wisely, there can be an overall MPG benefit. When on long trips, like vacation when there is no charging available at the destination, I will take advantage of Charge-Mode to supply electricity for later when going out in the evening for dinner or getting coffee the next morning... using EV to avoid engine warm-up. Notice the results on this drive. That's quite impressive. 49 MPG overall, despite the cold. There is 1 mile of electricity still available for EV at the end too: [Charge-Mode in Winter](#)

2-10-2018 **Prius Decline.** Between the challenge of Nissan & Tesla production ramp-up and the struggle GM is having, there's no big players to provide news for right now. So, there's retrospectives being published... many with errors & spin. Looking back is never good. So much detail is overlooked, forgotten, or omitted, the objectivity is lost. It doesn't matter though. The point of those articles is to hold onto the regular readers by giving them something to participate in. The resulting comments are all over the place as a result. So, it's a winning formula... especially if you want to spread misconceptions. Unfortunately, this lull cannot be avoided. News about mainstream offerings isn't exciting anyway. That dooms Prius Prime to ridicule. We certainly are seeing a number of snide remarks too. The antagonists don't want the message of a natural transition from hybrid to plug-in hybrid to catch on. That low impact approach is very difficult to combat. Look at how hard Hyundai is working to offer something comparable to Toyota. It takes a serious investment.... a reality others aren't willing to accept, hence all the attempts to spin a story of Prius decline. I replied to today's spin with: Worldwide rollout all in the same year meant limited inventory available. 51,000 were sold though, despite people like us in the center of the US not having any to speak of. That shows potential, helping to confirm Toyota choice to focus on a well balanced offerings (lots of features, yet very affordable) is a good approach.

2-10-2018 **Leadership & Late.** Wow! It's happening again. Remember the attitude from Two-Mode supporters? They attacked Toyota & Prius relentlessly. In the end, it was another case of "*over promise, under deliver*". GM's reputation had been reaffirmed in a dramatic way. That's why I was so amazed that the gen-1 Volt enthusiasts would so blindly follow in those same tracks, repeating the very same mistakes. Sure enough, it was the same outcome too. That failure didn't deter gen-2 Volt from repeating that history, yet again. Wow! Now, we are seeing it emerge from elsewhere. Claims of Toyota falling far behind and losing any sense of leadership keep coming up. None have any substance though. All are based on nothing but the fact that other automakers have ambiguously committed to EV delivery. No over promise this time. In fact, no goal is ever actually stated. It's all so vague, there's no accountability whatsoever. Victory could be declared on anything. It's the worse I've ever seen. People are so desperate for good news from their particular automaker, the only recourse currently available is to attack Toyota's success by portraying it as a failure to advance. Only Volt enthusiast did that in the past. But now that they are gone, others are feeling the same pressure. No surprise there. I just pointed out some facts: Affordability isn't leadership criteria? Including carbon-fiber & aero-glass isn't? The new vapor-injected heat-pump isn't? Delivering great kWh/mi efficiency isn't? There's a belief that larger battery-packs is the measure of progress. Those who believe that are in for a rude awakening when it comes to mass-market appeal. Mainstream consumers have very different priorities from the early adopters here. Take a look at the 51,000 sales of Prime last year around the world for a perspective of what's really important. Reaching ordinary consumers with such a well-balanced profitable vehicle is the game changer... the same goal all the other automakers are striving for. Think about the wide variety of hybrids Toyota now offers and how many of them now use lithium battery-packs. That claim of being "*late*" doesn't have merit

- 2-10-2018** **Ugly.** When all else fails, call the vehicle ugly. Antagonists are busy now. They see the rise of Prime and are trying everything they can possibly do to undermine the name of Prius. Their panic reaction is a sure sign of mainstream advancement. Nothing is working. The real-world data speaks for itself. Plug-In hybrid acceptance is seen as a natural step forward, not a dramatic paradigm-shift as the "*EV only*" purists are trying to push. Their one-size-fits-all rhetoric is having quite a bit of trouble catching on... a problem we don't see with the plug-in hybrids. So, they attack the look of Prius, the one without a plug, with the hope it will somehow sour appeal for Prime too. It's not working either. Just like in the past, attempts to impede are eventually overcome. Having lots of video to share already is helping speed that process along. Yeah! In the meantime, we have to respond to the nonsense being posted: Toyota made Prius the standout hybrid it was always characterized to be, providing a market offering for those wanted exactly that. So what if you don't like it? The market isn't a one-size-fits-all situation anyway. Camry hybrid... RAV4 hybrid... C-HR hybrid... Corolla hybrid... those are the hybrids Toyota is focusing growth on now... along with the rollout of plug-in options. Look at how competitive Prius Prime is with traditional vehicles. You can get a solid 100 MPG vehicle, delivering lots of EV driving, with lots of features for a MSRP of \$27,100.
- 2-11-2018** **Smug.** Now that Volt is dead, the inevitable new set of enthusiasts has emerged. It's bizarre how clueless they are. Knowledge of how Prime works is based upon nothing but a rudimentary understanding of hybrids... which wouldn't be so bad, if they had some type of business background. That complete absence of knowing how any of the automotive fundamentals actually work make any type of argument futile. When you bring up the concept of mass-appeal, there's nothing but an arrogant reply in return. It's the same thing every time too. Toyota is late. That is so horribly vague, there's no point. Late for what? Who cares if early adopters have nothing to purchase. Rarely will a vehicle targeted at them ever appeal to the masses anyway. Mainstream shoppers have very, very different priorities... the lesson Volt enthusiasts learned the hard way. Ordinary consumers couldn't care less about a vehicle that isn't affordable. It's difficult to believe anyone could be so blind. You'd think that would be obvious. Clearly, it is not. History is repeating the cycle again. Those gullible people who don't bother to actually research are beginning to post snide remarks. You can see that same smug coming back again. Ugh.

2-11-2018 **Big Oil Fear.** The poorly informed tend to look for conspiracy. Not understanding complex problems results in that jumping to conclusions like that. If you are not for what they are endorsing, you must be against it. In reality, situations are rarely that extremely. Often, they true stance is somewhere in the middle. That doesn't work well for online commentary. So, personal attacks result. Today, it was my apparent support for the oil cartel. That couldn't be further from the truth. But with such rudimentary knowledge of how hybrids work, that tends to make sense. If you aren't in favor of EV here & now for everyone, you must be an opponent. Ugh. That kind of thoughtless, knee-jerk response is what Volt rhetoric shoveled for years... which turned into a monumental fiasco. Anywho, I responded to that nonsense with: Assumption based on limited & anecdotal evidence is incorrect. In fact, you couldn't be more wrong. My effort is to push for plug-in hybrids as quickly as possible. That elimination of traditional vehicles will result charging infrastructure setup at the same time. Jumping straight to EV is totally unrealistic. No part of production or sales is ready yet for that scale. Comprehensive evidence of that is plentiful. That belief that revolution is necessary is a fundamental mistake. There's no reason to present the situation as a fight when you know an evolutionary step can be quickly achieved and set the stage for that paradigm-shift.

2-11-2018 **Wishful Thinking.** Drawing conclusions with little to no data was common in the past. Now, some just declare victory without any supporting facts. They just plain don't care. They call your observations wishful thinking. Anything to stop the progress of Toyota. It's really sad... and fortunately, very easy to rebut...

Here's actual achieved results in 2017 outside of North America:

191,600 sales of C-HR hybrid.
130,900 sales of Yaris hybrid.
58,500 sales of Corolla hybrid.

That show very real growth potential when those are rolled out in this market. No wishful thinking required.

Here's more actual achieved results, Toyota's worldwide annual sales totals:

1.22 million = 2012
1.28 million = 2013
1.27 million = 2014
1.20 million = 2015
1.40 million = 2016
1.52 million = 2017

The data tells a very different story. There is clearly no decline as claimed, only a dip as gen-4 Prius availability approached with undeniable market growth following.

- 2-12-2018** **Retroactive Credit.** Surprise! We can claim more of a tax-credit on our 2017 return than expected. That was something I had just accepted as an opportunity missed, when it expired the end of 2016. We weren't ready for the idea of running new conduit & wire, then purchasing 240-volt chargers. Heck, my wife wasn't even going to consider replacement of her car until 2018. But things fell into place with several upgrades all within a few month's time. We got a remarkable amount done in the first half of last year and it is now going to quite literally pay off. In addition to having enough tax-liability to claim \$4,502 for each of our Prime purchases, we can also claim several hundred for the charging setup we invested in for our home. The amount can be up to a maximum of \$1,000. It's a 30% reimbursement. I'll have to dig out our receipts to see how much we qualify for. It was expensive, since we didn't skimp. 2 cans. 2 meters. 2 conduit lines. 2 sets of wiring. 2 breakers. 2 outlets. 2 chargers. Sweet! Strangely though, there are a few supporters scratching their heads wondering how rewarding those of us who took the risk will benefit from a retroactive credit. Don't they think we'll put that money to good use? It equates to free recharging elsewhere, funding to promote public charging-stations by patronizing them without concern of having to pay. Why not? It's exciting to help promote. A bit irked, I pushed back their pushback with: Don't be so quick to dismiss. Retroactive is how you encourage early-adopters to share what they learned. That gesture of acknowledgement is very powerful.
- 2-12-2018** **Priorities.** The final, foolhardy messages attempting to obscure Volt's downfall are now being posted. It's an end more painful than the sudden, abrupt stop, we witnessed with diesel. Quite literally overnight, the impediment to green advancement vanished. It was dead. With this, it's like they are beating a dead horse. Rather than focus on the clear winners in the next stage of ending the reign of traditional vehicles, they are trying to hold onto the memory of victories from long ago. Bringing up the past... looking backward instead of forward... is an obvious sign of denial. The job now is to promote realistic challengers. Prius Prime is the clear leader. It is the only affordable offering capable of standing out among a showroom floor filled with strong sellers. Oddly, that means the regular model of Prius will be cannibalized in the process. But that's progress. For those who have an outlet available, it's a very reasonable consideration. It holds enough potential to possibly sway those considering a Corolla or Camry too. That's why GM's approach of simply offering as much EV as possible made no difference. Someone shopping for a traditional vehicle couldn't care less about getting a maximum return. They just want a simple transisition to electric. Only needing an ordinary 120-volt outlet and not having any concern whatsoever about the engine starting is really, really important. It's a basic approach that won't intimidate. This is the same thing Hyundai & Kia are hoping to aggressively pursue. That's an opportunity GM never showed any interest in... which Volt enthusiasts have learned in a very painful way. They refused to recognize what mainstream shoppers really want, what they consider priorities. Toyota carefully studied this, taking it very seriously. I pointed that out on a regular basis, as I did yet again today: Know your audience. Understanding their priorities is key to drawing their interest. They seek a well-balanced choice, not one making sacrifices to go faster & further.

2-13-2018 **Late & Laggards.** The desperate efforts to save some pride from Volt's demise has been interesting to witness. So many people are now writing obituaries, those posts of rhetoric simply fall on deaf ears. No one cares anymore. Commenters have better things to spend their time on. GM squandered, missing opportunity after opportunity. It has been a disaster of epic proportions. Seeing such a grand experiment fail on such a colossal scale is remarkable. Everyone in the early-adopter crowd know Volt well. It was nice car... to lease. Few actually owned one though. They didn't want to take the long-term risk and saw no reason not to take advantage of such appealing lease offers. This is the statistic they did their best to suppress. That's why conquest continued to get so much attention. To address the problem of retention meant asking for a fight. So many went elsewhere when their Volt's lease expired, the remaining group of enthusiasts became frighteningly small. That's how a knew the goodbye was real. Those still left starting naming off big names of the past, people who moved on and were rarely ever heard from again with respect to Volt. They now own other plug-in vehicles. Heck, one of them even became such a huge Bolt supporter, he recently got banned from the Volt forum. That's when you know it's over. Anywho, the few left keep trying to start a narrative of Toyota being "*late*" and often resort to "*laggard*" name calling. It's so childish. Nothing is ever provided to support their claim. They are just desperate to get attention off of Volt. All those obituaries are difficult to deal with. What's even more of a problem though is the acknowledgement of true innovation... and many are happy to point out the lack of it from GM by just offering the most battery-capacity, rather than actually developing more advanced tech. I was happy to join in that discussion today with: More credit is given to having more battery, even if the vehicle guzzles electricity. It has been the braindead mantra of bigger being better. Actual innovation has been pushed aside. That's why the effort to deliver a battery chemistry & design that doesn't require liquid-cooling treated as a shortcoming, despite it being an obvious step forward. This is also the reason why the use of heat-pump, carbon-fiber, and aero-glass are all looked down upon. Technology advancements and cost reductions are not considered innovation. That's a very real problem.

2-13-2018 **Goodbye Messages.** It has been interesting to read post after post about the death of Volt's biggest promotion source. This was the sign-off from a long-time participant today: "*GM knows what to do (like supporting this website and promoting electric cars) but just cannot bring itself to do what is right.*" That was followed by a goodbye. 7.5 years after rollout began, with the obvious rise of "*anemic*" offerings from other automakers, there is literally no hope remaining. They exhausted every possible excuse and insulted every possible source of conflict. The rhetoric was amazing. When you evade & deny for that long, such an outcome is inevitable. They didn't want to accept the growing evidence of trouble. That meant the problem would never be dealt with. Rather than address shortcomings, the choice was to avoid mention of them. So when I brought them up for constructive discussion, it was always a shoot-the-messenger response. To think that a select group of people would become such staunch enablers. They were the very thing they hated most: fanboys. Coming to realize their error after defeat is the ultimate vindication for me. They wanted a fight to the death, but never imagined actually losing... and would never, ever consider surrender. Ironically, all I was ever looking for was an ally. There is no way to win the war against traditional vehicles without friends supporting other automakers. Clearly, that won't come from GM owners. Their numbers will be far too few; instead, I'll be looking toward those choosing plug-in hybrids from Hyundai & Kia. Perhaps we'll see high-volume sales from Honda, Chrysler, and Mitsubishi too. What Volt couldn't accomplish, they have the potential. That serious concern of "*too little, too slowly*" has been confirmed. We got yet another "*over promise, under deliver*" from GM. Volt demonstrated the opportunity for its technology to be exploited, but that step was never taken. The initial offering is fading away into memory without any successor. All those tax-credits were wasted on conquest. The expectation of that generous subsidy being used to establish a base of loyal buyers wasn't pursued. The ultimate question of "*Who is the market for Volt?*" has been answered. It was a niche GM did not want to transform to a mass-market offering. Goodbye.

2-13-2018 **Playing Offense.** I went on the attack this evening: To those who turned a blind-eye on the management problems related to both the EV1 and the Two-Mode rollouts, choosing to focus exclusively on engineering instead, you've learned a very painful lesson. Volt failed to attract GM's own loyal shoppers, a problem that will be greatly compounded when the tax-credit expires. Now, we watch attention shifting over to the struggle Bolt is having with the very same problem. Those shopping for a GM vehicle couldn't care less about a compact wagon. They want to purchase a SUV. Where is that choice? GM revealed the Saturn Vue plug-in SUV back in early 2008. What's taking so long? We need to ask what should happen next. No more efforts to change the topic. Those attempts to focus attention elsewhere were childish acts to avoid dealing with the problem at hand. What should GM do? Management must decide how to move forward. Supporters can help with that. The time to take a stance is long overdue. Blindly trusting they'll make the right decision will allow the history of mistakes to repeat again. State goals. Be concise. Stand firm.

- 2-14-2018** **Change.** The turn of events recently has been remarkable. Watching things fall apart for Volt is not how I anticipated the end to come. Ironically, that daily blog for Volt was a cheerleading website... and cheerleading was exactly what I posted late last night. They weren't happy. I thought it was best to share the love, considering what today is supposed to represent. After so much hate, closure of any sort is a true step forward. Good or Bad, it doesn't matter. The time to move on has come. So much opportunity has been wasted. Choosing to fight fellow plug-in supporters rather than focus on goals was too difficult to accept. Pride is very difficult to overcome. GM screwed up. Who cares? You fall down. You get back up and try something else. Continuing to try again with the same thing isn't wise. Volt failed twice. Neither gen-1, nor gen-2, was able to capture the market. Sales are shrinking, rather than achieving the growth promised for so long. Just think of what could have been if that second model with a smaller battery-pack had actually been offered. The lower cost would have been quite a tradeoff. So what if range would have been reduced. The resulting weight reduction would have delivered higher efficiency and less need for power. Enthusiasts were unwilling to compromise though. Now, they see the consequences of their choice to retain the status quo. Fighting change was unwise.
- 2-14-2018** **Love.** I'm not giving them any chance to recover. It's over. Done. They have been called out for being hypocritical. Volt was to be the icon of the future. No worry about finding a place to recharge. You could enjoy electric-only driving without ever any concern. They declared EV offerings a terrible approach, a market doomed to failure. Now, they find their own arguments a contradiction. Looking back, its easy to see how often they promoted purity of no gas the goal. Finding out Volt could not fulfill that promise as well as Bolt is the ultimate in examples of irony. They defeated themselves, beating the farm on the very thing they disliked. Oops! They own favor of avoiding use of the engine proved it wasn't really necessary for their audience. My reason for asking the "Who?" question is obvious now. I recognized the conflict and was attempting to politely nudge them back on course; instead, they accelerated in the wrong direction. It was quite rewarding to post this summary of the situation and ask the course-correction question: Remember how anti-EV this group had been? All that "range-anxiety" promotion has faded away as Bolt took the spotlight. Where does that leave Volt approach for GM?
- 2-15-2018** **No Fate.** They are victims of their own choices. I continued to point that out too: This site turned fanboy. As sales for Volt got worse and gains for other plug-in hybrids became obvious, rhetoric grew. Any post pointing that promises were clearly not delivered was unwelcome. It turned into an effort to defend reputation at all cost. There was no more objectivity, no effort to progress forward. To complicate matters, GM has pretty much abandoned Volt in favor of Bolt anyway. Now well into year-8 of sales for Volt and still no mainstream offering, what hope is there? We've seen this history ploy already. Two-Mode suffered a similar fate. Fanboys eventually just gave up. What purpose does this site now serve?

- 2-16-2018** **It's Over.** Watching things crumble to dust provides a sense of wonder. Nothing is left. There isn't anything to fight for anymore. It's all gone. I put it this way: Model 3 deliveries have begun here. Leaf gen-2 arrivals will soon become a reality. Clarity, Pacifica, and Outlander sightings now happen. Prius has moved on to embrace the plug. We expect new offerings from Hyundai & Kia. It's over.
- 2-16-2018** **Criticism.** Seeing recognition & acknowledgement that I wasn't actually the problem has been pleasing. A few have turned on their own with the hope of something constructive emerging: *"Take some constructive criticism for a change. You are a contributing factor for why I no longer post and have moved on from this site. While you may not agree with the OP, name calling and profanity should not be necessary to make your point. Why would someone want to have to spend their life moderating what you post and reminding you of basis civil discourse."* I climbed up on that same soapbox when they were finished: The goal was and will continue to be getting GM to offer something profitable for the masses. All those posts stating *"too little, too slowly"* were genuine concern that GM was missing out on opportunity to deliver something appealing its own shoppers prior to the tax-credit expiring. I was one of those who stuck around because I wanted Voltec to diversify quickly. Who cares if some of that GM success would transform from conquest to following the footsteps of Toyota. The other automakers are pursuing that path to profitability too. GM screwed up. So what? We're still in the early stages anyway. True, no more gloating superiority for Volt, but that's no reason to give up. Join the rest who want plug-ins to succeed. We can't end the reign of traditional vehicles alone. All the automakers must send the same message now.
- 2-16-2018** **Didn't Care.** The use of insults & profanity always amazed me. How do they expect anything good to come from that? It's not the slightest bit constructive. But when there is literally nothing left to gain, convincing yourself you went down with a fight is important to those dominated by pride. Honor is not earned from surrender and there concept of compromise is considered a sign of weakness. Ugh. What a waste. Fortunately, I was able to stay true through all that rhetoric. Seeing the nonsense spin into efforts to inflict harm is not anything I ever want to be associated with. that's why I keep repeating my own purpose over and over: To achieve & sustain high-volume profitable sales has always been the goal. What sets this group apart from all the other Volt supporters is that wasn't taken seriously. Instead of actually embracing what needed to be done, those here kept exclaiming the faster & further mantra... which has overwhelmingly been proven a terrible decision. That approach failed to achieve the goal and shows no prospect anymore. As other automakers have confirmed, a balance of price & performance is the better choice.

- 2-16-2018** **Uncaring.** The desperation is building to remarkable levels: "*2012 Toyota, feeling the pressure, attempts a plug-in hybrid, but only gives an EV range of 6 miles, or 11 blended.*" He's trying to rewrite history and using lies to distort it. That is supposedly how you cover your tracks. I wonder how effective he expects this final effort to be. A few searches is all it takes to reveal Toyota's interest in plug-in hybrid augmentation back in 2009. As devoted supporters, we knew that gen-2 design supported 100 km/h driving with just electricity. Unfortunately, battery technology of the time fell far short of market expectations. So, Toyota focusing on refining design while waiting for those advancements in the world of rechargeable batteries to take place. After all, the phone & computer efforts were pushing hard for cost-reduction and energy-improvement. He doesn't care about what actually happened though. The intentional misleading confirms it. With so much information readily available proving those 11 miles were not blended, it's hard to believe he would think people are naive or gullible enough to just accept what he posts. Treating people like idiots is not how you earn their support or respect. He keeps lying anyway. This was the latest example. What I find most baffling though is trying to figure out what purpose looking backward serves. What does it serve when the present is such a disaster anyway? Apparently, pride clouds logical thought. He believes changing perception of the past somehow makes the current situation better. Ugh.
- 2-17-2018** **Perception.** Speaking of looking back and attempting to rewrite history, I found it necessary to point out how that actually happens today on the big Prius forum: Anyone else notice the effort to make a vehicle styled to stand out vehicle has been given a stigma by using the "*polarizing*" label? People unknowingly pick up on the term and pass it along. That's how you effectively undermine a product. Those excited about it not being like everything else on the road is the trait that antagonists attack... relentlessly, using the label so often in a negative context that it eventually becomes a core part of the narrative they wish to portray. That effort to impede does indeed work too. We have seen this quite a number of times with Prius history. We have also seen the reverse. Remember the SUV back in the mid 90's? Those wanting them to become a daily commute vehicle gave it the "*car*" label. That seemed absurd at first to be calling a vehicle with heavy-duty suspension, aggressive tread tires, and 4-wheel drive something you'd drive everyday to work a "*car*". Yet, the term caught on to become the norm anyway. Long story short, ask yourself why "*polarizing*" seems an appropriate fit. Do you really want a vehicle that looks like everyone else's, plain and about to become outdated?

2-17-2018 **Bitter Ending.** The frustration related to that final nail in the coffin of the long dying daily blog for Volt has been interesting to witness. Those left know that what I had promoted was right all along for the larger market. Their carefully worded replies couldn't conceal the disingenuous plug-in offering from GM. It was a niche and they have known it for a very long time. That's why I was so relentless asking: "*Who is the market for Volt?*" Nothing was ever delivered for the wide audience. Hope without anything supportive would eventually give out. This 2-week span of no new topic to discuss has done that. Even their personal attacks fell apart: "*And BTW, you're not actually considered part of this group.*" After so many years of arguing, there was nothing left. Even the lies fell apart. After posting 2 links to videos I had to rebut with real-world detail, it was this summary to bring it all to a bitter ending...

Why would I want that? This group was established based on the belief that the following would be delivered by late 2010:

- 40 mile EV range
- 50 MPG depleted efficiency
- priced nicely under \$30,000

Conflict arose right away, when constructive discussion came up asking how that could possibly be achieved. Toyota had been pursuing the plug since late 2003, when they rolled out the gen-2 Prius able to deliver a top EV speed of 100 km/h (62.1 mph). Back then, it was clear that energy-density was far too low and battery-cost far too high to exploit that aspect of the hybrid system's design.

In late 2007, they repeated the statement of battery-cost being too high still. This group took the "*not ready*" part of that out of context, making it seem as though Toyota was actually against lithium batteries. It was a clear effort to misrepresent, yet many here became enablers to promote that message of deception. Calling it out is when my presence took a very unwelcome turn.

From that point on, the misleading about Prius really ramped up. Later when the first Toyota plug-in offering was rolled out, the lies about goals and how it actually worked really got intense. The ambiguous reference to "*electric-only*" rating was taken advantage of. The hard-acceleration test during the EPA measurement cycle was at the 6-mile mark. Many here worked to make people believe no battery-capacity remained at that point, attempting to conceal the 5 miles still available.

Despite countless reputable websites calling out that attempt to misrepresent, some continued the subterfuge anyway. In fact, someone did in this very thread. Allowing lies like that to persist is why this venue fell apart. People of integrity (true Volt supporters) moved on, leaving the dishonest enthusiasts behind.

Now, we see the potential for Toyota to actually deliver what GM set out to deliver becoming a reality:

- 25 mile EV range
- 54 MPG depleted efficiency
- priced starting at \$27,100

That system is designed to accept a larger-capacity battery in the future too, without requiring generational changes. A simple mid-cycle upgrade could deliver increased EV range... should cost drop enough and energy-density increase enough.

Remember, the goal is to replace traditional vehicles by offering a choice compelling to loyal shoppers... those on the dealer's showroom floor. That potential to draw new interest to a plug-in is key. It requires a MSRP that's competitive in a vehicle loaded well to appeal to ordinary consumers.

In other words, I don't agree with what this group has promoted. So, I am grateful not to be thought of as part of it.

2-18-2018 Efficiency Rating. Wow! Some EV supporters are totally clueless about what the numbers actually mean. Confusion that emerged from my mention of an efficiency rating resulted in a number of bizarre responses. You'd assume someone promoting plug-in vehicles would be aware of how their consumption is measured and what the various related terms actually mean. Turns out, many don't. They just latch on to the concept of plugging in, then support it without actually studying the topic. It almost just boils down to Oil = Bad and Electricity = Good. That certainly covers the mindset of those troublemaker Volt enthusiasts. They couldn't care less how inefficient their vehicle was, just as long as no gas was used. That's really unfortunate. Waste is still waste, even if the fuel is clean & renewable. Frustrated about having learned how much this new audience still has to learn, I posted: Writers here really need to publish & promote an article explaining what those numbers actually mean. Far too many EV supporters assume incorrectly. I have seen quite a few comments in various articles with that same mistake repeated. "*kWh/100 mi*" is a measurement of EV efficiency. It states the amount of KWH the vehicle takes to travel 100 miles. It has absolutely nothing to do with how many miles you'll get per charge; yet, we see replies everytime a rating is posted with that belief.

2-18-2018 Costly Mistake. There are some who still don't get it. That trophy mentality will make them pay the price. In the meantime, there's still a state of blissful ignorance... well, flat out denial. It's clear certain individuals just plain don't care. The hollow victory of a short-term lead is all they are interested in. I'm happy to point out that focus should be on the long-term, changing the status quo rather than just celebrating a perceived lead: Prime is designed to take on direct competition with traditional vehicles. Owners will experience many drives that are exclusively EV and get absolutely outstanding overall efficiency regardless of when the engine runs. The smaller battery-pack gives it that edge needed to keep MSRP business strong, no tax-credit required. Starting at \$27,100 makes it a very realistic for deep penetration into the mainstream. I drive my Prime hard, with 2 no-recharge trips over 1,700 miles each (much at 80 mph) and having to deal with the extreme cold of Minnesota winter. No big deal. 98.5 MPG as of 10.5 months (14,500 miles) and climbing as the temperatures warm. Remember audience. Prime's target includes showroom shoppers. Being able to grow the market is vital. Focusing only on low-hanging fruit (early adopters) can be a costly mistake.

- 2-18-2018** **Status Quo.** It is interesting how some spin what you just said to mean the opposite: "*Sounds like you are happy with the status quo.*" That's a clear indication they actually did read & understand what you posted. The hope is by firing back the same sentiment, readers won't notice. Somehow, they think the reversal will hide the behavior. It's like when someone guilty of something accuses you of that very thing. Anywho, I see how desperate the Volt enthusiasts have become. Their venue for daily greenwash has collapsed and they want someone to blame, even though they are the ones who brought it to that end. Gotta love the irony. I let them have it with this dose of reality: Sounds like you are unfamiliar with diminishing returns. Investing heavily in faster & further did not result in market growth. In fact, quite the opposite happened. The risk of cost, resulting in a MSRP too high to compete directly with traditional vehicles, has been confirmed too great of a tradeoff. Sales dropped. GM should have kept the power & range unchanged for gen-2 and focused on making Volt an affordable choice for their loyal base of owners looking to replace their aging GM vehicles. Status quo for an interim generation would have been a wise choice. Gen-3 could have been the upgrade which offered the next improvement for power & range. Now, there's a risk of losing everything. The generous tax-credit will expire prior to having established profitable & sustainable high-volume sales... the return GM sacrificed by choosing to not deliver a well-balance design. Their favor for faster & further resulted in a vehicle mainstream consumers (Chevy shoppers) weren't interested in.
- 2-18-2018** **Ask Questions.** My follow up to that group of losers... those who ultimately lost their greenwash venue... by doing what I routinely do, ask questions: What is GM's electrification plan? With Toyota, we already see that Corolla & C-HR hybrids are selling well elsewhere. So, they are now faced with the decision of whether or not to roll them out here or go straight to plug-in hybrid. Next year, the EV model C-HR will be rolled out in China. So, there will be that option here too at some point. For larger vehicles, the production of Highlander hybrid in Texas will become a reality next year. From GM, we have no clue what the next steps may be, just vague ambitions... which is what this group used to thrive on. But even that has faded. It's that lack of any message that cause people to stop participating. So, what is or should be the plan?
- 2-19-2018** **Innovate.** Desperate efforts to spin the loss as something else, we got this: "*I keep hoping Toyota will innovate again.*" Their fanboy site is dead and they know it. Today marks 2 full weeks without a daily post and I was delighted to chime into that attempt to lick their wounds: Innovate = to introduce something new; make changes in anything established. Delivering extremely low-cost way of offering EV drive doesn't qualify. Delivering high-efficiency electric-only cabin heating doesn't qualify. Delivering carbon-fiber for a lighter weight hatch door doesn't qualify. Delivering aero-glass for higher efficiency and wiper elimination doesn't qualify. Delivering a collection of safety features standard on all vehicles doesn't qualify. Rolling out hybrid systems to all vehicles for a simple path plug-in offerings doesn't qualify. Transitioning hybrid systems from NiMH batteries to lithium doesn't qualify either. The word "*innovate*" doesn't mean the same here as anywhere else. That is why this is a fanboy site... which is what makes this a fanboy site without purpose anymore.

2-19-2018 **More Innovation.** Clearly annoyed by my comprehensive reply about being innovative, I fired more ammunition at their attempt to recover. There is no way I'm letting this go. Their reign of greenwash is over. It was amazing how terrible some of their posts had become. Attacking the messenger turned to dishonesty on an entirely new level. At least in the past, there was some basis of truth. Now, they are just saying whatever they want, without anything to support their claims. It's what happens when pride takes over. Facts don't matter anymore. Goals don't matter anymore. Cost doesn't matter anymore. All they want is to protect reputation. That's sad. This is how I responded to that nonsense:

btw, in Japan you can options from Toyota that aren't available here...

- AWD option for Prius
- Thermal-Resistant paint
- Solar-Roof recharging
- CHAdeMO recharging

...which is why this group associates anything not related to power or range a waste, not considered innovative.

2-20-2018 **Old Audience.** Attempts to join in, to say that's what they wanted all along is a sign to watch for: *"Most people here have been yelling for the past several years for a AWD, EREV, Voltec power plant in a Equinox/Terrain platform."* Their true stance is easy to confirm. Just look for patterns. They didn't ever actually do anything. It was nothing but an online campaign to build an impression of progress. No outreach beyond posting messages is a complete failure. The point of exchanging information online among enthusiasts is to build support, to become supporters. They never did. They just kept reciting rhetoric to each other, the same old audience. If you don't make an effort to entice mainstream consumers, what's the point? I sounded off to their nonsense with: Barely a whisper with no lasting effect, drowned out by those fighting to keep the spotlight on Volt. Opportunity was missed. Calling the effort to break that status quo (finally move on) trolling is sad. This site was founded as strong endorsement of what was hoped to come. Why is there still no effort whatsoever to do the same for the supposed desire for diversification? Making excuses and diverting attention elsewhere only makes it worse. That total absence of a message forward is why some other site will take over.

- 2-21-2018** **New Audience.** Abandoning the dead fanboy blog to post on websites more in tune with the plug-in market as a whole presents new challenges. That new audience isn't well informed. They don't think things through either. They just see how the technology works and assume that's the only issue. It goes far beyond just good engineering. Those nasty Volt antagonists learned that lesson the hard way. Blinded by enthusiasm, they didn't bother to study acceptance, hence my repeating advice: Know your audience. Not everyone is fortunate enough to have an outlet available. For that matter, even fewer have enough amps. There are very real logistics issues needing to be addressed. I brought that to their attention with: Initially, it's easy to embrace the plug. The lack of diversity presents a simple path to follow. The situation becomes quite complex as you try to move beyond that though. The perfect example is the dead silence that comes from facing the reality of a multi-plugin household. The effort to supply enough electricity to that first charging location is thwarted by the need to add a second. It's much more difficult to find a convenient place for the second charger and there simply may not be enough amps available without major rework. It's unfortunate they don't recognize the problem yet, but it will emerge as a very real barrier at some point... as will other unforeseen challenges related to mainstream penetration.
- 2-21-2018** **Lost Purpose.** It came down to pointing out the fact they did everything possible to avoid acknowledge of: This is a fanboy site that doesn't want to admit it is a fanboy site. That identity clash ultimately tore it apart. There was always a push for EV purity, but an anti-EV sentiment. Then when Bolt came along, Volt became a lost cause. What is the purpose of this site now?
- 2-21-2018** **Purpose, advocate.** I ask questions: What is the plan for Volt? We see GM favoring Bolt, but that's only in the realm of plug-in support... which is tiny. GM's presence at the autoshows is all Pickups & SUVs. Their interest in cars is basically abandoned now, just like it was leading up to the bankruptcy. They are slipping into the same financial trap again. With the GM tax-credits hitting phaseout the end of this year, it makes that struggle with Volt even worse. The growth necessary to be able to share a presence with Nissan, Hyundai, and Toyota simply isn't realistic. Those legacy automakers have a clear advantage in terms of both production-cost and market-targeting. What will GM do?
- 2-22-2018** **Purpose, antagonist.** They respond with efforts to divert attention: "*BTW, over the same time frame, PHV/Prime sales: ~61,000*" I was happy to sound off about that: That is not a BTW, since the purpose of PHV/Prime was profoundly different than Volt. GM bet the farm on Volt, placing the entire fate of plug-in offerings on its success... and failed miserably. That's why the namesake of Bolt came about. GM was forced to start over, abandoning all that "*range anxiety*" campaigning to now endorse the very thing it was against. Toyota never had high-volume plans for gen-1. It was simply a mid-cycle rollout to just 15 states for the sake of research to build a viable gen-2 upon. Phase 2 of that research never happened. Toyota learned what it wanted sooner than anticipated. So, the effort was halted. In the meantime, rollout of new hybrid models to someday also offer a plug took place. We got 2 new models of Prius, a compact SUV, and a compact CUV. They also ramped up lithium battery production, moving all but an ECO model of Prius away from NiMH. Now, we see there is indeed a viable gen-2 offered... and Toyota didn't squander tax-credits on conquest sales... leaving them in a profoundly different position than GM.

2-23-2018 **Facing Reality.** It is very difficult; though, some do try: *"I still think GM is in the EV market kicking and screaming."* I found that intriguing, especially as it invites the opportunity to respond with some closing insight:

The reason why this group has such repugnance for me is now becoming difficult to deny. What I've been pushing for all along is exactly what they need. Those with long-term vision and experience see it as obvious. They have had an extremely difficult time with just getting beyond the tax-credit though. Volt's dependency on it meant only an audience of enthusiasts would be interested. Volt was doomed to being a niche as a result.

But now in 2018, there's a necessity to deal with sales that are not fully subsidized. Next year, that financial crutch will be completely gone. That means reaching mainstream shoppers. Growth isn't possible otherwise. The key to that is a concept this group hates with a passion... cooperation with other automakers, giving up superiority for the sake of moving beyond that initial market. Gasp!

Having to reach out a hand in partnership is difficult. I sucked it up right away, seeing GM as the automaker with the greatest potential of being able to break out from those challenges holding back plug-in vehicles. I saw that they had to opportunity to exploit batteries once production-cost came down and energy-density went up enough to make them directly competitive with traditional vehicles on the showroom floor.

They are too proud to also suck it up at the moment. Hopefully, that will quickly change. Joining me in the fight against the reign of gas guzzlers isn't a level of maturity this group wants... yet. Read the previous posts in this thread. Their attempts to mislead and divert attention are clear evidence of them kicking and screaming like GM. Fortunately, there are now other partners are showing very good potential.

It's really unfortunate that so much time & effort was wasted on conquest. It is not too late. There is opportunity to make up that lost ground.

2-23-2018 **Sending a Message.** Being clear & concise is a dead giveaway that the person is making an honest effort. That's what is often hated about me. I'm that broken record, the scratch they keep hearing. Over and over again, my message is present and cannot be avoided. Stating it today certainly stirred a lot of anger: *"My message was has always been that the offering must be targeted directly at showroom shoppers and be both profitable & affordable with sustainable high-volume sales."* That's how you get labeled as a troll... especially when it is posted about the topic of sales. They feel emotionally stirred and take that as an effort to provoke, rather than being a reminder of purpose. See, when purpose goes unfulfilled, the group struggling will come up with other achievements to focus on instead. It goes back to the teacher giving the student a failing grade for not following instructions. Even if the student did remarkably well with whatever homework was turned in, the failure to actually do the work assigned is a very real problem. They get anger for not getting the reward they feel they deserve. I see an attempt to manipulate. So, you said a message so clear, there is no doubt of the attempted deception. In this case, those needed sales were not achieved. You must deliver what is required. Period. Then if you do, there's always the opportunity for extra credit.

2-24-2018 **Cooperation.** You don't state goals when you want a someone who shares your values to remain a foe. The idea of cooperation makes the "*vastly superior*" sick to their stomach. That's why we get a constant stream of "*fugly*" & "*slow*" comments. They literally have nothing useful to contribute, so they revert to the childish act of being a bully. Calling names and drawing attention is something the rest of us learned as what not to do as some of the first lessons taught in school. It's hard to believe such primitive acts can dominate situations so often. But when you have nothing else to lose, they don't see any reason to play fairly. That sounds a lot like the political situation we are in now too. Unfortunately, it is a reality it both the plug-in hybrid and the electric-only vehicle markets. That's really sad... but also an encouraging sign, since it confirms very real change is taking place. The problem with that is progress forward means some initial efforts will be revealed as unsuccessful... and not everyone deals with failure well. Learning what works and doesn't work isn't supposed to hurt someone's pride. Most people take the constructive criticism as upgrade suggestions. But when a product like Volt comes along, where there's no realistic chance of upgrade money being available, those stuck with that product unable to achieve high-volume sales face a very real problem... and having to cooperate with a former foe for help is too much to accept. So, they fight. Ugh. I certainly try to extend a hand though: The reason why this group has such repugnance for me is now becoming difficult to deny. What I've been pushing for all along is exactly what they need. Those with long-term vision and experience see it as obvious. They have had an extremely difficult time with just getting beyond the tax-credit though. Volt's dependency on it meant only an audience of enthusiasts would be interested. But in 2018, there's a necessity to deal with sales that are not fully subsidized. Next year, that financial crutch will be gone. That means reaching mainstream shoppers. The key to that is a concept this group hates with a passion... cooperation with other automakers, giving up superiority for the sake of moving beyond the initial market.

2-25-2018 **Short-Sighted.** Reading through the long series of posts over the past 3 weeks, the pattern became easy to see. When you only live in the here & now, seeing anything else becomes nearly impossible. You make up excuses to justify your stance. It doesn't matter what's presented at that point. You've made up your mind that the decision made was the best one and nothing else matters. Whether or not someone points out a disastrous situation building doesn't matter. Everything is just fine. I hadn't expected the upcoming tax-credit phaseout to create such determination to save pride. Rather than Volt enthusiasts moving on to Bolt like the supporters, they are standing their ground. All bets are placed on faster & further finally winning over the masses. No logic about other priorities matter. They see that as the only solution possible. It's like the recent hope of winning the SuperBowl by having one of the best thrower in the league. That only works if all plays are somehow tied to throwing. If not, your doomed. They don't see that though, since all games leading to that point have been wins. The catch is, with Volt sales, all were to early-adopters drawn to the opportunity conquest presents. With a \$7,500 tax-credit or extremely low lease payments, why not? Trouble is, ordinary consumers don't think that way. The low prices won't be available for too much longer either. Losing at some point is evitable. But they don't see that far. The short-sighted nature of their perspective based solely on small victories is a terrible guage for the larger win. Sales on a much larger scale aren't realistic.

- 2-26-2018 Purpose.** Lack of it was why that now dead daily blog was attacked so often. The enthusiasts remaining used it as a venue for posting greenwash material. My attempts to inject constructive discussion and get the topic back onto that original message of promotion never worked. They'd just get angry at whomever was taking advantage of the ability to post anonymously, then take out their frustrations on me. I became the scapegoat. They'd blame me so often for their sorrows, the fact that I wasn't responsible for what they were blaming me of didn't matter. I had supposedly done what they came to despise. It was a odd situation. Since the only real data they had was the dropping sales of Volt and the modiacre efficiency, focus on performance alone was quite a stretch. I never cared about faster & further either. They knew my push for diversification... offering a second model of Volt, then later a SUV variant... only made things worse. The act of addressing the obvious need to expand production meant addressing shortcomings. That was painfully difficult for them and painlessly simple for me. It's the reason why they worked so hard to always keep the Toyota rhetoric focused on Prius. Consideration of Camry hybrid wrecked virtually all of their arguments. That larger, faster, and more powerful system delivers incredible efficiency and stands great potential for plug augmentation. Honda's newest offering, the plug-in hybrid Clarity, makes that all too clear. That effort to portray Toyota as a laggard have fallen apart, exposing GM as having that very problem as a result. Each attempt to label me as hypocritical only exposed them of that guilt too. Without any choice remaining but to become a team player, they chose to lose instead. Why state a purpose only to draw attention to the problems you are facing? So, they didn't.
- 2-26-2018 Final Replies: ELECTRICITY USE.** I fired off a series of replies, as the ship was sinking into the abyss... EV1 was an exciting offering from GM. It was a full electric vehicle, which made remarkable use of battery technology of the time. Small & Expensive didn't even matter then. It worked and showed potential. PNGV was to deliver the family-sized vehicle with the power & affordability that EV1 didn't. So, complimentary offerings were a great idea. Different propulsion technologies would co-exist just fine. Problem was, electricity was very dirty back then. With coal being the dominate source, it was actually worse for a air to use that for propulsion then some type of hybrid... especially with Prius having earned a SULEV rating from CARB. The belief though was that would get cleaned up over time, due to the growth of the solar & wind industry. So, no concern... until GM pulled the plug on the program.
- 2-26-2018 Final Replies: STOP GAP.** I had no idea just how relevant this would be after so many years later... A nasty campaign was launched by GM when the gen-2 Prius rolled out. The final year of gen-1 Prius had become profitable and the sales of this new generation had already hit mainstream level, despite no tax-credit being offered. The rise of the SUV with the promotion of being "*good for the economy*" made the attacks on small vehicles that were clean & efficient especially vigorous. People feared change and they no had a symbol to focus their feelings on. It got pretty nasty, but not as childish as the attacks now. It was a blatant effort to greenwash. Media sources would publish information that was just plain not true. In fact, this is how the diesel scandal came about. Being dishonest was not an issue. It was all about saving the status quo. Sound familiar?

- 2-26-2018** **Final Replies: SIGNS OF TROUBLE.** The ever-changing story from just this one particular automaker was always a sign for concern... GM changed its mind about hybrids after its financial situation became a concern. There was a substantial investment in development of the technology. That brought about the focus on making SUVs more efficient, the biggest potential return on such move forward. Two-Mode was born as a result. It would be the Prius killer, a technology that could be spread throughout the fleet to make everything cleaner and more efficient. Great! Only problem was... the technology was expensive and it didn't work well. Power was reduced to make the vehicle more efficient & cleaner. It showed less potential than what Ford & Toyota were both pursuing. So, focus shifted to adding a plug. Bankruptcy interfered with that, but Volt emerged as the ultimate launch of GM's first battery-centric vehicle for the masses.
- 2-26-2018** **Final Replies: STATING GOALS.** It was obvious the enthusiasts had trouble to come, since they couldn't even say what their intentions were... That's been the source of the problem since day 1. GM intentions would have sounded realistic, if it wasn't for the aggressive self-imposed deadline. How in the world could so much be delivered in such a short amount of time? Turns out, it couldn't... and a few people here got burned really bad by that, holding a grudge and looking for a scapegoat. Gen-2 would be the solution to that. After all, sales were low enough with gen-1 that a significant number of tax-credits would still be available then. Unfortunately, GM followed the suggestions of enthusiasts of Volt rather than supporters. That difference meant catering to a small niche, rather than adapting the technology for a larger audience. That ended up being a horrible mistake. Gen-2 sales ended up dropping, rather than sparking a plug-in revolution. Now we see the nemesis rising, Prius plug-in. Even with distribution to only have the country the first year, sales still bet Volt... which is what made things turn very ugly here. Volt losing the spotlight was unacceptable, especially with other automakers like Honda & Chrysler showing so much potential too.
- 2-26-2018** **Final Replies: PARTNERSHIPS.** The idea of cooperation is repulsive to them, as if it is an admission to failure... Reading through the posts in this thread, that pattern of superiority becomes easy to see. Volt offers more range and more power, so that makes it better... period. Any reference to other consumer purchase priorities or to the importance of either automaker or dealer business is just shunned off as an effort to promote Toyota. It such a desperate act, pretending GM should have no concerns for anything other than range or power. Reality is, we see Hyundai and Nissan and Honda and Chrysler and Mitsubishi and Toyota and Ford all striving to deliver on those priorities deemed unimportant in the name of pride. Who cares if GM isn't recognized as leader anymore. The goal is to build a strong team. Like it or not, the success of plug-in vehicles requires cooperation. That means sucking it up and working to establish partnerships.

2-26-2018 **Final Replies: EXPECTATIONS.** They don't have a clue which direction to take, which is why a fate from inaction is now playing out... The purpose of this site changed from exclusively supporting the plug-in hybrid Volt to discussing daily topics about anything related to electric propulsion & support. A big part of it was the shift from "*range anxiety*", which was very much an anti-EV approach, to embracing the EV. That's what actually ruined this site. The expectation had been set that vehicles like Leaf and Model S were the competition. When that didn't work out, attention shifted to Prius instead. Mixing of messages like that and no longer having any clear purpose caused a number of regulars to leave. Some more simply left when their lease expired, since they were only conquests with no loyalty to GM. Indication of lost purpose became clear when topics about Volt dwindled. As time progressed following the struggle with gen-2 rollout, the parent site started to mirror daily blogs. The topic would be posted there first, then repeated here after a day or two. Blaming the change exclusively on me doesn't hold merit. I was the one pointing out the change and attempting to start-up the next chapter. Expectations were changed by others.

2-26-2018 **Repeating History.** It's bizarre how some people are so blinded by the idea of success that they refuse to acknowledge patterns of mistakes. What I've witnessed lately is a deep hatred from having made that error in the past. They blame something, then never look back... ever. There isn't any recognition of repeated actions. That contributes to a history which becomes more and more distorted over time. My confirmation of those events are these blogs. Having documented each as they unfolded in great detail, it's simple to recognize that past accurately. Important tidbits of information easily overlooked or forgotten are right there for the reminding. There is no stone left unturned when you read back through those days as they played out, when I was frustrated and wanted a record of what happened. Having a resource like that is really nice. It's quite uncommon though. So, you often get accused of lying. Anywho, their interpretation of what happened long ago becomes so misleading, they don't notice anything. It's all dismissed as an effort to undermine, blaming you rather than ever taking the time to wonder if they contribute to the problem. In this case, I was digging deeply to find out if the cycle would be restarting again. Because if it does, there will be significant losses. There's no need to cooperate with someone hell-bent on harming you... even if it ends costing them. They were warned, after all. The choice is between pursuing an upgrade proactively or just sitting back and reacting to whatever happens. Oddly, the decision to just hope for the best and accept the consequences is what they are going with... again!

2-27-2018 **Selling Points.** Ultimately, that's what the research should lead you to. After identifying goals about what needs to be sold, you then need to figure out how to sell it. Pushing for what the enthusiasts deem of value, beyond just faster & further was very important. Proper representation depends upon getting lots of accurate feedback... which is why I went directly to the source... especially since that audience was absolutely clueless about how business works. It's amazing how simplistic they always believed the situation was. They'd say "*If GM would only advertise Volt, sales...*" over and over again. That was so idiotic. Promotion is one of the few things an enthusiast can actually have a great deal of influence over. Just look at the commercials Tesla owners filmed to spread the word themselves. Consider how much owners of Prius have done over the decades. Neither automakers needs to advertise when you have that many endorsements from owners. Yet, those supposedly supporting GM never got off their butts to do anything. It was so odd to see them do nothing but complain and attack the messenger. Interestingly, my efforts to find out what they would endorse didn't lead to any type of revelation. There really isn't anything to focus on outside of EV range. Taking a close look at Malibu & Cruze, you see why GM so heavily advertises them. They have many nice amenities and are really fast. Comparing electric-only driving distance to Prime is the only thing Volt has going for it; otherwise, you just purchase a Chevy car... which is exactly what loyal GM customers have been doing. Selling Volt is extremely difficult. There's so little to stand out, showroom shoppers simply aren't interested.

2-27-2018 **Playing Nice.** When a paradigm shift begins, that unstoppable threat to the status quo stirs quite a bit of emotion. The reaction is to find a scapegoat, someone to blame for that inevitable outcome. I have been watching that slowly play out with Volt. That's why I always played nice. You can't ban someone who is polite and stays on topic, even if the facts posted stir some anger. Change happens. It's the natural course for any product. You know the early-adopters will have little in common with mainstream-consumers. Hope is that whatever trait responsible for sales initially will continue to be of interest to that harder to reach audience. That's why I pushed so hard for a definition of EREV. Being so vague and having changed several times over the years, it was no longer a selling point... because even among enthusiasts, they had no idea what it actually represented. Is that vehicle also an EREV or what makes it different? No concise answer spelled doom. But those without a business background have no idea that such a distinction is even necessary.. hence getting labeled as a "*troll*". Even though you are trying to help, they interpret those actions to clarify as an attempt to expose a vulnerability. Technically, that is true too. The act of pointing out the lack of an easy-to-understand definition is exposing a vulnerability. The difference is providing the definition solves the problem. The enthusiasts absolutely refused... without any idea of the consequences of such inaction. They only see you as not playing nice. They want group-think as their guide, not someone who stirs emotion. Ironically, stirring emotion is exactly what you want. That's how a coach prepares a team for competition. You win by understanding strengths & weaknesses, then build excitement by getting everyone to work as a team to take advantage of that knowledge.

2-28-2018 **Facing Reality.** It has been over 3 weeks since the last daily blog topic was posted. The same thread has been used for final thoughts. It should be obvious that the enthusiasts are at a complete loss. They have no idea what to do with their only venue now dead. No where else is there a place for them to conceal their identity or hide posts they don't like. It's the end of 11 years of bliss. They could say & do whatever was wanted to keep their artificial dream alive. It wasn't real though. Business need would eventually catch up, revealing their tiny niche as a hopeless cause. Sadly, it didn't have to be that way. Potential for a constructive outcome was within reach. They just didn't want to make compromises. Trading off capacity for affordability or power for efficiency was unacceptable. Fight any type of opposition. It was a self-destructive choice; yet, that is what they fiercely protected. A bitter end is what they are dealing with now. Facing reality like this is interesting to observe. It reminds me of diesel's death. It was abrupt & undeniable. There simply isn't anything to fight for anymore, nothing to defend. Surrender isn't necessary. New battles may emerge from new foes later, but this war is over. All is lost. The absurd obsession with EREV nonsense served no purpose. It was a ever-changing set of goals without mutual agreement. People got frustrated with the confusion that caused, then left. Without an objective, why bother? They didn't understand audience. Who were they targeting. For that matter, who did they represent. I pointed out how that lack of clear message would be their downfall. There's no possible way to grow sales without addressing those basics. They didn't. Now, the consequences are obvious. So, they lash out to save their pride. I just fired back, to get the last shot out: This transition from early-adopter to mainstream-consumer was inevitably going to be painful. So, calling "*troll*" from pointing out the status quo stir was anticipated and prepared for. No group of enthusiasts will welcome it, since that change requires acceptance of traits they don't find appealing. Going from standout to ordinary makes it a harsh reality to accept. Blame me all you want for highlighting this new chapter in plug-in hybrid history. Glad I could serve as a scapegoat. It provided excellent candid feedback I couldn't acquire from any other source.

3-01-2018 **Final Replies: LAST WORD.** Watching the blog finally die, long after it should have been sunset, is odd. All those years ago, I fought to make their forums the focus. It was a unused part of the website. People preferred the daily blog. It was nothing but a brief exchange of thoughts, refreshed every day. There was nothing that persisted... other than the daily reset. It was a maddening existence, a source of greenwash rhetoric. They fell deep into group-think, transforming the hope of it being a valuable resource into just a gathering place for fanboys. It got so bad, they could make up whatever narrative they wanted... since there was no accountability. No logon was required. You could post as whomever you wanted and history was never tracked. And if you didn't like what was posted, the comment could be hidden. They selected to read only what they wanted, dismissing anything that didn't cast a favorable light. All these years later, as things are coming to an end, they chose to make it bitter: "*You are driving traffic away! I post GM and EV news but you don't!*" That obviously wasn't true. Their dishonesty & hostility is what actually drove away most of the traffic. All the bait-dropping by the enablers made it especially nasty, knowing they were attempt to spin whomever responded to it as a troll. Always being polite and working hard to stay on topic, that attempt to place stigma didn't work. The definition of that label simply didn't apply. I was the one staying true to purpose of the blog. They abused. They harassed. They didn't care. It had become a venue for chest-pounding. I simply replied to that nonsense with: It's not me. I post about GM products and GM shoppers. Someone else always jumps in to inject a comment about Toyota, drawing focus away from GM. That pattern is easy to recognize.

3-01-2018 **Sales Results.** Count of Prime purchases is climbing. It's being recognized as a top-selling choice already. The potential is obvious... hence the flurry of attacks. That's annoying, but it doesn't matter. I'll just keep filming videos in the meantime. That collection of real-world material is priceless... and well ahead of need this time. Having experienced generational upgrades before, knowing the significance of this one and preparing for its huge potential is vital. I'm scrambling to research & document as much as possible. It's quite a challenge, with so much other stuff to participate in too. My life is filled with friends & family and a thriving career... hence the positive attitude and such a hopeful outlook. Being on the precipice of this new chapter in plug-in history makes it even more exciting. There's a lot to look forward to. So, no need to dwell on the present... even though it too is so positive. Looking further out, understanding the potential, I posted this about last month's Prime sales: Doesn't matter. The middle of the country has nothing to sell yet. No supply means distorted demand impressions. The coasts are all that got 2017 models. The 2018 are only now being delivered. So, once Spring arrives, we'll get a better representation of actual demand.

- 3-02-2018** **New Video Opportunity.** I have been testing out the latest updates from a phone-app being updated to support Prime. It already does a great job showing Prius data. Like the phone-app I used in the past with the PHV model, it has PID codes to read information you wouldn't normally see. This is the stuff that really teaches you about the hybrid system. It's that deep understanding which empowers. When you can actually see values with a technical connection, it can really open up a new world of appreciation. There's a lot required to make a system clean & efficient, without becoming too expensive. I will soon be filming some drives. Using the ability to capture video on the screen of the phone itself, rather than a translate or transfer, the quality should be outstanding. I will be able to display battery level (the actual value, not the useable representation), along with the power output, and battery & motor temperatures. There's even an illustration that shows you when regenerative braking switches to friction. It's really exciting to have such a resource available. I'm very thankful to the development team who shared it with us. Their work to is really appreciated.
- 3-03-2018** **Video: Early Spring - To Work.** New application. Lots more data to share. Using the latest update from "*Hybrid Assistant*" has allowed me to capture a lot more information in a single window on my phone while driving. Combined with the window & dashboard cameras, there's quite a bit of real-world data for you to see. Watch this wealth of knowledge for both your education & entertainment. It's just my daily commute to work. But using the technology for a clean & efficient drive leads to an entirely different situation when dealing with that traffic... [Early Spring - To Work](#)

3-03-2018 **Final Replies: SALES GROWTH.** That state of panic has subsided. It's over and they know it. The fanboy venue is dead. It now serves as a monument of the naive. They fell into the very trap they denied could ever exist. No matter how much the pattern of repeating history was pointed out, they didn't care. It was an impossibility. That could never happen. Yet, it did. no matter how much their beloved vehicle fulfilled their desires, it simply never appealed to the wider audience... and sales indisputably confirmed it. Not only hadn't growth been achieved, the sales of Volt are now rapidly declining. There's no potential to build upon either. The market clearly isn't interested in an expensive compact hatchback. GM shoppers want SUV choices. The doom they steered toward must finally be acknowledged. I was happy to provide a summary of the situation:

Doing everything possible to avoid dealing with sales growth has been the theme of this daily blog for a very, very long time. Spinning stories to evade the lack of progress problem has been an intense effort for enthusiasts. But with stability, it was manageable.

Sales leading up to gen-2 rollout were flat. We saw monthly returns between 1,600 and 1,700 quite consistently. That value was well below the need, offering no guarantee of profitability or even sustainability once the tax-credit expired. The rollout of gen-2 didn't change that situation.

2 years later, we are now witnessing monthly sales drop below 1,000 with no expectation of improvement. Less expensive (lower MSRP) choices from other automakers are now entering the market and GM shoppers simply aren't interested in the purchase of a compact hatchback.

Enthusiasts here did an embarrassing minimum to promote the great technology they had. Volt barely had any presence outside of the blogging world. We now see plug-in owners groups emerging to fill in that missed opportunity, where Volt is barely a participant. There are virtually no Volt owner resources still. We see videos, applications, lots of how-to sharing for other vehicles. Why not for Volt, especially after so many years?

The answer should be obvious. There was such an obsession with range & power that the other aspects of appeal were neglected, dismissed as unnecessary for sales growth.

Enthusiasts were wrong, very wrong. But rather than make an effort to change that, taking advantage of the evolving market pause, they continue to squander time by avoiding what needs to be done.

3-03-2018 **Final Replies: TRAINING.** This post was the ultimate goal, leading up some shaming. All those claims over all those years of being helpless were outright lies... and they can no longer evade that truth. From the very beginning, they had the power to influence. Rather than being reactive, a proactive approach should have been taken. That's what the whole fiasco around EV1 taught us. That lesson of having a voice louder than the propaganda of a single automaker was clearly not learned. Their problem from the start was the refusal to create a partnership. GM was superior than others and their smug attitude was all that was needed. They believed they had a "*vastly superior*" product to promote, so there was no need to ensure mainstream buyers understood what that actually meant. The nonsense of "*EREV*" made that all too clear. It's meaning was uncertain. Different enthusiasts interpreted different ways. It was a fundamental flaw in their approach. No cooperation from within or without. GM support was conflicted. Plug-In support was conflicted. It was a disaster. As enthusiasts, they made that worse by not taking any initiative. There was nothing to show for all their years of posting. I collected priceless findings from my years of research, participating in hostile venues for the sake of getting direct & unfiltered feedback. They remained clueless, asking why I was there on a regular basis. I found it ironic how they'd dismiss my replies and having nothing of their own to reveal. It was nothing but fanboy spin to defend & offend. Constructive efforts never emerged. What a waste. There was so much potential, so much missed opportunity. Oh well. It's not like I didn't tell them over and over and over again... as I did today, one last time: How many of you here have stopped by your local dealer and offered training, demos, or even printed material? Poorly informed sales staff is within your power to change. That situation is missed opportunity. You all complain about the lack of promotion, yet do nothing about it.

3-04-2018 **Video: Early Spring - From Work.** My commute home, captured with the new app, gives you a lot of real-world to watch & consider. Seeing the actual kW value from the electric motor is quite informative. You get to see the actual battery state-of-charge value, compared directly to the percentage shown on the dashboard representing the usable capacity. (There is always a buffer saved at the top & bottom for battery longevity.) You can see motor & battery temperature, in addition to the the coolant temperature for the engine. There's an indicator to inform you when the friction brakes are engaged, so you can tell when just it switch from regenerating electricity. Notice the improved lighting for the dashboard capture too. The quality of filming continues to improve each time I drive. It's very rewarding to be able to share detail like this now. My original drives from all those years ago sure are crude in comparison... [Early Spring - From Work](#)

3-04-2018 **Energy Storage.** Anytime something very positive comes up for Toyota, the antagonists bring up fuel-cell vehicles. All they see is the lower efficiency of hydrogen conversion. That narrow-mindedness prevents any type of constructive exchange. They draw the line, then attack. It's sad. They don't bother to look at the bigger picture. It is always an assumption that large quantities of electricity will always be readily available and very inexpensive. They are quite wrong. Making it worse, they don't recognize the importance of diversity. It's a one-size-fits-all situation as far as they are concerned. The idea of co-existing technologies is unacceptable. The concept of mutual benefit eludes them. That's sad... and quite a barrier to overcome. I keep trying though: How else will massive amounts of electricity be made available for rapid transfer to commercial vehicles? Do you honestly think the grid can supply it or having local banks of batteries on site? In other words, you clearly haven't the bigger picture yet. That's typical for those making "*fool cell*" remarks.

3-04-2018 **Video: Early Spring - Charge-Mode in Winter.** Charge-Mode can boost overall efficiency, if used wisely. For example, you recharge the battery while on the highway so you can later avoid an engine warm-up for city driving long after it cooled down. I have done this while on vacation, when there isn't a place to plug-in where we stop overnight. This video demonstrates how that could be done, condensed into a single drive for the sake of filming simplicity. In this case, we stopped at a craft shop along the highway while on the drive home. I engaged charge-mode after getting back on the highway, then shut it off shortly before getting off the highway. Using this feature while cruising takes advantage of engine efficiency while traveling at a sustained rate. The charging itself takes place at a rate faster than what you get when plugged in to recharge. Like with a regular hybrid, the gas engine is used to generate electricity. But with Prius Prime, you have greater flexibility about when & how that energy stored in the battery is to be used later. Watch the wealth of detail available on the video. Note that the temperature outside is still cold, so MPG is lower than in warmer months. That's because air is more dense and winter-formula fuel is less efficient. Nonetheless, results are impressive anyway... [Early Spring - Charge-Mode in Winter](#)

3-05-2018 **Last August.** Remember how different things were back then? Bolt was brining its first year to a close. Taking the market by storm, showing GM superiority to Tesla, didn't happen. In fact, Bolt was nearly dead on arrival outside of the early-adopter market. Ordinary consumers have not shown any interest at all. It's nothing but a curiosity. That "*someday perhaps*" is the common response. There simply wasn't and still hasn't been a movement toward acceptance by the masses. A big part of that seems to be the complete absence of any charging infrastructure. People don't show any desire for a car that may leave them stranded. In other words, we're back to why Volt was promoted so much. Only thing is, the demand for Volt is pretty much non-existent. Total disinterest is a very real problem. That's why the article from back in August with this title drew attention again: "*Why Does Anyone Buy a Toyota Prius Prime?*" With inventories so low and clearance time in full swing, Prime was basically an unknown still. That's changing, as this recent comment posted for that article represents: "*Well, as of February 2018 sales showed a big jump on Prius Prime sales, and Volt sales are way down. I was so surprised as I had also considered the Prime a much inferior product. I 'm not the only one, seems like every review from the many magazines and other sources agree the Volt is a much better product. I guess the only explanation is the belief in Toyota brand regardless of the product.*" Antagonists of Toyota still cannot comprehend how a well-balance offering is more appealing than one which favors performance. That terrible mindset of GM's product being "*vastly superior*" remains a big problem. They just plain do not understand the ordinary consumer. You know, the kind who wants an affordable, comfortable, reliable vehicle to get from place to place with. Not being willing to pay a premium for more range & power baffles them. They cannot relate to the mainstream perspective. That boggles my mind. How can such ignorance persist? Anywho, I replied back to that with this: Know your audience. From an enthusiast perspective, the assessment of "*inferior*" is easy to justify. But from an ordinary consumer perspective, that same set of criteria is considered overkill. Why pay a premium for a vehicle that is less efficient in both EV & HV modes and offers fewer features?

- 3-05-2018** **Yet, Again.** Watching history repeat is a source of intrigue. The enthusiast never seem to get it, as this confirms: *"This just shows that Prius/Toyota PHEV buyers don't really care about EV performance or EV range, they are still mostly gas heads who thinks in terms of MPG. And market sales shows."* Balance doesn't make sense to them. This is why the problem of innovator's dilemma is so hard to overcome. They figure since EV performance and EV range was a strong selling point initially, that it will continue to be as the audience grows. Finding out that's not the case is costly mistake. Ordinary consumers will pay for a feature if it is affordable. That's why there are package options. Some choose them, others don't. Offering only a maximum is like only trying to sell a vehicle fully loaded. It's simply not worth it for everyone, especially those who just happen to stumble across the vehicle while wandering around at the dealer. That chance discovery will get dismissed at an instant if it raises the sticker-price too much. This is why Prime is hated so much by certain individuals. Having such a low MSRP compared to Volt gives it a significant advantage. It's a far more compelling choice to someone with thoughts of perhaps buying a Corolla or Camry. Annoyed, I shot back with: Same old rhetoric... GM enthusiast doesn't like mainstream shopper priorities. GM enthusiast insults the vehicle most appealing to that audience. Trading efficiency & features for the sake of fulfilling an expensive want simply isn't worth it... and the sales are now beginning to show it. We saw this nonsense repeated over and over throughout Prius history. It was ugly. It was slow. It was a market leader.
- 3-05-2018** **Learning.** There was an antagonists clearly quite upset by my final reply: *"Maybe you should stop by fueleconomy.gov and get a little learnin' yourself."* Knowing how rude & insulting he has been in the past, my reply showed how well prepared I am for a fight: I learned a long time ago how some post using vague & outdated links for the sake of misleading. Again, what have you done to promote Volt? Seriously. Salespeople really do need that knowledge sharing from owners. This is what I shared yesterday... [Early Spring - Charge Mode](#) ...to help people better understand charge-mode. Just think of how useful that would be when stopping at a dealer for a test-drive only to find the battery isn't charged. You just go for a drive in charge-mode, then switch it to EV on the way back. No plug necessary to experience the electric-only driving. Go on, keep belittling Prius, or finally step up to start promoting plug-in vehicles.
- 3-06-2018** **Expensive.** There have been quite a number of EV announcements recently. Nearly all luxury models though. It's the Prius conundrum finally playing out. All those years ago, Toyota's system delivered a smooth & silent ride only available from a luxury vehicle. Mainstream consumers thought that was great. Luxury consumers pretended that wasn't the case. With the hybrids, avoiding the inevitable wasn't too hard. But now with Tesla making such an impression in Europe and the affordable EV choices emerging here, the ability to ignore that paradigm-shift is becoming quite difficult. Not only are ordinary middle-market shoppers beginning to take notice of the smooth & silent, they are also discovering the lack-of-power belief to be just a misconception. The industry response is to bump up the game by focusing almost entirely on expensive offerings. Fortunately, we see Nissan & Hyundai already striving to break through the ploy with affordable choices. Toyota's effort isn't as obvious, since their focus is on components rather than the vehicle itself. You get the point though. They are preparing to take full advantage of the next generation battery. In the meantime, choice will be limited. That makes you wonder what GM will end up doing. My guess is very little until then. The same is likely for Ford as well.

3-06-2018 **Goodbye.** Angered by my obvious win, I got this: "*...where he's not wanted, with non-sequitur comments...*" It was buried within a rant, in an attempt to vent frustration from the blog having died. An entire month since the most recently daily topic brings everyone to the same, undeniable conclusion. The owner decided to stop feeding the enablers. Seeing them fight constructive discussion, insult & belittle anyone not in agreement, and outright dismiss facts and lie, is simply not worth supporting. They can just use the forum instead. That's all I wanted all along anyway. So, the anger is understandable. I get what I wanted. Using a venue which strives for some integrity is much better than being a breeding home for antagonists. To one of them especially rotten antagonists, I posted in response with: Breaking of the status quo is rarely welcome activity. As for claiming non-sequitur, that's the enablers at work, doing everything they can to divert. It's doesn't matter though. Time was wasted, exactly what the "*too little, too slowly*" concern was all about. Despite so many claims of GM being years ahead of everyone else, this weekend a friend of my purchased a Kia Niro PHEV. There simply wasn't a SUV choice available from GM. Opportunity missed. With the tax-credit expiration approaching, the situation should have been taken seriously. There was so much the enthusiasts could have done to help promote...

3-07-2018 **Ambiguous News.** The vague announcement anticipated from GM in January didn't happen until today. As usual, the comments are so ambiguous, this news is nothing but imagine-building nonsense. It's amazing how little was actually said. All we are told in the long press-release was that Bolt production would increase late this year. That was it. How many? What seems such a logical question resulted in a flurry of hostile responses from GM defenders. They felt deeply offended by us not blinding praising such an announcement. It's the same old gullible spin of the past, where the enthusiasts feed on the vague then amplify expectations for GM, thereby removing any accountability in the process. We aren't given any specifics; yet, that is supposedly enough to declare superiority over all other automakers. Based on what? There was literally nothing to refer to. Making matters worse is the fact that GM depends heavily upon LG for virtually all of the vital components for Bolt. That relation goes well beyond just being a supplier. There are very real limitations that cannot be quickly overcome. Offering an increase is complex & expensive. That's why the way Toyota will leverage hybrid design for plug offerings provides greater flexibility at lower risk. Anywho, it boiled down to posting this summary: More and more, the impression is that Volt will fade away. There simply isn't a market within GM's customer base for an expensive compact hatchback. The realities of production cost could not be avoided. Later on, it's easy to see a small SUV with a plug emerge. So much for their supposed industry lead.

3-08-2018 **Common Error.** Whenever GM makes a crazy vague announcement, it stirs posts about Toyota. Nowadays, that means we get misleading & misinformed comments about Prime. This time, it was: "*I put it in EV mode and it kept automatically bumping it out of EV mode.*" It's easy to see the unfortunate reality of someone unfamiliar with Prime to make assumptions about how it works. After all, how would you research it? There is no quick-guide available... yet. That button labeled as "*EV Auto*" can easily be misinterpreted as meaning it is some type of EV mode invoke. It's not. Instead, it means you want the system to come out of HV mode as quickly as possible to resume EV mode when power demand is no longer peak. Many have no clue they got it wrong, thinking you are forcing into EV mode to stay. That's such a simple thing to learn, it's not the slightest bit of a problem for new owners. But for someone doing a quick review without any study whatsoever, they'll assume incorrectly... as was the case this time. Who knows how he'll interpret this attempt to convey that knowledge: That was your mistake, a common error among newbies. EV mode is default. Pushing any button instructs the system to also use the engine. In your case, you likely switched it to "*EV Auto*" mode.

3-08-2018 **Patterns.** They are simple to observe, if you take the time to look for them. The gullible & lazy nature of so many who randomly participate in green vehicle threads make them easy victims of intentional misleading though. They just believe the narrative being expressed, rather than doing a little research of their own. That most definitely was the case topic. This particular individual got quite angry with me. He clearly didn't have the background. His assumptions were obvious. There was nothing provided to support claims. Even the most staunch of enthusiasts will make some type of reference to raise/restore credibility. He had nothing. GM had never done wrong, ever. No automaker is perfect. That's why there are generational upgrades. Heck, that's why we get mid-cycle refreshes with more than just cosmetic tweaks too. Learning from experience is normal. In fact, it is an expectation. The catch is, you try to avoid repeating the same overlook again. GM doesn't. In fact, quite the opposite happens. We get these statements of grand achievement yet to come... but, it rarely ever does. Volt gen-1 fell well short of expectations. Volt gen-2 did as well. And now, we see Bolt floundering in missed goals. The same pattern keeps repeating. Rather than aiming for the middle, something realistic, it is always a claim to superiority. Ugh. This is why GM stands out among the legacy automakers. Others have learned not to do that. GM clearly hasn't. Yet, the die-hard enthusiasts don't notice that pattern. Why? Are they just so poorly informed, my mention of it is the first they have ever heard such a claim? Anywho, I posted this to draw attention to repetition: No, I'm just well aware of GM's reputation... over promise, under deliver. Notice how the announcement is void of any actual detail? That pattern is all too familiar. Tell us, what specifically will be delivered? When? Where? How many?

- 3-09-2018** **New Attacks.** There is a very real hate for anyone who stirs the status quo. The act of trying to be constructive is clearly not looked upon favorably. Level of hostility from recent posts make that quite obvious. Nonetheless, I persist: None of the other legacy automakers set such unrealistically high goals. GM did and missed them quite a number of times... hence their reputation. Calling someone a hater for pointing that out is an absolutely terrible way to get constructive feedback. Again, GM set a target MSRP for Volt by 2010... missed it by a wide margin... tried again for gen-2... missed again. The reason for such a vital goal made sense, they needed that MSRP low enough so Volt would be competitive with traditional vehicles without tax-credit dependency. Neither Toyota nor Hyundai stated that goal with the same deadline. Yet, both actually delivered already. Prius Prime and Ioniq PHEV have prices that low. We still wait for GM.
- 3-09-2018** **2019 Corolla.** The reveal was today. With Corolla being the best-selling vehicle of all time for the entire industry, likelihood of it representing the tipping point for traditional vehicles is quite strong. This would be a very good reason for Toyota to invest as much as possible in the traditional technology, making the final fling worthy of competition for years to come. After all, you don't want to waste resources on something that won't last. Meanwhile, everything else will see that shift to hybrid in bulk sooner. Look at how impressive the new Camry hybrid is. Anywho, this upcoming Corolla will introduce a next-gen CVT. It will include a "*launch gear*". Think of it as a type of low gear for the cone & belt transmission. This approach will allow for efficient starts from the vehicle being stopped, in addition to making the CVT itself more efficient. Not needing a "low" for power anymore allows the belt size & angle to be optimized for cruising, since less demand will be put on it. Oddly, it will still offer shift-points with paddles, even though there really aren't gears to shift. This is why the introduction of the hybrid model (available as Auris in Europe and Corolla in China) will eventually find a place here. There's still enough of a difference. Who knows how things will play out. If Prime really does redefine Prius as more of an upscale offering, a Corolla with a plug would fit right into the product-line. It's a big step toward sunseting traditional tech for the entire fleet. The tech must be spread. Product diversity (good business) requires variety.

- 3-09-2018** **Reluctance.** Not understanding the complexities of automotive business decisions make this comment a really big deal: "*The reluctance that Toyota shows towards putting a plug on their vehicles is so strange.*" From that person's perspective, they sense reluctance. Adding a plug seems such an obvious opportunity being missed. That often comes from not having any clue what the tradeoffs are. Those challenges from just the engineering approach are immense. But then when you factor in the resistance to change from competitors, as well as customers, you end up with a confusing mess. This is why software developers (like myself) never aim for more than 90% success. That extra 10% is incredibly expensive to address. In fact, with so many unforeseen potential issues, even just reaching an 80% success rate can be quite a stretch. To minimize risk, as well as cost, the approach of incremental updates is taken. In days long before the computer, this was known as the "*muddling*" technique. Nowadays, we just called that upgrades. You know what you deliver won't ever be perfect, but feel comforted by the ability to adapt to an ever-changing market. With respect to Toyota's stance right now, I put it this way: Waiting until the price-point is competitive isn't reluctance, it's smart business. You bring up the base in the meantime, which is exactly what Toyota stated they would do... what we are witnessing now. The step from hybrid to affordable plug is far easier than from traditional to expensive plug. Remember, sales at mainstream volume won't have tax-credit subsidies available.
- 3-09-2018** **Cannibalization.** The short-sightedness continues: "*Prime is already cannibalizing Prius sales.*" You'd think the transition would be obvious. But then again, online commentary often comes from those who really don't give much thought to what they are posting. That becomes quite clear if you ever ask someone what their purpose is. They can't actually articulate goals... or refuse to. That's a sign of bias, in addition to not thinking long-term. It's really annoying to have to deal with that. But you have to, Since newbies aren't aware of the efforts to undermine. Keeping the response simple is what tends to be most effective: Cannibalization implies an unintended consequence. That most definitely isn't the situation. Toyota wants to transition from hybrid to plug-in hybrid.
- 3-09-2018** **Hate.** This is what usually brings about the short-sightedness. The person has some dislike or problem from the past that has mutated into hate. Once that happens, they really don't see anything else. So, we end up with hypocritical accusations and double standards... which is how you identify hate. Watch for those signs. Anywho, this is what stating goals is so important. They can be broadly applied and measured objectively. So, when I detect the hate, I call in out in some manner to draw attention to the situation and away from the emotion: No automaker should be given a free ticket to make unrealistic promises, then never be expected to get called out on it. We want choices targeted at showroom shoppers, so dealers can confidently stock plug-in inventory. Heavy dependence on tax-credit subsidies for low-volume conquests sales is most definitely not what we want... yet, that's what was delivered. Labeling discussion of it as hate doesn't fix the situation.

3-10-2018 **New Participants.** The previous chapter in plug-in history, that early-adopter phase, consisted primarily of those with engineering backgrounds. They were either actual engineers or knowledgeable in the realm due to their extensive exposure to niche vehicles. This was similar to the earliest days of hybrid history. A profound difference is emerging though. This next batch of active online participants don't have any business background. They are basically clueless. That's bad, really bad... since the next phase is mainstream penetration. Reason for this is simple. We're seeing an onslaught of high-performance EV announcements. Coming from luxury automakers, where paying a very high-premium is the norm, that's no big deal... for them. But for the audience of ordinary consumers, those people who come into a dealer to shop, there's a distorted perspective. When you don't have anything specific in mind, gravitating to the high-performance the high-premium delivers is easy. The catch is, legacy automakers won't be stocking that type of inventory. Everyday vehicle purchases are simple sales with affordability as the focus. Whether it is a low sticker-price or low monthly-payments, that is the key to the business-sustaining sales the dealers & automakers depend upon for profit. Niche vehicles don't provide that. Unfortunately, these clueless new online participants don't understand that. They are so focused on that in-the-now perspective, seeing beyond low-hanging fruit sales or the discounts from tax-credits doesn't happen... and anything you point out in respect to that is viewed upon as hate. It's really unfortunate.

3-10-2018 **In The Way.** That was how I saw Volt. Had the promises been fulfilled, it would have been different. Instead, it was just meritless bragging. Mainstream sales were not achieved. Now, we see Prime stepping up to fill that role. In fact, we routinely get comments about Toyota "*imitating*" what GM delivered. That obviously isn't true. Toyota didn't sacrifice affordability for the sake of more range & power. Yet, we get claims of Prime not advancing the automotive industry forward. Reaching that audience of ordinary consumers is far more difficult than those nasty antagonists ever want to admit. They somehow think sales will suddenly surge among the masses, despite the loss of the generous government financial incentive. How? Sales are terrible now. Losing \$7,500 will make the situation even worse. I was annoyed... and find those enthusiasts very much in the way, as I stated: Early Adopter = Tax-Credit subsidized purchase. That stage is rapidly coming to an end. Toyota knows this and is positioning its products to be directly competitive with traditional vehicles. The loss of that incentive will have little impact. Their hybrid reputation and solid performance record will make the transition to plug options easy. GM will be in a world of hurt soon, as the recent statement from its CEO to have tax-credits extending clearly confirm. The choice to deliver Voltec in a small vehicle with emphasis on range & power has proven to be a big mistake. Sales growth was not achieved. Claiming Toyota is "*standing in the way of a better tomorrow*" by disregarding the terrible business choices GM made is just plain wrong. GM squandered the early-adopter opportunities by focusing on conquest. Toyota focused on appealing to their own showroom shoppers instead... an investment that is about to really pay off.

3-10-2018 **When It Began.** The death of that daily blog has allowed my thinking time to shift back over to the big Prius forum. True, I learn more about the market by participating on those diverse & hostile venues, but returning to friendly territory is a welcome break. Today, I was summoned to provide some comments about the past. Turns out, I've become a bit of a historian with all my efforts to document. That's cool. Anywho, this particular feedback was in respond to dealing with those opposing anything disruptive to the status quo:

I still remember that first time witnessing a freak out. My mere mention of a hybrid sent that SUV owner into a state of panic, as if she had been confronted by death itself. Rumors of these new green vehicles had caught her attention and created such a deep fear of losing her SUV, the encounter with me triggered an intense emotional reaction. Her faced turned red and she started screaming about having to give up that vehicle she loved so much. It was surreal. It was 17 years ago.

The crazy large SUVs hadn't been introduced yet. Gas was less \$1 per gallon. The term "*climate change*" hadn't even been coined yet. We were just blissfully consuming oil with little concern for carbon or smog emissions. Think about how much has happened since then.

Proving an automotive-grade battery could be robust enough to last the lifetime of a vehicle was still a monumental challenge. Most people didn't even believe they could deliver enough power to propel the vehicle to be safe on roads. Most people also thought that hybrids needed to be plugged in to recharge. It was a very different time.

When Prius began to shock the world, greenwash attempts emerged in abundance. Many were exploits of misconceptions. Those hoping to undermine steps forward pushed assumptions in the wrong direction, leading you to incorrect conclusions. As time proceeded, the deceptions got more vindictive. Eventually, things became desperate. Rather than just omit vital information to mislead, some turned to dishonesty. They would just outright lie. They just plain did not care. They weren't ready for their world to change.

The most effective tool I have found to combat those efforts to retain the status quo was video loaded with lots of data. It's extremely difficult to distort reality with such detail information readily available. The footage reinforces Prius reputation while at the same time exposes claims of supposed superior technologies as meritless. Just ask the antagonist to show you their data.

Long story short, there are people who will work to impede progress any way they can.

3-11-2018 **Supply & Demand, part 1.** This was interesting to read & respond to: "*GM doesn't talk numbers because it was badly burned after its then-CEO predicted production and sales numbers for the Volt in 2011 and 2012 that it didn't come remotely close to meeting. And, quite frankly, given all the cynicism and pushback by EV enthusiasts (your comment is arguably a typical example), what would be the upside to the company of doing so?*" The comment/suggestion/question was from a perspective of removing all accountability, rather than working to make the setting of expectations more realistic. Those the words of someone fearful of continued losses. No surprise, coming from a staunch GM supporter. So, he didn't take well to my request for detail... rather than just accepting the ambiguous announcement without any actual thought or consideration. Needless to say, I fired back: The downside is the announcement is taken as an empty promise. Setting realistic expectations should be the initiative. That's how you avoid cynicism & pushback. Remember how Toyota set an expectation of 13,000 sales in the United States for Prius PHV's first year? That wasn't a high number like GM's plan for Volt, which may have disappointed some supporters, but it certainly was realistic. The final tally ended up 12,750. It provided an upside of proving that Toyota was taking a serious approach the market, showing they were accurately interpreting demand and doing their best to match supply. Remember, over or under production is costly to both the automaker and the dealer.

3-11-2018 **Supply & Demand, part 2.** Wanting to just how different GM's approach was with Volt, I replied to my own comment. Keep in mind that GM had hoped to achieve minimum mainstream sales volume (60,000 annual) by the end of year-2. That was first-generation expectations GM set. Enthusiasts watched the nightmare of missed goals unfold, resulting in a shift of those same expectations to the end of year-2 for the second-generation. That point in time was just reached. The goal was missed to such an extreme, they are angry at anyone drawing attention to it. Selling only roughly 1,000 monthly is far short of the 5,000 expectation they set... the precedent they pushed heavily. Falling so far short, despite such a large tax-credit, is why the blog ultimately died. Support was abandoned. That failure was good reason to try something else. My question has been what? Specifically, I'd like to know why the attacks on Prime continue. Will they be pushing the EREV approach in some revived form (change the definition, yet again) or just switch over to their former enemy, endorsing the EV instead of pushing a "*range anxiety*" alternative. I really wanted feedback before that final thread on the blog vanishes. So, I added: Prius PHV was a mid-cycle release to only 15 states. So, it was inevitable that it would be perceived as a compliance car anyway. Fortunately, the research Toyota hoped to gather from that effort paid off. They were able to get a clear understanding of where the market was and where it was likely to go.

- 3-11-2018** **Target Market.** Coming from a new plug-in website, I was especially intrigued: "*Feel free to build a list of main street auto vendors more aggressive on EVs than GM.*" That group of regular comment posters include strong support for Nissan & Tesla. So, the scope of that particular comment was what I wanted to push to find out more about. My guess is this's just another post without substance. They focus so intently on the here & now, addressing the wider audience isn't even a consideration. Many just blow off the idea of that next audience as years away, something to be addressed by the next-gen rollouts. That's why Prime isn't taken seriously. They see no reason to strive for appeal to ordinary consumers yet. I beg to differ. If the design doesn't stand a chance of appealing to my Mom, it is too limited. She's a great example of the indifference far too common in our market. That audience has absolutely no idea how their vehicle works, they just want something affordable, reliable, safe, and comfortable. That's why I get so annoyed with the performance obsession from enthusiasts. They are so blind to mainstream buyers, it's virtually worthless to ever argue. Regardless, I still keep trying: Changing the entire fleet or just pushing a showcase model? There's a big difference. The latter only focuses on low, hanging fruit (early adopters). Reaching the masses (ordinary consumers) is far more difficult. In other words, the term "*aggressive*" doesn't identify target market.
- 3-12-2018** **Spin. Spin. Spin.** The hate that comes from being on the losing side of a long fought war is difficult to overcome. That's why you give the losers an opportunity to vent. They need to get it out of their system. It's why I haven't abandoned that Volt blog entirely. Using me as a scapegoat is a means of unloading that stress. Winning some battles gave them a false belief of an ultimate victory. GM wasn't interested in that war. So, I could see their efforts were futile. I was also quite curious what they were holding on to. What was the point? What did they hope to achieve? What did they actually lose? Regardless of those answers, it is necessary to make sure this chapter comes to a close. Pushing even harder for closure by shouting a little can be quite effective. That's often how beating-a-dead-horse threads get shaken up to arrive at a conclusion, to end the spin. So, I gave it a try here: GM'S OWN LOYAL CUSTOMERS, SHOWROOM SHOPPERS LOOKING FOR A GM VEHICLE TO REPLACE THEIR OLD GM VEHICLE, HAVE BEEN ABANDONED. They are stuck choosing traditional guzzlers and you just plain don't care. Thanks for the confirmation. It wraps up the chapter on the fall of Volt nicely. Just imagine if GM had focused internally, rather than wasting time & money on conquest.

- 3-15-2018** **Focus on SUV.** Ford finally got into the game. Remember the last time they did that? All the attacks on Toyota from GM enthusiasts fell apart. A new, much more influential, enemy emerging meant a harsh & abrupt end. This marks the first page for a new chapter in plug-in history. The one with emphasis on affordable EV rollout is over already! Now, there is suddenly a turn of interest back to hybrids... specifically, choices in SUV form. Ford is basically abandoning their "car" advancements. Interest in truck platforms is so intense, they simply aren't going to bother anymore. A bunch of unibody designs are on the way. The bulk coming from SUV choices is what their audience wants. But rather than pretend that isn't the case... as GM did, they are declaring intentions for focus on that. In fact, they even stated this will pass Toyota's efforts. No detail was provide. It didn't matter, since that put GM in a spectator position. Not even acknowledging GM as competition is quite an offensive maneuver for Ford. Of course, anyone paying attention could have seen the pressure building. Volt now on its 8th year of sales and no SUV using that same technology even announced is very disappointing. There's no way to spin anything positive about that... which Ford is well aware of. Interesting, eh?
- 3-16-2018** **Clueless.** The problem of Volt being in the way is quickly fading. Rather than always getting a "better" mention whenever Toyota's design is highlighted in a published article, it's now just a footnote with a growing negative slant. In other words, GM had its chance, but nothing became of it. So, we are getting a refreshed look at Prius history and future potential. was intrigued what the Volt forum had to say about the article, with the hopes of taking it to the blog for feedback. Sure enough, there were posts. None addressed actual efficiency of design. They all focused entirely on battery-capacity. The attitude of more being better is so prevalent, they don't even recognize other approaches as a solution. It's so stupid, I can't help but to shake my head. Using less electricity in the first place should be a priority. They obviously don't see it that way. Carrying around that extra weight and requiring more time at the charger is a non-issue, as far as they are concerned. That's sad. I just happened to have a post to reply to with that very denial too: Turns out, those on the forum still don't understand. 31 kWh/100mi = Volt. 25 kWh/100mi = Prime. The offering from Toyota is clearly more efficient than GM... specifically it consumes less electricity to travel the same distance.
- 3-16-2018** **Unwanted Attention.** It needed to be said: The blind obsession with capacity will continue on, in some other venue but with better controls. That has always been and will continue to be the point. It's really unfortunate. Wasting electricity is still waste, even if it is clean. Think about the context of that discussion topic. Why would you want an electricity guzzler hogging the charger? The mantra of "*less is better*" really comes through in this example... which is what makes Prime a better system than Volt. Reality is, Prime will get an upgraded battery-pack at some point... perhaps a mid-cycle update. Without doing anything other than swap the pack, it will appeal to an even wider audience. That is the point of improved energy-density. The added capacity would allow for greater kW draw too, resulting in a power increase. Added capacity wouldn't help Volt. Added power wouldn't either. In other words, GM's choice to compensate both EV and HV efficiency shortcomings of Volt by just adding capacity is becoming easier to notice. In this case, we have ChargePoint drawing attention to it.

3-17-2018 **Personal Attacks.** When you don't like the message, you shot the messenger: *"Who feels like pulling up John's post from before where Prius PHV was the answer and GM missed with only a 4 seater? Not me :) Then if I mention my Volt uses much less gas than his Prime in MN, he pivots to ICE MPG as he racks useless miles driving around in an effort to justify his stats."* Having witnessed so much and having watched so much history rewritten, I'm surprised they'd bother. Knowing none of it works. Why? There is literally nothing left to gain. For that matter, there's nothing to defend. It's all gone. A soapbox still remains for posting though:

That history is what reveals the problem with those who participated here. Way back then, I raised concern about *"trophy mentality"*. It started with that *"230 MPG"* campaign. There was such an extreme fixation on that single attribute of the vehicle, red flags emerged about the willingness to accept balance. And sure enough, vital aspects of mass-market sales were simply abandoned. That reply... all these years later... still confirm it.

Calling the attention to point out other aspects, like HV efficiency or base MSRP, make those with that problem cry *"pivot"* trying to avoid acknowledgement of being well balanced. As for making a claim about driving around to justify stats, who do expect to believe that? It's clearly not true and there isn't even anything to support that. Seeing the *"vastly superior"* attitude still taken, rather than doing something to help GM customers actually get plug-in hybrid choice, is sad.

Mocking Toyota and Prius doesn't change anything. It probably doesn't even make you feel better, since you know more plug-in hybrid choices are on the way from Toyota. You also know that Honda Clarity will be stealing away sales from Volt, as Chrysler Pacifica has begun to do. There's the enigma of Hyundai Ioniq too.

GM needs a something that can be sold in high-volume for a profit, not a trophy. Finally adapting the tech in Volt for use in a SUV, like Trax or Equinox, is the solution we wait for. Ford announced intentions to deliver their own plug-in hybrid SUV. Kia Niro and Mitsubishi Outlander already have.

3-17-2018 **Smug.** How else would you describe a cherry-picked sampling followed by a comment like this: *"Put those numbers in your Prime and Smoke It."* That's a true sign of defeat. It never ceases to amaze me how constructive discussion attempts end up breaking down to childish name calling. That's why I never got banned from that daily blog for Volt. I kept the things active with my counter-posts and was always polite doing it. For that matter, I kept the discussion on-topic too. The enthusiasts hated me for that. I thrived on their feedback. It was an incredible source for opposing perspective. True, they suffered from group-think. But at least what they believed was candidly stated. No holding back is what made that particular venue so valuable. They'd use their best material. Then when it was exhausted, they'd turn to insults. That's how I knew there was nothing left. Anywho, that happened today. He was very upset with the efficiency rating and had nothing constructive to counter it with.

- 3-17-2018 All Talk, No Action.** As expected, there was upset from me calling out those who don't ever do anything other than post rhetoric. No one is supposed to notice their pattern of enthusiast propaganda. They try to pretend to be constructive, but most posts are without any substance. For example: *"Anyone who asks, I'll gladly state the pros and cons of the Volt."* Naturally, when asked, nothing is ever provided. Unwilling to play the game anymore, I stick to the painful realities. It's amazing how much effort is put forth to spin, distract, and attack. What a waste. None of that actually helps advance them forward. You have to share & educate. Simply stopping by a dealer to show them a few things about the car from an owner's perspective is a powerful means of stirring interest. Without that, what incentive is there to even bother? Expecting excitement from a vehicle that requires answering a lot of questions and only getting a modest commission in return isn't realistic. You have to give them something they can easily entice the customer with. You can also go directly to customers. There's this thing called the internet, where people go to for more than just blog & forum information. My sharing of videos on YouTube has drawn interest from a very diverse audience. There's no reason they couldn't do the same. Anywho, I stated a con, knowing that message would get through and cause even more upset... perhaps enough to provoke some action, finally: PRODUCTION COST is too high to make it competitive with other GM vehicles.
- 3-17-2018 Parting Advice.** Not much has changed. The advice now isn't really any different from how it all started: This is the opportunity. Don't let that slip by. Seize it. Seeing the other automakers jumping on board, making announcements of their intention to deliver SUV choices with a plug, is what those who participated here waited for. We all know how difficult the transition is... especially for GM. Volt floundered. So what? It's ironic, but that has passed. A new chapter has begun. Knowing that Ford is going all out, that barrier has been replaced with anticipation. We're witnessing a paradigm-shift with the entire industry. This is when the intent from GM should be solidified. Mistakes of the past can be avoided this time around. Clearly state what ordinary consumers, not early adopters, will purchase. That means no subsidies and competing directly with traditional SUVs. Support GM by focusing on audience, their own loyal shoppers.
- 3-17-2018 Video: Early Spring - Engine Warm-Up.** Near the end of the drive, you'll see the purpose of this video. It's to demonstrate a full warm-up cycle of the engine. Leading up to that is a climb out of the river valley at highway speed, passing someone on the highway, an opportunity to drive at 80 mph, and hard-acceleration from a stop. All that drained the battery quicker than usual, but it worked nice for a well-rounded EV drive sample. On the display, notice the "usable" capacity of the battery-pack dropping to 0%. On the readout from the phone-app, actual capacity drops to 13%. At that point, the cold engine finally starts. Watching coolant temperature for the engine closely, you'll see it climb to fully-warmed threshold. At that point, the engine shuts off and driving without resumes. The engine will start again when more power is needed or the HV capacity for electric-only is used up. The engine will shut off later, automatically when conditions are right. This is how such high HV efficiency (driving without plug-supplied electricity) is achieved. Carefully study detail provided by the phone-app. There's a lot to discover about how the system in Prius Prime operates... [Early Spring - Engine Warm-Up](#)

- 3-17-2018** **Final Post.** It really is coming to an end, 6 weeks later: Spin is the most compelling part of the blog. Participants here did not believe in balance. So, regardless of what was stated, it would end up being interpreted as an absolute. This final exchange was a nice example of that. What was the most informative was how business-need was never taken seriously. Thinking great engineering would be enough was futile. Yet, the idea of tradeoff for the sake of appealing to a wider audience was always dismissed. As for the attempt to find a scapegoat to explain dwindling Volt interest, give it up. When those impressive lease deals expired, former owners moved on. Early-Adopters fulfilled their role and mainstream consumers weren't interested. So at the end of all of this, there is still no plug-in hybrid for GM's own loyal customers. That long awaited Trax or Equinox with Volt technology will happen someday, but the hope being years ahead of other automakers didn't work out.
- 3-18-2018** **True EV.** Attacks elsewhere are having trouble. They emerge, but the audience isn't receptive. The antagonists weren't aware of just how much of a fanboy site their blogging venue had become. Using me as a scapegoat blinded them to what was actually happening. They'd forget both friend & foe. There had been a diverse group of posters. That participation is what caused it to thrive. That all fell apart over time, mostly due to the lack of any clear message... except EV purity... which ironically, is what ended up tearing it apart. Looking back at post from long ago, you can see a strong endorsement for what Bolt became. They really didn't want Volt. After all that, it was a lesson hard learned about stating goals. Nonetheless, there are still a few unwilling to recognize that conflicted past or what it means for the future. I took the offensive on today's spin attempt on one of the new venues: The reality of being a "*true EREV*" is just marketing. That claimed "*full*" power is actually an extra boost to an already quite capable of all aspects of driving. It is unnecessary, a want. I have to deal with that spin from Volt enthusiasts routinely. They claim the engine in Prime is necessary, but can't ever support the claim with real-world data. Meanwhile, I keep publishing video after video confirming their FUD nonsense. Notice in the following example how the engine never starts the entire time plug-supplied electricity is available. The power & speed demands are handled just fine entirely with just the 2 electric motors... [Early Spring - Engine Warm-Up](#)
- 3-19-2018** **Misleading.** The new attacks on new venues continues: "*Everything I read everywhere, including the Toyota Manual, and multiple reviews all indicate if you floor it, prime will start the gas engine.*" That's an outright lie. There's quite a bit of promotional material where Toyota explicitly states the "*pedal to the floor*" is all electric. My response was followed by attacks on me personally, blatant attempts to avoid having to actually provide any proof of his claim. I finally ended up posting: That is false information, being spread by people not bothering to confirm sources. The engine does **NOT** start when you floor it in EV mode. What do you need as confirmation of that? I have already shared video showing the 68 kW draw (pedal to the floor) with 0 RPM for the engine. This is the type of real-world data we'd like to collect for each of the automaker offerings. Reviews & Hearsay with incorrect information are still far too common.

3-19-2018 **Meaningless.** Back on that now almost completely defunct blog, there's some of their own parting thoughts being posted. Naturally, I get called out with efforts to discredit: "*Personally, I stopped reading his meaningless posts...*" From an fanboy perspective, what I post is indeed meaningless. They couldn't care less about sales. It was always just having something to be proud of, something to brag about, something to make them feel better than others. In fact, I remember the one particular individual still holding a grudge bragging about how Volt would deliver 60 MPG after depletion. He had no evidence whatsoever to support that. In fact, everything known about the "series" type hybrid stated the opposite. Volt would be less efficient than Prius when in HV mode. He was proven wrong in an embarrassing manner too, by his own peers. So, you could imagine how much he feared I'd remind everyone of that. I didn't though. I just kept reminding everyone about purpose... even if they continue to find it meaningless: Enthusiasts have been shunning business-need since the automotive age began. Dislike for the necessity of a vehicle to deliver high-volume profitable sales is not compatible with their wants. Posting about range & power is much more exciting than accountability. That's why anything related to being held accountable is negative voted until the content is hidden. This group established the precedent, declaring Volt "*vastly superior*". Yet, the sales that were to come about as a result never materialized. That's why I post asking what the goal should be now and will continue to until GM finally offers something for its own showroom shoppers capable of competing directly with its own traditional vehicles.

3-19-2018 **Anti-GM.** It is quite remarkable how some people get so frustrated, they don't perceive anything but hate. It's like people struggling with a problem. Any advice you provide is taken as criticism, with the intent to make them feel bad about their situation. No matter what you say, they never hear anything positive. They search so hard for a negative motive, as if you are setting them up for failure by undermining any opportunity they may have, that trust is gone. They choose to never take a chance. Ironically, it's that close-mindedness which causes them to miss opportunity. Anywho, I got this today: "*You have an irrational hatred of General Motors, and this site, particularly.*" I posted a reply, knowing it will just get negative voted until hidden anyway. Nonetheless, it is my own opportunity to reply:

Quite the opposite, I support GM. You want so bad for me to be anti-GM, but that isn't the case. I recognize the engineering and see the potential. It's the terrible configuration of Volt which I keep drawing attention to that irritates the heck out of you. Missing opportunity after opportunity for GM to get on the right track makes it even worse.

We've seen the market reject Volt due to its packaging & price. You know all too well that a second model with a smaller battery-pack... which I pushed... would have been what swayed favor enough to entice GM shoppers. But that never happened. GM focused even more on SUV offerings.

Trax emerged as a popular choice as a result. That seems the best candidate now for the technology in Volt to finally migrate to. Too bad if the High Priest was right about what the next steps should be for GM.

And yes, I know you'll spin it to say that's what is coming in the next 18 months anyway. But I'll just point out that the "*too little, too slowly*" concern fits the situation nicely. Waiting until a 2020 model, after the tax-credit has run out, is not at all what anyone had hoped for.

Remember, my goal for coming here all those years ago was to seek out allies. Toyota had designed a system to exploit battery tech, once it finally became affordable for the masses. Automakers like Nissan & Hyundai are joining in. GM should be part of that. Their own goal of "*nicely under \$30,000*" is still quite relevant... whether I'm here to point it out or not.

3-20-2018 **Goodbye.** I thought this was a good way to wrap things up: Telling yourself what you like to feel better doesn't change the situation. GM has the potential, but has rested on its laurels not actually taking that step. Volt tech must be adapted & spread. Twisting that to make it be about Toyota was the efforts of others, not me. My goal has always been to get GM to offer something appealing to its own loyal shoppers, not conquest buyers. Remember, all that emphasis on sustainable & profitable high-volume sales?

3-20-2018 **38 Minutes Later.** What an amazing sense of timing. 6 weeks after the mysterious silence of that blogging site, something from the owner was finally posted. Knowing for the past 2 years things were falling apart for Volt, it was obvious new daily topics would be a challenge. There simply wasn't anything good to post. Gen-2 was a disappointment. Engineering expertise had been wasted. We all saw the potential gen-1 failed to deliver, but there was always a lingering confidence the upgrade would correct previous executive choices. Don't blame those who designed it. Blame the decisions behind the design. In other words, management screwed up... twice. There was simply no way to spin a positive about it either. The reason why was simple. Gen-1 supposedly had a purpose of proving the technology. (We know that isn't true, but that's the narrative enthusiasts pushed.) Gen-2 would be the version that resulted in high-volume sales that were both sustainable & profitable. That obviously didn't happen; instead, the main writer of those topics had a nightmare to deal with. 6 weeks ago, it came to an end. Nothing was published. The final thread just kept going... day after day... week after week... until 38 minutes ago. A new post emerged right after I said my goodbye. (Hmm. Was that just a coincidence?) The site owner stated new articles by new writers were to come. That's it. Nothing else. No purpose stated. Audience unknown. Just a break in the silence.

3-20-2018 **Tax-Credit Worry.** We're seeing growth in the concern for tax-credits expiring late this year. For GM supporters, that emotion comes in the form of worry. They are all too aware that GM squandered opportunity, focusing far too much on conquest. Sacrificing actual change for the sake of publicity is already looking like it will be a costly mistake. Volt was a flop. The technology from it carried over nicely to Bolt, but that too has been a flop. Remember how GM was going to squash Tesla? Rolling out over a year sooner than Model 3, we were supposed to see Bolt dominate demand. Supply was to be stretched to the limit, with wait-lists confirming the legacy automaker's ability to compete with the well respected EV leader. Instead, the anticipation for Leaf put a huge damper on the market. Ordinary consumers wanted that offering from Nissan. Early Adopters would get their want fulfilled by Tesla. GM simply fell by the wayside. After all, who wanted a great performance, long-range EV in the form of a compact wagon? It was a bizarre mismatch offering. No investment in infrastructure (no high-speed charging network of any sort), combined with the MSRP destined to struggle when the tax-credit phaseout begins is a big problem for Bolt. Dealing with that basically means abandoning Volt in the process. GM's message of what solves "*range anxiety*" is a very nasty issue. They polarized their own solution. Oops! Anywho, rather than figure out how to overcome that, some choose to divert attention instead. They find insults to Toyota pleasing. By calling the automaker a "*laggard*", they hope to cast a halo worthy of praise for GM, enough to get tax-credits extended. I asked: What is the goal of the tax-credit? You can't just label some automakers with "*laggard*" but not state what that actually means. We want quality, not quantity. Simply cramming a large battery-pack into an inefficient system isn't much for progress. Guzzling electricity isn't the kind of advancement to endorse. Wasting fuel of any sort is still waste... especially if you are waiting for that vehicle to finish using the charger. Making the motors, inverters, chargers, and heaters use less electricity is advancement not recognized by the misguided method of determining worth we currently employ. Why continue an approach that doesn't properly recognize engineering achievement?

- 3-20-2018 Profit & Generalizations.** There's one particular PHV owner who frequents the big Prius forum with such vague posts, they become a source of misconception concern. He has no intent to mislead, but doesn't recognize his contributions can be harmful. At some point, they won't be considered innocent mistakes. Pointing out the issue can only happen so often before acknowledgement cannot be avoided. Until then, it is dealing with stuff like this: *"I would say the same goes for all plug-ins."* Drawing conclusions without sighting detail or reason is never a good idea. State why. Don't just make a claim. Ugh. Anywho, I hit back with: That's a generalization based on what? We know for a fact that Toyota's battery choice for the initial offering of Prime gave cost-containment high priority. They specifically told us that the packaging decision was to keep it affordable. So, even though it could be small, expecting profit is realistic. That is key to sales. Toyota would like to achieve high-volume with this generation. First year sales of 51,000 put them on the right track for that. In short, not all plug-ins.
- 3-21-2018 Max Defrost.** Apparently, the power argument for EV mode has fallen apart. Antagonists can't claim the danger now that more people are learning what "EV-Auto" mode actually is. Their attempts to spread that misconception are failing, so another is attempted. They are always watching for new exploit opportunities. In this case, it is trying to mislead people about how defrost in Prime works. The physical dedicated button on the dashboard is the MAX button to make the maximum defrost mode engage. The hope is you'll assume that's the only defrost available, since it forces the gas engine to start. The regular defrost does not. That's why it is located in with all the other electric-only options. Featuring it on the screen among the climate-control settings does make it easier to overlook. Antagonists hope you won't discover that. It's why they get so angry and lash out when I bring that to the attention of everyone reading the discussion. Then of course, I get accused of lying or not understanding. It's quite pathetic how desperate some have become. Being so dishonest without any care is quite a stance to take. You really don't expect that. But they'll do anything to misrepresent Prime. Being deceptive to lead them to believe the engine must run to keep the windshield clear when it is cold or damp out is now something I'm seeing more and more of... especially now that it is getting to warm out to need that electric-only feature. That goodness I filmed a bunch of EV video during the Winter.
- 3-22-2018 Collapse.** The restart of that old blog with a new set of writers and a uncertain purpose is bringing out all kinds of upset: *"I guess if GM doesn't want to sell to me in the future (I own a Volt and a Bolt) then Tesla or a foreign company can have my next purchase. Nice going, GM."* I can't imagine how much of a wake-up call it is reading that on a venue I don't participate. It's my message of missed opportunity conveyed by others. They enthusiasts did everything they possibly could to shut me up, claiming what I said was meaningless. Now, new voices are sounding off with the very same sentiment. Engineering expertise was wasted. Being years ahead only stands true if progress continues. Ironically, the accusation of resting on laurels about Toyota turned out to be the case for GM instead. I knew it would. The corporate approach hadn't changed. Management was still focusing on easy profit... which trapped Volt as a niche. Enthusiasts denied that could ever happening, choosing to be carelessly optimistic. That hope has been crushed. We are now witnessing the collapse.

- 3-23-2018** **Getting Worse.** That same message of disinterest keeps getting repeated: "*GM has been hedging its bets with the Volt and Bolt, but are not willing to lead the industry by putting EV tech throughout their product range.*" I pushed and pushed for diversity. It started simple, by just suggesting a second model of Volt. The enthusiasts absolutely freaked out. Fearing the worse, they sighted claims of trying to kill Volt entirely by diluting the design with a second model offering a smaller battery-pack. They were so insecure, that just plain was unacceptable. Nothing convinced them of sincere intent. Mistrust of the supposed competition blinded them to the actual enemy. Opening their minds to other automaker supporters for the sake of promoting plug-in vehicles as a whole was impossible. GM was vastly superior, period. They were blinded by hate of the past, preventing them from achieving a new future. They dug their own grave. That's why I blogged so much about that past, as it was unfolding. I knew that present would someday become an unfortunate part of their history, by their own choosing. And sure enough, each worsening post is confirming that foresight.
- 3-24-2018** **Expectations.** Fortune does not favor the foolish. Assumptions can be costly. The enthusiasts who blindly followed without doing any research are now feeling remorse: "*After buying my 2014 Volt, I was so impressed with the technology that I assumed that I would soon be replacing my Subaru Outback with a GM PHEV SUV. GM has proven that they are not all in with EV drive.*" Their problem came from study of only the engineering. That's an easy mistake to make. They believed the effort put forth by GM was to be an on-going investment, one of many steps forward. That's why whenever I brought up Two-Mode, its history was immediately dismissed. Enthusiasts felt it had no relevance to what was happening now. They were wrong, very wrong. I recognized the pattern and was shunned for it. They attacked relentlessly, claiming my true purpose was to undermine GM's efforts. Sadly, I have been vindicated. That pattern was indeed playing out. It has been confirmed that the effort with Volt fizzled. GM hasn't shown interest. There's nothing to expect anymore. True, something will eventually emerge. But the hope of leading is gone.
- 3-25-2018** **Speed, part 1.** People obsess with it. We've been brainwashed into thinking faster is better, even though need was exceeded years ago. Marketing caters to want, selling you more power than you'll ever actually need. They focus on rare circumstances, trying to portray them as normal. Others will present the situation as if you are in grave danger if you don't have that. It's a game that is ultimately lost. We've seen that payout with computers. Faster was no longer the most important priority. That's how laptop computers transformed into tablets, pads, and phones. Speed simply wasn't a selling point anymore. We're not quite there with cars yet, but mighty close. That means you still need to play the game a little. So, when the topic of "fastest" came up again, I chimed in to answer that question: Prime is governed at 103 mph. I tried it out on a lonely highway in South Dakota. I also tried it with the PHV. It is governed at 104 mph... which are both worthless trivia. Knowing you can sustain a cruise at 80 mph for 2 hours non-stop and achieve MPG in the upper 40's is information of true importance.

- 3-25-2018** **Speed, part 2.** To my surprise, there was quite a bit of positive feedback to my post. This comment added some dimension to the discussion: "*I got tired of people asking me if the car could keep up with traffic on the freeway...*" Bringing a little history perspective into the topic was an unexpected plus. So, I added so more to find out just how constructive we could get: It was amazing (and quite annoying) how widespread the power misconception was. People genuinely thought electric motors wouldn't have enough power for freeway speed. My guess was household rechargeable batteries of the time were weak. So, they just assumed automotive-grade would be too. Of course, there are some who... still to this day... trying to undermine Prius by spreading FUD like that.
- 3-26-2018** **The Other Shoe.** Former enthusiasts continue to sound off: "*Yet another sign GM just doesn't care about EREVs anymore...*" This came from the fight GM's CEO has engaged in against the state of California, pushing for those standards to be lowered. She wants requirements for fuel-efficiency to be reduced, eliminating that increase the previous administration had targeted. Rollback & Elimination of improvement goals is sickening. When you know the technology is realistic, why fight against using it? This is especially concerning with the knowledge of just how much damage to the environment will happen as a result. But even worse, it's handing over opportunity to others. Rather than engaging automakers producing vehicles here in the United States, they turn a blind-eye to the doors the resistance opens elsewhere. It's not like the rest of the world will ignore climate-change or oil-dependency. Only we will. Allowing them to develop & refine technologies while we remain back in the past is economic suicide. Why would anyone sacrifice so much just to retain the status quo? Turns out, GM is willing to throw away what they had worked toward. Today, we found out Terrain will get a diesel option too, adding to the non-pickup choices from GM. Ugh. Seeing Cruze & Equinox offered that way was bad enough. But we all know Two-Mode was supposed to be the efficiency choice for GM's future, offered as a hybrid and a plug-in hybrid. Instead, the choice has become diesel. There's nothing to deny anymore. That other shoe has dropped.
- 3-26-2018** **More Generalizations.** It's too easy to jump on the same bandwagon: "*Toyota, Subaru and a few others are quite behind the curve...*" This time, it was a poster on a blog who seemed to not give any thought to what was actually posted. He just made the claim with nothing but an anecdotal observation. That's unfortunate. But maybe it is possible to get a change from pushing back with more than just a gentle nudge: Reality is, Toyota produces 1.5 Million hybrids per year now... each with an electric-motor & battery-pack. No amount of rhetoric can conceal that production shift. The foundation is being laid by getting dealer & consumer to abandon traditional vehicles. That first step is the hardest. Each purchase after that is far less intimidating. It's unfortunate you perceived them as behind, since they clearly are not... and you have been informed why.

3-26-2018 **Video: Early Spring - Bike Trail (To).**

On a gloomy Spring day, when the sky is gray and the temperature still chilly, thoughts of going to your favorite bike trail dominate your mind. That opportunity to actually use it is still a month away, but driving to that scenic location to capture valuable data on video could happen right away.

If the 4K camera didn't overheat, I would be able to share round-trip footage of that entire trip. With the variety of conditions... country road, open highway, extreme hills, and a climb in & out of the valley... it would be quite a scenic drive. So, I gave it a try. Here are the results:

TO: 31.1 miles / 104.2 MPG = 0.298 gallons

FROM: 31.2 miles / 79.3 MPG = 0.393 gallons

OVERALL: 62.3 miles / 0.691 gallons = 90.2 MPG

The advice given to Prius Prime owners is to save EV driving (plug-supplied electricity from the battery-pack) for non-highway driving. With the variety on this trip, that was an easy thing to do. Watch the "*EV Mode*" indicator. Also, what what happens on the crazy up & down of those hills and the effect that valley where the trail is located.

On those glorious days of Summer, I hope to get down there for actual biking. Who knows if I'll be able to capture that drive. There will be hours delay before the drive back too. Efficiency from the warmer weather is much better too. Nonetheless, the results of this particular round-trip provide ample real-world data to consider.

Hope you enjoy watching it... [Early Spring - Bike Trail \(To\)](#)

3-26-2018 Video: Early Spring - Bike Trail (From). To my delight... and relief... the video in both directions turned out. Being able to document the entire drive was important. But with technical obstacles, you just never know. Opportunities to try again if something doesn't work are few and far between. I got lucky with this. It was my first vacation day of the year, where I figured there would be a little relaxation time between household tasks I still needed to do. Rather than go out for a coffee to blog, I setup camera and hoped for the best. It paid off too. I think being able to refer to this footage later will come in really handy. Detail at this level is hard to come by. That's how the rhetoric is able to persist. It goes on and on if you don't have anything but hearsay to counter with. This is video with multiple feeds... 4K driving location & conditions, dashboard gauge information, and data from an OBD-II reader... all assembled into a convenient link that's easy to share. Yeah! Too bad I didn't have such a powerful resource at my disposal in the past. That sure would have made the online combat a whole lot easier to fight. Here's part 2, the drive back home... [Early Spring - Bike Trail \(From\)](#)

3-27-2018 Leadership, intent. Figuring if someone is poorly informed or if they simply are trying to mislead is very difficult. Take this example: *"There's a huge difference between a hybrid like the Prius and a 100% battery electric vehicle. While other auto companies have been working on architectures, drive and power systems for some time, Toyota has been focused on Fuel Cell which for a manufacturer is much closer to ICE than a BEV is. Unless Toyota have a quite large group hidden somewhere working on this then they are a considerable ways behind the rest of the industry."* Did the just succumb to the hydrogen rhetoric or are they completely clueless about how Prius actually operates? It's very hard to tell and you don't want to offend someone who is just naive. There are a lot of people passionate to improving emissions & consumption that have no idea how any of the technology works. Some don't have any engineering background whatsoever. This may even be there first encounter with anything beyond just plugging in their phone. There's a lot of incorrect assumptions you can make with such lack of education. Oh well, sometimes you never find out the true intent is. But at least I know Toyota is doing far more than this person was aware of: That's interesting. I didn't think there were any newbies on this site, still unaware of Prius Prime. That model offers full EV. You can accelerate up to 84 mph and sustain that speed using only electricity. It offers an electric-heater more advanced than Volt. In Japan, you can even get a CHAdEMO connection for fast charging and a solar-roof for green charging. I'm approaching the 1st anniversary with mine. 16,100 miles so far, with 2 trips over 1,700 miles mostly driven at 80 mph. Despite that, along with a Minnesota winter, I have a lifetime average of 101.7 MPG. In short, that claim about Toyota not being focused on delivering EV is quite incorrect. They have been refining design & production of motor & battery all along, you just hadn't noticed yet.

3-27-2018 Leadership, change. I got the impression from this that the person simply has no engineering background: *"Prime simply adds a plug to a hybrid. Good that they did but this is still a totally different animal than a 100% BEV built from the ground up to be a BEV."* Reading other posts, the vague nature of those claims seemed to confirm that too. It's strange to think some people have no idea how certain advancements come about. It's like they are totally unaware of the upgrade process, assuming a new product comes out of nothing and it an immediate success. Those are the same type of people who think a singer with a #1 hit had incredible talent, that their 20 years of refinement singing in dumping venues to get to that position never happened. The odds of an overnight sensation are virtually impossible. Reality doesn't favor luck. You have to work very hard to succeed. This type of extreme thinking is why change is so difficult. The status quo always has a large group fighting to retain that stability, fighting change any way they can. It's starts simple, like when an definition is altered, then you just keep telling yourself nothing actually changed. I dealt with that denial all the time: Nope, that's just semantics, easily disproven by Honda Clarity and Hyundai Ioniq. Both are offered as EV, despite also having a model with an engine. The body used for that is not relevant to the production & sale of the vehicle. Consumers will get an electric-only driving experience regardless. So what if the electric-only is short-range? You still get the full EV driving experience. I routinely see 0 RPM on the tachometer for the engine on my entire commute.

3-27-2018 Leadership, failure. How someone handles the failure of others is a sign of leadership too. Toyota can't do it alone. Neither can Tesla. Whomever it may be pushing to draw in a new audience, there will always be a point to which they realize doing it alone is impossible. GM never had an market for their small hatchback or their small wagon. Those plug-in vehicles were clearly design to appeal to outside buyers, to score conquest sales. Their own customer base didn't change. Those same owners of old traditional GM vehicles will replace them with new traditional GM vehicles. Status quo remained the same. That's not leadership. Recognizing that and providing the means to change is. We are witnessing Toyota and Tesla do exactly that. Hyundai and Nissan are standing strong immediately behind them. It's a team effort. Breaking ground isn't the only task required; yet, it is the only which gets deemed leadership. The idea of each doing their own part to fulfill their own need to a concept beyond the grasp of the simple-minded. Each automaker must excel in its own way. GM's obsession with Pickups & SUVs meant it should have focused on Pickups & SUVs. After all, that's what Two-Mode was all about. We didn't like that obsession. But it was obvious from the start the effort to develop Volt did not have a sincere goal of changing their customers. There was a trophy-mentality right at the beginning of it all. It was doomed to fail as a result. There's no benefit from "*I told you so*" now either; however, that history does reinforce audience. Leading means understanding who you intent to lead.

3-27-2018 Leadership, semantics. It only took a few more comments being posted before he backed himself into a corner. The lashing out and belittling of Toyota came about from the Fuel-Cell investment. There are some who only want purity, a single choice for all. The idea of diversity is unacceptable. That one-size-fits-all belief is clearly alive & well still. So, anything that Toyota did was a step in the wrong direction, regardless of what it actually was. The example his sighted as where Toyota went astray was with RAV4. That EV was the solution... abandoned, in his mind. Only problem, his argument took on the purity requirement. The vehicle had to be built for the sole purpose of being an EV. No conversion of any type was acceptable. Oops! He contradicted himself. I jumped in by pointing out that neither Honda Clarity nor Hyundai Ioniq would be acceptable based on his criteria either, despite both being pure EV. Having a counterpart of any sort meant the automaker was really trying, it was an after-the-fact hack. Catch is, that has been proven untrue. Prius had EV ability way back in 2003. That's where the 100 km/h ability originated. But without enough battery to support that, the ability was never exploited. The tech back then was far too expensive, with energy-density far too low. So, we had to wait. The design was already in place for electric-only travel, hence the low speed & power ability Prius did deliver in the meantime.

3-27-2018 **Risk & Spin.** There are a lot of people online who are poorly informed, which results in their posts contributing to spin. It gets so bad sometimes, they become antagonists by pushing their incorrect perceptions so hard. That's quite remarkable to discover after having fought with someone so hard only to later discover what bit of information it was that they were not aware of. My hunch is this is one such example: *"Toyota is like Ford. They were on a path to be competitive in the future, then they decided they'd rather fall behind and risk destroying the company."* Lacking any type of economic, accounting, or marketing background makes such a statement easy to feel passionate about. Destroy? How? Pushing a product likely not capable of sustained high-volume profitable sales may look impressive from the autoshow presentation, but that isn't at all what a dealer will support. They couldn't care less about the engineering achievement. That business uncertainty is far too deep of a concern to take on the risk. So, they don't. They seek a more realistic solution instead. I put it this way: Changing their base from traditional to hybrid is a path to the future, one far more realistic than getting people to jump straight to EV. Think about how simple offering a plug-in model to the mix will be with the hybrid selling well. Remember, the true competition is their own traditional vehicles. In other words, you're not looking at the big picture for EV sales. The heavy dependence on tax-credits limits them to early adopters. Reaching the masses is far more difficult.

3-27-2018 **Lost Meaning.** What is leadership? Some don't put any thought into how change is actually achieved. There's an over-simplification. I see it a lot. This was an especially annoying stir. Having to face it, yet again: *"No Plug, No Sale."* When a slogan loses its meaning, you have a very real problem to deal with. The mantra becomes a disconnect. They say it, but don't understand its purpose. For that matter, you usually can't even get the person saying it to explain their own intent. The devil is in the detail. Ask for it. Most of the time, that ends the discussion. They really don't know. In this case, I followed up with this perspective: NPNS is itself antique. It's so vague, there's no value. Meaningful comment come from specifying detail, like price or range. The variety of offerings a plug can provide makes understanding goals vital. In this case, a worthy hybrid offering sours appeal for transitional models and paves the way for plugs. Again, the most difficult step is the one away from transitional. Going from hybrid to plug-in hybrid is much easier.

- 3-27-2018** **Perception.** The idea of what leadership can be continues to suffer from the simple-minded, those believing only one path to success exists. Ugh. RAV4 provided a great example of that today. Toyota revealed the next-gen upgrade today. A number of plug-in supporters threw a fit, complaining about how Toyota isn't investing in EV production. Naturally, they turn to fuel-cell advancement as the primary argument. It's amazing how that lack of support for diversity blinds them to all the work being done to replace traditional choices. They couldn't care less about hybrid, despite that being such an obvious big step away from guzzling. That NPNS mantra overwhelms logic. They only perceive progress by a measure of how far EV capacity reaches. Change for ordinary people not needing or even wanting such range is not of any concern for them. That's really unfortunate. It's how we got into the SUV mess in the first place. If people in general actually cared about wasting resources, they certainly wouldn't have chosen that vehicle type. But they did. And rather than face that reality, they turn a blind eye and place judgement against Toyota for actually addressing it. Ugh. What can you do other than point out what's happening? I try: Notice how many SUVs are sold by GM; yet, there is still nothing beyond the traditional choice? No plug-in. No hybrid. What expectation should be set for an automaker with a perceived lead, but nothing actually revealed for their primary customer?
- 3-27-2018** **Cost Effective.** Lack of business understanding often leads to over-simplification. How to best deal with that continues to be a mystery. It's challenging to get someone to recognize something they have been overlooking for years. That's what makes exchanges online turn into intense debates which ultimately can lead to hate. They just don't believe you. Without training in the topic, it's nearly impossible to convey the idea. Then when you consider the brevity of posts in forums & blogs, the odds of getting someone to see beyond their own exposure falls apart. It's pretty much futile. This is why concepts like being cost effective fall on deaf ears. They see a niche effort and give far more praise than it actually earned. That's why they insult & offend those that don't make advancement obvious. Those efforts behind the scenes aren't ever given credit. Only what's showcased is acknowledged. Appreciation for the complex doesn't happen. It's a sad reality. They judge the book by its cover and don't see the value in anything else. So, a rebuttal like this is basically a waste: Scaling up existing production is quite different from not producing at all. Any type of plug-in requires motor, battery, controller, and charger parts to be built. Refining that process prior to scaling up is time & effort well spent.

3-28-2018 **Meritless.** The title of this article sure caught my attention: "*Hyundai IONIQ Leaves the Prius in the Dust.*" To what was that referring? The opening line made me even more curious: "*Hyundai's extended-range hybrid proves the automaker knows more about EV technology than Toyota does.*" Huh? I was really baffled at that point. Knowing the source, it was promising to be a good read. That was posted on the Volt forum, since that old blog is totally dead now. The supposed new daily topics never happened. Perhaps the interval will change to something like once per week. Whatever the case, that group of individuals would surely tear that new fodder to shreds. So, I read the article before reading their comments. Nothing. There was literally nothing of any substance. It lacked any type of merit whatsoever. The detail seemed to be a strange mismatch of specs. It was quite confused. How should such a bold statement lead to such nothingness? Turns out, that article was written over 2 years ago... prior to rollout. The writer was just guessing and totally mixed up information. The comments posted were just as confused. Their lack of any unified message was obvious. Still, after all this time, they have nothing to fend off Prius with... even when dragging another automaker into the discussion.

3-28-2018 **New Combat, Old Foe.** The death of the Volt blog has caused some to migrate, looking to resume their antagonist trolling elsewhere. Oddly, they don't even try to blend in. Their provokes are blatant. So, I'm left with the quandry of how to respond. What worked best in the past was direct confrontation in the form of a question. Today, it was attacking Toyota for not having rolled out an EV yet. The fact that the other automakers, including GM, have all announced plans that are 18 to 24 months out doesn't matter. The fact that Toyota has been investing heavily to shift from traditional to hybrid doesn't matter. The fact that there's still a heavy dependency by the supposed leaders on tax-credit subsidies doesn't matter. All they care about is making Toyota appear behind. It's just like using me as a scapegoat. If they can direct attention away from their own problems, it makes them feel better. What a shallow & selfish attitude. It doesn't matter to that. Winning new combat of any sort, especially with an old foe, is considered a victory. Ugh. I kept my reply to that nonsense short: What do you suggest for quickly phasing out traditional vehicles on the grand scale? Think about the effort needed to first spread TNGA (Toyota New Global Architecture) in order to achieve the lower cost, higher volume potential.

3-28-2018 **Timing.** The poorly informed... or limited perspective... are not just antagonists. Some are supporters who don't bother to study the whole situation. They prefer just their own little corner of the world. Interestingly, they do reach out sometimes: "*So how many states is prime currently carried in?*" Asking questions is an encouraging sign. Of course, I don't know how that information will be interpreted. Nonetheless, I shared the knowledge:

2017 model-year cutover prevented the initial spread from growing. You don't send new inventory to dealers at clearance time.

2018 model-year rollout is impaired by the usual winter sales doldrums. You don't send new inventory until spring arrives.

It's all normal business. Profit is not made with unpredictable deliveries.

Keep in mind the first-year rollout was worldwide. Toyota delivered 51,000 spread across several major markets all at the same time.

3-28-2018 **Audience.** It continues to be quite a challenge trying to figure out if someone is sincere or not. When there is a person who hides behind an avatar, there really isn't any reason to trust them nowadays. That's why so many of the blogging sites have switched over to account signon. It doesn't matter which of the providers you choose for handling your posting activity. The point is to supply readers with background information about you and a means of following your comments. That accountability is priceless. It raises the integrity of the site as well as reinforce rules of etiquette. You simply cannot hide behind anonymity anymore without that effort looking suspicious. That's why when things like audience are brought up, it doesn't make sense that someone you see posting on a regular basis wouldn't understand what you are talking about. How many times can the same message be repeated? It's ok to call them out. The internet no longer finds deception, misleading, or concealment acceptable. Even so, I still try to be polite: Wow, you haven't been paying attention. Knowing your audience is all about consumer, dealer, and automaker relations.

3-29-2018 **Banning PHEVs.** The first city in the nation to ban plug-in hybrids from public chargers just made the news today. They only want EVs to recharge. If the vehicle has an engine for when the battery-pack is depleted, they feel it should be used. That counters exactly what we've been trying to promote. Even a short-range PHEV can drive entirely without gas if given the opportunity to recharge along the way. Why should a vehicle with greater capacity be allowed priority, especially if it isn't even going to be driven that far? Who should be making such an arbitrary choice? Absolutes like that are trouble. Worse though is that reality that true supporters of plugging in have failed to address this... despite knowing that diversity is key to market growth. Ugh. I jumped into the very active discussion today with:

I see a lot of complaints about vehicles with slow charging rates. I also see them about small battery-capacity. Notice how no one wants to address the next stage in being green?

Some plug-ins guzzle electricity. It's a very real problem when you step back to consider the bigger picture, when many are waiting to charge and time is limited. Why should those that waste be given priority to recharge?

31 kWh/100mi = 25 kWh/100mi

That equation is detail revealing the problem, because those electricity consumption-rates can make a big difference. They are not equal. Taking more to travel the same distance becomes an even worse problem when you consider the next person in line waiting to plug in.

This is why EVs are great for us enthusiasts, but still not quite ready for people still quite content with traditional vehicles. We need to work out these issues before they give a plug-in purchase some consideration.

3-29-2018 **It's Over.** They certainly are trying. The EV blog posted a review on Prius Prime and the troublemakers immediately emerged to do their best to undermine. I didn't bite. There's no reason to even bother. Volt is withering on the vine now, without any clear purpose anymore and subsidies about to fade away. It's really unfortunate the tech wasn't diversified. So much for the supposed leadership. Anywho, unwilling to play their game, I posted: Reading those same old attempts to degrade & belittle plug-in Prius over the years has been quite interesting. It's an exercise in futility. They don't understand the audience. As enthusiasts, they feel necessity for range & speed, placing that as a very high purchase priority. Ordinary consumers don't. They just want a well-rounded vehicle... reliable, affordable, with a nice mix of features. Toyota recognizes this and strived to deliver exactly that. They targeted mainstream consumers, as they clearly stated during the rollout. The couple looking to replace their older Prius and no longer have the young children have a compelling choice. You don't like Prius Prime, just wait for the other plug-in hybrids. There are a number which could also offer a Prime model. This isn't rocket science. It's an expected step forward in the phaseout of traditional vehicles.

- 3-30-2018** **Almost 1 Year.** Ownership in all 4 seasons, which are quite pronounced here in Minnesota, is almost complete. 1 day left until its first year anniversary. 16,292 miles on my Prime so far. 102.6 MPG average, which includes the nasty cold in this northern state and 2 trips to Wyoming each over 1,700 miles (mostly 80 mph travel and no plugging in). That's a solid real-world result, an easy to understand step-up from regular hybrids in an affordable package. We are at the threshold of that paradigm-shift becoming noticeable. The technology for plugging in is well proven. This next stage is delivering affordability. Toyota is pushing that message hard... and taking a lot of flack for it, from early-adopters with no concern for tax-credit dependency. Fortunately, we have Hyundai coming in close behind with their own affordable offerings. That endorsement is vital. You need choices in the market all sending the same message. That's why there was so much hostility coming from the GM crowd. We witnessed 7 full years of their don't-give-a-crap attitude toward affordability. There was much talk about cost-reduction, but none of that translated to a sticker-price appealing to ordinary consumers. So, it's up to those like me already driving the solution to share their experiences. Being able to report such remarkable results after a full year of ownership is very exciting. Hooray!
- 3-31-2018** **Daily Dump.** The death of that daily blog has been a severe blow to antagonists. They had a venue to dump their rhetoric daily. Every morning there was excitement about the opportunity to refine propaganda material. Then at the end of the day, the thread would be abandoned. It was a seemingly endless cycle of undermine training... which finally came to an end. Hey, when you don't have a product capable of speaking for itself, you speak ill of the supposed competition. Quite a bit of hate emerged from those Volt enthusiasts. Thank goodness their collapse emerged from within... exactly what I warned them about for years. GM struggled with internal conflict prior to the bankruptcy. Seeing signs of that approach still existing afterward should have been taken seriously; instead, their mindset was to pretend all was going to be just fine. That fundamental mistake has cost them dearly. Bolt represents the ultimate antithesis to Volt. That's left them completely defenseless. Their own beloved GM turned on them. All that anti-EV campaigning forgotten for what? Volt seems to be abandoned entirely. No message of the technology being used elsewhere has emerged. Bolt appears to be leading the way to an all-electric future, one where the idea of "*range anxiety*" is solved by just having a larger battery. It's so hypocritical, the enthusiasts are at a complete loss about what to do next. There are no steps forward. It's a dead-end they got to on their own with all that AER propaganda. All-Electric-Range was self-deprecating. Oops!

- 4-01-2018** **Easter Egg.** Since today is April Fool's Day, Easter Sunday, and my 1st Anniversary with the Prime, I've been hoping for some type of surprise. I got one too. It's not mind-boggling. It's actually rather obvious. I hadn't ever given it any thought though. The HD radio has a 15-minute buffer. Being digital, that makes sense. You get the ability to rewind or pause what you are listening to. Since I rarely ever get calls on my phone, the idea of that feature applying to it hadn't crossed my mind. Today though, I witness it firsthand. The radio suddenly went quiet, a pause symbol appeared on the screen, then I heard the phone ringer. I answered (pulling over on the residential street was easy) that call, then hang up when done... all using the buttons on the steering-wheel. When the connection ended, the radio automatically resumed exactly where it had stopped. I pulled up buffer info on the screen. Sure enough, it was just like when you pause a DVR. I could pick up exactly when I left or jump ahead back to the live broadcast. Sweet. I'll count that as a "easter egg", since the feature would be something you'd need to hunt for. It's a stumble-across ability, rather than being an obvious benefit.
- 4-02-2018** **EPA Rollback.** I'm seeing a look of advertisements now for Terrain. That's the next size larger SUV from GM than Equinox. It's a beast, yet they are presenting it as an everyday vehicle. The next size larger than that is the Suburban... which delivers a combined estimate of 18 MPG. Labeled as a "*family hauler*", there's no doubt of the obsession with size & power. The minivan and van are dead, family haulers long forgotten. Brainwashed into thinking a 355-horsepower 8-cylinder engine is necessary explains why the EPA finds the idea of rolling back the efficiency mandate so easy. Who is going to oppose when such a large voice in the industry is praising giant guzzlers? We are slipping back to conditions over a decade ago, back when few cared about oil dependency or clean air. It is sickening to find out some people just plain don't care. This is why I was so hard on the Volt enthusiasts. They were naive, they argued with hostility claiming this could never happen. Yet, here we are... facing several enemies so selfish, they couldn't care less what our children inherit. Even though we had the technology to prevent financial, political, and environmental struggle, we chose not to use it. Ugh.

4-02-2018 **Lost Now.** Those antagonists from the dead daily blog have no where to congregate anymore. Each is trying to stir trouble on new venues. It's not going well either. We're calling those efforts out. For example: *"battery technology moved, today's is cheaper to have a big pack of low-cost low-power cells than a smaller pack of fast charging cell"* It was an attack on Prime. They despise the idea of sharing public-chargers... knowing benefit is greater the smaller the size of the battery-pack. That gain from a short recharge while stopped at the grocery store is greater for Prime. In just 10 minutes, I can get from my local shopping lot to home entirely on electricity from time I was there. Efforts of those enthusiasts-gone-bad were to never arrive anywhere without electricity available... making the gain from recharging far less than what Prime would experience. Again, this is more self-deprecation they are now suffering from. They shot themselves in the foot with their choice of how to promote Volt. Big Oops! Oh well. Too late now. Being dishonest about the circumstances only makes it worse. I called him out on it too:

Without actual data, there's no reason to believe that claim. The devil is in the detail. There are tradeoffs, not a single factor to making the decision. For example, that claim of *"with at least 40 miles of range like the Gen 1"* was very misleading with so much detail excluded...

2011 = 35
2012 = 35
2013 = 38
2014 = 38
2015 = 38

Notice how none of the model-years ever actually delivered 40-mile ratings. During the warm months, 40 could indeed have been delivered. But in winter, not even close... and heater type makes difference, a factor not mentioned anywhere.

Notice how vague GM's statement is? They thrive on ambiguity, releasing information that really doesn't tell you anything specific.

In other words, read with care and look for what's missing.

4-03-2018 **Sales.** As expected, the fade away of the Winter doldrums has resulted in a climb for all. Prius Prime did especially well, despite the fact that inventory is almost exclusively limited to remaining 2017 models in the half of the country rollout reached last year. Soon, we should be seeing new inventory elsewhere. That means the potential goes up significantly... while we see the enigma known as Volt. What GM intends to do next is a complete mystery. We just got word that sales results will only be posted quarterly now, rather than monthly. That's quite a change for an automaker which thrived on those numbers, feeding the stockholders with hopes of profit dividends. But with Volt only selling at the volume it sustained back when gen-1 was struggling, there's little hope for gen-2. All those improvements didn't lead to the much needed growth, prior to tax-credit phaseout. We all know the situation will become far worse when that generous subsidy vanishes. The guess is Volt will too. After all, GM other message today was that Sonic production will end and Impala is likely to be phased out too. The preference of GM to only sell Pickups & SUVs is rather blatant now. That puts Bolt in a very awkward position. It also puts Toyota in a interesting situation. They can exploit that American desire by pushing the hybrid RAV4 even more. That sets the stage quite nicely for a Prime model. Anywho, we see the Prius with the plug doing well with a very encouraging outlook. 2,922 for the month of March was great. The 4,128 for RAV4 was impressive too. (4,064 for the regular model Prius.) But what really stands out is the non-hybrid model of RAV with 34,937. It's an incredible volume, especially with Camry drawing 35,264 at the same time. 31,392 for Corolla is nothing to overlook either. It puts some perspective on the challenge still faced for mainstream acceptance of anything other than traditional choices.

4-03-2018 **Overdue.** The end is being ratified by former enthusiasts: *"GM definitely needs a Volt-based PHEV in the lineup. Either replacing the Volt outright or offered along side. Chevy Trax, Equinox sales numbers were the best they've ever been last month. Even taking a small slice of those sales with a CUV/SUV Voltec vehicle would immediately launch it to the top of the EV sales board."* Their disappointment is obvious. That nasty Prius owner who kept sounding off concerns about time wasted and opportunity missed has been overwhelmingly vindicated. It's really unfortunate they fought the wrong battles. Losing the war as a result hurts. I don't feel bad. The hell they put me through... and I ended up being correct. All along, I kept saying diversity is was necessary. They feared that would dilute the message, impeding any progress that could be made. Talking about learning the hard way. There is still a glimmer of hope. All is not entirely lost. Though, it is a new war they must fight now. The early-adopter audience is gone. This new audience consisting of mainstream consumers is far more difficult to sway... especially when there won't be a tax-credit available. There are major challenges to still overcome as a result of past mistakes. Oh well. All I can do at this point is agree with their sentiment: Yup. Offering something in CUV/SUV format will draw upon a large potential market. The idea that there's a market for a compact hatchback still, especially with the upcoming tax-credit phaseout, is futile. Everyone who wanted one got one. There's nothing left to prove for the technology. With the obvious demand for Outlander and seeing the potential with Niro, it is time for GM to focus on mainstream shoppers. A larger vehicle is overdue.

- 4-04-2018 Perception.** It's a powerful element. Used for undermining, it can tell a story of struggle & loss. Used for promoting, it can convey a sense of hope. What ultimately gains attention is the presentation of detail. For example: *"For how well Toyota generally designs things, adding a battery here seems like a total after thought. I need to be able to throw a bike or dog crate in back there."* In this case, that doesn't even need to be numeric measure. Numbers aren't always necessary. Sometimes, all you have to do is present more facts. For the reply to this, I just supplied more information by sighting what others can easily observe... if they take the time. Give it a try by simply posting what hasn't been discussed. Remember, perception can be altered by excluding detail. See: That's just online spin. They don't want you to recognize the possibility of an upgrade for this current generation. We know with certainty the approach was cost-savings, to provide a robust battery sooner that it would take for the next round of chemistry updates to be delivered. Like with several other plug-ins, it is realistic to rollout an improvement mid-cycle. As for throwing in a bike, you can. There's plenty of room. And for dog crates, a medium would fit fine in the area where the seats fold down. You need bigger, you buy the bigger Prius or RAV4 when it is later offered with a plug. Heck, the C-HR could work too. In other words, there's no reason to portray this first offering as an end-all-be-all solution.
- 4-04-2018 Slow & Small.** It didn't work. That line of argument failed to reach beyond that of early adopters. Yet, some enthusiasts keep trying: *"The slow as molasses and small battery factors have been my major issues with the PP. Wish Toyota would get more serious about PHEVs/EVs."* I wonder how much longer that will continue. There is no audience left for that anymore. The active discussion venues have very different priorities. History is on the side of mainstream consumers too. It's very easy to dismissed efforts which failed to reach them, especially after so many years of trying. I fired back at that nonsense with: Toyota is much more serious than the spin using *"slow & small"* as an excuse. Unlike GM, they took COST very seriously, building a flexible platform that could offer a PRICE low enough to compete directly with the true competition... traditional vehicles ...even without a tax-credit. Of course, anyone paying attention knows that size & power was never the key to success for Prius anyway.
- 4-04-2018 Cannibal.** They keep trying. When one topic fails to stir interest, they try another. Now, it's the attempt to portray Toyota's transition from hybrid to plug-in hybrid as an accidental oversight... which makes sense to them, since the claim of Bolt replacing Volt is the narrative they are now telling. That doesn't make any sense though. Why would GM simultaneously develop gen-2 Volt and their gen-2 EV at the same time? That's a huge waste of resources, one that cannot be addressed without being hypocritical. So, they try to divert attention. Ugh. It would actually make sense if that next-gen Voltec had been on a platform GM's own customers would be interested in... like a small SUV. It wasn't though. The same conquest audience had been targeted instead. Again, what a waste. At least Bolt offered a tall rear-seating area.... like a small SUV. Anywho, it should be easy to see how Toyota will be able to offer a Prime model of Camry and RAV4. Both are strong hybrid contenders with lots of potential for supporting a plug. That's progress, not cannibalism. Oh well. They can relish in their fictitious victory. I'll keep asking why their claims don't support what we are actually seeing: Planned progression is not *"cannibal"*, since offering a plug is the next logical step. That's quite a contrast to GM, where Bolt is the antithesis of Volt. Remember all the *"range anxiety"* promotion?

- 4-04-2018** **Losing Money.** I was delighted to see this called out: "*They sell it at a loss...*" That nasty antagonist constantly trying to mislead about Toyota continues with his meritless claims. Others are taking notice: "*Do you have evidence as to your assertions or are you just blowing smoke as to Toyota?*" Knowing how dishonest he has been in the past, it's obvious he doesn't have any evidence. It's nothing but a desperate act of repeating the same claim over and over again until it is accepted as the truth. When people continue to hear the same message, they tend to not question it. That's how you normalize an extreme. It works with dishonesty too. That's all it really takes to mislead when the venue is loaded with enablers. Of course, all it takes is a few to question credibility of the statement itself. You can talk about that antagonist in the third-person for extra emphasis. I did too: After being asked countless times over the past few months, he obviously has no evidence. In fact, he hasn't even bothered to provide any reasoning as to why you'd even doubt profit. Toyota produced and sold 51,000 Prime worldwide last year. Most of the inner working are the same as the regular model of Prius. Basically, just swap batteries and add a clutch & charger.
- 4-04-2018** **Competition.** Rewriting of history usually takes place when the person disliking that reality chooses to misrepresent it with an alternative of their own. They seem somewhat credible by twisting facts and omitting vital detail. In this case though, it was just flat out dismissal: "*The original Prius never had any real competition...*" That complete absence of any effort at all to even try was good reason to punch back hard without any interest in rebuttal... which I was delighted to do: That's a load of garbage. Competition against Prius was intense. There's was what became dieselgate, efforts to mislead about Prius by promoting diesel through dishonest means, on one side. On the other, there was GM with it's anti-hybrid campaign pushing Hummer with the backing of a \$10,000 tax-credit. Nothing in support of battery or motor propulsion had been proven yet either.
- 4-04-2018** **Just In Case.** The double-standard from an antagonist now disenfranchised: "*It really feels like GM wants to have enough experience that if a rival suddenly starts building an EV in large numbers and starts to take market share from GM, then GM will build a car that people really want.*" Seeing the same of Toyota is impossible for them, even though we see that effort being pushed even harder. Knowledge of how Toyota architected powertrains based on TNGA and is pushing hard to get that deployed throughout the fleet, it should be obvious. That lowers cost across the board and refreshes virtually all of the high-volume offerings. Combined with the experienced being gained from Prime/PHV advancement, there shouldn't be any conclusion draw other than it be preparation to start building large numbers. Yet, that is what we are dealing with still. Their stance is remarkable; however, it is not surprising. They've always had the choice of what to accept. Seeing this attitude shift is confirmation of that. Rather than actually achieve mainstream sales as long promised, they are preparing to do so. That is a recognition of problem they had previously denied. Claiming a just-in-case approach means affirming there was a need to better understand audience after all... since what was delivered clearly didn't appeal to those consumers... those shoppers at GM dealers.

4-05-2018 **Already, competency.** Was this an attack or someone woefully uninformed: *"Toyota needs to focus on batteries and battery technology IF they want to complete. In terms of business this is what would be considered a lack of a core competency."* It is still very difficult to tell on that general audience venue. Unlike the daily blog for Volt when you knew they just wanted to belittle Toyota, intent is far from certain here. So, I jumped into the discussion with: Prime already delivers a full EV driving experience. You can go up to 84 mph, complete with electric heating & cooling. Camry delivers a more powerful motor. RAV delivers all-wheel drive. That core is clearly being addressed already.

4-05-2018 **Already, disagree.** The response was dismissal. But was this an attack? I still couldn't determine intent: *"I disagree. A plug in hybrid is very different than a pure EV. The battery parameters as well as the electronics have to be redesigned."* My hope was the poster was simply naive about the design, making incorrect assumptions: You cannot disagree with a fact. I can pull out onto the highway and maintain a cruise at 80 mph, even with the heater running... never using any gas. It's all electric. Those behaviors of Prime are like a pure EV, period. Assuming the hybrid system wasn't designed to do that is your mistake. You overlooked the redesign that already took place.

4-05-2018 **Already, why?** Nope, still unknown. However, it did appear that his measure of progress wasn't technical. It seemed more just a generic assessment based on whether or not the vehicle had an engine still. This is what summed up his soapbox sermon: *"Then why does Toyota NOT have a pure EV out to compete with Tesla?"* I climbed up after he was done:

First, you failed to acknowledge that oversight. Again, you cannot disagree with a fact. Prime delivers EV driving. Period.

Second, the answer to your question is another fact. Toyota has a very different consumer base than Tesla. Their consumers purchasing Corolla, Camry, and RAV4 couldn't care less about a \$35,000 vehicle. They simply don't want to spend that much.

Know your audience.

Third, we will be getting more plug-in choices from Toyota in the next 2 to 3 years. In the meantime, they will continue to rollout TNGA and use Prime to educate dealers, salespeople, and consumers.

Keep in mind, legacy changes are far more difficult than the low-hanging fruit Tesla has been enjoying. It's all about producing millions of vehicles per year, not just appealing to eager early adopters.

4-05-2018 **Already, uninformed.** Turns out, he really didn't have any idea what he was talking about. His assumptions were that the design was a heck, the same as the aftermarket upgrades we saw a decade ago. It makes me wonder if the Volt antagonists were really just too stupid to realize they made the same mistake. Being clueless for at the beginning of a discussion is one thing, but holding onto that false narrative for years is entirely different. So, I went for clarification:

Interesting. You genuinely don't know what a Prime is. Those assumptions are incorrect. I'll have to re-evaluate my approach. That description of what Toyota's plug-in hybrid system is perceived to be is quite different from what they actually delivered.

Prime uses a PSD (power split device) designed to offer much higher RPM and is connected to a secondary PSD in place of a reduction-gear. Combining that with a one-way clutch allows it to deliver an EV experience at all speeds, without sacrificing electric-only efficiency.

That is very, very different from the hack years ago that aftermarket providers offered. Their design simply added battery-capacity, without allowing more power & speed like Prime does.

Prime also offering high-speed DC recharging. In Japan, the CHAdeMO option is available. Prime also uses an electric heat-pump for cabin warming, a more efficient option than what some EVs employ.

In other words, Toyota was able to deliver a redesign without you noticing. That's how a paradigm-shift takes place, when it is so subtle, the change gets overlooked.

4-05-2018 **Already, thanks.** Sure enough, he really didn't understand. My patience... and apparently just the right amount of push... managed to draw attention to his mistake without causing embarrassment. So, he didn't take offense. Instead, I got a thank you. Phew! It's always a risk. You don't want to create a new enemy, especially when you know how long a grudge can be held. Some of those Volt enthusiasts remained angry at me for years. But I had to do something. Whether you are trying to stir a misconception or you are just an enabler of it, that's very real damage to the market. Potential is lost when incorrect information is spread. In this case, he was wrong about how Prime operates. I pushed to find out why. My reward for doing it judicially was finding out how to approach future encounters like this. It's how misconceptions are squashed. You must find a way to overcome them. It takes effort and sometimes things take a turn for the worse. In this case though, it worked out nice.

- 4-06-2018** **Already, observations.** It didn't take too long after that to confirm the problem was conclusions were being draw on nothing but anecdotal observations. No substance behind the claims made confidence for eliminating doubt solid. That belief of Prime being just an after-thought matched up with what the Volt enthusiasts believed. They didn't understand what had actually been delivered either. Their assumptions had also been based upon design from long ago. That's what happens when you don't actually read what's posted, when you brainlessly negative vote information to hide it. This is where that label of "*deplorable*" originated. You can't just turn a blind-eye to what displeases you. Pretending there isn't an issue doesn't make it go away. Yet, those die-hard GM supporters did exactly that. Volt was "*vastly superior*", as they exclaimed over and over with the hope that you'd never question how that was achieved. More range & power was all you needed to know. That fact that Toyota strived to deliver something affordable was meaningless, as far as they were concerned. That's how why we encounter such naive beliefs elsewhere now. Fortunately, that reality if tax-credit dependency is making itself known even without much effort now. The venue for breeding antagonists is dead. Now, it's just an effort for Prime supporters to get word about what Toyota has already done. Squashing misconceptions isn't easy, but success with others of the past ultimately happened. We just need to keep repeating detail of the design. I'll continue to provide that information with video. Another is on the way.
- 4-07-2018** **2018 Inventory.** Exactly as predicted, anticipation has been replaced with confirmation. Phew! The new model-year (2018) is being delivered to regions that didn't carry the previous model-year (2017). That always made sense. You don't introduce a new product during clearance time. It's a logical approach to sound business. Passionate emotion must be replaced with sensible patience. Now that Spring is just about here (4 to 6 inches is forecast for tomorrow, but a week from now temperatures should reach the 50's), it makes sense ramping up sales. Before that, you just don't get many shoppers. No one wants to deal with the mess. Even test-drives are a challenges when it's still cold & wet. I did a quick such. 9 dealers had a total of 42 Prime freshly delivered or scheduled to be. That's a very thin spread, especially when you take into account the big Toyota dealer a few miles from me don't have any inventory yet. Rollout is usually slow. Dealers & Salespeople need to become accustom to the new offering. With Prius, that often comes in the form of well researched consumers leading the way. They study the material provided by early owners (like me!) who share their real-world experiences. Each generation has seen great success with that approach. Interest grow as inventory climbs... right on schedule with Toyota's sound business plan for sustained & profitable high-volume sales. Woohoo!

- 4-07-2018** **Outright Lies.** There are a few Volt enthusiasts who hate Prius so much, they'll just outright lie about it. To make the claim really stick, they'll make the situation sound as if you're getting called out for being dishonest. Here's the entire quote I was faced with today: *"Defog isn't defrost. The fact that you think blower air clears just fine means that you are making excuses for something that is incapable of doing. In Northern California, the winter is rainy and foggy. That means every time it rains, the defogging is needed. That means the engines starts in the daily rainy weather for about 6 months of the year!! Stop your spin!"* That came after a folly of posts attempting to belittle & misrepresent Prius Prime. There's a very real resentment for EV abilities that Toyota vehicle delivers. Exceeding Volt in several important regards makes the antagonist desire to insult range & power quite difficult. Prime's efficiency & affordability is more important to mainstream consumers... and they know it. So, posting lies about how the system works is what they have resorted to.
- 4-08-2018** **Called Out.** My rebuttal was terse, yet polite. I really wanted to make the point but without pushing too far. It was an effort to educate, not to offend. I want to avoid a repeat of this same encounter elsewhere. Making the video a clear source of contradiction to his claim will hopefully squash the obvious attempt to mislead. This is what I posted, along with a link to the video itself: I am pointing out facts with detailed captures of real-world driving. When someone makes a claim that is false, attention will be drawn to prevent the mistake from being spread. That footage & data clearly shows under those conditions the gas engine is not required and was never used. What started as an incorrect assumption will not be allowed to become a misconception. The 18.7 mile drive in that video was at 32°F in very wet conditions. You can clearly see the snow falling and the air quite moist; yet, there is no fogging whatsoever using the regular blower. That MAX mode simply is not necessary.

4-07-2018 **Video: Early Spring, Winter Returned.** This is what I published... [Prius Prime - Early Spring, Winter Returned](#)

Squashing misconceptions is an important part of Prius history. Having video available to counter the intentional spread of misleading claims is essential.... which is exactly what this particular footage provides.

On the dashboard of Prius Prime is a dedicated button for clearing the windshield of moisture. When pushed, it will engage the MAXIMUM mode for the blower. This starts the gas engine, since your request was for the fastest and most powerful means available.

If you don't need MAXIMUM clearing, you just use the regular window blower option. This is the feature included with all the other settings on the Climate-Control screen. The key difference between this and the dedicated button is it will not start the gas engine. This option is entirely electric.

Those individuals determined to undermine the success of Prius Prime will lead you to believe an electric-only option is not available. When confronted, they'll claim the feature in Climate-Control is not effective in cold & moist conditions.

This video features those very conditions, an extremely wet commute to work with the temperature at freezing. Watching the detail provided very clearly shows the gas engine is unnecessary, that the entire drive was exclusively with electricity and at no time was window clearing ever an issue.

To those dishonest about how the plug-in hybrid system works, you now have this video to prove you wrong and expose your attempts to spread a misconception.

And for those who took the time to read this entire comment, yes, that is indeed a Tesla Model 3. By lucky coincidence, this filming just happened to be my very first sighting of one. I was thrilling to have the camera capture that moment.

4-08-2018 **New Audience, New Document.** It is somewhat surreal promoting Prime. The mainstream market is basically clueless about plug-in vehicles, just like when Prius was new. The first generation hybrid model went almost completely unnoticed. Sound familiar? That's the same way PHV was. Now, we see this newest generation about grab the attention of ordinary people. Most won't purchase one though. Just like with the no-plug generations, it won't be until the next that takes the market by storm. That's the natural progression of technology. Each audience has a very different approach to adoption. In this case, many will accept the idea but not embrace it until an upgrade comes along. That may not necessarily be a Prius either. We could see the first really big seller as a RAV4 or C-HR here. Cars simply aren't that much of a draw now. Of course, that doesn't mean Prime won't sell like hotcakes. It just means the other offering will be even more popular. That's what is leaving me scratching my head about next steps. It seems as though I should focus more on the concept rather than the vehicle, creating a document for the technology rather than a true user-guide. There's much to teach, lots of opportunity to share, an entirely new audience to inform. Thankfully, I don't have to do it alone. There are many who like to contribute ideas. That's what makes the gatherings so fulfilling. In-Person exchanges are very insightful.

4-08-2018 **6 Minutes.** That was the extent of my stop to get coffee from the Starbuck's in the grocery store. Parking in front at one of the charging-stations makes a quick in & out possible. I get enough of a recharge to travel the remainder of the distance home using only electricity. In just that short amount of time, the charger sent 0.3 kWh to my Prime's battery-pack. That's roughly 1.5 miles of range. The drive to my house is half that. Since we often stop there to pick up something fresh for dinner, that EV opportunity is especially nice after having driven well beyond the pack's capacity. It's also a nice top-off during peak hours, when I'd pay a higher-rate. Instead, it's free while shopping. That's an effective way to attract business.

4-08-2018 **Video: Commute Home (Ultra Cold).** Archived long ago. Shared today... [Prius PHV - Commute Home \(Ultra Cold\)](#)

This is footage & data collected years ago from my Prius PHV, but never published. It was a very busy time in my life then, so the approach was to save what I could for use later.

This drive was the commute home, to the old house on an extremely cold Minnesota evening. This plug-in generation didn't have a battery warmer, so efficiency in such low temperatures was really a statement of impressive design. The system worked very well.

This is one of my more complex captures, where I used an ODB-II reader to save data for visual presentation. Each passing second wrote data to a file in spreadsheet format. From that, I converted the numbers into image frames to combine with the window & dashboard video.

It turned out really nice; though, the cameras available back in 2014 weren't as good as what I use now with the Prius Prime.

4-09-2018 **Traction-Control Off.** I never believed in spinning tires wildly to get out of slippery snow. It leaves a streak of ice behind for the next person who encounters that same spot. Why would you knowingly do that? To make matters worse, it hard on the tires. If you get out and look at the location afterward, the snow will be sprayed with a light layer of fresh rubber. That's why having a means of disabling traction-control wasn't ever any interest to me. Nonetheless, that button is available in Prime. No magic override from an option on a hidden maintenance screen with this model. It's right there on the dashboard. So, I gave it a push. I hadn't all Winter and this was hopefully the last snow of the season... unlikely, I know, this is Minnesota. Anywho, the results were spectacular. The car went from having a solid grip on the road to swaying from side to side. The reduction to traction that had really surprised me. You don't realize just how much the technology is working to keep you safe until shutting it off like that. Whoa!

4-10-2018 **Threatened By Change.** His rant got surprisingly intense. Starting with dismissal, it became a defending of pride. Volt was better, period. Sales didn't matter. He just insulted all the Prime owners and moved on. That was intriguing. My focus is always on the automaker, not people who choose to purchase. In fact, I congratulate & thank owners of all plug-in vehicles. It's the short-sightedness that has always been the problem. If a choice for the masses doesn't emerge prior to tax-credit phaseout, there will be very real problems to deal with. Anyone who dismisses that is a barrier to success. After all, the goal is mainstream acceptance. So, who was this person hell-bent on taking me down? His attack pattern perfectly matched that of the past, just like what I dealt with from the EPA spin attacks. Coincidence? Nope. Doing some searches, I was able to confirm his id had recently been switched. With over 30,000 posts, it was easy to see how he feel threatened. This change is just like how the others from long ago fell. Overwhelmed with evidence of a paradigm-shift, his kingdom has fallen apart. There's nothing left to defend anymore. Seeing Toyota, Honda, and Hyundai/Kia take over is devastating. So, he finds a scapegoat to blame. Shoot the messenger with the hope that distraction will save some pride. It's sad, really sad. It's undeniable evidence of change too. This new chapter defines "*vastly superior*" as a vehicle capable of competing directly with traditional vehicles... not simply offering more range & power.

4-10-2018 **Looking Around.** It's becoming very difficult to not see change. Accepting what it actually is can be quite disheartening. That realization of it being an abandonment of cars expresses a clear indifference to emissions & consumption. We are at the precipice with EV rollout. Tax-Credit phaseout means that challenge to appeal to ordinary consumers will become much harder. Very few had been taking that situation seriously anyway. Now with the inundation of bulky guzzlers, we have trouble brewing. It is rather fortunate that those large bodied vehicles can more easily support a large battery-pack. But the cost will make the technology more of a reach to obtain. We know GM and Ford are actively moving away from smaller vehicles. It's when you have other automakers, like VW and Chrysler, staying silent there's a need to look at the recognized efficiency leaders... like Toyota. I see a ton of RAV4 and C-HR in dealers lots. Toyota is racing to establish choices that will appeal to the masses as plug-in hybrids. Camry should survive the SUV/CUV onslaught, but only due to it being the market leader. That makes the choice to make Prius Prime more of an upscale offering an obvious choice now. Those who thought that an absurd conjecture 2 years ago now have reason to take pause. It's beginning to really make sense. Honda's new Clarity is somewhat of a bulky beast itself... what Volt should have been. The much larger interior justifies the price. No smaller offering though. Thankfully, Hyundai offers Ioniq. They quickly diversified to both a larger sedan and a CUV. So, we do see targeting plug-in hybrids at the affordable size. Not many though. The same is true for EV offerings. Looking around, it's easy to see the cars are starting to become fewer. That makes the transition to electricity appear to be even more of a problem. But then again, tipping points can be reached faster when the journey to it is filled with carelessness.

- 4-11-2018** **2019 Refresh.** It sounds like a mid-cycle refresh for the hybrid Prius will be more than just a few cosmetic tweaks and some possible system refinements. The rumor circulating today is it will take on a look similar to Prime. That makes sense. There was much benefit to the polarizing look. But once its role was fulfilled, it's time to move on. Why must the entire product-cycle be squeezed into a 6-year span? With vehicles now being designed on computers instead of being craved out of clay in full scale, it doesn't make sense not being receptive to market feedback. If there's a trend to take advantage of or a shift in market desire, why not capitalize on it? You search for interest, then jump when the opportunity presents itself. That's why the computer design was adopted in the first place. That flexibility reduces time & resources needed to reach production. I see the refresh as a refreshing new trend. Why must a longer product-cycle still be required? After all, aren't suppliers looking for opportunity too? Not being able to plan the next year to chase an advantage emerging how money is made. You don't want to get stuck with a product facing a downward trend. Becoming the trend is far better. Somehow other manufacturers have been able to incorporate flexibility into their business approach. Why not automakers too?
- 4-11-2018** **6 Years.** Some still assume that's how long the first Prius was around. They have no idea there were actually 2 offerings within what they believe to be a single generation. That has come up several times just today alone, due to the 2019 rumor. I posted this in response: That misconception is an interesting one. It reveals much about the understanding/recognition of how generation is actually defined. What criteria do you use? Gen-0 (many programming languages start counts at 0, not 1) was the first 3 years. The following 3 were what we know as Gen-1, to account for the 6 people assume was all the same. That unknown past comes from only being available in Japan. It was a major update very few here knew about... the bumpers were gray, the screen wasn't touch, the engine had less power... but most significant was the battery upgrade, from "D" packaging to prismatic cells.
- 4-12-2018** **Genius.** I asked: How do you break a typecast problem, especially one on the magnitude Toyota faced with Prius? They have other hybrids, but no way to draw attention to them. 52 MPG from the new Camry is amazing. Most shoppers have no clue it even exists though. Giving Prius a standout look is a stroke of genius. It prompts the customer to ask if anything ordinary looking is available. The salesperson response is "*Well, as a matter of fact...*" There's a next-gen RAV4 hybrid on the way too. This is the classic negative-promotion technique, an approach proven to be very effective when you step back to consider the overall goal. After all, Toyota is working toward the phaseout of regular hybrid in favor of the plug-in model. Abandoning that polarizing look mid-cycle and replacing it with something that resembles the desired target makes the transition easier. It's a sensible method, which also earns a reputation of being responsive to market feedback. Rather than waiting a full cycle, the automaker responds with a refresh along the way.

4-12-2018 **Nope.** The spin about sales cannibalizing keeps coming up, but no one can actually back the claim with anything of merit. In fact, most only make their statement by omitting detail then don't like. They establish a narrative with just anecdotal observation. Most people don't bother to do research of their own. So, the message is usually just accepted at face value and passed along to others. That spread of any type of message with facts to support it is unwelcome. I interject information, ask questions, and disagree. Sadly, most don't take on the challenge. They just repeat the same dribble elsewhere. But at least its not totally without resistance-free acceptance: Nope, since that would imply intentional sales loss. What they did was take risk, pushing appearance to an extreme with the attempt of attracting new customers. Market growth is essential. In the land of SUVs all sharing a similar appearance, it was a logical step to go in the other direction. Keep in mind the goal of 5,000 sales per month is still pretty much intact.

4-13-2018 **Hybrid Option.** Some people are in agreement: *"I have looked forward to the day (and we're slowly getting there) when a hybrid drivetrain is just another option -- 4, 6, diesel, hybrid, and other variants."* Seeing that shared sentiment, I joined in:

- Camry hybrid
- Avalon hybrid
- Highlander hybrid
- RAV4 hybrid

They are all available here from Toyota already.

- Corolla hybrid
- C-HR hybrid

They are available already elsewhere. The entire passenger product-line is getting the hybrid option... exactly as Toyota has been targeting for 2020.

4-13-2018 **Daily Blog.** Every day in and day out, it was the same old nonsense. That daily blog kept the routine going for an entire decade. A new topic would be published at 6:00 AM Eastern, then enthusiasts would come out to feed on their prey. They would pound their chests and dump on all other plug-in vehicles until the day came to a close, then it would all come to an end. The topic would be abandoned. New attacks would begin the next day on whatever was published then. That cycle repeated hundreds upon hundreds of times. Unless you were paying careful attention, striving to see the bigger picture, the cliff they were racing toward wasn't visible. GM delivered a vastly superior vehicle, period. Nothing from any other automaker ever made any difference. Those enthusiasts would just spin excuses. Many became hypocritical. You cannot avoid facing goals for that long without them finally catching up to you. Their inflexible nature ultimately led them astray too. GM delivered Bolt. That basically killed Volt in every respect. Watching the battles from day to day made that clear. It was an enemy from within. Time had been squandered. Ironically, they rested on their laurels... the very thing they accused Toyota and supporters of doing. Each topic was a celebration of the past. Having no future become evident to even the most stubborn, eventually. Today was that day. Friday the 13th ushered in new topics, almost 10 full weeks later. Only a hint of what might come had been revealed prior to that. This was the full introduction to what the restart of that dead blog would bring. There were 5 new topics all at once. The site has become an ordinary news outlet! That place for antagonists to breed has vanished. Killing the venue that encouraged hate actually happened. Ownership was taken back. They want integrity to return. Being overrun by fanboy attacks is now just an unfortunate memory of the past. They made it quite clear too, by reaching out and asking for topics & purpose to be agreed upon. No where in those statements was anything about Volt superiority. To make matters worse for the troublemakers, people like me would have specific goals to refer to... which makes undermining, impeding, and misleading far more difficult... if not impossible. Needless to say, that chapter has come to a close. I toughed it out, reading everything they posted. Participation on a hostile forum is how you get the most direct & comprehensive feedback. No such place exists anymore... for Volt, anyway. GM can still screw up their next effort. But there's far less potential for the antagonists to gain control as they did with the daily blog.

4-14-2018 **Car Sales.** The reason GM gets mentioned so much is GM keeps denying its own wants. I was asking "*Who is the market for Volt?*" long before rollout, back when the vehicle was still being designed. It simply made no sense that an automaker obsessed with SUVs would abandon their behemoth hybrid system in favor of a small car with a plug. That's why there was so much conflict with enthusiasts. They knew I had identified a key weakness. Volt would die simply from disinterest. No amount of engineering could bring about mainframe sales from management unwilling to promote. Cars were never a priority. Dropping purchase numbers overwhelmingly confirm that. Spin about Prius sales being a struggle requires the omission of the entire market shifting to larger vehicles. This is why Cruze is seeing such a decline. Trouble is, Cruze doesn't get the investment Corolla does. The new transmission Toyota will be delivering the end of this year will carry it for years to come. That CVT with a launch-gear is a move back to simplicity without sacrificing power or efficiency. GM hasn't taken any step like that. You'd hope something would be made available for those unable to take the step to plugging in, especially when a hybrid model won't be offered. Needless to say, the news making the rounds today highlight a consequence of such inaction: "*GM cuts hundreds of jobs as car sales continue to slide.*"

- 4-15-2018** **Topics Vanished.** Curious to see what became of the daily blast, I checked up on that forum blog site. To my surprise, 2 of the 5 new topics had vanished. They were removed entirely. What I had in cache on my computer was proof of their previous existence. The one was titled: "*A question for our readers.*" And the other: "*Next Chevy Bolt EV Reportedly Not Coming Until 2025.*" It doesn't take much imagination to recognize how the one soliciting feedback resulted in a lot of controversy. That's what the group of enablers thrived on. More conflicting posts attract more posting activity. Don't ever allow any proof of shortcoming get attention. Fight. Fight. Fight. The other confirmed my concern of "*too little, too slowly*" was far more of a problem than anyone ever wanted to acknowledge. I suspect the stir that topic brought about angered the enthusiasts. The last thing they ever wanted was a moderator taking my side. So, all we have now are the titles of the topics. The link saved in my browser's history no longer works and there's no evidence of them ever having been available.
- 4-15-2018** **Logic & Reason.** I enjoyed the irony of this statement: "*Why Toyota even decided to go with this look for the fourth-gen model is beyond logic and reason, but here we are.*" It came from a source unwilling to see beyond the tree they are looking at. It's the classic "*can't see the forest*" problem. We are surrounded by a sea of blah. There are plain looking SUVs everywhere. There's nothing to make them stand out or even appear special. There's a crowd with your vehicles somewhere in it. This nothingness is the very reason people seek out different. They get tired of what's been identified as normal, which is really just a trend. The market cycles, eventually. Whatever the hot new thing is that begins to outsell all the rest, later to become a trendsetter, started as an outcast. That logic & reason doesn't make sense in the moment, but looking back afterward it certainly does. Remember how the SUV started? For that matter, remember the birth of the minivan. People claimed they wouldn't be caught dead in one. Then years, they purchased one anyway.
- 4-16-2018** **Wild Guess.** This came from that Prius PHV owner who continues to make vague claims and draw uninformed conclusions: "*For those who use their phev as a phev, 15% loss is no big deal. for those of us using it mostly in ev, you get used to the initial range, and are disappointed when you can't reach the places you used to without the engine.*" Oh well. All you can do is provide information so posts in the future are better: That's just a wild guess, based on assumptions from early-adopter purchases. In reality, we have no idea what the situation will be +7 years from now. Think about how many more charging-stations will be available. If you can easily plug in to top off, what's the problem with some normal age-related degradation? After all, capacity fluctuates more than that each Winter anyway. Think about how compelling the new choices will be +7 years from now too. We've seen other families use the older Prius as a hand-me-down, using that as a great excuse to purchase a next-gen offering. Why would this be any different? Think about how inexpensive the option to upgrade the existing battery-pack could be. We are already seeing Nissan & BMW experiment with used packs. The capacity remaining is quite sufficient for other needs. After all, a trade-in program would be a new source of revenue for legacy automakers.

- 4-17-2018 Cold & Unplugged.** My Prime was parked outside for a day and a half without being plugged in. It snowed and the temperature was still below freezing. We jumped in for a drive. Just a quarter-mile from there was a very long, steep hill we needed to get onto and quickly get up to 45 mph... which is great for regenerating electricity from on the return trip. This was the other direction though, we everything still quite cold. I was quite curious if that extreme condition, yet ordinary situation, would necessitate the engine starting. The full 68 kW draw would likely not be possible, but the rapid acceleration to 55 mph a half-mile from my house never triggered the engine either. The promise of all-electric has been confirmed again and again. Prime delivers EV whenever called upon when the temperature is above 14°F. Sure enough, this aggressive climb did just find too. My Prime made the accent using only electricity, without any concern for more speed or power. We are over a year into the proving that this design will be able to reach a very wide audience. When the other variants become available, this choices will draw new attention. Market growth is quite realistic.
- 4-17-2018 Subaru Evoltis.** That's the automaker name recently registered. We assume it's for their first plug-in hybrid offering, the one planned to use components from Prius Prime. Configuration of engine, motor, and battery are completely unknown still. Speculation isn't held back though. There is clearly interest in this first offering beyond Toyota's intial choice. It's hard to know what will be delivered. There's a lot of opportunity. It will help shape the market for whatever follows from Toyota. Ideally, I'd like to see the Prius V replacement be the next. Equipped with a more powerful engine, motor, and battery could make the rumored CUV a complimentary alternative. It won't deliver MPG as high, but the larger body & components are what some have been yearning for. We'll see. I suspect details will remain sketchy for a few months still. Holding off on vitals until the approach of Fall wouldn't be a surprise. Much will happen with plug-in vehicles between now and then.
- 4-18-2018 Buick Enspire & Velite.** Both will be coming to China within the next year or so. Enspire is expected to deliver 550 horsepower and do 0-60 mph in 4 seconds. Talking about gross overkill. It's more of the GM nonsense we've been dealing with for years. Rather than offer a product for the masses, they focus on high-end choices. Do you really need 370 miles capacity? That would be nice, but imagine price for so much range. Velite (the plug-in hybrid model) seems as though that could be a potential mass-market choice. Details are quite vague though. Velite (the EV model) will supposedly deliver 434-mile capacity (700 km based China estimations). Nothing has been said about choices for the United States. It does make you wonder what to expect. We've been led astray so many times by GM over the years, there's no reason to plan anything... especially considering GM's history of slow and lack of commitment.

4-18-2018 **New Misconceptions.** The battery-pack in Prime is small enough that a high-speed charger (Level-2 type, those that connect to a 240-volt socket) isn't required. It's a nice-to-have feature you can upgrade to later. Being an entirely new product makes it good fodder for misconceptions. Sure enough: "*The wall mounted ones, you take nothing with you. It's more or less permanently connected to the wall.*" That was posted on a thread asking the difference between 240-volt chargers and a EVSE... which in itself is a misconception. That's the same device, just referred to in a different manner. EVSE stands for Electric Vehicle Supply Equipment, which is rather vague. Making the assumption that only means the slow-speed (Level-1) type is understandable. Ironically, that is actually the opposite way it is used among the early-adopter posts. Anywho, there is obvious confusion. I jumped in to help: Looks like the Home-Charging guide will need an additional photo, since that appears to be a new misconception in the making. My wall-mounted charger takes 2 seconds to remove. All you have to do is unplug & lift. That's it. The unit hangs from a bracket. You can even purchase extra ones for convenient mounting at each location you transport it to. You can even purchase a bag for transport.

4-18-2018 **Reflection.** This quote posted today came from an antagonist whom I fought for quite some time about misleading statements, exactly like what he's complaining about now: "*The EV miles are not free miles, so the 'Inflated' gas mpg numbers are not good for anything, except misplaced 'bragging rights'.*" Is this a case of reflection, where he continues to do what he accuses others of, or a situation of reform? I'm hoping to get an answer. Finding out someone who pushed misconceptions in the past can be taught to step back and look at things objectively would be great. Hopefully my effort to find out will be revealing:

Yet, that's what we have to deal with. Volt owners set that precedence, despite the obvious attempt to mislead. We fought the "*not free*" for years... and still do...

31 kWh/100mi for *Clarity*

31 kWh/100mi for *Volt*

25 kWh/100mi for *Prime*

How often do you see those efficiency numbers posted? Eliminating gas usage entirely reveals not all electric travel is the same. Some use more than others to drive the same distance. Posting inflated values will conceal that fact.

For Clarity, that value isn't so bad, when you consider how much larger it is than Prime. But when you look at Volt, it's a guzzler of electricity compared to Prime. Requiring an addition 6 kWh to go 100 miles is a big deal. Those EV miles are not free miles.

- 4-18-2018** **Lexus Plans.** They are uncertain, but we do know there will be electrification pressure coming from legacy sources like BMW. There's an obvious aware of Tesla too. Early-Adopters got hung up on the past: "So... about those "nobody has 4 hours to sit around and charge" ads?" With so much time having passed since then, I was curious about that too: What about them? Since then, investment in extremely fast DC charging has taken hold. Wasn't that the point of drawing attention to the need to wait? What harm came from having taken that chance with advertising? We certainly haven't observed any with respect to the addition of a plug for Prius. Keep in mind that short-sightedness of both marketing & audience. Times change and negative publicity can be a powerful motivator.
- 4-18-2018** **Short-Sightedness.** This was the response I got to posing that question about about Lexus: "*point me to a thread/post where John has said something negative about Toyota/Lexus....would be a sight to behold...like a unicorn or the Yeti*" It was a great opportunity to highlight the effort to dodge the bullet. Rather than actually make an effort to answer the question, it was trying to shoot the messenger. Could it be possible that I actually have researched enough to know what I'm talking about? How would a something negative reinforce that anyway? For that matter, why was my message considered positive? Just because I pointed out another perspective does not mean I took a stance. Of course, not doing anything makes routine observers enablers, making them supporters because they don't speak up. In other words, some like to spin so much, you lose track of intent. I go out of my way to remind everyone. That restating of purpose usually becomes annoying, like a broken record, but it keeps us focused on what's really important. Like today: Point me to a thread where long-term plans are discussed without short-term noise drowning out the message. Notice how many are actually discussing the market beyond tax-credit dependency? That short-sightedness a very real problem few are willing to address.
- 4-18-2018** **Overlapping Threads.** The short-sightedness came up on another thread, that one about things not being free: "*It is not a big deal. It's \$0.72 per 100 miles.*" I caught him in the act, attempting to downplay. Refusing to consider the bigger picture is another form of short-sightedness. Counts are just as important as timelines. I let him know it too: Just because something is affordable is no reason to waste it. Switching from guzzling gas to guzzling electricity is not a comprehensive solution. Emissions are still very much a problem when that consumption is considered on the large scale. 17,000,000 new vehicles are purchased in the United States alone each year. Worldwide the count is somewhere around 60,000,000. We don't have enough solar, wind, and hydro power to supply that much clean electricity, nor do we have the infrastructure to support it. This is a perfect example of the short-sightedness problem I just pointed out on another thread.

4-19-2018 **Delusional.** He posted this, as an obvious lashing out: "*pretty sad that Toyota will be very last to the party*" Insulting Toyota was the only option he had left at that point. So, he did. My reply got that one-word response: "*Delusional*". Recognizing that pattern from that past was quite reassuring. Now, the die-hard Tesla supporters are beginning to attack. It's that same old "*vastly superior*" attitude again. That means using the same approach to dealing with it would be wise: Know your audience. They aren't interested in an early-adopter party or even being first. Selling something in high-volume that's both profitable & sustainable is a huge challenge. The path for Toyota is very different from that of Tesla. Each could achieve the same criteria just fine, but premature celebrations aren't a good idea. There's a lot of resistance to come. Changing the status quo is far more difficult than appealing to early adopters.

4-19-2018 **Uninformed.** Obviously angered by my response, kept the information flowing. This was becoming a "*not the same*" effort, yet another lesson history has taught about how to deal with irrational defensive posts. Seeing only their own narrow perspective, you do everything you can to widen the view. Force them (or at least lurkers) to recognize that there is more at play than just the facts they choose to present. It's a form of cherry-picking that comes from not being aware of everything involved. I posted:

That's my response to your claim, which is far better than what I've dealt with in the past... denial. I asked the fanboys "*Who is the market for Volt?*" countless times over the years. Being well informed, I was well aware they were just leaving in the moment seeing sales only from an early-adopter perspective. The problem of subsidies going away and audience changing was outright dismissed too.

Those fanboys absolutely refused to acknowledge the flat sales (consistently between 1,600 and 1,700 monthly) would become an incredible challenge to grow when faced with innovator's dilemma. Sure enough, that's exactly what happened. GM targeted that same group for the gen-2 upgrade. The result has been a drop in sales instead of the much needed growth. Oops!

Toyota is running a business that depends upon reliable profit. That means delivering a product that's simple to sell to the masses, those mainstream consumers who have very different purchase priorities than the fanboys. They want a nice balance for a good price. That's why Prius has been such a great on-going offering.

The introduction of a plug brings about the necessity to carefully evaluate what their ordinary showroom shoppers will find a draw when doing comparisons at the dealer. That's a drastically different approach from what Tesla is doing... a non-legacy automaker with a limited product choice and basically no showroom.

4-19-2018 **Understanding Business.** The major of people I communicate with online don't have much business background. In fact, I would say a large number don't have any at all. They make claims that don't fall into any type of logical approach for sustainability. They focus almost exclusively on engineering merit. That certainly is an aspect of business success, but it is most definitely not what you bet the farm on. GM learned that lesson the hard way with Volt. Their enthusiasts insisted for years the fastest & farther approach was all that would be necessary. They were wrong, very wrong. That takeaway from all those arguments was learning just how deep some of that stubbornness runs. Whether they base their belief on assumptions or simply narrow their focus to a specific ability, it doesn't matter. They are unwilling to accept another perspective. So, having to deal with stuff like this elsewhere years later is very much the anticipated outcome: "*You are really hard to communicate with...*" It was yet another example of forced context, where they cannot follow what you are saying because you are not saying what they expect. That become frustrated that you stand firm with a stance they don't understand. Having researched the issue so extensively, I know they aren't grasping the concept of other view-points and other needs. This is why fundamentals, like the tradeoff of efficiency for the sake of being cleaner, still eludes some. Anywho, my attempt to close up this line of arguing was: How many economic, accounting, and advertising classes have you taken? That lack of a strong business background makes communication extremely difficult, if not impossible. I often find engineers beating their heads up against the wall trying to get their message across but failing to understand when management expects an entirely different means of expressing purpose & process. The reverse is true as well. For a rude awakening about related issues, I suggest a course in Six-Sigma. This is why I kept repeating "*Know your audience*" over and over again.

4-19-2018 **Lots Of Potential.** It's both exciting & intrigued to witness the stir that upcoming plug-in hybrid from Subaru is causing. The most obvious is the realization that there is already an AWD model of Prius available. All-Wheel-Drive in Japan isn't what you'd expect for that market. But then again, they don't favor SUV use the way we do here. In fact, that's why RAV4 hybrid is so popular here. Knowing Subaru will be using some tech from Toyota means there's anticipation of some type of announcement for a RAV4 plug-in offering on the way. I suspect it will follow, allowing the competition to get a foothold first. That's what Toyota did with Ford. Giving them a year lead with Escape hybrid prior to rolling out Highlander hybrid was a very effective way to build market. Some type of shared mission needs to be expressed. Growth is far more difficult without a sense of partnership or even competition. Going at it alone is limiting. I started up today's discussion on Evoltis with: This offering will be a nice demonstration of the platform flexibility. People like to portray Prius tech as slow, but that requires the omission of how it is used in other vehicles. For example, the new Camry hybrid offers more power, yet still delivers 52 MPG. We all know battery-packs can be upgraded along the way too. In fact, mid-cycle improvements are becoming an expectation. That means Subaru will have a choice among a variety of configurations. We won't know what engine, motor, battery combination they'll choose for Evoltis. But the effort to demonstrate flexibility will be achieved. There's lots of potential.

4-19-2018 **Toyota Downplay.** We see it all the time. There is always a few narratives at play. Each requires you to disregard something history from the past to make it work. Omitting facts is a common technique for misleading. So, that's a dead giveaway of intent... especially when coming from a source known to do it, like he did today: "*The batteries would not have come as far as they have without Tesla, Nissan, and GM bringing cars to market.*" The massive investment Toyota made to develop & advance the hybrid batteries is clear evidence of that not being the case. We also now the market cannot move forward with deeper penetration until more players are involved. This is why Toyota leased their technology to other automakers. It's a risk reduction for everyone involved. Nissan used tech from Toyota. Toyota used tech from Tesla. We saw the cross-licensing with Ford, as well as the rollout timing cooperation. Now, we see Subaru is joining in to do the same thing. So, the effort to portray Toyota as a recipient rather than a participant doesn't match what those with good memories (or an extensive blog) can recall. References to the past usually fall on deaf ears though. Antagonists just dismiss facts they don't like. That means taking a more general approach to counter claims: What does "far" actually mean? Toyota has been pushing the development of affordable air-cooled battery technology all along. You can't just pretend the chemistry, packaging, and production efforts they pioneered & pursued. Sounds like the "*more range*" argument verses the effort to reach affordable markets.

4-19-2018 **Meaningless Labels.** In terms of getting people out of traditional vehicles, Toyota is the undisputed leader. So naturally, there are some who work hard to change what leadership means. It's easy to slip into that rabbit-hole too. That's why stating goals is vital. Notice today's attempt: *"Yes, it lost its position as industry leader in a market segment."* This is where pride gets in the way. Some get so hung up on labels, they forget about purpose. When you create an indifference to what's trying to be accomplished, progress becomes increasingly more difficult. This is where the problem of diminishing returns come into play. The perspective of leadership being a measure of EV range is the most common example. Does the higher price for more actually result in more sales? At what point does the difference become a moot point, or worse, a deterrent? Needless to say, I have much at stake in this topic. If the effort to replace traditional vehicles is impeded by labels, I'm going to draw attention to the problem:

That claim of *"leader"* is meaningless without a qualifier. There are many categories of measure. To which are you referring?

This is business 101 stuff. You need to know what will be delivered. EV Range has absolutely no relation to Customer Satisfaction; yet, both are priorities. Then there's the monetary measures, like those related to Sales Volume, Gross Profit, and Dividend Payments. Each automaker will place different weights on the importance of those. There's also the difficult to evaluate categories, like Environmental Impact. Take all that, then consider the profoundly different mission statements...

"To accelerate the advent of sustainable transport by bringing compelling mass market electric cars to market as soon as possible."

"To attract and attain customers with high-valued products and services and the most satisfying ownership experience in America."

Think about how that influences approach and decisions. In other words, what type of leadership are you referring to?

4-20-2018 **RAV4 PHV.** Another Prime model of hybrid from Toyota should be obvious. Why wouldn't that step to diversify be taken? After all, it should be easier to fit a larger battery-pack into a larger vehicle, especially one that rides up higher. Prius already demonstrated how simple the augmentation was too. Of course, that addition of a one-way clutch to take advantage of more electricity for added power is such an easy step, many like to spin it as a hack after the fact. Accepting the possibility that Toyota planned for such an upgrade, rather than being forced to completely redesign, is too much... despite all the evidence supporting a system that considered future upgrades many years ago. Whatever the perspective, it doesn't matter anymore. There's nothing to argue at this point. The following translated phrase was shared today from a Japanese article published early this year: *"Meanwhile, we will start production of RAV 4 based PHV at Takaoka Plant (Toyota City, Aichi prefecture) even in the spring of 20."* My response to that was as simple as the design: There is no reason not to expect the progress of hybrid upgrades to continue. RAV4 is a sensible choice in the product-line to get a larger battery and plug.

4-21-2018 **600 Miles.** It was a bizarre road-trip. We would just barely miss the approaching winter storm... which ended up dumping 14.6 inches of snow at home. It was coming down so fast 40 miles into the 200-mile drive that traffic slowed to 40 mph at times on the highway, despite the constant flow keeping lanes clear. At the halfway point, we stopped for a late lunch. That location was just beyond the nasty part of the storm. It was just normal snow at that point. About a 30 minutes from there is point at which things got interesting. A semi truck & trailer had very recently been pushed off the road. There was a small strip of exposed highway where the snow had blown across and turned to ice. The Prime got pushed into the next lane as I slowly drove by the people standing outside their vehicles looking at the wreckage in the ditch. It was a surreal experience. Too bad I hadn't been filming at the time. Oh well. The rest of the time up north was quite uneventful. Without a place to plug in, I ended up using Charge-Mode a number of times. That worked extremely well for those times I needed to drive somewhere and wanted to avoid engine warm-up... a penalty well worth avoiding. Overall, you save gas by judiciously choosing when to use the engine and when not to. In this case, it worked especially well, since we still had several inches of snow to deal with prior to the drive back... which was much warmer! I averaged 65 MPG on the way back, despite it being almost all highway (some at 65 and some at 70 mph). Unfortunately, I forgot to look at the results for the trip as a whole when I got home. It's easy to forget when going weeks between refilling the tank, even on an escape like this. I filled up the end of last month, once while on the trip, and won't again until sometime next month.

4-22-2018 **Earth Day.** There were many plug-in vehicle events to choose from, especially when you have Prius Prime... since there are so few in Minnesota still. Inventory has been basically non-existent. That means sharing the presentation area with quite a few of the other plug-in choices. There were 5 Teslas at first. More kept coming. I'm not sure how many were there total, but they overwhelmed the Bolts & Volts in attendance. I parked at the end, where a lot of the foot traffic came. The bright blue really stands out among the sea of black & gray. It was a great opportunity to compare notes on how to entice traditional vehicle owners to take a closer look at plug-in choices. Selling the idea of a plug-in hybrid is quite a bit different from an electric-only. Both have terminology & measures the typical consumer has absolutely no understanding of. Even the basics, like consumption rate, are beyond most everyone's experience. They simply have no idea what their current vehicle gets for MPG. Without even that, there's no possible way to discuss anything else, like gallons-per-month. Influences like temperature are totally unknown. Not ever thinking about topics like that make the setting of expectations pretty much impossible. That's why seller guzzlers is so much easier. Automakers don't bother. They just appeal to emotion instead. Try that in a parking lot when you've got 10 to 20 seconds of attention. This is why I had those "*Info Sheets*" way back in the beginning. It was a for-dummies type handout, featuring a few photos along with carefully thought out wording... just enough to entice the person to want more information. Whether they ask there or follow-up on their own later, you need to make the best of those few precious seconds. Today's research on how to do that went well.

- 4-23-2018** **New Propaganda.** Seeing the extreme trouble plug-in vehicles are experiencing with audience, it makes sense that more focus is being directed toward autonomous features. Problem is, people have no clue what that really means. They are completely unaware that different levels of automated control exist. We are hearing "*driverless*" mentioned more and more without any technical detail. It's unfortunate that this avoidable mix up is taking place. It didn't need to happen. But the challenges involved with rollout of new technology will be a problem regardless of approach. Much of it stems from how vehicles were promoted in the past. Automakers appeal to emotion, rather than educating about need. Want is a much stronger marketing tool. The catch is, seeing a vehicle slide sideways, climb up a mountain side, or towing a massive trailer is something most owners won't ever do. With autonomous features, that isn't the case. They will be exploiting whatever that technology has to offer. The extreme will be normal, since we're talking about safety... not bragging rights. There's a profound difference... hence the problem. That's really messing up expectations for plug-in vehicles. It's an unfortunate situation that could have been avoided. Now we have to deal with some of the misconceptions resulting from lack of understanding. Bummer. Oh well. For now, I'm just going to keep my posts on the topic brief: Sounds like some people have no idea what "*driverless*" actually requires. Many of the safety features provide the base technology. It's like the tech sharing between electric and fuel-cell, where many assume they are mutually exclusive. They are not.
- 4-24-2018** **Autonomous.** Someone took the time to spell out Toyota's approach to autonomous driving by pointing out details of how they are focusing on safety first. When you augment what people are already doing as part of the driving experience, it's a lot more difficult to notice. You don't do anything differently; yet, the outcome is greatly improved... should an accident situation arise and the system activates avoidance technology. Having that already in place positions an automaker well for future enhancements, like not having to hold the steering-wheel while cruising on the highway. A few accidents recently where technology & driver shortcomings resulted in a lot of unwanted attention are likely just the first of many. It will take several generations for the technology to become robust enough to meet the expectations of the masses. In the meantime, note this list of features Toyota has already delivered and continues to refine: *Cameras, Radar, Sonar, Navigation, DRCC, LKA.*
- 4-24-2018** **Planning Ahead.** I really liked reading this in that now quite long discussion thread about autonomous driving: "*My guess is that Toyota's doing things behind the scenes, but doesn't feel the need to spell out their 5-year plan to develop autonomous vehicles at this point.*" I was happy to jump in to provide some perspective on the matter: No guessing necessary. Toyota is just repeating their own success model. Prius delivered 100 km/h (62.1 mph) propulsion using only electricity way back in late 2003, an obvious upgrade over the previous generation. Unfortunately, battery-tech was far too primitive still for them to take advantage of the design. So, they kept refining it in the meantime. Several upgrades later, we got Prime. The cost & capacity started to become realistic enough to begin to capitalize upon that opportunity. So what if the current design "*only*" delivers 25 miles of range. The system is loaded with EV optimizations already. Who else in the industry has delivered such an efficient heat-pump? That 25 kWh/100mi efficiency rating is quite impressive too.

4-25-2018 **The Time Has Come.** We always wondered if Detroit would ever just give up and abandon cars all together. Rather than conceal their desire to only sell Pickups & SUVs by providing token offering of cars, they just outright said we're not going to even bother. Today is was headlines like this causing quite a stir online: "*Ford to stop selling every car in North America but the Mustang and Focus*" It's actually even worse than that first appears. The vehicle called "*Focus*" won't really be a car anymore. It will become a CUV, kind of what Toyota did with C-HR using the Prius platform... only Ford won't offer the car version anymore. Their entire product-line will be guzzlers... since Mustang obviously isn't an efficient car. True, those larger vehicles do make plug-augmentation quite a bit easier, but the cost & efficiency in return isn't anywhere near as good as what a car can deliver. Ford doesn't care anymore though. Neither does GM. Why waste so much money on something no one in their employ is interested in? After all, we can just drill our way out of this environmental disaster that is just hippie propaganda. It's all a hoax. There's no shortage of oil and no damage could ever be caused by pipelines. Climate change is just political spin too, right? Wow! It's amazing to think things could have become so bad. This explains why Toyota continues to invest in production facilities here in the United States. When people say "*Buy American*", you'll scratch your head wondering what the point of that actually means. Is it to purchase an extremely efficient Japanese hybrid car built in Kentucky, Tennessee, or Alabama? Or is it to purchase a Japanese hybrid SUV built in Texas? Needless to say, there is much change taking place. The time has come where lines are blurred to such a degree, much of the old propaganda is losing effectiveness to the point of becoming a moot point.

4-25-2018 **Corolla Prime.** It was announced today, for the market in China next year. Of course, there it will be known as Corolla PHV. That's a devastating blow for the antagonists attacking Toyota with their "*too little, too slowly*" spin. The endorsement they provided for Volt was based upon its ability to be adopted quickly by other vehicles, spread throughout the fleet much faster than what we saw with the tech for Prius. No only has GM been slower, it now looks like it may not happen for several years to come. The expectation now is that GM will abandon Volt entirely in favor of a plug-in hybrid SUV instead. Watching Toyota pass by at so much faster of a rollout pace is the ultimate humiliation... for those who value pride so highly. Think about what GM will need to do to make that eventual offering affordable. Range certainly won't be 53 miles for so much heavier of a vehicle. They don't like that at all... so posts avoid discussion of it. I'm happy to point out the reality of the situation: Affordable as a priority is still beyond the grasp of some here, who instead continue to focus on factors that haven't drawn mainstream attention. Sales have clearly confirmed lack of interest. \$27,100 base MSRP for Prius Prime is overwhelming proof that Toyota has developed a plug-in hybrid system to compete directly with traditional vehicles... quite unlike those who endorse trade-offs requiring subsidy dependence. Seeing that tech offered in the body of a Corolla completely eliminates rhetoric of involving aesthetic appeal, as well as show a commitment to ending the reign of guzzlers. Just imagine the rest of the passenger fleet offering a PHEV model... Camry, RAV4, and C-HR are already available in hybrid models. Adding a plug is the next logical step. Let's not overlook just how much of an improvement to emissions & efficiency a smaller battery-pack can provide, especially when it can easily be recharged overnight using nothing but a 120-volt outlet. It's all about finding a way to get ordinary consumers to purchase, who have very different purchase priorities than early-adopters.

4-26-2018 **Incorrect.** There's a sense of panic growing. You can tell when statements like this emerge: "...these cars based on Prius template, the motors are puny and engines come on frequently during routine driving, which really negates the whole EV experience." They make incredible vague comments, hoping to they will be accepted without opposition. More and more experiences are being shared online about how nice the electric-only driving Prime provides really is. Suburb driving is EV in every respect. You can step down hard on the pedal and get a surprising amount of power, more than you'd get from a gas engine when trying to avoid high RPMs. That's why so many people with powerful guzzlers don't actually accelerate hard. They don't like the revving. I see it on a regular basis, as I whiz by in smooth silence. All you have to do is take a test-drive with a fully charged battery-pack. This is why antagonists hoping to undermine focus so heavily on highway operation. They don't want you to consider what the EV experience is on suburb roads. My EV driving on the 70 mph highway is great, since my daily commute is within range. Acceleration from the ramps is never a problem either. But arguing that with just words is a challenge. This is why I've been filming a wide variety of driving situations. Today, I shared this in response to the attempt to mislead & misrepresent: No, that is quite incorrect. Prius Prime has a one-way clutch which combines both electric-motors for increased power to deliver a full EV driving experience up to 84 mph. Notice that at no time during this recent commute I filmed did the engine start, despite driving on the 70 mph highway with the heater running... [Early Spring, Winter Returned](#) Again, that assumption is not how the system actually works. Watch the gauges. It can pull up to 68 kW from the battery-pack. That's more than enough power for everyday driving entirely in EV.

4-26-2018 **Audience.** It comes up again and again. Today, it was yet another attempt from that Volt enthusiast turned antagonist. He is now without a venue to spew his propaganda. So, he keeps attempting to stir trouble elsewhere. I am so glad that daily blog finally died. Who would have ever imagine a resource for so much hate would emerge... and then be so difficult to bring to an end. Yet, it happened. Fortunately, I documented its entire lifecycle in extreme detail. Those who participated there made a fundamental mistake of not understanding who the customers were. If you don't have thorough knowledge of purpose, you're doomed to fail. They did. I keep reminding those involved why: Know your audience. Current EV owners are not representative of ordinary consumers. They are early-adopters, which have very different priorities from mainstream buyers. Assuming they are the same is a mistake known as "*innovator's dilemma*". This is when audience changes as a new product attempts to grow sales, but the aspects of appeal are different from that of the original audience. The results is a struggle to draw new interest. In this case, the assumption is being made that EV range is of the highest importance for purchase criteria. A great recent example of this mistake is with Volt. GM assumed increasing battery capacity would result in significant sales growth; instead, it made no difference. Mainstream buyers place a much greater emphasis on purchase price. This is why Corolla PHEV holds a much greater potential for high-volume sales. It will be affordably priced, able to compete directly with its traditional counterpart even without a tax-credit.

- 4-26-2018** **Compliance.** This was an interesting comment to make today: "*Speaking of compliance, Volt Gen 2 got 2 credits since it had AER over 50 miles, but this year it gets about 1 credit.*" That tiny morsel of data is a gold nugget with respect to intent. Most people have absolutely no clue about CARB credits. They have no idea that automakers will produce a limited number of green vehicles for the sake of collecting the pollution exemptions they provide. As a whole, you can offset dirty vehicles with cleaner ones. It's overall impact to the environment that's considered, not just individual vehicles. In the states that follow this practice, you'll commonly find a greater selection of plug-in vehicles. In other states, selection can often be limited or non-existent. This is why the potential for Prius Prime is so much higher. That inventory is expected nationwide, simply because it that plug-in model is such an easy step above Prius... making it easier to sell, even when there is no CARB credit incentive available in that state. Volt is far more difficult. It has nothing to leverage. It is a small hatchback at a place where almost all the other vehicles are either Pickups or SUVs. Now that we know there's less of an incentive for the automaker to produce them, inventory is very likely to be reduced. Why bother selling something so expensive, offering so little (if any) profit, when it only returns half the green credits now?
- 4-27-2018** **Silly Argument.** The only tactic remaining to deal with the problems enthusiasts now face is downplay. They have nothing else to work with now that real-world data is plentiful and readily available. That's why I worked so hard to deliver so many driving videos, especially during the extremes of Winter. It's very difficult to mislead about design when evidence contradicting undermining claims is just a click away. You can debunk quite a bit by referring to real-world detail like that. So, the troublemakers turn to efforts to de-emphasize. This is what I got as a result of referring to actual sales: "*Why you cling to silly arguments is beyond me...*" When you provide counts, they don't have any type of rebuttal. Numbers are especially helpful to explain the bigger picture. They immediately draw attention to any attempt mislead through omission. In fact, selective fact sharing is really becoming a focus now that the phaseout of some tax-credits is about to be triggered. Less than 6 months is left if any type of meaning production is delivered. If not, little progress will be made simply due to inability. Either way, we see that 2018 is turning out to be a very pivotal year. I put the situation in context of plug-in sales as a whole, forcing a look on a larger scope: 329,196 sales of Corolla in the United States last year alone. Focusing solely in initial purchases is intention cherry-picking, a narrative I refuse to support. We all must consider the bigger picture. Think about how quickly the 200,000 tax-credits will be used up. That's a total per automaker. The small quantity remaining won't even remotely cover a single vehicle's product-cycle (generation). It's a business with the expectation of sustainable high-volume profitable sales. Calling that a "*silly argument*" is evidence of not taking the situation seriously.

4-27-2018 **Limited.** Spin about automaker intent often emerges when there's a popular discussion topic and the participants are poorly informed. They'll just guess based on anecdotal evidence readily available, rather than take the time to actually research the topic. Antagonists exploit this inherent online forum weakness by providing their own narrative. Unfortunately, both types of commentary cause harm. They undermine true motives by misrepresenting them. That happens frequently when it comes to Toyota. Problems typically emerge from people not having a world view of production. They base progress solely on their own local observations instead. So, on a regular basis I share "big picture" data. Today, it was in response to a claim of limited availability for Prius Prime: 51,000 were produced last year, introducing several new & upgraded technologies. Distributing that to Japan, Europe, and US/Canada all within a single year was quite an accomplishment, especially with a design targeting such a low MSRP. The cutoffs with model-year complicated matters. You don't want to ship outgoing inventory to brand new markets. 2018 is already bringing about change. Here in the middle of the US (specifically Minnesota), we are finally getting to see them offered.

4-27-2018 **Repeating Questions.** That new forum is really proving to be a struggle for my old foe. Nothing works to stir arguments. It's a new venue with a new audience and a new interface. That means none of the old tricks are working well. I know this because he has reverted to the same technique I see elsewhere in the same situation. The antagonist just repeats the same questions over and over and over again. If they cannot redirect focus, that at least keeps you from making any progress... or so they think. In this case, it was: "*Who's goal? Who defines niche?*" The catch is, you have to take their trolling bait. If you don't bite, they just simply get left behind. No one appears to care either. He doesn't have any enablers here. That old daily blog was loaded with support who wanted to see me fail. That isn't the case at this new location, where a far more diverse group of people participate. It's quite a difference from what a Volt fanboy site offers. So, I don't have to even show any interest. I just post something relevant to the topic at hand and move on. Today, in response to his questions, I simply kept to my one-sentence approach with: GM and Ford are dropping cars because their sales are too low for them to sustain a profitable level.

4-27-2018 **Undermining Efforts.** That daily blog for Volt is quite dead now. There is one troublemaker who followed me that is very frustrated by his inability to stir insult for Toyota & Prius. There is another who was very anti-forum who is now reluctantly trying to transition from what that blog had offered to thread posting. You can tell he's frustrated too, since after an entire decade of it being available he has posted only 113 messages there. That level of activity took less than a week on the blog. Anywho, the reason for the blog's death is now quite obvious. It did nothing to discourage inappropriate behavior. Retaining a message posting approach from so long ago allowed their terrible conduct to thrive. They exploited it while other venues worked to prevent that with minor interface upgrades. That only works for so long, before even the small improvements elsewhere really add up... drawing participants to it... who abandon the old as a result. That's why the daily blog kept losing so many regular posters until there was no one left except the most corrupt. A popular plug-in support site I now frequent is one that just happened to get a major upgrade recently. Some of the long-time users there have expressed immense gratitude for it too. My favorite new upgrade there is the voting. Rather than that terrible blog which allowed spoofing (you could vote multiple times by simply connecting from another IP address) and concealing activity with total, it shows the plus & minus votes separately. You can't ever hide a post by voting it down to a count of -10 negative either. That fundamentally undermines the antagonist's ability to undermine. Software improves to preserve integrity. The fact that the other site never upgraded speaks volumes to its intent. It makes the efforts of fanboy activity much more of a challenge now. Of course, with Volt being overwhelmed by better choices, they really don't stand a chance at surviving anyway.

4-28-2018 **Predictive Efficient Drive.** This doesn't get talked about much. It simply works so well, you don't even think about it. The automation is so seamless, it's like when the engine shuts off while in HV mode. That feature is so easy to overlook, comments like this come about: *"...I will say that the Prius and Prius Prime have similarly inconsequential regeneration levels when letting go of the accelerator."* You forget about things that you don't have to interact with. You ever think about gears in an automatic transmission? How is this any different? In a sense, it's just downshifting. But rather than the energy being wasted, as a traditional vehicle does, that opportunity is taken advantage of to send some of it back to the battery... even though you never actually stepped on the brake. It's smaller improvements like that, the refinements others don't offer, which sets Toyota a cut above. They deliver a system that seeks out those otherwise missed chances to squeeze out even higher efficiency. I responded to that comment with: Predictive Efficient Drive hasn't been mentioned. Rather than needing to decelerate yourself, Prime does it for you. The system logs the most frequent 1,000 locations you routinely decelerate for, then automatically provides initial braking using regeneration when approaching them. In other words, the *"inconsequential"* statement above is false for models with that feature.

- 4-29-2018** **Advertised MPG.** It's difficult to know how to respond to a question like this: "*Why am I not getting advertised mpg?*" That couldn't be any more vague? What advertisement is the owner referring to? What is a television commercial, something from a dealer in print, or a comment from a salesperson? To what value are they referring? For that matter, how much is the MPG off by anyway? Then you have to wonder how much they actually researched their purchase. Perhaps all the information actually came from a review instead. Needless to say, void of any detail makes providing an answer nearly impossible. To make matters worse, the owner may simply be disenfranchised for some other reason and they are looking for a venue to vent. It's quite a mystery when a post pops up with a complaint of that nature. Heck, they may actually be getting outstanding MPG but just not interpreting it correctly. For example, not noticing the overall average and focusing solely on the low while accelerating will give a false impression. Anywho, this is how I chose to respond: Start by reading what the advertised information actually tells you. There's far more than just what the big values. Expectations are a range that will fluctuate based on driving conditions. As others point out there are quite a number of influencing factors to be aware of. You'll witness MPG go up & down as you become more observant. That data shown while you drive can really teach a lot about efficiency.
- 4-30-2018** **Vehicle Color.** On a very regular basis, I get unprompted compliments about the color of my Prime. Heck, I even got one up north (in truck country) from a pickup owner who was quite impressed to discover the vehicle that caught his eye was a Prius. He went out of his way to tell me how nice it was to see the look having improved much with the latest version. Finding out from me that it was also a plug-in really stirred interest. That smart approach to drawing attention seems so basic. You compliment style with color. Oddly, most automaker offerings lately don't. The look on roads now is blah. There are a ton of black, white, gray and silver vehicles now. What happened? How did we end up in such a drab phase? Why have the choices turned so plain? Is it the reality that focus on SUV offerings has rendered visual appeal a low priority? After all, if you park a bunch of white SUVs next to each other, they all look remarkably similar. It's quite bizarre how change like this can come about.
- 5-01-2018** **CAFE Standards.** The talk of regulation is heating up again. The horribly short-sighted and uncaring administration we are dealing with now is busy at work trying to undo progress. The latest is the draft of an EPA memo proposing a freeze if economy improvement requirements. Remember how the CAFE standards were set to incrementally raise the MPG overall for fleet measure? The current was expected to increase soon. Now, they are hoping to hold it there until 2026. What incentive is there to even try anymore? Oil dependency and the quality of our air certainly hasn't been a motivator. We obviously don't see interest in facing climate-change contributions either. It's really sad. They just plain don't care. We are witnessing a shift from being leaders to followers. How is one supposedly to deal with such complacency? I jumped into today's discussion on the topic with: From concern about "*too little, too slowly*" to it now just being "*if*". That's a terrible sign. Remember how both Ford and GM used to offer SUV hybrids, but then stopped? Why did they abandon their effort to improve efficiency & emissions in larger vehicles? In other words, what will be the incentive to restart that effort again? What will they end up delivering? All those questions bring us back to the original concern. Neither automaker strived to advance or spread their technology. We witnessed full product-cycles run their course without anything following to attract a large audience. CAFE standards were not taken seriously.

- 5-01-2018** **FUD.** Gotta like seeing this still: "*Has to be the on-going concern that the Prius Prime plug-in is just being bought for the HOV lanes where Z number of owners do not even bother plugging it in.*" Who does he expect to believe that garbage? With such a small battery-pack and blending being a fundamental for the first-generation plug-in Prius, that type of misleading was much easier. People didn't understand the technology and all they knew of was Volt. But now with the flood of choices and the obvious upgrade, it's much harder. Yet, they try to keep the greenwash going anyway. Efficiency is outstanding from the 25 to 30 miles of EV you get from the battery-pack in those HOV privilege states. So, I just call out for data to back the claim. There's a lot more Prime. That makes ignoring the request a problem. This is how I responded to today's FUD nonsense, in this case the "U"ncertainty attempt: FUD being spread by others about supposedly never plugging in shouldn't be re-posted here without supporting evidence. Now that the weather has warmed up here (Minnesota) I'm seeing 25 miles of EV on the highway and close to 30 in the burbs. A little warmer, I'll be back to low 30's. In other words, there's a very large gain to be had from a seemingly small battery-pack.
- 5-01-2018** **Horrible.** The attacks keep coming: "*I don't get the Prime sales. It's truly a horrible car...*" You know Toyota has a winner when the onslaught of undermining is an endless effort. They fear that any loss of momentum for a struggling vehicle... like Volt... will result in huge market loss. The catch is, Volt never had any mainstream market in the first place. It was nothing but conquest sales... which is quite odd, since the enthusiasts touted that fact routinely. What a bizarre world when a lost-cause embraces the very element causing them the most trouble. But then again, it makes sense that an enthusiast would focus on something that gives them a great deal of attention. That's why they absolutely hated when I requested goals to be stated. Drawing attention to purpose wrecks their empty celebrations. Anywho, quite annoyed by such desperate efforts to impeded progress (the penetration of plug-in hybrid sales into the mainstream market), I punched back with: Spoken like a true enthusiast, out of touch with mainstream consumers. Reality is, the bulk of automaker sales aren't exciting. Focus is on attributes like affordability & reliability along with a variety of creature comforts. That's what Prime delivers, as well as a full EV driving experience. So what if it doesn't perform like more expensive plug-in choices.

5-02-2018 **Pride.** When trolling gets really bad, that technique of pushing the antagonist away by posting nothing but a single concise sentence isn't enough. You step up your game by posting about them, instead of making direct contact. Talk about their activity, pointing out how the intent is to mislead, doesn't really have any effective response available. They are getting called out, exactly what the troublemaker tries to avoid. They do everything possible to draw attention to you personally, hoping that will distract from what they are up to. I've been dealing with that spin for far too long to let it contribute to a backlash; instead, I take advantage of the opportunity. Their sense of pride will often cause them so much frustration, they'll end up revealing something they didn't want me to know. Lately, I've been using those discoveries to create driving videos. Inspiration about what to specifically film results from those confrontations. In this case, the troll was attempting to undermine a thread featuring a recent review of Avalon hybrid. I fought back with: You know Toyota is really on to something when a Volt enthusiast works so hard to misrepresent the technology. In this case, we see yet another hybrid with potential for plug augmentation. Prius already has it. Corolla hybrid will be getting it next year. C-HR hybrid is expected to follow. With the success of Honda's Clarity, we can easily see Camry hybrid. Then of course, there's RAV4 hybrid. It doesn't take too much imagination for one to wonder about Avalon hybrid. Again, to augment the hybrid system, it's basically just a matter of adding that one-way clutch for more electric-only power, along with the larger battery-pack and a plug.

5-03-2018 **Distraction.** Successful undermining requires the participation of an unsuspecting reader. They get sucked into the discussion through intrigue, wanting to find out more: "*Why do you care which system has more power?*" Asking that was exactly what the antagonist hoped for. He stirred interest with his off-topic comment. Think about this situation. He was attempting to disparage Toyota's success with Avalon hybrid by posting about a perceived weakness of the design when augmented with a plug. Supposedly, offering more power from the gas-engine rather than the electric-motor disqualifies the technology from any real consideration going forward. It's an exploit of a meaningless point. It's like arguing about battery-pack size. What difference does it actually make if you aren't using the entire capacity anyway? If you do, how often comes into play. Watch for requests of detail related to actual operation being deflected. To effectively undermine, comments much remain vague... at best. The preference is to change the topic entirely. All it takes is a few red-flags to reveal true intent. I pointed that out this way in response to that particular "*Why?*" question today: It's a distraction technique used to draw attention away from the goals achieved. Cost, efficiency, and emissions are very important, but result forgotten when arguing semantics.

5-03-2018 **31.9 Miles.** You know Spring has finally arrived when EV range estimates after a full recharge exceed 30 miles. This afternoon, following the charge at work, the value on the dashboard revealed a very pleasing estimate of 31.9 miles. I seem to be getting that full amount for suburb driving too. When cruising on the highway at 65 and 70 mph, the resulting EV distance drops close to 25 miles... which is what the EPA rating states as their measure for their variety of testing conditions. YMMV is important to remember. (Your Mileage May Vary). More can easily be achieved if you place less demand on the system. The same is the case for pushing the system more; results will be less. It's a matter of being aware what the values are designed to inform you of. They are not expectations, as so many assume by looking at nothing but the large numbers on the window-sticker. It's amazing how many people don't bother to actually read the fine-print. And that's just the problem with estimates. Consider how few ever bother to do any research themselves. Marketing revolves around the reality that most consumers have absolutely no idea what actually happens when they step on the "go" pedal. That's why we see such heightened aware from Prius drivers. Having that wealth of real-world data presented to you with such simplicity each and every time you drive, along with a history to look back upon later, is quite empowering. You begin to understand the inner workings of the system without even trying. Patterns are recognized after a while. That repetition of results is key to opening a new world of understanding. It starts with the most basic elements. In this case, an estimate of EV distance available.

5-03-2018 **Facts.** It is ironic that rebuts to claims of "*facts*" are evaded with fierce efforts to prevent detail from being posted. That behavior was quite obvious today. It really got stirred up by this: "*Gas is still stronger than electric motors in all generations of Prius... facts remain that when power demand is high or highest performance required, gas engine will be the main power provider.*" That's an exploit of a fact which really doesn't have any impact to the outcome. Influence of design can often be misunderstood when comments are vague enough to sound convincing. In this case, the antagonist is hoping no one will ever research the claim. Online misleading is effective due to the readers not questioning what they read. They just accept what's claimed as truth with integrity. That naive & gullible nature is a common problem. I combat that exploit on a regular basis. In this case, I did some research using the collection of detailed video filmed over the past year with my Prime. That provides a wealth of information to fight back with. This time, I uncovered this valuable tidbit of real-world data and posted: Facts are a means of deception. They can be used to mislead by implying importance to trivial or extreme circumstances. Detail reveals the true story. In this case, you're make a huge deal out of less than a 7 horsepower difference. 73 kW output is max when the gas engine is used during hard acceleration and 68 kW for the electric. Neither will last more than a few seconds and max is rarely ever called for. Much ado about nothing.

- 5-04-2018** **Undermining Combat.** You know you've made progress when attempts to exploit new characteristics of operation as an undermining topic are abandoned. When that happens, it can be subtle. Watch for it. That type of weakness helps to confirm new participants have ill intent, rather than just being poorly informed. This was a clue I picked up on when that happened today: "*It cannot complete the EPA test cycles under electric power only...*" That switch to a focus on EPA testing was important, since it really didn't relate to the discussion of design. Even so, you still want to make sure you effort to confirm activity isn't perceived as an attack. That combat should be avoided until you know with strong confidence posts are with the hope to undermine. Stay observant. You'll notice patterns after a while. I probed the discussion to find out this way: You are clearly mixed up information about generations. That was the case for the previous (2012-2015) but most definitely is not for the current (2017-). It was the hard-acceleration segment of the EPA measure that had triggered the engine to start in the original model. Toyota has since enhanced the design to allow you to accelerate all the way to 84 mph with the pedal to the floor entirely using only electricity.
- 5-05-2018** **Threatened.** Ranting from that "*facts*" guy continued. His territory was being invaded. Looking back, I remember his harsh lashing out from me posting real-world data about my Prime. He accused me of working for the petroleum industry. I was bringing about a change to the status quo he had enjoyed for years. I know this, since I checked. With over 30,000 posts isolated to just one particular posting service, it was obvious. I could tell his ill intent simply by the nature of the immediate comments. Past comments are all blocked by using a special feature which allows you to hide activity. That in itself is a red flag. But then when you use searching tools to look for what isn't readily available, you find a lot of blatant greenwashing. That fact that he recently changed his id to include "*volt*" explains his position. It goes without saying how I got called a "*GM hater*" by speaking praise of new choices... like Leaf gen-2, Clarity, and of course Prime. Attempts to shut me up by making it personal and diverting the topic don't work either. He begins his misleading unprompted, posting negative comments right away. Then when someone posting something to threaten his control... like real-world data to contradict his claims... it's an all out attack. The same old desperate tactics don't work as well though... when you utilize more effect means of conveying information, like my very detailed 4K videos. It's quite pathetic how someone would fight change like that; however, it is also quite an endorsement for Prius Prime. That particular topic really stirs the anger.

5-05-2018 **Competition.** No one should be asking about competition anymore. The need to replace traditional vehicles with cleaner and more efficient choices is obvious. Of course, you'd never know that from the backward administration we are having to deal with. But when it comes to online comments, there is a time to make the message very clear:

Excuse the shouting. In some cases, it is valuable to make sure an essential understanding is conveyed with importance.

THE COMPETITION IS OTHER VEHICLES ON THE DEALER'S SHOWROOM FLOOR, NOT OFFERINGS FROM OTHER AUTOMAKERS.

There is always competition. It is a presence that should go without saying and the who is obvious. That misunderstanding of purpose & audience was fundamental mistake enthusiasts of Volt made.

It was absolutely vital that GM shifted from conquest sales to drawing interest from their own loyal customers well in advance of the tax-credits expiring. That subsidy was provided with the intent of changing mainstream purchase preference; instead, we saw it squandered for the sake of feeding pride. This has become a modern example of unintended consequences, when an effort to promote change results in a massive waste of opportunity.

Consider what shoppers see when they go to a GM dealer to shop for a vehicle to replace their aged GM vehicle with. Nothing became of the "EREV" marketing. Volt remained a small & expensive niche vehicle. Bolt emerged as expensive choice, undesirable without tax-credit incentives. The commitment to endorse guzzling Pickups & SUVs is obvious.

Consider what shoppers see when they go to a Toyota dealer. There is a variety of affordable hybrid choices with the first plug-in hybrid priced with a choice of affordability and some enticing package options. The commitment to shift away from traditional vehicles is obvious.

Understand why the shouting was necessary?

5-05-2018 **Kerfuffle.** Time has come to pile on, tackling the beast that didn't actually advance us forward: "*And on the topic of the volt...*" The thread had veered off on a tangent and participants were excited to indulge on the opportunity. Sure, we did see Volt help prove out an aspect of plug-in technology. But the point of changing mainstream priorities failed miserably. Only early adopters were interested and only because there was such a generous tax-credit. Without that \$7,500 incentive, it just plain wasn't worth it. That's why Toyota only released a mid-cycle update and only to a limited market. GM didn't care. Pride was more important... hence focus on conquest. That's becoming very difficult to deny now... hence the pile, which I was happy to join: Correct and we look forward to someday GM offering something that won't actually be high-end. The kerfuffle with Volt was simple discussion topics... just like this... weren't taken seriously because it was struggling with sales so much. Enthusiasts would distort anything related to the other plug-in choices to keep understanding of design a mystery. That way, the shortcomings of Volt wouldn't get in the way of propaganda. We saw the same thing play out with diesel. It's easy to see the problem now, long after evidence has been collected. But while there was lots at play, those efforts to deceive were quite effective. People didn't know enough then to connect the dots. Think about how little most people understand about plug-in vehicles still.

5-06-2018 **Entire Life-Cycle.** Within these blogs is the entire life-cycle of that daily blog for Volt. It started from a modest beginning, then almost immediately got out of control. The hope transformed to vaporware promises as if overnight. I'm sure it took the founder by surprise. He kept with it though. Major events, like the body-style change from concept to production-intent didn't shake the website to its core... though, it should have. The count of those who were interested in purchase weren't allowed to change their status, despite such a dramatic appearance alteration. That's when the major misrepresentation efforts really took hold. It's one thing to make unsubstantiated claims about design, it's quite another to use data confirmed invalid. Things got progressively worse from there. When rollout finally happened, several disasters had already taken place. The design wasn't at all when enthusiasts had hyped, cost was far more than expected, and efficiency was well below what anyone had anticipated. Sales were a struggle as a result. Attention turned to next-gen offerings instead. The rhetoric turned into propaganda. They spread misleading efforts everywhere. Greenwashing became such a norm, it was easy to lose sight of goals... for GM support, anyway. Ironically, that same information was used by Toyota to make the first full-cycle worldwide offering of their plug-in Prius a strong contender, while its use by GM ended up making their niche offering even more of a niche. Volt fell into the "Innovator's Dilemma" trap. Of all things, this is what the biggest troublemaker of them all kept claiming about Toyota. It was classic reflection, accusing the other of what you are guilty. Anywho, we know how that played out. Gen-2 of Volt did indeed target a very specialized market, rather than mainstream consumers... and the plug-in Prius seemed to have reached that intended wider audience. This point though is the finale. That biggest antagonist, an underminer willing to post anything to make Volt look better, has abandoned both Volt and GM. Rather than following supporters to embrace Bolt, he purchased a Tesla Model 3. The ultimate in hypocritical actions is exactly what he did. All that spin about how EREV would be the "*vastly superior*" option over everything else was abandoned. Nothing to see here, move along. Pretending none of that nonsense ever happened is what has brought the trouble he helped to create to an end. The life-cycle of such a terrible venue is complete.

5-07-2018 **Conquest Sales.** There was always an overall objective of changing the market. It was generically defined as a goal to get customers purchasing the new product. Specifically, that meant current owners of GM vehicles would replace that older vehicle with a new one from GM. Attracting shoppers from other automakers, known as "*conquest sales*", didn't accomplish anything in that respect... since the technology had already been proven. Gen-2 was supposed to reach that audience of loyal GM customers, an obvious shortcoming from the first-generation. It didn't. That meant major problems to come, since virtually all the gen-1 owners were abandoning GM. When their Volt lease expired... or in the most recent example, their Tesla order fulfilled... or their early-model (rollout began in late 2010) simply became too old... they moved on, rather than purchasing something again from GM. There was never any sense of loyalty, only a lot of "*shill*" behavior to favor their interest at the time. This is why stating goals and answering the "*Who?*" question was evaded on such a regular basis. Accountabilities to work when all you are seeing is conquest sales... especially when those buyers are clearly identified as just early-adopters taking advantage of tax-credit opportunities. It was doomed to failed.

5-08-2018 **Target Market.** It has become undeniable at this point that GM really messed up. After all those years of me asking "*Who is the market for Volt?*" that question is finally recognized as a very real problem. No one cares anymore. They've moved on. Sales have been terrible and so many other vehicles are getting attention, why bother? The approach of trying to sell a vehicle that's too small and too expensive didn't work, period. No amount of "*fun to drive*" could overcome that major obstacle of appealing to the masses. The target market has never been interested in speed & power. That's why there were always enthusiast offerings. The draw of large, bulky vehicles as been dominant for 2 decades now. Remember the mid 90's when SUV marketing began? Detroit automakers very specifically targeted their own loyal car buyers. They wanted them to purchase a SUV instead, since those were far more profitable. The deception used to entice was safety. They were promoted as being a safer choice... even though the data said the very opposite. People were gullible and quite easy to convince with gas prices so low. 20 years later, gas prices are low again. But rather than give buyers a choice, the Detroit automakers won't even bother to produce cars.

5-09-2018 **Understanding Interest.** Enthusiasts are learning the hard way that expressing interest has no reflection upon action. This isn't just about the failure of Volt to attract sales. It's about the reality that tax-credits and leases played far more of a role stirring interest than just about everyone cared to admit. I hear quite a bit still about range-anxiety. That is obvious from the most basic questions asked upon pretty much every encounter... "*How far can you drive?*" and "*How long does it take to charge?*" Answering that puts you in a bit of a conundrum too. In general, people aren't actually impressed by 200 miles. True, supporters understand that is plenty for daily driving. But the reality is people have become accustomed to having much more. Breaking them of an unnecessary requirement is extremely difficult in a market where want & need are often confusing terms. The answer to that second question makes the situation worse. Using 6.6 kW rate for charging (your standard 32-amp draw from a 240-volt home charger) for 8 hours would return 52.8 kWh of electricity. Keeping in mind that rate slows as the battery reaching full capacity and that there are losses in the conversion from AC to DC power, you can safely round the results to 50 kWh. Don't forget about electricity used for pre-conditioning either. Given an efficiency return from the vehicle itself a rate of 4 kWh/mile, you get a range expectation of 200 miles. See the complication? With efficiency increases and more time to charge, you really aren't going to squeeze out much more than another 50 miles from charging at home. So, whether you have a basic or a comprehensive understanding, there are barriers of concern... without even taking cost into account.

5-10-2018 **Reducing Cost.** That topic sure is getting attention now... since we are at the point of which you can say "*Oops!*" Far too many focused on range & power with hope that cost would drop fast enough to usher in mainstream acceptance on a rapid schedule. It was assumed effort to refine design wouldn't be necessary. They are finding out the hard way that original requirement of being affordable shouldn't have been neglected. It looks like that will be much more of an impediment to progress than just about everyone imagined. That's because most didn't know the audience. Cost concerns are foremost on people's minds. They fear battery replacement cost and have no real idea how much they actually spend on gas. It makes appealing to them even harder, beyond the terrible struggle to overcome misconceptions. In other words, we can realistically expect a few years of challenging sales. Being an obvious solution to future energy & environmental issues isn't a given. We'll see the price tags quite high on the really desirable plug-in choices. Fortunately, a few everyday alternatives will still be able to sneak into the driveways of ordinary consumers... with Prius Prime being one of the leaders... simply because Toyota has already addressed cost, placing an extremely high priority on making the price competitive.

5-11-2018 **No Labels.** We had an event yesterday host by the local electricity provider. Outside, there was a gathering of plug-in vehicles for people attending to look at. None of them on display were labeled. That made for very interesting conversations with those stopping by to check. Participants would intermingle with owners, asking questions when curiosity about something struck them. Most had no idea what was what or how any if it worked. This is exactly what I meant by missed opportunity. After all those years, Volt had remained an unknown. GM did a horrible job of promoting. In fact, Bolt was just outright dismissed in that display parked near a Model 3. People understand exactly what Tesla is. That put the new Leaf in an odd position. Since gen-2 looks so different and has a much lower price, it's not considered competition. It is simply looked upon as the plug-in offering from Nissan. The same holds true for Toyota. Prime is a nice looking vehicle (I got lots of compliments) with a clear understanding of origin. Toyota offers an affordable & reliable choice that now comes with a plug. Delivering a Prius with that upgrade is a no-brainer, the approach to electric augmentation is well recognized. So when you point out new choices, like the Outlander there in attendance, it is seen as Mitsubishi trying to deliver something similar. Unfortunately, we didn't have Honda in attendance. Seeing a Clarity would have been impressive. It's large & comfortable with an obvious investment in the future. Long story short, this stage of soon-to-end subsidies is making things very interesting. The past really only serves as a practice round for promotion, so not much as really be lost. Most people still have pretty much no clue what plug-in vehicles have to offer. I suspect labels will emerge though, once the tax-credits are totally phased out.

5-12-2018 **Adoption Speed.** Change can be quite perplexing sometimes. For example, millennials have come to look upon car-payments as an on-going expense, like the bill for their cell-phone. That makes the appeal to leasing stronger... since those payments are lower per month compared to a regular car-loan. So, the idea of paying off the vehicle simply isn't a priority. Knowing that, combined with the knowledge that their age-group has only been part of a market that pushed SUV appeal, makes it easier to see the shift. In other words, the higher profit from SUVs is influencing what automakers produce more than regulation or even doing the right thing. Of course, if GM and Ford had delivered hybrid models, that would have made the situation quite different... but they didn't. This is making the speed of plug-in adoption even slower. It is so obvious with Volt & Bolt that no one wants to discuss the problem anymore. That makes issues like home-charging complete non-starters. The topic is basically impossible to bring up when there is no SUV option to purchase. Models with plugs are tiny cars... which none of their own customers have any interest. Being so correct about the "*too little, too slowly*" concern is quite disturbing. GM didn't diversify. The technology in Volt was never spread to a SUV, which ironically is where it originated. Remember Two-Mode? It's sad that we are dealing with a crawl as slow as molasses. Looking back at the inspiration for Volt was the frustration about Toyota having so much success with Prius. After all these years, we see that the automaker repeated the same mistake again. Ugh. Transitioning away from traditional vehicles is taking forever. The reason why sure makes for interesting history though.

5-12-2018 **More Hate.** Posting started with this: "*So for part of the year Toyota might have one, wow almost impressed, (not).*" After a series of replies, confirmation this person was just a desperate GM defender was provided. He started lashing out without any rationale. I got a hint of that early on with the spin following my initial reply. That all-too-familiar effort to evade what was being discussed made it undeniable. When the thread is about cost-reduction and your affordability references are countered with off-topic replies, you know. It becomes quite obvious after a while. What I hadn't thought about coming from encounters like this is the absence of attention could be making them crazy. Think about Volt enthusiasts without a venue to practice their greenwash anymore. It was pride, the meritless bragging-rights, which kept the hope alive. But now with things falling apart due to poor sales and the rapidly approaching tax-credit phaseout trigger, the desperation is quite understandable. It's too bad focus wasn't focused on goals instead. What a waste. Anywho, I started my replies with: Shortsightedness is a common problem. Much of that originates from not being well informed. While busy with rolling out their first affordable plug-in hybrid this year, Toyota is working on delivery of their second next year... Corolla PHEV. At the same time, Toyota has delivered 3 hybrids all easily upgraded to offer plug augmentation... Camry, RAV4, C-HR. There is a larger model of Prius in the works too. It's all about reaching ordinary consumers, an objective that doesn't impress enthusiasts. That's why Nissan's focus on cost-reduction has so many of them speaking unfavorably about the 300 km (188 mile) range being considered enough. Changing the fleet is far more difficult than just rolling out a few expensive niche offerings. Notice how well Prius Prime appeals to mainstream consumers?

5-12-2018 **Ignored.** That problem of GM not getting attention anymore is getting worse. This trolling effort to drop bait for the opportunity to inject Volt into the discussion fell apart: "*The Prime has around 25 miles of AER if you drive it gently.*" I wasn't about to let that well known antagonist get away with his attempt to redirect focus either: The effort to undermine Toyota by misrepresenting Prime is becoming more telling as more of those driving gently report numbers close to 40. You know I have shared video showing it reaches 30 without any effort. Even the math confirms more than just 25 miles. EV-capacity is from 83% to 12% of the 8.8 kWh battery-pack. That gives you 6.25 kWh of usable electricity. So, even with just a standard consumption-rate of 4.7 miles/kWh, you effortlessly exceed 25 miles by 4. My own personal daily drives currently deliver efficiency over 5 miles/kWh, which easily puts me above the 30-mile range. It doesn't matter anyway. For the plug-in presentation we had at the community-center last week, all I needed to tell people the odometer showed 268 miles since filling up and the tank still indicated full. No amount of EV-range misrepresentation can outweigh results like that.

- 5-12-2018 *The Bigger Picture.*** To my surprise, the next stir attempt and belittling of Prius Prime came from someone in Europe: *"Now it's just a washed up ICE-converted PHEV with too little range and a little too late."* That presented yet another opportunity to post more information about the bigger picture... as well as hint at how GM is being dismissed as a serious player, by not even mentioning them: From a mainstream perspective here in the United States, there is literally nothing to support such a claim. Tax-Credit dependency is the most obvious reason why. Another reason is how tiny sales actually are still even with them. Infrastructure is only in its infancy too. Prius Prime is first of the truly affordable plug-in hybrid choices, with many more on the way. Next year, Toyota will rollout the plug-in hybrid Corolla for the market in China. We will likely get something to follow shortly after that... either a mid-cycle update for Prius itself or one of the other hybrids introducing a plug. Think about what our SUV-obsessed market here would do for a RAV4 hybrid with a PHEV option. As for the market in Europe, your own obsession with Tesla doesn't really reflect the efforts of automakers there. We'll see a variety of types of offerings from VW and BMW. Renault will likely continue to follow parent-company Nissan in the pursuit of affordability too... just like Toyota intends with its first mainstream EV. Mitsubishi has been selling well there and has made a good initial splash here. Don't forget about Hyundai/Kia or Honda either. In other words, it is far too premature to draw any conclusions yet. Things are only just getting started.
- 5-12-2018 *Distorted History.*** There's a strong desire to parallel the progress of Tesla to that of what Toyota did with Prius. That doesn't make sense if you have knowledge of what actually happened. Most people don't though. So, their own narrative typically goes unchallenged. This time, I stepped up to fill in the information they were missing: Looking back at Prius history long afterward often returns a very distorted interpretation of what actually occurred. Most common of errors is to assume the first model-year sold in the United States was a full year. In reality, sales began the last week of August 2000. So, all reports of demand are incorrect due to misrepresentation of time. Confusing matters more was the fact that Prius could only be obtained 2 ways back then. Either you placed an order online and waited 6 to 9 months for delivery or you got really lucky and were able to purchase a demo-model. Keep in mind that inventory on dealer's lots did not become available until May 2002. So, all reports of demand are incorrect due to misrepresentation of supply. Complicating the situation even beyond that mess is the fact that Toyota only allocated specific quotas for each year of sales. That meant demand could never be accurately gauged during that entire generation. In other words, if you weren't blogging about those events as they played out (like I did), you may not have an accurate understanding of what really happened. There is much detail people are not aware of.

- 5-13-2018** **Mi/kWh.** It is quite refreshing to have an informed & constructive discussion. Today, that came about from this comment: *"The past several daily mi/kWh readout have been between 5.0 and 5.2"* Most owners don't have an idea what that means. In fact, I'm willing to bet they haven't even noticed that value yet on their collection of data readout screens. In the past, this was a source of hatred from some Volt enthusiasts. Remember how they would treat electricity as if it was free & unlimited? Simply reducing gas consumption is not enough. Wasting electricity is not acceptable either. This value depicts the reality of that situation, revealing a story of some designs being better than others. And of course, it confirms Toyota delivered a more efficient electrical system than GM. Prime uses less electricity than Volt to travel the same distance. They hated when I would point that out... since it cancelled out all arguments when considering the reality that Prime could later get an upgrade to deliver a range increase... less battery needed to travel the same distance. I kept that knowledge to myself this time, keeping the response simple: I have taken a lot of flack over the years from some when pointing out how not all EV is equal. There are a few plug-in vehicles that guzzle electricity in comparison. This is proof of that... and confirmation of how efficient of a system Toyota delivered.
- 5-14-2018** **Future Audience.** I have wanted to blog about this topic for quite some time. But with such an evolving market, its becoming a non-issue. The crazy efforts by Volt enthusiasts to undermine Prius are now just a part of history few will actually believe. Those that were part of it will downplay & deny. It's how history repeats. Troublemakers disappear and evidences of their misgivings vanish. They were wrong and don't want anyone to find out. Just like all the attacks we had to endure from diesel supporters. What happened to all the lies they spread? For that matter, what happened to their victims? Think of the collateral damage too. Anywho, that look backward is very important when you look forward. You don't want this next audience to fall into the same trap as in the past.; however, this future will be quite different in terms of technology. There is nothing to prove anymore with respect to speed or power or even cost. There is an opportunity to spread FUD about reliability though. Antagonists will do everything they possibly can to exploit that too... everything. Don't let your guard down. Remember that real-world data is the most difficult challenge they face. Enough of it will drown out their rhetoric. That's what we want this future audience to focus on. We tell them about the simplicity of plugging in to recharge. It's so easy, the habit becomes second nature. It's like shutting the garage door after coming home. You just do it without thought. That is how basic the benefit of recharging will become. You'll just do it and reap the benefits without thought. Convey that message. Don't feed the trolls.

- 5-15-2018** **Fancy Label.** Despite so much fallout with Volt, there are a handful still trying to push the superiority status: *"Apart from i3 Rex and Volt, all the PHEVs on the market are much closer to a regular hybrid, indeed any regular ICE, than to a typical BEV in this respect. If PHEV was restricted to only be the range-extended kind..."* Accepting the fact that there is now a variety of plug-in hybrids to serve a variety of audiences is too much. They want to hold onto the early-adopter phase, where those owners were a very specific buyer willing to overlook shortcomings of mainstream appeal. That's why there is so much resentment toward Prime. Toyota delivered a model of Prius able to overcome those barriers. It's really unfortunate these few individuals screamed the mantra of niche so loudly that GM followed their misguided advice. Ironically, they argued intensely about not having an influence over GM's decisions. They were wrong, very wrong. Big oops! My reply to the greenwash effort kept focus on real-world results, diverting this attempt to make labels more important: 328 miles on this tank so far and it still reads full. Those results from my Prime are not closer to hybrid, period. The marketing of *"range-extended"* clearly doesn't equate to much when looking at real-world data. Remember the goal is to deliver vehicles which significantly reduce emissions & consumption. To actually achieve that, they much be able to compete directly with traditional vehicles... not just be an offering with a fancy label.
- 5-16-2018** **Label Rhetoric.** Exactly as anticipated, this well known Volt enthusiast lashed out. With so few remaining, that was easy to predict. They have been misplaced. Death of their daily blog disbanded that shared voice they took advantage of to push rhetoric. The most glaring of their efforts was *"EREV"* marketing. It was a label used to isolate Volt as a standout among the plug-in hybrid offerings to come. Only problem was, each reveal of a new offerings caused their definition to change. They would get called out routinely on their contradictory posts... which I was happy to point out. Their own history had come back to haunt them. Choosing to focus on labels, rather than actual results, has a way of harming those who use them to deceive. Anywho, once again, I called it out: Your rant serves no purpose. The 20 years of hybrid history overwhelming confirm that labels make no difference. People will simply coin a new one to replace the old. A simple look at how clueless consumers are about specifications should make that point obvious. Real-World data is the solution. Focus on that is the only meaningful step forward. Otherwise, it's really just marketing spin.
- 5-17-2018** **Video: Full Commute, No Recharge.** 31.1 miles of EV (electric-only driving) for this commute to & from work on a beautiful Spring day. That speaks for itself. It wasn't the best efficiency I have seen. That comes with Summer driving, when another 2.5 miles of EV can be observed from the same drive. The difference is temperature; a little warmer is the ideal for efficiency. Nonetheless, you can clearly see how easy that was to achieve, despite the impact of speed & traffic. It clearly shows the official *"25 mile"* rated capacity is understated, even for the standard testing criteria. Watch the cluster of aftermarket gauge information on the right. That shows detail you don't see from the dashboard instruments. Knowing what actual values are from the battery-pack provides insight to how the system actually operates. You get a better understanding of why this design is so dynamic. Lastly, note the results at the end of the drive. See how running the engine with the best load for maximum efficiency results in some EV range being generated... [Full Commute, No Recharge \(31 miles of EV\)](#)

5-17-2018 **Unexpected Share.** The interface for Facebook can be clumsy at times. There is a lot there and its easy to overlook or to simply forget about. That happened today with the share of that newest video. I was on a group dedicated to Prius Prime, but didn't realize a post while viewing that content wouldn't default to the group. It goes to public instead. That explains why the post was there for a moment of confirmation, then vanished. Where did it go? A little late, I got a like from a friend not in that group. Huh? Oh well. It's good to target a wider audience from time to time and the content of this video was a nice wide-audience topic... though future-oriented from their perspective. Turns out, I stirred interest of a developer for the phone-app. So, my link got shared with an even more people I wouldn't normally reach out to. That was an unexpected outcome. Here's what I actually posted in addition to a link to the video itself: How often are you asked the question: "*How far can it go?*" Having a commute on video to share is nice. This is what I experienced on my commute... 37 miles total. What's most interesting is when the engine shuts back off following the warm-up cycle. MPG stays above the 199.9 readout maximum (for the 2017 model) and a mile of EV is generated, despite the HV driving. btw, that display on the right is an app on my phone connected to the Prime OBD-II port via Bluetooth.

5-18-2018 **Refreshed Attacks.** Another one of the misplaced Volt enthusiasts returned to posting rhetoric on the big Prius forum. I wondered if he would behave this time. Years back, it was blatant misleading. He would post false information about how the plug-in Prius operated, spreading those lies where ever he could. His posts on the member-only forum for Volt were especially deceptive. Feeding greenwash is something I don't tolerate. So, I have been keeping a close eye. Today, he started up again: "*A similar PHEV could have done this 'commute' without...*" But now being in the role of playing offense, I took advantage of the table having turned by calling out his attempt to spin... an obvious attack in his own subtle way , which I have become all too familiar with:

I am well aware of your history with Volt and your perspective for Prius... with the hope you wouldn't stir that pointless pot again. That similar PHEV is so far beyond affordability & profitably, my question to you is: How does that make any difference to ordinary consumers?

The point of that video I just filmed & shared was to answer that question. It clearly shows there is no need for more range & power. Sure, more is nice to have, but is by no means required to significantly reduce emissions & consumption.

GM simply isn't interested in selling an expensive small hatchback, period. That's why I asked the "*Who is the market for Volt?*" question hundreds of times over the past decade. It never made any sense. There was no target audience within the base of loyal GM customers. They clearly desire Pickups & SUVs instead. That's why Volt sales were limited to just conquest buyers taking advantage of early-adopter discounts.

200 MPG for an ordinary commute is what will a major draw for Prius Prime. It's hybrid that offers so much EV driving, use of the engine is a complete non-issue. Efficiency is outstanding regardless of how you drive. Emissions are too, since that plug-supplied electricity is used as much as possible. All that from an affordable package that will appeal to dealers is a winning design that will draw interest from the masses. It is clearly a mainstream vehicle from automaker to ordinary consumer.

5-18-2018 **Early-Adopter Spin.** Not all posts that I deal with come from antagonists. Some are just poorly informed. Sadly, that doesn't happen much anymore. I wonder why. Hmm? Finding out there is less confusion about how plug-in hybrids work would be great. That's the impression I have got so far from our plug-in owner's group presentations. Time will time. In the meantime, I still have to deal with crap like this: *"Most hybrids do give range anxiety, at least plug-in hybrids. Imagine the horror when the range ends and... *gasp* ...the ICE kicks in. I'm not kidding, it's the main annoyance of the PHEV owners I've met, not enough electric range."* As expected, another Volt enthusiast was sounding off with again. The narrow-minded perspective is what got that group into trouble. A few obviously still haven't learned that *"know your audience"* lesson yet. That self-inflicted problem cost them dearly. Ugh. Oh well, all you can do is point out the problem: That is the message early-adopters have sent, a problem they created. For ordinary plug-in hybrid owners, they experience remarkable efficiency and simply don't get worked up when the engine starts. In my Prime, the tank reads almost totally full, despite 400 miles since the last fill-up.

5-18-2018 **Spinning Problems.** We get this on a regular basis. Antagonists will invent a problem for their solution. This is how you recruit enthusiasts. It sounds like a great idea. The reality that there really wasn't a problem in the first place doesn't matter. Spin is why certain issues never die. Since they don't exist in the first place, there's nothing to actually fix. Recognition of this at play is to watch for who the solution is directed too. If the target hasn't been complaining about that, it's likely a want, not a need. If there is no requirement, there is no problem. Annoyed by having to deal with this so often, I posted:

It isn't really a problem... if you understand audience.

GM made the fundamental mistake of asking gen-1 Volt owners how to make gen-2 better. That flawed approach doomed them to delivering an even better niche, rather than a vehicle for mainstream consumers. They repeated a mistake others have made, called *"Innovator's Dilemma"*. Toyota was smart enough to steer away from that, well aware of what pitfalls there are when focusing in on the wrong target market. That's why gen-1 plug-in Prius rollout was halted. Limited to 15 states and without a successor, the gen-2 design wouldn't suffer consequences of misguided expectations.

In other words, Toyota is basically starting from scratch with Prius Prime, since most people really don't have any clue how Prius works anyway. I know this from the countless encounters I have had with ordinary people walking by the charger at our local grocery store. They see me holding the cord and asked questions. A past without the being able to recharge from the wall is meaningless to someone who never owned a hybrid. Having that ability to plug in seems perfectly nature from their perspective.

I simply tell them it takes 5.5 hours to recharge with a common household outlet and 2 hours with a 240-volt connection. From that, you get about 30 miles of real-world EV driving. There's no confusion. They get it... especially when I mention the base price of \$27k.

5-19-2018 **Customers.** Still annoyed, the feeling amplified when I got this in return: " '*profitability*' ? *What consumer EVER cares about that?*" Yes, it came from some troublemaker pushing Volt. Like rhetoric of the past, he has no concern whatsoever for anyone except early adopters. No one else is important from his perspective. To be so self-centered you don't notice the rest of the world around you. Ugh. It's the "*buy American*" spin. That really means money must only go to Detroit. The fact that supposed "*foreign*" competition employs tens of thousands of Americans to build, deliver, sell, and service the vehicles all here in the United States doesn't matter. Again, ugh, especially when you realize some of the Detroit production actually takes place in Mexico & Korea. Anywho, I treated it as an attack from the naive rather than someone intentionally trying to undermine & mislead: Such a fundamental error... Not knowing audience is a huge mistake quite common to posts like this... Ugh. DEALERS ARE THE CUSTOMERS, NOT THOSE WHO PURCHASE THE VEHICLE !!! Understand why? You should. If dealers aren't interested, there's nothing for the consumer to actually purchase. That was a major reason why Volt struggled so much. Dealers simply weren't interested. Why offer a small, expensive, difficult-to-explain hatchback that provides a razor-thin return when you can just offer highly-profitable, easy-to-sell SUVs instead? It's amazing how so many people claiming to understand the market don't recognize the importance of how vehicles are sold. What incentive is there for a salesperson to bother when the dealer they work for shows no interest?

5-20-2018 **Forcing Simplicity.** It never works. They keep trying though: "*If we had only ever had PHEVs, there would likely be less confusion. Has a gas engine, and also has a battery you can charge. Very simple.*" Some people cannot comprehend or deal with a complex world. That's why we see them attempt to force generalizations. They want a simple perspective, nothing requiring anything more than a first impression. Extensive study to correctly grasp an abstract concept doesn't ever happen. They need everything dumbed down... which doesn't work in the real world. Things are never really that basic. I punched back at that quoted hope with: History has overwhelmingly proven that false. Even when there were just 2 hybrids available, the differences were so profound, they could not be considered in the same category. The designs were fundamentally different. One has a single tiny electric-motor directly linked (RPM locked) to the engine. The other had a small electric-motor and a large electric-motor, each with independent control to connect them to the engine. Yet, both were given the same "*hybrid*" label. We already see that problem emerging again for plug-in hybrids. Design varies dramatically, yet some people want to represent them as having a shared design with only battery & motor size as the difference. That's how greenwash is spread. Omitting important features, like the type of heater or charging speed, contributes heavily to misconceptions and disappointment. In other words, it is far from a simple matter.

5-20-2018

Jumping Ship. I found this intriguing, since it came from a posted topic about Tesla interest: "*Toyota is way behind in recognizing the potential and significance of battery-electric vehicles, following their strange fascination with FCEVs.*" Are people posting that because they are so poorly informed or are they just dismissing what they don't like to hear? I pressed to out how by posting:

Spreading of misunderstood intent needs to stop. We are the ones who can help with that.

Fuel-Cell use will be significant in the future. That's how power-suppliers will compensate for high-demand, using stored hydrogen to supplement peak need rather than continuing to depend upon the dirty sources. Just talk to someone in the industry, that switch-over is something they are very much looking forward too. There's also the commercial use of fuel-cells. Think about how incredibly practical that is for buses, construction, delivery trucks, and portable power. Most people don't.

Most people only see the personal transport rollouts... and totally overlook the reality that those taking the leap are the ones who will promote use for fleets. Think of how important it is to have rapid refill for a parking lot full of vehicles all needing to be deployed at the same time.

As for Toyota not recognizing, that hasn't ever been true. The first model-year of the first-generation actually had a plug. We saw the 100 km/h design rolled out in 2003 for Prius. Back then and as of recent, the barrier to reaching the masses is cost & capacity. There should be no doubt that the perceived legacy leader from Detroit who supposedly gave a full endorsement for plug-in vehicles will be in a world of hurt soon when tax-credit phaseout begins, making their struggle for sales even more difficult. Cost is still very much an issue.

Haven't you noticed how hard Toyota has pushed with lithium battery technology? They made all but 1 model of Prius us it. That step in the direction of high-volume supply & demand effort should be obvious. Less obvious is how hard Toyota has pushed to not require liquid cooling. That raises cost & complex issues, ones Tesla much also address by does not have legacy constraints to also deal with.

In other words, labeling Toyota as "*behind*" serves no purpose when the bigger picture is taken into consideration.

5-20-2018 **Kicking & Screaming.** It's time to stop acknowledging this narrative: "*The legacy automakers are being dragged along, kicking and screaming.*" A good reason to just pretend that wasn't ever posted is that it's so vague. What does that actually mean in regard to choices that are made. Actions we see are that of slow change. Ask yourself why. The reasons are far from clear, as they are portrayed to be. I'll post some of the complexities. But realistically, most of it will just fall on deaf ears:

Generalizations are not helpful... perhaps some clarity about that specific resistance you feel still persists.

Toyota is converting its entire fleet to offer hybrid models. Camry hybrid is an outstanding example of a compelling alternative to traditional propulsion. Think of how valuable Corolla PHEV will be to that effort. We know there will be an EV model of C-HR. We also know there are plans for a PHEV model of RAV-4. We may see a mid-cycle upgrade of Prius Prime too. So, it's safe to say Toyota is working toward mass-market change.

What about GM with their 2 conflicting approaches, neither one which is of any interest to their customers who overwhelmingly prefer SUV choices? They are being dragged, kicking, or screaming. It's just what they turned in as homework wasn't what was assigned. Remember how the goal of electrification was to get automakers to switch over to vehicles with plugs? If all that automaker does is offer niche vehicles for conquest sales, that goal is being missed entirely.

Sadly, there will always be a level of push back, but you can see very real change coming when ordinary people are drawn to a choice without any special incentive. Watch what happens when tax-credit phaseouts are triggered.

5-21-2018 **The Game.** A classic antagonist move: "...why would Toyota want to get in that game?" They ask a question about the point you had already made. Doing anything possible to avoid drawing attention to a conclusion having successfully been reached in very important, since they don't want the status quo to change. I kept my response brief: While tax-credits are still at play, it is very much a game for legacy automakers. Avoiding that mess will likely prove a very wise move... especially knowing how long a product-cycle can be.

5-21-2018 **The Count.** They also do everything they can to prevent you from looking ahead: "*Meanwhile, Toyota has yet to even bring a BEV to market.*" It requires quite a bit of willful ignorance to work though, as I pointed out: Turning a blind-eye to the lithium battery use in Prius is a very real problem. Why aren't you acknowledging the choice to use lots of small packs to reach lots more people? Think about how important it is to reach the market now with some type of electrification. When solid-state does become realistic, they will have a large market of potential already established. Look at how terrible for job GM did rushing to market. Nothing but conquest costly mistake.

5-21-2018 **The Premium.** They also tell you what to do & think: "*We can't let our disappointment cloud our judgement.*" I wasn't about to listen to any of that dribble by making sure the answer to "*Who?*" was clear:

Know your audience.

How many hundreds of time have I said that? The repetition comes from some still not recognizing the fundamental difference between who they are and mainstream consumers. Ordinary showroom shoppers see the world very differently. Toyota understands this... hence the success for decades with Corolla and Camry.

Electrification is a paradigm-shift so profound, it's easy to frighten people away. Think about how difficult it has been to get people to embrace smart-phones. Many who finally switched to one use only basic features. That's a cheap & easy upgrade compared to the purchase of a vehicle. It makes the idea of really taking advantage of what that tech has to offer a painful reality to accept... since, most will not.

The key is finally ways to compel that fickle audience. Tesla isn't even bothering to target them. They offer an outstanding product for those aware & willing to pay that premium. Toyota is going after a much different group of buyers. So, even just the idea of "*jumping ship*" is rather absurd. The groups are far too different.

Know your audience.

5-21-2018 **The Point.** Every now & then, someone posts a sensible message: "*But some of us still want a hybrid for the convenience of traditional fuel and distance to travel. Tesla has only 1% market share at this time. That's one week of sales for GM or Toyota.*" Perspective like that is what causes a lot of anger. It makes sense. What kind of precedent is set when being logical online makes sense. People are often driven to participation on forums due to a need to emotionally express something. Responding to a feeling usually isn't constructive. In fact, some people just want to vent and couldn't care less what others have to say. So, who knows where this will go: The point of all this here was to shake out that very point. Well said. People need perspective. Yes, it is easy to claim & confirm marketing issues, but that requires cherry picking. There's simply no way to look at the big picture and not see the very limited scope of market penetration so far. There are major barriers to address still that have nothing to do with the engineering focus here. Distractions only make that worse. Plug in your car at a very busy public location while smiling at people walking by. Say "*hello*" with an inviting tone. The feedback you'll get from those individuals is priceless. They couldn't care less about TCO or FCV. In fact, they don't have any clue what those mean. It comes down to basics. How do I equip my garage with the ability to high-speed recharge? How much will that cost? How much benefit will that provide? What about just sticking with an ordinary 120-volt household outlet? All you here can argue until the cows come home. It won't matter to the 99%. Convenience. Distance. Price. Things like that are what compel people to take a closer look.

5-22-2018 **Branding.** There are attempts to move on to other topics: *"The Prius brand is so strongly linked to hybrid that I think Toyota would do best by marketing any future BEV as... something other than a Prius."* That was part of a discussion addressing the future, trying to set realistic expectations for product offerings. It continued on with: *"If you want to really normalize electric cars in society, you need to stop highlighting the distinctions and just refer to them as *cars*."* You know how much I despise generalizations. Dumbing things down to be so vague they don't serve any clear purpose anymore contributes to trouble. Remember how the lack of information "hybrid" conveyed that the term ended up leading to disenchantment? All those years ago, we'd encounter those who had purchased a Honda hybrid expected it to behave like a Toyota. They figured out it didn't and were let down as a result. That's why people like me pushed the ASSIST hybrid and FULL hybrid terms. That drew attention to the fact that there were distinctions. For similar reasons, that's why I kept fighting Volt enthusiasts. They decided upon EREV as a term to use to draw attention that it worked different from other plug-in hybrids, but they kept changing the definition. In other words, it was a marketing ploy to deceive rather than being used to convey information. This is why we always much return to basics. What is the technology attempting to accomplish? For Toyota, there was always an effort to lead to a better future. That meant Prius was just the leader, not the solution itself. Other hybrids were to follow... which did indeed happen. The same will for plug-in hybrids too. So, focus on branding really doesn't achieve that specific goal. A naming link would achieve the association of leadership though, which I gladly pointed out: Ironically, that's the benefit of Prius being associated with hybrid. It's neither a traditional vehicle, nor something bleeding edge. It's well established... just a normal car at this point. Keep in mind how important the reputation of Prius for value & reliability has become. It's a proven launch vehicle for next-step tech.

5-23-2018 **Work Parking.** Many of my videos feature the ramp I park at for work. After all, that's where I drive to on a very regular basis. The catch is, that was scheduled to be changed. This Fall, the plan was to replace that nearly 50-year-old structure with a modern one... complete with a section devoted to charging-stations. Unfortunately, it experienced some trouble... despite all the work over the years to reinforce with new rebar and add more support to guarantee integrity. A crack developed and chunk of ceiling broke loose. As a precautionary measure, they closed the ramp for inspection until further notice. That may mean I'll simply end up finding an alternative location to park for quite a while. So much for offering consistent data measure over time. Oh well. Variety is good too. Eventually, the new ramp will open. But you know how budgeting and contracts go. That's a very slow & complicated process. It could take quite some time before returning is realistic. We'll see. Perhaps certain sections will be opened for limited use. Maybe I'll get lucky with the location of the chargers. Whatever the case, there is another ramp nearby that may have room for use to plug in. Not being able to park as close to work is a bummer. I sure was lucky with that old setup.

- 5-23-2018** **New Zealand.** I stumbled across 2018 first-quarter sales results for New Zealand. That's quite a unique market. Limited in resources and isolated to an extreme, what is their approach when it comes to transportation? Turns out, Prius Prime is doing well there. Of the 12,100 plug-in hybrid sales, Toyota's was the top-seller. Sadly though, the exact quantity wasn't actually mentioned. There were counts for hybrids though. C-HR hybrid was the leader in that category with an amazing 52,301 sold. Whoa! Prius came in second with 46,652 sold. Following that was Suzuki Spacia, a hybrid I haven't ever heard of. Fourth place was capture by Prius c (known as Aqua everywhere but here) with 39,252 purchases. In fifth was the Vitz (aka Yaris) hybrid with sales of 37,080. Those are impressive numbers... especially for a population of 4.6 million. It makes sense that hybrids would be popular there.
- 5-24-2018** **Tribalism.** It's easy to get off-track and flustered when people put up barricades, unwilling to listen to other points-of-view. This expressed that sentiment: *"I have avoided further comment on this thread because it is symptomatic and symbolic of what is happening in the US society today, TRIBALISM. it comes down to "what I believe is right and what you believe is wrong", whether we are talking about politics, religion, environment, cars, etc. for example."* Sharing that view, it was easy (and vindicating) to post: I ran into that many years ago, as well as recently on this thread. It's a one-size-fits-all belief. The close-mindedness is really unfortunate. They want change to fit into their template only. Nothing else matters. In fact, no matter what you say, they only hear "Toyota" or "range" or "profit", since the idea of multiple solutions or approaches is impossible in their mind. That wall is extremely difficult to overcome. Real-World data has proven to draw attention through all those shouting their perspective. You'll encounter pushback & dismissal, even when they are proven wrong. You'll encounter a lot of distraction too, extra noise that confuses focus. It's very easy to lose track of goals. Keep your message clear. Knowing purpose is helpful to everyone. Most often, conflict comes from limited score... time & audience.
- 5-25-2018** **Marketing.** The same thread that's been going on for days has taken a turn for the better: *"Ironically, Toyota is really not "marketing" Primes either, at least in Southern California, that I know. They're relying on word-of-mouth to sell the car; there are no ads!"* That's getting back on track, figuring what works and what really matters. I jumped back in with: Word-Of-Mouth has been how all of the Prius were originally sold. Toyota wants the limited initial supply to go to the well-informed... which means knowing someone who already owns one. It's you and I that begin the process, sharing what we experience firsthand. That information reaches those who seek it, the savvy online participants, who ask questions in return. Think about how long it takes just to gather enough real-world data to set realistic expectations. Greenwash & Disenchantment are problems avoided by targeting specific audiences first. The wider market will naturally follow, once there is a path laid down by us. In fact, we're the ones who provided detail about how Toyota should formulate the general audience advertisements.

5-25-2018 **Whining.** Sometimes, that seems the best recourse: *"It feels like most of these manufacturers just push their money grubbing SUVs and trucks, as long as the masses will suck 'em up. I'm waiting for those nice, big fat gasoline price increases to bring back religion to the marketplace! Then let the whining begin."* The better thing to do is share insight into the situation and reflection upon the past. Knowing history and getting an idea what to expect is help... though, whining provides a good feeling. Guess what I did:

It's a sad reality watching the cycle repeat. That desperation for profit leads automakers down that easy path, one that's self-destructive. They don't care though. It is very much a live-in-the-now situation. Leaving their successors to clean up the mess is a normal part of the game they play.

We saw that happen before the recession. Unfortunately, we have even seen it happen with plug-ins. Remember how literally everyone involved with the Volt development program *"moved on"* prior to rollout? That makes no sense whatsoever. You don't work on a project for years, then walkaway just before people begin to use what you developed. It was an *"abandon ship"* no one seems to actually notice.

We're going through that again. These big guzzlers don't have anyone to be held accountable when things go bad... which they inevitably will. The price of gas is going up and mainstream consumers are witnessing hints of plug-in success. From our perspective (the well informed), we are witnessing quite a fight taking place to retain the status quo.

The only fortunate thing out of the @#%\$!& guzzler mess is those unnecessarily large commuter vehicles can accommodate a battery-pack easier than a car. That wasteful space in a SUV can actually be used for some good. True, those vehicles will be expensive & inefficient compared to the likes of Prius Prime, but buyers of SUVs aren't known for placing a high priority on cost-of-ownership anyway.

5-25-2018 **Repetition.** You know when an antagonist says it, times are changing: "*Sounds like a history repeat.*" Yes, it's ironic that seeing the repeat represents change. But at least being in a cycle means the next step is a predictable... which opens up the opportunity to influence. Eventually, a pattern will break if you know exactly how & when to push. That's what I've been hoping for. Think about the gap being created each time. Between the successes & failures, it widens. At some point, drawing enough attention to that will cause the resistance to weaken... which is why I keep bringing up goals? Think about technology advancements. When does it start to appear silly to fight change? For example, when did you stop using a landline at home? Why did you make that decision? How long did it take for that change to come about? Did you upgrade your cell-phone several times before realizing that phone still connected with a cord wasn't serving any practical purpose anymore? You get the point... eventually:

The repetition isn't as obvious sometimes though. I was attacked relentlessly on GM forums when pointing out the pattern Volt was following. It was the same disaster as Two-Mode playing out again. GM was focusing heavily on size & power again. Only this time, the measure of "size" was range rather than physical dimension. GM sacrificed affordability then and was repeating it for gen-1 Volt. Then then did it yet again with gen-2 Volt. Now, we are witnessing that same obsession with Bolt.

Ironically, that "size" issue will be the center of attention yet again. GM will finally have to deliver a plug-in their own loyal customers will actually be interested in purchasing... a SUV. Imagine trying to squeeze 53 miles of capacity into an Equinox. It's just plain not realistic (weight, efficiency, cost, etc). This is why we don't see any advertising of gen-2 Volt. Each time the cycle repeats, they move back the goal-posts.

We'll see a more modest design... all those who absolutely insisted more was needed and that Toyota's approach wasn't enough would have vanished. It is a reset... which they will likely make the same mistakes, yet again.

5-26-2018 **Goals.** There are some who like to brag. When Model 3 comparison info clearly bias toward Tesla, was posted on the big Prius forum, a few of us pounced. What was he expecting with such obvious trolling? I pointed out his use of bait, asking for him to state goals. Of course, he didn't. Instead, he just bounced the question back to me with: "*State your goals then.*" That act of deflection is a clear sign of his true intent. He was just looking for an easy fight to win. Sadly, that's the behavior of a bully. Some people never outgrow inappropriate acts. Anywho, I punched back with:

I already have... countless times now. They haven't changed in the past 18 years either... to significantly reduce emissions & consumption in a reliable & cost-effective manner. That means I call of those who misrepresent the needs of mainstream buyers. There's nothing wrong with supporting something you believe in, but if it's different from what ordinary consumers will care about, expect attention to be drawn to that fact. In this case, Tesla is a great car that simply isn't something you'll be able to most everyone we know to seriously consider for purchase.

How many people where you work would even be remotely interested in any type of plug-in vehicle now, in 2018? Most choices are just plain not realistic. When tax-credit phaseout begins, that situation is going to become even more of a grim outlook. That's a fact, nothing which can be debated. True, it will change over the course of the next few years, but that's not what you just tried to present... hence the request for goals.

Think about how few of your friends could just jump into the deep end without any hesitation. Installing a 7.7 kW charger connected to a dedicated 40-amp line in their garage is too much for most... and that's just a minimum for plug-in vehicles with 200-mile ranges. How many households have more than just 1 vehicle? Upgrades at home to accommodate recharging take time & money.

Prius Prime is extremely realistic for serious consideration in 2018. Toyota's well proven tech is now offered in an affordable package. You don't need anything more than a normal 120-volt outlet to greatly benefit from it either. This is the first plug-in hybrid to be realistic competition directly against traditional vehicles without any subsidy.

I watched both generations of Volt fail miserably, based on the sales goals we were told to expect. They were to "*leapfrog Prius*" with its "*vastly superior*" technology. That most definitely did not happen. Being able to change the status quo is remarkably difficult. Impressive engineering from GM or Tesla or even Toyota isn't enough. Careful consideration of need is required. Appealing to want just plain does not work outside of the enthusiast audience. Mainstream consumers have very different priorities.

What are your goals?

5-26-2018 **Ignore Rhetoric.** As a senior leader of effort to promote, there's no reason to put up with any of the rhetoric anymore. There's plenty of real-world data to work with now. So, I'm back to playing offense. When an antagonist jumps into the mix, I don't even bother to respond directly (unless there just happens to be an opportunity for useful feedback). My post focuses on promoting. For example, today there was an article on "*hot plug-in hybrids*" which naturally stirred up some vastly superior nonsense. I ignored it, choosing to post this as a new comment (rather than a reply) to draw attention back to what actually matters: 5.7 mi/kWh is what I saw on my most recent commute home from work in my Prime, with the A/C running. That's value most people... even some plug-in owners... don't recognize the significance of yet. Anyone can brag about EV range from a larger battery-pack, but it's how that electricity is actually used is what really matters. Admittedly, I don't see efficiency that high routinely. But for the month of May (so far) here in Minnesota, my average is currently at 458 MPG. So, even when the freakishly efficient gas engine starts, there isn't a major impact to overall results. As for what makes a "*hot plug-in hybrid*", all you have to do is answer the unsolicited questions people ask when you are using the free chargers at the local grocery store. The most common are "*How long does it take to recharge?*" and "*How many miles will it go on electricity?*" Upon providing the answers, slipping in a "*Sticker-Price starts at \$27,100.*" stirs further inquiry... rather than the instant dismissal you get with more expensive offerings. It's very clear ordinary consumers are looking for a balance, not an emphasis on range or power.

5-27-2018 **500,000 Dieselgate Vehicles.** The numbers are quite staggering, so far. 300,000 are already stored at 37 facilities around the United States. Another 50,000 being retrofit for resale. Ultimately, there will be 500,000 from the buyback, resulting in \$7.4 Billion paid back to former customers. 85 percent of the work must be complete by June 2019, or there will be additional payments required. A total of \$25 Billion will be spent to deal with the situation. The videos & photos stir emotion. There's a sea of parked cars shown in each flyover. What will become of them? It's an amazing mess. We were lied to. Diesel enthusiasts attacked hybrid supporters. How many do you think apologized for that?

5-27-2018 **Spinning Reality.** It's quite bizarre to read such inaccurate claims: *"Toyota likes to spend a lot of time perfecting something before releasing it to the public. It has served them well in the past. Unfortunately for them for them, the plug-in vehicle market is evolving too quickly."* They are just spinning their own reality rather than acknowledge, or even recognize, what actually happened. My guess is people posting greenwash like that are clueless, totally guessing about the history they had no part of. After all, it's easy to make fundamental mistakes about a past looking backward using only vague references you stumble across in recent posts. Annoyed, I fired off a contradiction to that dribble with actual facts: Toyota's electrification history is filled with incremental upgrades. That has been anything but unfortunate. Prius was rolled out in 1997, then got a major mid-cycle upgrade for the battery-pack in 2000 prior to arriving in the United States. In 2003, the gen-2 of Prius was rolled out. By 2006, the technology has been upgraded & spread for use in a sedan (Camry), an AWD minivan (Estima), and a SUV (Highlander). In 2009, we got the gen-3 Prius was rolled out. In 2012, the first-gen plug-in Prius was rolled out. In 2016, the gen-4 Prius was rolled out. In 2017, the second-gen plug-in Prius was rolled out. What part of that doesn't confirm the moving quickly? You do realize how easy it would be for Toyota to rollout a mid-cycle upgrade for the plug-in Prius? An upgrade to the battery-pack for a bump in range & power is quite realistic. After all, Toyota did exactly that for the gen-1 Prius.

5-27-2018 **Admit What?** News from Toyota that automotive-grade versions of solid-state batteries won't be realistic for at least a decade (roughly 2 product-cycles) is naturally stirring spin. No one takes into consideration that they could work just fine for next-gen offerings, but be so unrealistically expensive that they aren't used. Sound familiar? That's exactly why the plug-in Prius didn't come out sooner. Even with limited capacity, the pack wasn't affordable. Anywho, there's quite a bit of brainless attacks now. For example: *"With hybrids you increase the power train complexity and cost for minimal increased efficiency. This is why they have never caught on. Toyota can't admit it because they invented the tech and have a lot invested in it."* I was annoyed by how meritless that claim was. Worse though is the thought that this audience could be so poorly informed or so gullible as to accept the claim without question. Ugh. It could happen. There's so much tribalism now, some people simply don't bother to listen anymore. Remember how bad it got on the daily blog for Volt? They just stopped caring. Oh well. I can at least try to convey some sensibility to the discussions: Real-World data proves that false. 12 million have been sold, the emission & consumption reductions dramatic, and the cost is competitive. With my Prime, the current tank just barely reads below full, despite having driven over 700 miles already. I have been averaging over 100 MPG for lifetime efficiency. That's an incredible result from a hybrid with a MSRP starting at \$27,100. Toyota has already delivered a full EV driving experience. Whether or not the first non-hybrid plug-in offered here uses solid-state batteries doesn't matter. In about a year, the EV model of C-HR will make its debut in China. So what if it uses the most advanced lithium battery with electrolyte instead? There is nothing to admit.

- 5-27-2018** **Cleaning What?** Attempts to belittle Toyota's approach don't have much to work with anymore. So many automaker announcements are for offerings a few years from now that anything with respect to a need to wait reference is hypocritical. Yet, some try anyway: *"Always waiting for some next development while someone else is cleaning their collective clocks."* It's basically the new twist on *"behind"* claims. I'm not going to accept any of that nonsense: Who is cleaning what? We aren't even out of the early-adopter phase... clearly marked by the presence of subsidies, in our case generous tax-credits. Whether or not any legacy automaker can achieve sustained mainstream sales volume (at least 5,000 per month) to compete with the true competition remains to be seen. Traditional vehicles pose a monumental challenge to overcome still. Don't be fooled into complacency by initial sales to those willing to accept new technology that isn't able to take on the legacy offerings yet. Remember, appealing to ordinary consumers is much, much more difficult than our group here.
- 5-28-2018** **Too Expensive.** That's what it boils down to. Being cliché conveys the point well. Those GM enthusiasts still clinging on to hope, rather than being realistic about the situation are losing attention. Non-Enthusiasts simply aren't interested due to high sticker prices. So, the fact that tax-credit phaseouts will soon be triggered basically ends even the most optimistic. That's why most have vanished. I made that all too clear with: The cold, hard reality is you don't want to acknowledge the problem of cost. Saying Toyota should at least have as much range as Volt overwhelmingly confirms that fact. It's simply too expensive still. You would be just as disappointed if price has been raised to compensate for that increase. Keep in mind how high of a priority sticker-price has been for Prius. Toyota has stayed true to that, not giving into tax-credit dependency like GM. Looking at Volt sales, it's quite clear that the loss of the \$7,500 subsidy is going to make that bad situation even worse. Another thing to keep in mind about Toyota is the spin coming from antagonists. Remember how much rhetoric we had to deal with when gen-1 Prius PHV production ended. There were countless posts for months about how Toyota didn't believe in plug-in cars. The internet is filled with those who are short-sighted and those hoping to disenfranchise. Don't listen to their claims. We'll get an increase of range & power as costs justify. Toyota is not going to compromise affordability just for the sake of pleasing enthusiasts. Their focus is sustainable high-volume profitable sales to mainstream consumers.

5-28-2018 **Big Oil.** So much spin has emerged that the basic unstanding of "*peak oil*" has been lost. We hit that point a number of years ago. It's easy to recognize when you step back to look at the big picture. That was the moment when stability became uncertain. For different audiences, that realization happened at different times. It did happen though. For everyone, that is now in the past. There's no guarantee of anything anymore. Price, Supply, Demand... are all anyone's guess. The industry has no idea what to invest in now. Peak occurred already. How long the downfall will take is extremely uncertain. There's nothing to bank on at this point. We see success from vehicle electrification and the undeniable pushback against pollution sources. That future is cannot be argued. How we get there is subject of debate. But the nature of the course doesn't matter, since we all see a common destination... one that no longer includes Big Oil. I summed up the situation as of mid-2018 with: Oil isn't only used for personal transportation. Commercial use beyond just transport is an array of petroleum based products. There's also the reality of product turnover. Buying a new camera no big deal. The purchase of a new vehicle is an entirely different matter. It is far more expensive and you don't replace anywhere near as often. The problem of where to plug in won't be overcome quickly either. It will take a long time, but it will eventually happen.

5-29-2018 **VIDEO: Using the Electric A/C.** I especially enjoyed filming this trip. It's a really nice location I have been taking Prius photos at from the very beginning, all those years ago. The park has been improved upon over the years. There is now a charging-station and more trails. So, that's a very appealing destination. Anywho, you get to see my drive to & from there in this newest video:

A/C use requires electricity from the battery-pack. That need to stay cool will shorten EV driving distance available.

This example, where I go for a drive to the bluffs along the river (great bike trails there), shows how the impact hot conditions. Normally, I would just plug in while parked to recharge the Prime. But in this case, I immediately did the return trip to show total EV distance available in that heat while driving the scenic country road.

Watch the temperature on the dashboard display rise. You start cool from having begun with a car in the shade. But as you drive, even with the air blowing from the drive, that nasty heat eventually registers. The video states 92°F to be reflective of an average for the entire trip.

EV distance for that charge was just shy of 27 miles. Total distance driven was 33 miles. Overall MPG for the round-trip was 342 MPG.

Note that the gauge data in the lower-right is from an aftermarket application, captured with my phone using an OBD-II port reader.

Watch it here... [Prius Prime - Using the Electric A/C](#)

- 5-29-2018** **Doom & Gloom.** I find it quite amusing how some obvious Volt enthusiasts hoping to undermine Toyota don't really listen to what they are actually saying. They try to spin a story of doom & gloom, but don't recognize it applies to the very thing they are trying to provide an endorsement for. That's why they are enthusiasts, rather than supporters. Blind hope and claims without merit don't account for much. But that lack of recognition of the situation is why they shouldn't be taken serious. Though, I do humor some with questions from time to time: What automaker are you referring to? Looking at GM, we see no path to the future. It offers 2 low-volume, unprofitable plug-in vehicles that don't appeal to their own loyal customers. GM shoppers want nothing to do with a compact hatchback or wagon. They want SUV choices... of which, GM offers none with a battery-pack. Toyota, on the other hand, has a clear path laid out for electrification. There's a wide selection of hybrids now that will lead to plug-in hybrid and EV models. It's an obvious stage being set for their entire consumer market, a diverse offering from a wide variety of shoppers.
- 5-30-2018** **Big Wind.** I was listening to videos while commuting to work. Letting YouTube serve up recent news clips can be quite informative. Today, that was especially the case. When the advertisement between clips mentioned "*Big Wind*" it gave me a sick-to-the-stomach feeling. I had stumbled across propangda. The rhetoric was quite obvious too. They voice kept stressing how much money would be wasted on solar & wind investments because the needs of customers don't happen exclusively when the sun is shining and the wind is blowing. For you to be suckered into that belief, you cannot be informed that there is no means of storing that electricity. Knowing that banks of batteries or tanks of hydrogen can be used to hold that energy in reserve until it is needed later completely wrecks their argument. You also cannot be informed that the grid itself can help for distribution, since cloudy & calm days don't happen everywhere at the same time. Another thing you shouldn't be aware of is how quickly that field is growing, the number of employment opportunities solar & wind are creating. It was really sad to hear the desperation of Big Oil playing out. But then again, they would only use such deception when the cards are stacked against them. We know the end of petroleum use for personal transportation is approaching.
- 5-30-2018** **Brake!** That was sweet. I was reminded just how smart the accident-detection system is in Prime today. A vehicle up in the distance suddenly braked really hard. The sensors detected its abrupt stop and made me aware that it was no longer in motion. That's a really big deal. When a vehicle comes to a full stop, rather than just continuing with a slow roll, it can be indication of a problem. So, an alarm sounded and "BRAKE" appeared in red on the dashboard. Since I was following with a generous gap, there was plenty of distance for me to stop too. I had forgotten just how far ahead and how sensitive that detection is. Preventing accidents is very, very important. Yet, most people still only focus on crash-test ratings. It's really sad that avoidance isn't promoted much. Thankfully, we have been seeing mention of it from time to time with auto-braking advertisements. But it is still far from being an expectation. People think of it as a nice extra, rather than a must have.

- 5-31-2018 Fizzle.** Think about how many times I asked for enthusiasts to state goals. Think about how many times they changed the definition of EREV. It's easy to become frustrated or disenchanted afterward, when clear expectations were not actually set. For example: *"I think a lot of people are unfairly judging the Volt as if it's a type of car it was never meant to be."* That comment was made following a post of what will likely be the outcome of May sales. He never actually stated what it was meant to be. So naturally, the likelihood of sales continuing to struggle is a source of frustration. Demand should have been so strong at this point that GM would be struggling with supply. After all, that was the point of provided tax-credits. The money was meant to subsidize sales so production could be ramped up to a profitable & sustainable level prior to phaseout. GM fell well short of that, not even close. Having delivered a niche for enthusiasts, rather than a plug-in replacement for traditional vehicles spelled doom & gloom right from the start. And sure enough, all these years later, that's exactly the problem faced now. Ugh. I kept my response to that short: Volt was promoted as a vehicle for mainstream consumers, a choice that would *"leapfrog"* the green market leader. Technology that doesn't reach ordinary people unsubsidized in high-volume is a failure in that regard. GM's leadership fizzled. Their own loyal customers are still waiting for something to replace their current GM guzzler SUV with.
- 5-31-2018 Low Volume.** Don't you love how claims like this come out of no where: *"Model-3 will retain the sales crown as Prius-Plugin is only a low volume car."* The person saying that pretty much never provides any supportive data either. They just make the wild statement, then vanish. It's a blatant effort to undermine. Make a vague post as if it is fact, without bothering to supply anything of any merit as proof. It's just like our current president... keep interjecting the same lie into comments, repeating it so often people take it as true. Seeing that type of nonsense play out in the automotive industry is very frustrating. But to see the same behavior on that political scale is very disturbing. We'll see oil & coal get support to further environmental damage... to the world. It's hard to believe such activity on the basic online forum emerge on such an enormous scale, the same spin. The suggestion to combat that is to inform as many people as possible through real-world data. They'll try to debunk everything you say, but witnessing it firsthand conveys the message better. That's why I film so many drives. Each video is packed with detail. You can't deny that much evidence after awhile, especially when it is so easy to share with others for review & feedback. You can break first impressions that way, get beyond the problem of anecdotal observation. People don't research. They often just accept what they read as fact. So, that is where you start... especially in the case of availability. Make them curious enough to start watching roads more. They'll notice, eventually. In the meantime: Low volume car based on anecdotal observation would give that impression. In reality, the first year was a worldwide rollout, so availability was very limited. Despite that, there were still 51,000 delivered.

- 6-01-2018** **Volt Trouble.** The spin was intense right from the start today. Volt is in trouble. GM hasn't expressed any interest. Selling it has become pointless. Bolt was to be the replacement, but it too is struggling for attention. If you want a seriously nice EV, you buy a Tesla. There's no debate. For an affordable solution, it's well worth considering considering Nissan. Those are the EV choices. It's either Model 3 or Leaf. That's why Prime has emerged as the plug-in hybrid of choice. True, we see other options offered, but the market is so limited they have no following established yet. So, the spin to keep Volt relevant is well underway. I hit back with detail to debunk the effort: "*Volt Gains Ground*" doesn't reflect history. Monthly sales of 1,600 to 1,700 was the trend throughout a bulk of gen-1 offerings, with the exception of year-end rushes and the price-drops. That was considered poor no matter how it was looked upon too, which is why much higher expectations were set for gen-2 sales. For any plug-in to be realistically competitive with traditional vehicles (a true mark of replacement progress), unsubsidized monthly sales here must be at least 5,000. Below that, the status quo simply isn't getting changed. To sustain momentum into the world of electrification, significant growth is required.
- 6-01-2018** **Confirmation.** GM really screwed up by putting so much emphasis on range & power. More and more of the enthusiasts are pointing out the shortcomings as a result. Today's complaint emanates from the sales report being so bad. Even though GM switched to quarterly reporting (to obviously conceal their trouble), the process of estimating sales based on inventory is accurate enough to still reveal the trend. The use of "*gain*" really being a spin to hide the fact that "*recover*" is actually the proper term is telling. But more importantly is highlighting the reasons why sales have been such a struggle. To get certain features, you much choose the most expensive package for the GM plug-in vehicle... since range & power were deemed much more important. I knew when enthusiasts blew off everything but those traits, they would be in a world of hurt later. Ordinary shoppers want a balance of features... exactly what both Volt & Bolt lack. A complaint about that emerged in today's discussion. I was happy to point out why: Adaptive Cruise (aka: Dynamic Radar Cruise Control) is included standard on all the common Toyota cars... RAV4, C-HR, Corolla, Camry, Prius. GM's sacrifice if leaving off features like that hasn't proven a wise choice. It's more confirmation of having focused too heavily on enthusiast interests, rather than mainstream consumers.
- 6-01-2018** **Audience, again.** Debate about the 2 top-selling choices is inevitable, regardless of how meaningless the claims are. It is madness that anyone could even imply Tesla and Toyota are targeting a single group of consumers. They clearly are not. Yet, we have endless arguments sighting contrary points. Ugh. Oh well. At least it is well documented that someone had a solid understanding of who within the mindlessness: There's no reason to take banter on this thread seriously... since it makes no sense whatsoever comparing vehicles so dramatically different. They clearly don't target the same audience. Many here simply thrive on the participation, which is fine, but important not to overlook. It's that problem of normalization. Enthusiasts sharing information isn't an issue in any regard, as long as the context of what say, they are all aware that much of what's discussed won't apply to ordinary shoppers. Know your audience.

- 6-01-2018** **Audience, push.** I'm unwilling to allow the status quo to continue. Back to playing offense means I push, like when seeing this: "*The Ioniq for the most part reminded me of the Prius, weak acceleration*" Coming from a frequent antagonist (know your audience) who thrives on negative attention, I mixed it up by taking over the narrative. Not allowing the pattern of belittling to continue is all it takes. Step up, rather than be an enabler. So, I did: Sloppy or Careless reporting will get called out, as I am doing now to that. Off the line, I'm almost always the leader of the pack. The electric-motor has substantial torque with zero noise or feel penalty. So, being generous with the pedal is very realistic. We also know for a fact that the Toyota system delivers more electric-power than Hyundai's. Of course, how often do you actually need maximum EV power? I find it quite rare when merging onto the highway. So, that vague use of "weak" is misleading at best. You can always switch to HV mode for more power anyway. Remember, the audience for Prime is quite different from that of Tesla.
- 6-01-2018** **Defeat & Hope.** It's over. You can tell by looking at the sentiment of hope. That transformed from pushing wants to finally acknowledging need: "*I hope someone at GM is taking note of these trends and will consider a decent ad campaign for and larger follow-on to the Volt.*" This came from an nasty antagonist on that daily Volt blog, but posted on a general-audience EV blog. He absolutely hated my one-size-fits-all compliant. Hearing me push for diversity made him absolutely crazy. The lashing out at me for expressing "*too little, too slowly*" concern was deep, deep denial on his part what was necessary. Diversity is essential. It's a basic principal of good business. Yet, he fought me with every possible attack method. In his mind, that next step would dilute the EREV approach... which was so vague, it didn't actually represent anything anyway. But holding onto hope is all some people have. Admitting defeat is difficult when you don't have a solid plan for progressing forward. Volt was a gamble, a huge risk that failed to attract mainstream sales. Could advertising have helped? Yes, of course. But it was obvious GM wasn't interested... a stance still difficult for some to accept. GM's obsession with SUV sales should have made that crystal clear. After all, that is what I pointed out when suggesting the "*follow-on*" for the technology in Volt. Having someone like me be correct is difficult to embrace though... when you identify the competition as other plug-in vehicles, rather than traditional choices. It was a flawed approach from the start, hence the defeat... what I predicted a decade ago. That's how the "*Who?*" question came about.

- 6-02-2018** **Behind.** That rhetoric claiming Toyota is "*behind*" sure has fallen apart rather abruptly. GM made a series of announcements today. All had dates in the early part of the next decade... basically, following the same schedule Toyota had all along. Only problem is, Toyota's path to electrification is quite clear. Each hybrid will offer a plug at some point. That's simple. That's affordable. That's sensible. In other words, the automaker supposedly "*kicking & screaming*" about having to embrace the future obviously isn't. So, the antagonists have suddenly become quiet... especially since nothing GM announced mentioned the United States specifically. It all very much had a focus on the market in China instead. Volt & Bolt are being left to struggle alone. Meantime, we see Prius Prime advancing with an undeniable target of mainstream consumers. Nissan is sharing a similar course. Affordability with a nice balance of features is key. That makes the others... like Honda, Chrysler, and Mitsubishi... a bit uncertain. They are all much more expensive and each is rather specialized. There's lots of potential. Maybe we'll see more rounded options in the next few years. Hope from VW and Ford is realistic too. We see the industry changing... just not the way enthusiasts had claimed.
- 6-03-2018** **Waiting.** You never really get it. Progress is a moving target. There is always something better to wait for... at least, that's the situation with technology. We've seen it that way with personal computers for over 4 decades now. With vehicles though, there is a difference to that dynamic... being willing to pay for what you don't actually need. That type of waste isn't common with those daily personal electronic devices we carry... despite them being far less expensive than a vehicle. With that in mind, it makes you wonder how to respond to this: "*Do I really have to wait until I'm in a nursing home before they start offering an affordable truck?*" What exactly is he actually waiting for? It's somewhat of a contradiction wanting a guzzler to become more efficient, yet to still be within the guzzler category. Could something else achieve the same goals? As somewhat of a wake-up call, I formulated my by-the-way with: It won't ever happen. The reason for trucks being pushed so much is they are high-profit vehicles. Making them affordable would defeat that purpose. The only good to come out of the crazy obsession is that conversion to plug-in is easier than with a car. That wasted height & bulk can be used by battery.
- 6-03-2018** **Dying Industry.** We were presented with a plan today to force taxpayers to rescue the coal industry. The claim is investment by utility companies will strengthen our national security. How? That doesn't make any sense. Investing in a non-renewable source that causes harm to the environment is exactly what we should avoid. Wind & Solar can be widely distributed, located close to those who will consume the electricity. It can also be transport via wire without any resulting pollution. Coal is quite the opposite. What is the expected outcome anyway? This won't result in higher employment. Much of the coal industry has adopted large-scale automation. Machines are doing most of the work now. We know employment is growing in the renewable industry. Think about how many workers are needed to install all that new equipment. There's the upcoming energy-storage market too, where large battery facilities will hold electricity generated during times of wind & sun for use later when it is calm & dark. The same will come about for commercial hydrogen use too. Coal doesn't have a future. It is only a bridge to it. The plan today, which will ultimately raise energy costs (remember, coal competes directly with natural-gas), is harmful to ordinary consumers. They will end up paying the price.

- 6-04-2018** **Insufficient.** We are still having to deal with the "*bigger is better*" mentality. It's based upon lack of knowledge. Without real-world data, they just make assumptions. So, whenever the 25-mile capacity is mentioned, it's the same old rhetoric all over again. Their brainless assertions of "*insufficient*" make it easy to push them aside. I just keep posting more real-world data: 966 miles so far on this tank, which reads less than 1/8 used so far. That's what happens with a Prime when where you park at work and some destinations have chargers available. When you don't, results are still amazing. I wasn't able to plug in on Saturday. So, the 39.6 miles I did running around town were with just the overnight recharge. The result was 263.4 MPG. Yesterday, I got 67.9 MPG from my 31.5 mile drive today without any electricity at all. So, even when the engine runs, overall results are well over 200 MPG...which is quite sufficient.
- 6-04-2018** **Limited Scope.** It never ceases to amaze me how there can be so many plug-in supporters who see nothing but the plug-in market. They don't consider traditional vehicles competition. Their entire scope is limited to just vehicles with plugs... which has the unfortunate consequence of giving a distorted impression of what's actually happening with the industry. Ironically, it was GM enthusiasts who slammed Toyota for only delivering a "*compliance*" vehicle. For that to be true, they had to overlook the fact that Prius PHV was a mid-cycle rollout. Looking at Prius Prime, the first full-cycle rollout, that clearly isn't the case... which puts Volt in a hypocritical position, since it is one its second full-cycle and Toyota is already exceeding what GM was able to achieve. Watch for comments that don't take scope into account. Expect there to be many more with the upcoming tax-credit phaseouts about to be triggered. In the meantime, I'll keep posting comments like this one today: While tax-credits are still available, the game is rigged. Measure of true demand won't be accurate until subsidies are phased out and inventory is available locally for immediate purchase. Until then, you are just sampling enthusiast interest. Mainstream sales are far more difficult, but essential for sustainable profit.
- 6-05-2018** **Sad Reality.** There's not much to say when the situation is spelled out like this: "*People in America don't even attempt to disguise their corruption any more. They revel in it and defy anyone to do anything about it.*" That is what this nation filled with lots of short-sighted, self-centered people has become. I saw that transformation as the Two-Mode disaster unfolded... which is why it has been such a symbolic feature in these blogs. When it emerged as the biggest "*over promise, under deliver*" problem of modern time in the automotive business, the supporters developed an attitude... hence the emergence of enthusiasts. Not caring whether there was anything to actually support their claims of being "*vastly superior*" didn't matter. They had their talking points. The fact that their chosen technology was unrealistically expensive, making it unsustainable didn't matter. In fact, we are watching the final chapter of that playout now. None of them seem to show any concern about the lack of sales growth or the upcoming loss of the \$7,500 tax-credit. They just plain don't care. So, with an atmosphere like that, there isn't much of a barrier to keep corruption from filtering in. After all, we already saw that with the diesel scandal. It makes you wonder what other surprises could emerge if the usual checks & balances have faded away. We already know the expectations for solar have dropped dramatically due to the upcoming new tariffs. That will hurt EV support.

6-06-2018 **Market Understanding.** I summed it down to this simple perspective: "*Stage 1 = subsidized sales. Stage 2 = actual competition. Remember, the goal is to compete directly with traditional vehicles, replacing them with clean & efficient choices.*" It is truly amazing how few people online actually understand that. They think the plug-in market is isolated, emerging without any resistance from traditional vehicles. They are quite naive to think that those offerings will be embraced by resellers. Such a lack of business recognition is quite expensive of a mistake to make. But then again, GM has been doing that for years. All the "Who?" problems came from this same problem of not knowing audience. We learned that lesson long ago with Prius. Dealers weren't interested in carrying inventory which delivered a tiny profit that was a challenge to sell. That's why Prius required standout traits. It couldn't be just another vehicle back then. Now, we see amazing performance from the likes of Camry hybrid. Unfortunately, plug-in offerings aren't that well established. So, there's a conflict within dealerships... whether those online want to acknowledge the problem or not. Most think I'm nuts to show such concern for what seems to be a trivial point. They are wrong. Volt overwhelmingly proved it. Here's what they still need to learn: Plug-In vehicles are competing with traditional vehicles already. It is a fight to be carried as inventory and to be displayed on showroom floors. That perspective of the dealer is more important than that of consumers. Because if there's nothing offered to buy, the status quo will not change. In other words, the dealer is the true customer, they are determining who the competition is.

6-07-2018 **Damage Control.** The outcome of GM's attempts to deliver a mainstream efficiency choice have been one disaster after another. They equate to expensive conquests that never end up changing their status quo. That loyal base of GM customers continue to keep buying the same thing. So, it makes the announcement that GM just made about partnering with Honda appear quite different when you know the background. Volt enthusiasts really doing damage control, apologizing for GM stumbles by making it look that they are actually the ones helping: "*Honda is so behind on EV game, it's not even funny. Glad they decided to partner with somebody, anybody.*" The approach is to simply distract by posting something seemingly on topic. It's basically hiding in plain view, pretending everything is fine. After all, the damage is already done. Drawing attention to it only makes the situation worse in their mind. So, rather than learning from mistakes, they set themselves up to repeat them again. Ugh. Oh well, all you can do is point out what really happened: Honda has already delivered what we still wait for from GM. When Volt was rolled out, there's was an expectation for that technology to be spread to their core offerings... specifically, a model of SUV. It still hasn't happened. For that matter, there isn't even a full-size sedan comparable to Clarity announced yet. Why hasn't the technology from 2010 made its way to anything other than Volt in this market? The answer to that question is simple. GM doesn't know how to make what they offer affordable. Low cost wasn't part of the design approach, so now they are stuck with a difficult to sell technology. Some of us expressed concern about that right from the start. We saw the disaster Two-Mode had become and were witnessing the same mistakes being repeated with gen-1 Volt. Not only did that indeed end up being the problem, that very issue wasn't addressed for gen-2 Volt either. It's still not affordable. MSRP is too high to appeal to mainstream consumers. Knowing this makes it easier to understand how the need for a partnership came about. There's mutual benefit from sharing technology. Look at how well the carbon-fiber knowledge from BMW made its way into Toyota's plug-in Prius.

- 6-08-2018** **P0A80.** Helped a friend yesterday with his 2004 Prius. At 213K miles, the engine is still working great, but the pack is shot. It spent a lot of years used daily and without a garage, so it was a good lifetime. I was able reset codes to confirm it truly was just the battery having issues. This will be my first opportunity to witness a pack replacment. It is basically the same experience I had 20 years ago, when the transmission in my Taurus gave out. People do make that choice of major vehicle repair like that. In fact, this is what there were so many transmission shops. It happens. Strangely though, the outcome isn't so extreme. Putting a new transmission into a vehicle simply restores slipping gears. Putting in a new battery dials back the clock to a new status. It will be odd for a vehicle clearly showing age to be operating as if it was brand new again. You don't get as much stealth (the electric-only mode in the hybrid mode) as the pack ages. The engine runs more often simply due to the fact that capacity has faded over time. Remember, it bares the brunt of propulsion, protecting the engine from strain. With new cells, you get renewed life. The Prius will be back to favoring electricity more again. That certainly will be interesting.
- 6-09-2018** **TCO.** Total Cost of Ownership has been the approach many trying to endorse plug-in vehicles take. They feel a proper conveyance of overall savings will draw more sales. You prove to the person money is better spent by paying more upfront, since it takes far less with an electric motor & battery to operate. Reality of that approach not reaching this audience is becoming all too clear: *"I fully agree, but most people don't calculate that way. They respond mostly to upfront costs, and/or cheapest monthly lease cost."* This problem is why SUV acceptance has become so popular. People see monthly payments as managable and simply don't give it any more thought. It's an obvious mistake from the accounting perspective, but emotion... that feeling of just getting by... is all that some people want. They are not compelled to maximize. This is what our mainstream has become. True, other markets and those without disposable income, see the situation quite differently. But knowing this audience means taking a different approach. It's nice to see others beginning to recognize that problem. Imagine if that enlightenment would have happened long ago, when the "Who?" question was first asked. They couldn't figure out why their *"it's worth it"* logic was ineffective. Logic doesn't work for everyone. Know your audience. Anywho, I responded to that with: Bingo! That's a difficult reality for some to recognize. How do you appeal to people who don't place a high priority on saving money?

6-10-2018 **Compliance.** You gotta like this: "*I still want to see the COMPLIANCE automakers get their incentives taken away.*" The person who posted that believes "*compliance*" is the act of delivering something following the leaders. Whether or not the product to follow is superior doesn't matter. They couldn't care less if those later offerings learned from the mistakes the initial offerings made. They simply want the first to be rewarded and the later to be punished. Taking time to study the market and deliver a product capable of high-volume profitable sales means nothing to an enthusiast... hence the label. A supporter understands the difference. Using the subsidy wisely seems a waste to the enthusiast, who pushes a rush to market. Fix it later, rather than make it right from the start. Success of Prius has always involved patience. The mid-cycle rollout of Prius PHV to just limited areas was proof that Toyota was making an effort to ensure they truly knew their audience. In fact, it wouldn't surprise me at all to see a mid-cycle update with Prime as confirmation of being attentive to the market. Why should incentives be taken away for that? Annoyed, I posted: We watched GM do that with Volt, a vehicle clearly not targeted at its own loyal buyers. GM's heavy focus on the SUV market made it quite obvious a small hatchback delivered at niche volume without any real promotion (excluded from nearly all their product-line commercials) was not going anywhere. And sure enough, sales have fumbled 7.5 years... resulting only in conquest. The status quo of their own showroom shoppers didn't change. That certainly sounds like gaming the system for compliance.

6-11-2018 **Tariff Consequences.** We are witnessing the beginning of a nightmare. It starts with anger. This administration is hell-bent on superiority, regardless of cost. Feeling taken advantage of is an excuse for lashing out. The mindset of isolationism being necessary for national security means turning on allies, forcing them to take a side against you. It's a global market. That type of childish bullying is futile. You need trade partners... which requires balance through an effort to achieve mutual benefit. You don't just spite anyone who attempts to compete by improving their process, even if the means are not appropriate... because there are consequences of ill intent. This administration is so blinded by the letter of the law, they are clueless about what it means to deliver an act of kindness. Money isn't everything. You build trust through understanding & cooperation. We are going to watch industry struggle now. Tariffs have penalties. Complex products, like vehicles for personal transport, require a great number of parts & materials from around the world. Consumers will end up paying more as a result of tariffs, regardless of where the product is assembled. We are in a world of hurt already and this administration is striving to make that situation worse. It's hard to believe some people can be so poorly educated about how world economics actually work.

- 6-11-2018** **Blind-Spot Warning.** That flashing light on the side-mirror indicates a vehicle has been detected in that blind-spot for that side. It will continue flashing until your turn-signal is cancelled. Then, it just turns to a solid light to indicate the presence of something. That's all the more thought I had given to that feature until today. It was elegantly simple. What else could there be? I found out today. Rather than taking the advice of that warning, I pushed into the lane. It was tight pass, but that vehicle was going quite a bit slower. So, there wasn't any danger. The car only respond to detection criteria though. It's unaware of your intentions or the surrounding conditions. That means you continue to get a warning... but it gets bumped to the next level. The LKA (Lane Keep Assist) kicked in. I felt steering-wheel resistance grow. It was a subtle way of making sure I knew what I was doing. Feeling it push back like that was sweet. I hadn't thought about the feature being used for more than keeping you from straying out of your lane unintentionally.
- 6-12-2018** **Death of Diesel.** It's coming. We have seen niche offerings of diesel variants vanish. Cost is simply too high for so little in return. The first of the big names to end the offering of a popular gas vehicle is a sign of the next wave of change. That is what brings about paradigm shift. Kia announced their Soul in Europe would become EV only next year. That's really big news. Discontinuing a traditional choice is a really big deal. It would be like Toyota switching C-HR to only be a hybrid here. That is quite realistic, especially when you know that an EV model will be offered next year in China. This is why the effort to push Camry & RAV4 hybrids into the mainstream is so important. They deliver much cleaner emissions and higher efficiency than diesel, as well as pave the way for greater electrification. Remember, there are plans for Corolla PHEV next year. Sadly, we won't see it here. But knowing the another hybrid to plug-in hybrid variant is realistic for such a well-known vehicle is the final death blow to diesel. There is no reason to bother with it for non-commercial use. Of course, we are now seeing EV buses emerge into the market. The school district next to where I live has one already.
- 6-13-2018** **32 Amps.** Choosing how much capacity to setup our chargers for in the garage was quite a debate. The chargers themselves can deliver a rate of 10 kW. That translates to a steady flow of 40 Amps to the car, which means you need a dedicated 50-Amp circuit (since a 20% buffer is required for safety). Running a heavier gauge wire and using higher amp breakers would be no big deal. But even the fastest charging vehicle currently top out at 6.6 kW, which is twice that of the 3.3 kW we get from Prime. At best, the target for a high-speed at-home standard has been thought to be 7.7 kW. So, more is just overkill. After all, if you do the math, it reveals there isn't a need. 6.6 kW for 8 hours would give you roughly 50 kWh of electricity. (Keep in mind, charging slows as capacity reaches full.) At an efficiency level of 4.5 kW/mi, you'd get 225 miles of EV range. That's plenty for an overnight recharge. Turns out, Tesla agrees. That is what their latest at-home EVSE offers. Yes, their charger that comes standard with Model 3 and now Model S draws a sustained rate of 32 Amps. That means my choice to endorse the choice of a 40-Amp circuit is dead on with what a major industry player has endorsed. Sweet. I wanted a realistic recommendation for people setting up their garages to be able to accommodate the charging of 2 vehicles overnight and didn't want them to spend more than what would truly be necessary, even when planning ahead for a future vehicle.

- 6-14-2018 Battery-Pack Replacement.** Today was both interesting and a non-event. That good friend of mine with the Prius needing battery-pack replacement brought his car into a dealer for serious consideration of doing exactly that. It was a location clear across down, requiring a drive past several other dealers to get their. This particular Toyota location has been carrying Prime for a few months now and was the one that offered a lower quote for the same job. So, despite the possibility of the engine revving harder from the intermittent assistance from the pack, he drove out there. It wasn't a big deal. He got there just fine for the appointment. I eagerly await a report of what the mechanics find from their analysis. I bet they are too. It isn't everyday an opportunity to look at such an aged battery (the pack has 213,000 miles on it from 14 years of use).
- 6-15-2018 Playing Offense, differences.** It's really annoying when you point out similarities & differences and the person clearly doesn't actually read what you posted: *"Most people like to have the "differences" including that feature, pointed out when they are shopping for a car."* So, I tried again... since I'm playing offense now, taking the initiative rather than waiting to counter. That means hitting them with a follow-up with just enough info to stimulate discussion: You seemed to have missed the fact that the poster attempted to single out Volt as the only plug-in hybrid with that feature, making it appear to be a difference. When you drop the pedal to the floor in Prime, the engine remains off. The ICE does not start... hence no difference. Honda Clarity offers electric-only acceleration too, if you don't push the pedal past the click-point. Again, the ICE does not start. A plug-in hybrid that actually is different is Chrysler Pacifica. You don't have direct control of when the engine will run. When a kW draw threshold is exceeded, the ICE will indeed start. This also how the previous PHV model of Prius operated. Again, differences matters. Don't gloss over detail.
- 6-16-2018 Playing Offense, enemies.** There are times when you just have to pounce: *"I'm not your enemy, I'm giving you facts. Hybrids are transitional cars. The longer we drive them the slower the transition to green cars is."* That was the start of a reply that ended with: *"I'm saying the moment you put gas in a car it's not green."* It's that type of absolute close-mindedness that creates trouble. Life is not that simple. You cannot just take a situation to an extreme and disregard all else. Ugh. This is why the change from defense to offense is needed at times, like today: No, you are replacing a fact with an absolute. You can't outright dismiss the *"fossil fuels would be significantly reduced"* statement in your reply. I have driven over 1,500 miles on a little over a half tank of gas in my Prime since the last refill. That's roughly 300 MPG. Treating that as disappointing since *"You're putting a heat engine in a vehicle that supports fossil fuel."* is just plain wrong. You still have to plug in to achieve those results. That means the owner makes that behavior a routine part of their driving experience. That also means they upgrade their infrastructure at home to accommodate the need. Both are vital to promote electric-only vehicles. Getting that to happen now accelerates adoption. Think out how likely it will be that their next vehicle purchase will be an EV, especially if the plug-in hybrid becomes a great hand-me-down for a child. Think about how likely it will be for the owner of the first plug-in hybrid in the household to propose upgrading the garage with a level-2 charger so a second plug-in vehicle can be purchased. Think about how much of an enemy you will become if you don't think carefully about how you respond to this post. Plug-In hybrids provide a means of accelerating electrification. They are very green and promote plugging in.

- 6-16-2018** **Playing Offense, thanks.** That post about differences did indeed result in a positive outcome. I got a "*Thanks, I didn't know that.*" about the click-point feature. How do you spread knowledge of new behaviors? There are things completely unique to hybrids. Back when the Planetary-CVE was new, people used to frequently complain about the under-powered acceleration... until we pointed out to actually pay attention to the speedometer, not the feeling conveyed to your butt through the seat. That absence of gears shifting gave the impression of an engine struggling. Without noticing what a gauge was telling you about the true situation, it's easy to assume incorrectly. After all, you are also hearing the drone of a Atkinson-Miller pumping cycle... which sounds different from the common Otto. That mishearing solidifies your misunderstanding. What happens under the hood using new technology requires a bit of study. Some ask questions. Some get the information pushed on them by those like me hoping to prevent the spread of misconceptions. Thankfully, posts like that do get a thank you for the effort.
- 6-17-2018** **Playing Offense, goals.** Remember arguments of the past? Those efforts to win at any cost were amazing. It seems difficult to imagine anyone so desperate... until you encounter it again. Why do they fight so hard for a pointless victory? When there is nothing to gain, what compels a person to debate so relentlessly? I can think of countless incentives some have fought to hold the status quo, all with the goal of undermining Prius. But when it comes to EV support, there's an absolute. It's counter-productive to wait for purity. Yet, we hear arguments for it all the time. This is the outcome of Volt having failed to market "*range anxiety*" effectively. Acceptance of that loss is what we have to deal with now. I see it routinely, each time there is a new thread where plug-in hybrids get praise. I always direct the discussion to goals, rather than biting their troll bait. Toyota alone will sell 10,000,000 (yes, 10 million) vehicles this year. Think about all the automakers worldwide. How many new guzzlers are being put on the road and how long will they remain in service? Today, it was a blatant effort to pretend what happens in the meantime doesn't matter. I punched back with: Stating only LONG term goals is the problem. Stating an end-game with disregard for phases required to achieve, that is an avoidable communication issue. You need to state SHORT term goals too. Results of that will be arguing with a lot of people who agree with you, but see issues with steps being skipped... because you neglected to mention them. Notice how I had to push to get you to finally do that? In other words, don't force people to make assumptions. Provide detail next time.

- 6-17-2018** **Playing Offense, debate.** It became obvious all that person wanted to do was debate. He simply didn't care about the topic of discussion or even being constructive. He only posted to win an argument. Some are driven by that ego to compete. The reality that this was intended to be a constructive discussion didn't matter. He simply kept posting facts to favor his true agenda. It's easy to fall into the trap, both to bite the bait or to become the one trolling. A topic like EV advancement has a number of desirable engineering draws. Unfortunately, that means focus on the ideal, something worthy of striving for long-term... which means having to disregard when happens in the meantime. Ironically, that can often equate to losing the very future you desire... since sacrificing the short-term can have dire consequences. He didn't care though. Post after post was a provoke to debate. I ended it by responding with purpose & goal statements: Purpose = To significantly reduce emissions & consumption in a reliable & cost-effective manner. Goal = To achieve sustainable high-volume profitable sales prior to tax-credit subsidies expiring.
- 6-18-2018** **Reputation.** This is the stage which reputation is being established. That's why rhetoric from enthusiasts really doesn't make much (if any) of a difference. Know your audience. In the case of electrification, we want to see all vehicles embrace battery & motor technology. Heck, even fuel-cell vehicles will use both. That's why when there is a battery-related fire or some motor-power misrepresentation it's a potential source for undermining... since we know there is much to be lost by those who don't study the market carefully. Remember how poor of a job GM did with Volt? It started as an expensive technology, emerging from the Two-Mode disaster, then never recovered. What a waste. GM had a chance to establish a reputation for striving to deliver an affordable choice. Notice how Nissan took the opposite approach? Being able to overcome that price barrier for reaching mainstream consumers was vital... and was taken quite seriously. So what if range was shorter as a result? We all know EV capacity increases over time anyway. 21st Century consumers have come to expect performance increases from their affordable devices. But if the purchase is too expensive to begin with, it remains a niche. Notice how many people upgrade their phone every other generation or so? When a business depends upon repeat sales, that's what you need to focus on. Think about how many parents hand down their older vehicle to a child. That repetition is key. Notice how Toyota has captured the Prius market? Upgrades most definitely follow that success formula.

6-19-2018 **Regret.** We have been seeing a lot of that lately. Waiting... waiting... waiting. 10 years later, still waiting. I was relentless with my "*too little, too slowly*" concern. The enthusiasts of Volt harassed me as a result, claiming GM would deliver faster than Toyota. That didn't happen. Gen-2 was a horrible failure, a disaster so bad, Volt was basically abandoned. That's how we ended up with Bolt. It actually seemed a reasonable damage-control maneuver... just move on to a SUV for their premiere plug-in hybrid offering instead. After all, the power & range were overkill anyway. In a larger & heavier vehicle instead, it would be more of a sensible balance... though, quite expensive. But that is what GM shopper would be willing to pay for. They want SUV choices. They couldn't care less about cars. This is why a sense of regret is sinking in. I was right about Two-Mode all along. Calling out Volt as a poor business choice for high-volume sustainable & profitable sales way back when it was still be designed is too much to accept. They still hate me for pushing GM in the direction it needed to go... since that is what Toyota has been pursuing all along. Think about the positioning of Camry and RAV4 hybrids for plug-in augmentation. That's a natural fit. Corolla & CH-R potentially could skip the hybrid step entirely in this market, going straight to the plug-in hybrid models. There's a ton of potential... without even mentioning the rumored CUV model of Prius. We don't see that happening for GM though. A compelling plug-in hybrid SUV offering would cause serious harm to their guzzler sales, throwing them into supply & demand disarray... hence the regret. There was ample time to transition. That opportunity was wasted on conquest, instead of focusing on loyal customers. It's a monumental failure, which could have been avoided.

6-20-2018 **ICE'd by an EV.** That post, with a photo included, sure stirred discussion today. I was the first to jump into that: "*I have confronted several individuals who have done the same thing. Each one was unaware of the message they were sending and thanked me for the heads up.*" My comment got a surprising number of likes and quite a few replies. Think about what a passer-by would observe. They'll see a premium spot near the doors with a car not using the charger that spot was there for. It looks like a total disregard of purpose. Money was clearly spent to deliver the ability to charge while shopping, yet the plug-in owner didn't bother to plug in. That observation, whether accurate or not, is what the situation appears as. There's no excuse to justify the message being sent. Many people have a fragile opinion of EV potential. Risking a loss of interest, for whatever reason, isn't worth it. We must set an example by showing appreciation for the opportunity to plug in. Interesting thing is the owner eventually replied to our posts. Small world, eh? He had no clue that the predicament could be interpreted that way and apologized for the impression it made. Everyone needs to do their part to make this paradigm-shift to clean & efficient choices successful.

- 6-21-2018** **2019 Insight.** We are starting to get first reports from reviewers. Sales will begin by the end of the month. Price is expected to be similar to Prius. It's a larger car now, a sedan too. MPG is expected to be a little less, though it should offer more power. Safety options likely won't be as generous as with Prius. How consumers will accept it is anyone's guess. With the existence of Clarity PHV, this is a bit of a head-scratcher. For that matter, what can we expect from the hybrid market in general? How well is Hyundai Ionic doing? It's a rather odd situation for Honda to use the name "Insight" for a third time on a vehicle that is, yet again, quite different from its predecessor. Who knows. The preference of consumers can be quite difficult to predict at times. But at least from a business perspective, we can see a design clearly intended to target mainstream shoppers. That's really important.
- 6-22-2018** **Branding.** Here's something to ponder: *"I know I'm new here but the more I read, the more I think the prius brand is just a way to market cars to nerds."* That requires some perspective. Who are you? What do you represent? How are those around you fit in? Why makes you change? When should these questions even be asked? In other words, some are taking the time to step back to look at the bigger picture. The catch is, they have no idea what can be discovered. You have to watch for years before noticing patterns. I've been active with the automotive market since the late 70's. It was my father's passion. He taught me a lot. (I sure miss him.) Fortunately, his sensible approach lives on with me. I try to be as constructive as possible, seeking out what's realistic for the masses and recognizing what is only a niche. That's why I felt well qualified to insert this into that discussion: That's a bit of a odd statement, since basically everyone is a "nerd" based on the rate technology is accepted now. Camry hybrid is packed with tech too, as well as pushing a sporty look. How is it perceived? What about the 2019 appearance change expected for Prius? Keep in mind that early on, the biggest non-hybrid draw aspect was that it was the only midsize hatchback against look available in the US market.
- 6-23-2018** **New Phone.** I finally replaced my phone. Becoming 3 generations behind wasn't an expectation from me or those who know me. Other priorities come about. It served as a good example of how to relate to those unable to or just not interested in upgrading right away. It's an endless cycle. A better model is always on the way. When the appropriate time comes, you replace with newer. What's interesting about the process is knowledge that a great deal of effort was expended to deliver upgrades. So, there's little chance of disappointment overall. For myself, I have been pleasantly suprised by the multitude of improvements. Think of what it will be like for those who had or still have a Prius from years ago and purchase a plug-in model now. So much has been refined with so many aspects of the vehicle, that same sense of satisfaction is quite strong. It's a game of patience. Upgrades are well worth it. The situation is really just a matter of timing. When is appropriate? That's an important question to keep in mind when considering the replacement of any technology.

- 6-24-2018 Diesel Clatter.** That certainly was interesting to hear today. My old neighbor had a VW Jetta diesel for years, then replaced it with a "clean" model. I got used to hearing that obnoxious sound on a regular basis. Every single time there was a bizarre feeling of bewilderment. My Prius delivered better emissions & efficiency. Gas was less expensive per gallon than diesel too. It made no sense what she was driving. I blew it off though. She let it idle in the driveway for excessively long times during Winter, sometimes as long as an entire hour. She simply didn't care. Anywho, I heard that sound again today. We were at a park. It drove by. I had the same wonderment of why. Realistically, it doesn't matter. There is no future for non-commercial diesel. The passenger-car market is already dead. Competing with plug-in choices is very difficult already. Given a few more years, it will be impossible. No more clatter... just silent electric motors.
- 6-24-2018 Oh, that's the Plug-In!** We were parked next to a 2005 Prius. The owner just happened to be walking out to her car, from the park we were both at listening to a summer concert, when she said "Hi". As she was making a comment about the nice color from my wife's new Prius, she suddenly came to the realization it was the model with the plug. We both noticed the obvious rise of excitement. That was sweet to witness... an quite unexpected. We both have had quite a number of encounters with ordinary consumers. Plugging in at the grocery store makes that a very easy situation. The person initiating conversation is already aware of what it is though. This was the first from a fellow Prius owner who didn't realize that was a Prime, not just a gen-4. So, it was especially rewarding to experience that. Hopefully by this time next year, the situation will be quite different. Currently, the plug-in model of Prius is quite rare around here. There is good reason to expect that to change though.
- 6-25-2018 Dead.** Today's topic on what remains of that struggling daily blog was remarkable. There were 2 comments posted. That was it. I have been watching it die. The die-hard enthusiasts are having to deal with messages repeating what I posted long ago. They are echoing what had been predicted as a outcome. Volt was too expensive and targeted a market without growth potential. It was a disaster in the making. Now, it is dead. That's really unfortunate, since the technology itself had potential. GM engineers knew how to design & build what was needed. Problem was, management didn't want that. So, we ended up with a performance vehicle few wanted. Range & Power were overkill, too much for mainstream buyers to be willing to pay a premium for. Had that tech been modified to work in a SUV, where the motors would have to work harder and the battery drained faster, the result may have been a compelling compromise. But that kind of balance is not what enthusiasts thrive on. They crave excess, not affordability. That's how the death came about... an unwillingness to acknowledge need. Too much focus on want has consequences.

- 6-26-2018** **Pointless Bragging, part 1.** It continues... but now, I'm not drawing attention to comments of the poster, just punching back right where it hurts: Volt's dependency on the \$7,500 tax-credit was a terrible approach. GM sacrificed affordability for performance. That resulted in a niche very favorable to enthusiast boasting... and little else. Nothing became of the technology. For years, enthusiasts argued the "*too little, too slowly*" concern was just nonsense. Now over a decade after rollout, we still wait for GM to finally deliver a plug-in hybrid for its own loyal customers... Trax, Equinox, Traverse and the Blazer comeback all lack a green choice. Those vehicles targeted directly at GM shoppers are all guzzlers. Spin whatever you want about Toyota; it won't change that reality. In the meantime, we see Prius Prime without any dependency on tax-credit (MSRP starts at just \$27,100) averaging above 100 MPG. We also see Toyota preparing to deliver Corolla, C-HR, RAV4, and Camry hybrids with a plug-in option. In other words, that vastly superior claim for Volt falls on deaf ears. Mainstream buyers have different priorities, as do the dealers who serve them.
- 6-26-2018** **Outright Lies.** The acceptance of "fake news" as fact was troubling long before that term was coined. People would just say whatever they wanted repeatedly, until it was finally accepted as the truth. With group think, that problem was all too real. It's how enthusiasts are recruited... their hope clouds reason, which prevents them from verifying claims. Anywho, it continues with the spreading of lies about how Volt actually operates. I wonder how many gullible readers fall for such efforts to mislead... especially in this case, where the claim is used to belittle Prius. I fought back with: Volt is not a SERIES hybrid. It was intended to be, but that isn't what GM delivered for gen-1. The design for gen-2 took advantage of the engine for direct propulsion even more, which is how some of the improved HV efficiency was achieved. Label Volt as whatever you want, but you cannot under any circumstances put it in the same category was BMW i3 REX... a true SERIES hybrid, where the engine does nothing ever by generate electricity. Volt is far more similar to Prius Prime as you want to admit. Both can run exclusively with electricity, from a dead stop to beyond highway speed limits without ever starting the gas engine... even with the heater running. Lastly, that claim of SERIES being superior doesn't have any merit. Prius Prime delivers more efficient EV and more efficient HV operation. Using less electricity and less gas to travel the same distance is the goal. It simply makes no sense endorsing an approach that requires more fuel.

- 6-27-2018** **Chevy Blazer.** Surprise! GM is filling in their product-line of SUVs. Now, between Equinox & Traverse will be Blazer. It's being spun as a revival of the old model, but we all know it is to solidify the elimination of cars from their production. With Trax on the small end, they have all the size-categories covered. This is exactly why the *"too little, too slowly"* concern was expressed so often. I knew the answer to the *"Who is the market for Volt?"* question was not GM shoppers. It's the reason why Volt hasn't been advertised. Notice how it's as if gen-2 doesn't even exist? Heck, we barely ever hear anything about Bolt. Small cars are of no interest to GM. My push to get Voltec spread to other vehicles has been overwhelming vindicated as well intentioned. This is why even the most staunch of enthusiast, those who hated me with a passion, have vanished. They misunderstood the customers, the dealers, and the automaker. They now realize what I had posted was for their own good, pushing them to help prevent what they encouraged. Their own worse nightmare is now playing out... GM isn't a leading seller of plug-in vehicles and it looks like Toyota has a great deal of potential to fulfill that very role. Seeing lots of new Chevy Blazers on the road will be the ultimate let down. With a standard 3.6 liter V6 engine, you know it will be quite a guzzler. To make matters even more ugly, you don't need to look any further than sales for the first 5 months of this year. Equinox = 141,477. Traverse = 61,708. Trax = 37,173. Each of those Chevy SUVs outsell Volt by quite a large margin. This is why the hybrid system in RAV4 is so important. Adding a plug isn't a major undertaking. In fact, it will be a fairly simple process... for Toyota. There is no obvious upgrade for GM, since there are no hybrid SUVs still. Don't forget why these SUVs (or as GM calls them *"Crossover"* vehicles) are so important. They are what GM depends upon for business-sustaining profit. It's the very same dependency we saw before the bankruptcy. They are desperately trying to reshape the industry for their own survival... again.
- 6-28-2018** **Leadership.** It's nice to have a civilized conversation for a change. Today, it was with a very long time Prius owner... since way back in 2002. His wrap-up of a lengthy commentary about his new Prime was: *"But I think if Toyota wants the Prius to continue to be a leader then they need to go back and look at what made Prius great in the beginning, and it wasn't just high MPG."* The highest priority back then was emission reduction. That's why the idea of a plug wasn't embraced. Think about how dirty emissions were 20 years ago. That was well before natural-gas has really made any impression as a potential replacement for coal. It was actually cleaner to burn gas and scrub that exhaust through the sophisticated emission-system in Prius that it was to power an EV back then. That's what the SULEV rating was all about. Standout MPG was a secondary benefit. Neither was what won over buyers though. It was how practical that gen-2 model could be. A large hatchback with proven reliability and an obvious investment in the future made for a compelling draw. Toyota was sending a great message of hope. That's true leadership. I didn't point all that out this time though. I kept it short and relevant to that particular audience: I have the impression that is the plan for the new CUV model of Prius. This current Prime rubs some the wrong way, since they don't want it to be defined as something other than a *"family"* vehicle. Diversity is key to growth though and there is an undeniable shift away from what made the first hatchback Prius a draw.

6-29-2018 **Mid-Cycle Updates.** GM announced improvements coming for the 2019 Volt. This the usual upgrade approach known as "*mid-cycle updates*" which has become quite common for plug-in vehicles. That has become a normal expectation now. In fact, we have that to realistically look forward to for Prius Prime. In this case, GM is adding a feature everyone expected for gen-2 originally... faster charging. It was a somewhat pointless feature based on the way Volt has been marketed though. We've been told the 53-mile range was plenty... which would negate any benefit from recharging anytime other than when at home overnight. It's a goal contradiction no one wants to address. The other was changing the low-temperature threshold for the engine starting to a range most owners won't actually benefit from; for the rest, that feature won't provide as much of a gain as it implies. This is yet another "*devil is in the detail*" situations. A much better upgrade would have been cost-reduction to drop price significantly to deal with the loss of the \$7,500 tax-credit. Sales are struggling already. Achieving the necessary business growth is basically impossible with such a niche approach. Anywho, I posted: Better is dependent upon who the audience is. Ordinary consumers certainly haven't been asking for faster L2 charging. In fact, most mainstream shoppers have absolute no idea what that even means. Their primary request has been a reduced MSRP to make it a more compelling choice. As for the ability to run a power-hungry resistance-heater at temperatures below 15°F, that's nice but not feature many will actually be able to exploit. Even here in Minnesota, there simply are not that many days when that would deliver a huge payoff. Doesn't EV become available after the coolant reaches a certain temperature?

6-29-2018 **Who?** I've seen anger coming from that die-hard Volt enthusiast who sung praise for GM all those years, speaking loudly in favor of PHEV over EV, then abruptly jumped shipped to purchase a Tesla. That type of hypocritical behavior is typical of those who value pride above actually being constructive. So, I ignore him entirely. That kind of troll cannot thrive in a venue with such a diverse audience. He requires many enablers for that. This blogging sight doesn't have that, quite unlike the old Volt daily blog. There are less intense participants there too. They simply see power & range as superior and give no thought to what actually makes a difference. It's easy to deal with them with a few basic facts. I do that along with posing a question, with the hope of some type of sensible response to reply to: Volt is neither a leader with EV nor HV efficiency. Note the kW/mi and MPG ratings. Using less electricity and less gas is the goal, right? Also, GM's goal was to "*right size*" battery capacity. So, the option of faster recharging is a bit of a head-scratcher. Who would be interested in that option? Remember, GM's ultimate solution to "*range anxiety*" ended up being Bolt, which makes Volt without any specific audience now.

6-30-2018 **Pointless Bragging, part 2.** Someone else got snippy: "*Unless you need 5 seats, the Volt is a way better car than the Prius, and you know that. No amount of rationalizing will change that fact.*" It's the type of desperation I dealt with for years. They absolutely refused to accept defeat and move on. So, I keep fighting back with inconvenient truths: Being rational means recognizing facts that are moot... of little or no practical value, meaning, or relevance; purely academic. The goal of Volt was to "*out-Prius Prius*", which meant becoming a more popular clean & efficient seller. 10.5 years into Prius sales, the total count on roads around the world had already surpassed 1 million. (1,050,000 to be more precise.) Volt sales have been so much less that GM hasn't even the 200,000 limit for tax-credits in its own home market in that same amount of time, despite having so much more experience. Fact is, only enthusiasts saw "*way better*" as a reason to purchase. Mainstream buyers just plain were not interesting, quite unlike the history we've seen with Prius. GM did indeed deliver a nice product, but it simply did not match purchase priorities of their own showroom shoppers. Again, GM's focus is on Trax, Equinox, Traverse, and Blazer being top-sellers for ordinary consumers. Volt will remain a desirable niche.

6-30-2018 **Tariff Consequences.** The cost we will have to deal with as a result of having elected a narcissist to lead the country is going to be tremendous. He just plain does not understand the consequences of lashing out at those we are perceived to be taking advantage of us. True, there is an imbalance, but the tradeoff of stability is absolutely vital. You build upon that to achieve improvement. Good things can come from overcoming challenges. Simply doing things for spite can have terrible consequences... which are starting to see already as a result of the new tariffs: "*General Motors warned Friday that if President Trump pushed ahead with another wave of tariffs, the move could backfire, leading to "**less investment, fewer jobs, and lower wages**" for its employees.*" That's a horrible first line to read in an article published today on the topic. All the big news organizations had similar statements to share. Our president doesn't understand that who we trade with need to be treated as partners, especially with the automotive business. Vehicles are extremely complex products... sourced from a variety of locations worldwide, very large & expensive, and with long replacement cycles. It's not like other products. A massive amount of employment is required just to sustain. To be profitable in such an aggressively evolving market, you need cooperation. This is as if there's an effort to sabotage our own success. Why? What motives someone to be so reckless? These decisions will hurt so many... not to mention our environment.

6-30-2018 **Upcoming Fallout.** Yesterday's announcement about the mid-cycle updates for Volt was quite predictable. Monday will bring about the first counts since GM decided not to report sales monthly anymore. This quarter wasn't expected to be a good one, so the tactic to distract fits their behavior pattern. Not selling as much means the tax-credit will last longer. Not selling as much also means things aren't going well. It's the reason why enthusiasts are ramping up rhetoric again. I'm pushing back hard though, since there is no excuse to sugarcoat anything anymore. They know trouble is brewing and don't want to be trapped in their own hypocritical web. I endured years of their nonsense for this moment, when Volt is no longer a barrier to mainstream acceptance. GM really messed up the market... just like they did with diesel decades ago. Ugh. Oh well, not much to do about it at this point, other than document the heck out of the situation so lessons can be learned. Here's the way I put it: As logical & sensible of a configuration that may seem, the reality of sales struggle must finally be faced. That formula simply hasn't worked. Even with a \$7,500 tax-credit, GM wasn't able to entice many of their own loyal customers to purchase a Volt. A very large portion of sales were the conquest type, attracting outside interest without gaining any loyalty. Ironically, the biggest failure-point for Volt is what we heard mentioned heavily way back when it was still being developed... PRICE. The goal of "*nicely under \$30,000*" was talked about on a very regular basis. With a MSRP that low, it would stand a chance of competing directly against traditional vehicles by the time the tax-credit expired. \$33,220 is far too expensive, especially when you compare to the vehicle most often compared to... Prius Prime, which starts at \$27,100 and includes "*driver confidence package*" features you must spend \$4,350 more to get with Volt. In short, GM had a good idea but poorly implemented it. Faster charging won't change any of that.

6-30-2018 **Anti-L2.** This sentiment is emerging: "*The faster folks understand that L2 is for nothing other than overnight charging, the better off we'll all be.*" It's the latest form of being vastly superior. The belief is that the best 240-volt AC charging available is totally inadequate compared to the higher voltage DC charging. Pushing it as a mutually exclusive solution is the problem. Having a mix of AC & DC chargers is unacceptable as far as he's concerned. It doesn't make sense to invest in the more affordable choice, which would in turn mean more chargers could be made available. A few of the ones with a much higher cost are what he favors... as his history of posts clearly confirm. Well, in a way, this is progress. New issues are being brought up now, focusing on infrastructure rather than just the vehicles. I replied back to that with: Not going to happen. Think about how many parking spots there are at your local grocery store. A typical 20-minute stop easily provides enough range to get home. You can provide far more L2 than DC for the same cost. DC takes more real-estate to accommodate too. 19.2 kW is ample electricity rate for a restaurant or movie stop. So, the absolute of not offering L2 won't get much traction. You should focus on DC offerings at those coffeeshop/gas-stations combinations. That's a realistic bridge to the future.

- 7-01-2018** **Fast Refill.** This coming next was inevitable: "*The problem is that without the DCFC interface, that gas is the only way to fast refill a Volt.*" It's the problem that comes from dealing with someone trying to solve a problem exclusively from an engineering perspective. He's dead set against L2 use anywhere but for long-term parking. Simply stopping at a grocery store for a quick partial charge is unacceptable... despite the fact that it works so well for so many. I stop for a coffee or fresh food item, then leave shortly after. Those few minutes are more than enough to reach home with nothing but the electricity from the charger moments earlier. Needless to say, I'm getting tired of the close-minded responses: That's the fundamental mistake EV advocates are trying to get word about to other EV advocates for charging-station use. Spreading a belief that they are there exclusively for *REFILL* is counter to the effort so many have striven to deliver. They can be very, very effective used for just a quick partial replenish. Most of the time, you don't need full capacity anyway. Remember, the goal is to replace traditional vehicles... not to solidify an end-game. We are trying to establish charging-spots and built up patronage. L2 can always be upgraded later, especially once repeat usage becomes common. It's that initial investment we need to focus on now. Taking that first step is the most difficult. People will see charger availability and begin to feel comfortable with moving toward electrification. Fast refill is not necessary for that to happen.
- 7-01-2018** **Opportunity Recharging.** The fastest possible recharging isn't necessary. Most people only want a top-off so they can reach home using electricity. All those local shops... grocery, retail, hardware, coffee, snack, etc ...are brief stops with major payoffs from nothing but a L2 recharge. At venues where you will be spending more time, like a movie theater or sitdown restaurant or large mall, that still necessary. Seeing DC fast-chargers emerge along highway corridors makes sense but that isn't what the debate was about. He simply wanted to win a point. That's why his push for the off-topic content was so relentless. It's an obsession with "*best*" or "*most*" or "*superiority*" that wrecks constructive discussion. It is the reason I ask for goals... relentlessly. Finding out what motives that person is much more important than that facts at hand. It's easy to manipulate posts to change focus. You need to find out why they are doing it. In this case, it was the belief that charging as much as possible is the best outcome. I attempted to end the nonsense, seeing it was turning into rhetoric, by drawing attention to the fact that recharging during peak hours is not a good choice. That is often the most expensive and most dirty time to be demanding electricity. So, promoting a maximum then is counter-productive to a goal of being green... which is why "*opportunity*" should be understood as just what you need at the time you need it.

7-01-2018 **Fast Charging.** That long, drawn out, debate about DCFC had me quite curious. What was his goal? Eventually, I would find out... and after series of more posts, I did. He changed his story to now be about "*medium power*" for DCFC... which makes makes no sense, since the "*F*" in that acronym stands for "*Fast*". All along, he's been posting about how the kW rates are so much higher. Then, he abruptly changes it to mean just 24 kW. That's barely any higher than the 19.2 kW for a L2 running on a standard 240-volt connection at 80 amps. I jumped on him at the very beginning for even attempting to compare such different rates. Fast requires a 480-volt connection to actually be fast. He knows all too well I caught him on the cost barrier. That's a lot more expensive, especially if you require enough amps to truly be impressive. Complaints about 50 kW being minimal have lead to the unveiling of a handful of 150 kW chargers and the announcement of some future charging-stations delivering 300 kW. This is what he's been implying we should all favor instead, not to even consider slower technologies. What I get a kick out of is if that supposedly is "*medium*", what the heck is "*small*" for a DC charging rate? It seems bizarre to have an expensive charger output DC without any benefit of what a cheap AC charger can deliver. Needless to say, I caught him up in an effort to deceive. It has become clear he's simply an advocate of DC charging and didn't realize anyone who catch his bait & switch about speed. That was interesting though. I didn't even have to get into the cost of the electricity itself. When you require that much that quickly, the electricity providers place you into a more expensive pricing tier. Those higher fees are only affordable for commercial business making money from that usage. This is why free access to Tesla SuperChargers is so heavily desired. Without, it can be quite expensive to fast-charge. This is why L2 has been promoted so much. There will be fast-chargers too, but they will accompany L2. Not everyone is willing to invest so much for speed. The cost to a charging-station owner is especially prohibiting. Remember, L2 (level-2, the standard 240-volt plug) can still be quite a bit faster than L1 (level-1, the standard 120-volt plug).

7-02-2018 **Single Standard.** It came down to only wanting to support a single standard, but that idea being presented in a contradictory manner. He started with praise for the "*recharge the battery to 80% in an hour or less*", then carried on in great length about how vital speed was. Over and over, being fast was presented as key to success. The essential part of that was to not support L2 in an manner, that it was essential to only have DCFC. Then out of the blue, the focus shifted to medium. It was so hypocritical of a stance change, I was confused. What happened to the importance of being quick? Looking back at the posts, I see a long chain of "*limitation*" claims and the word "*wrong*" being used several times to describe L2 technology. Basically, it was just another encounter with an individual unwilling to accept anything more than a single solution. It's that one-size-fits-all mentality. Some people simply don't believe co-exist is a viable outcome.

7-02-2018 **Average Price.** This came from a 2011 Volt owner: "*Armchair quarterbacking at it's finest. You ever price the "average" car here in the US?*" I got the impression he jumped on the great pricing opportunity all those years ago and never really paid attention to the market. He clearly didn't like my reference to the "*driver confidence package*", choosing to go with the it's-worth-it argument. Ugh. There's far too much enabling nowadays, where people just go along with blind assumption. They just support what feels right, never bothering to actually do a little research or even ask a question. This basic approach to pricing provides a good example. It was void of any numerical information. Nothing whatsoever is a source for concern. Any type of detail... even just a generic category... can help narrow focus. That was so vague, it could have included everything. It makes no sense lumping together giant trucks and subcompact cars. Yet, that's apparently exactly the nonsense he attempted. I don't put up with that, especially when the first sentence in a reply is so snarky. I fired back with: Average is totally inappropriate. Proper pricing assessment is to compare vehicles with similar traits. The typical consumer will shop for "*compact car*" or a "*midsize suv*". They most definitely don't mix together everything available to come with an average. As for price, Volt is about to lose that generous \$7,500 tax-credit, which will make it compete directly against other vehicles in its same class. As for the effort to avoid addressing additional cost of safety features, that's online posting at its finest... just ignore what isn't liked.

7-02-2018 **Expiring Tax-Credits.** The fallout is about to begin. We expect news soon that Tesla crossed the 200,000 threshold, which will trigger tax-credit phaseout. That means things are about to get ugly. Focus is always on "*leadership*" in the form of which ever automaker delivered the most EV range. Supposedly, that is the only measure of worth. Being affordable or the most efficient is still being ignored. Enthusiasts are obsessed with battery-packs becoming larger and larger. That's really sad. Lack of balance is never a good thing. Success among mainstream consumers requires the satisfying of a wide variety of criteria. Their priorities don't focus on just the most of something. In fact, this has always been the secret to high-volume sales for Prius. It was never just impressive MPG alone. Yet, there are some that want to reward GM for focusing so heavily on range anyway. Virtually every day, I hear some enthusiast belittle PHEV offerings from other automakers for still not matching what Volt delivered all those years ago. Other factors are completely ignored. Again, that's really sad. So naturally, I have much to say about the upset related to expiring tax-credits. The purpose was to achieve high-volume sales prior to them expiring, which is why each automaker had their own time-table. GM clearly wasted that opportunity. Why should more be offered? Tesla, on the other hand, has actually achieved that. Kudos! That could be rewarded; however, the manner in which that occurs should be discussed. Progress means setting new goals. What should they be upon entering this phase, on focusing squarely on mainstream consumers rather than plug-in enthusiasts? I stated the situation this way: Sounds like some want to reward OFFENSE for winning the game. Don't overlook the importance of DEFENSE when it comes to what the team must do. Think about how much Nissan, Hyundai, and Toyota worked to deliver affordable choices that don't have any dependence on tax-credit help. Their efforts to deliver a sticker-price able to compete directly with other vehicles sharing the same showroom floor are vital. In other words, those who sought the low-hanging fruit shouldn't reap all the reward. It's a team effort. Spoils should be shared based on what we set for goals in this next stage. We are done appealing to enthusiasts. Are range & power really as important to draw mainstream consumer interest?

- 7-02-2018** **Unfair.** Discussions will likely go on throughout the remainder of the year, never really getting resolved. Think about how there is no sense of agreement among plug-in supporters about how charging-stations should be used. For that matter, there still isn't a shared approach agreed upon for how to deal with ICE'd parking spots. That lack of any clear message is how problems are created & sustained. Look at Volt for another example; enthusiasts disagreed about audience & purpose for years. So when it comes to an even more diverse potential audience, we're simply stuck. What to do in the form of subsidies to help promote growth is a complex issue with no easy suggestion. This is how I contributed to the discussion today: Unfair? What about those who wasted their credits, using them for conquest sales rather than attracting their own base? Remember, purpose of the tax-credit was to reduce each automaker's traditional production by getting loyal buyers to switch. Not using the subsidy for that purpose is good reason to prevent more from being wasted. Missing that opportunity was their choice. They had their chance, but squandered it.
- 7-02-2018** **Heavy Lifting.** New words, like "*punish*", continue to emerge. Other words, like "*ground breakers*", would be a welcome shift. That isn't realistic though. There isn't any sense of cohesion yet. I chose to focus on another today, hoping the drastic attitudes don't become the mantra: "*Heavy Lifting*" is cherry-picking. No large-scale rollout can succeed without significant investment in the work required to appeal to ordinary consumers... the unseen efforts... like what Toyota did to make hybrids such RAV4 and Camry a very easy transition to plug-in. Rewarding those who went after low-hanging fruit is helpful for next-stage market penetration.
- 7-02-2018** **Smart Incentives.** There is a growing effort to retain the status quo. Tax-Credit phaseout is becoming a terrible reality for some. That concern of "*too little, too slowly*" is too much for them to finally accept. So, they are choosing denial. Just extend the tax-credits. That's their solution, despite the obvious flaws. The biggest complaint was they favored the rich, rewarding them for endorsing vehicles far too expensive for any of us to ever purchase. Why provide such generous incentive for those who don't need it? Giving to the rich while doing nothing to help those who would gain great benefit makes no sense. Yet, that's what they want more of. Ugh. There has also been the problem of how overly simplistic the incentive actually was. There was nothing to promote actual merit, something to reward engineering achievement. It was nothing but showing favor for size... which we all know who exploited. Hope of a vehicle emerging for the masses prior to phaseout from GM clearly didn't happen. In fact, it is now rather difficult to argue Volt was designed to appeal to mainstream buyers. Anywho, I keep punching back at the effort. Today, it was on a long and very active new thread about the topic: What about having to meet a minimum efficiency level? Subsidizing vehicles that guzzle electricity certainly isn't a step in the right direction. Cramming more battery into a vehicle to meet an arbitrary distance doesn't promote efficiency. In fact, it wastes a variety of resources. We want smart incentives, not what seems good.

7-02-2018 **Ahead.** Antagonists are really working hard now to undermine the progress by Toyota. Virtually all of it is coming from EV supporters, those who believe "BEV" is the only solution. That means "*Battery Electric Vehicle*", which is a term used to disqualify plug-in hybrids and fuel-cell vehicles even though both can operate entirely with electricity. Don't only want purity and believe taking a single step with that as the ultimate solution is the only choice. That's quite unrealistic. The market is far too diverse and infrastructure far too limited to achieve that quickly. But since they don't believe in transition and refuse to acknowledge anything outside of BEV sales, it very difficult to get any type of constructive discussion. This is just like Volt of the past, they just plain don't care. Nonetheless, I continue to push back on their message that Toyota is supposedly dragging their feet: RAV4 and CAMRY hybrids are quite popular, not all at the "*old news*" narrative you attempt to portray. COROLLA is an extremely popular vehicle worldwide and will be making its debut as a plug-in hybrid next year. CH-R will be making its debut as an EV next year as well. That all represents wide-scale efforts to steer their own loyal customers toward electrification... putting them ahead of many other automakers.

7-03-2018 **Recognition.** Many, many, many years too late, at least what some of us had been saying is finally getting recognition as a next step: "*By all accounts the "voltec" drive system is very good. If they put it in a small crossover style body it would sell very well I think.*" The harassment I had to endure for saying the same thing... Ugh. The enthusiasts of Volt absolutely hated me for suggesting what GM do with the technology. It was amazing what they did to fight change. Any type of acknowledgement of that GM should do something else was, in their mind, an admission of defeat. So, it an endless stream of brutal posts trying to prove me wrong. That never worked though, since ultimately I knew my message would triumph. Diversity is absolutely necessary for growth anyway. But it was the reality of Volt being poorly configured to appeal to mainstream consumers that made them crazy. To succeed, they would have to compromise by giving up on an ideal. It feels good knowing all those confrontations were polite on my part. No matter how much they attempted to personally offend and hurt me, I remained true to my support of affordable solutions without ever lashing back at them on their terms. In other words, I was unwilling to stoop to their level, unwilling to give them the pleasure of providing a reason for them to call me out. I just kept repeating the same message of GM needing to spread their technology to other vehicles. Read through my older blogs for detail on that nasty past. Understanding how we got to this point is very helpful to know. We prevent future errors by learning from mistakes of the past... and they sure provided lots of educational opportunity.

- 7-05-2018** **Fake News.** We've been dealing with it for countless years, long before most people realized propaganda material would be disguised as news. It was so annoying to have to deal with that on a regular basis. Back then, there weren't comment sections associated with online articles. Instead, we'd have to try to fix the trouble stirred by the misconceptions being created. People would refer to those published articles as if that was a credible source never to be questioned. This is why I ended up pushing so hard with the videos. That real-world detail became a powerful tool. I remember so many posts stating the EV range of Prius PHV was only 6 miles, despite their being endless posts disputing the claims. It wasn't until people started seeing those drives easily exceed the supposed distance limitation that antagonists backed off... since they didn't want to get called out as intentionally spreading greenwash. I still remember filming a drive that delivered 13 miles and feeling so good. True, that was far from my record of 18 miles, but this was with the battery-pack now 4.5 years old. Sadly, some attacks using fake news are happening with Prius Prime too. Fortunately, I was lucky effort to capture a bunch of footage during my first year of ownership. So, there's lots of material to fight back with already.
- 7-06-2018** **Propulsion Power Reduced.** Today started with a stumble across a comment on the Volt forum about a "*PPR issue*" which caught my attention. Why hadn't I ever heard of that? Turns out, it's a problem antagonists have gone to great lengths to keep quiet. This is an aspect of Volt operation they clearly have been trying to hide, since knowledge of it helps confirm Volt is even more of a plug-in hybrid than any EREV propaganda would have you believe. Technically, it is this: "*At some point, the computer decides you're not allowed to pull any more out of the battery and reduces propulsion output to 55 KW in order to prevent any further drain from the battery.*" In other words, if the available capacity is too low, all power must come from the engine... which is a condition those nasty antagonists claimed would never happen. Demand for more will pretty much only happen when climbing a long, steep hill. But when you do searches for the issue, you will find a collection of owners who have encountered the situation. It's why GM introduced the hold feature and specifically labeled it as "*Mountain*" mode. If you don't use it, you may experience the issue too. Knowing some owners won't take that preventative action, which is what I wondered about, there is a system update available. I suspect this is applied whenever an owner reports the issue, as one had put it this way: "*As an aside, there is a software fix for the PPR issue, though you'll likely lose 10% usable battery.*" That would be a simple remedy when seeing the message on the screen and having the engine-light come on. It equates to 5.3 miles of range loss though, putting it dangerously close to Honda's rating. Being called out for hypocritical power claims and being matched by a clearly nicer PHV offering isn't the way enthusiasts hoped things would play out.

7-07-2018 **Distraction.** This gave me reason for pause: "*Trump is also a master of distraction, and he has a polished record of creating new political storms to disguise scandals and dramas that could damage him politically.*" Sound familiar? That's what contributed to a bunch of the blogging I did in the past. GM provided an endless source of the same nonsense. When something big approached and you knew the inevitable face-the-music moment arrived, there would be an announcement about something totally unrelated. That news would be spectacularly captivating. It would also be horribly vague... which contributed to a variety of understanding problems... exactly what you want when trying to distract. Enthusiasts gobble it up, taking it every word as a promise written in stone. It didn't matter how absurd or outrageous the claim was, they supported it as if delivery had already taken place. Their blind trust was appalling. Excuses were plentiful. Blame was obvious. It's rhetoric you cannot believe. How could so many people be so gullible? Distraction shouldn't be that effective. But when dealing with those who inattentive and lack constructive reasoning skills, you have an audience easy to manipulate. It's a scary part of "*know your audience*" that hurts to understand. He does. GM does too. They both have a past filled with examples of distraction. Sadly, we can expect more in the future too. Watch for it.

7-07-2018 **Inflicting Harm.** There are a few who do it intentionally. This was the case with our EPA administrator yesterday, hours before he resigned. He granted permission to proceed with business as usual for a diesel freight truck, which will equate to a major emission loophole. The argument (of course) was the financial hardship would outweigh the environmental benefit. I call that a load of crap. Allowing that particular vehicle to continue polluting as much as 55 times what emission-controls would restrict is absurd. One year's worth of its sales would release about 13 times as much NOx (the nasty smog type of emission) as all of the VW dieselgate cars combined. Remember that disaster? How can giving permission for more violations in the name of profit be acceptable?

7-08-2018 Punish Who? More and more people are making blanket statements like this without providing any reasoning: "*It punishes pioneer and rewards sluggish automakers.*" It's that complete absence of follow-up that gets me. Not stating a purpose of any kind makes the claim a worthless contribution to the discussion. Without anything to suggest what advancement should be rewarded, or even what inaction should be punished, why are they sounding off? Every time I ask, there's silence... which is a confirmation of not having actually thought the situation through. Anyone can make a generalization. Very few take the time to stand behind their decision though. That lack of commitment is a dead giveaway there's shortcomings not addressed. Needless to say, my perspective is quite different:

Economics state otherwise. In fact, we now have proof of that.

GM used their tax-credits for conquest, attracting sales from outside to sell a vehicle clearly not viable as a sustainable high-volume product that's profitable. Rather than using the money to subsidize a design to appeal to the masses, they wasted it. Why should more money be provided for the same thing?

Volt technology should have been adapted for use in a vehicle GM customers actually want. For many years, concern about the disinterest GM had to deliver a mainstream product fell on deaf ears. Gen-1 was clearly a niche. Gen-2 should have been an effort to rectify that; instead, it became even less of a vehicle appealing to their own loyal customers. How can rewarding that be justified?

Consider the number of Volt owners who abandoned GM when their lease expired. Consider how low the sales of Volt continue to be, even with that generous \$7,500 help. Consider how little Volt actually did to change the status quo. GM sells a massive number of guzzlers and has no actual path to electrification for them.

Meanwhile, we have Toyota being labeled as "*laggard*" even though their entire fleet has a clear electrification path. Prius has already been delivered as a plug-in hybrid. Next year, the Corolla hybrid will get a plug-in model too. That makes it very easy to see how Camry, RAV4, and C-HR hybrids could also offer a plug. So, why exactly is that an activity to punish?

Think about which will do more to replace traditional vehicles with something offering plug. With millions of sales each year, we should not allow more waste. It's the ability to bring about change the tax-credits should be used for.

Based reward on merit, not enthusiast praise. The homework assigned was to bring about real change prior to tax-credit expiration. In fact, that is the very reason why there is a phaseout stage that does not have a count limitation.

- 7-09-2018** **Pride or Hate.** After years of having to deal with belittle turned dishonesty, it sure feels good never having given in. Whether it was pride or hate, the antagonists simply wouldn't give up. When facts were not in their favor, they'd turn to personal attacks. I didn't respond with anything that could be used against me. They'd troll. I wouldn't bait. Each provoke made me carefully think & research to find a constructive reply. They hated me for that. I was supposed to provide them with material to call me out as someone just blindly loyal to Toyota; instead, I was a constant supply of debunking material. Never having waivered from purpose is what irritated them most, as today reaffirmed: *"Cherry-pick stats all you want, and keep moving the goalposts as well. Fact is, Toyota is in last place when it comes to plugins, no matter how you try to spin it."* Continued to repeat the same message of business success has been key. That goal never budged, not even a little. If the choice wasn't affordable and easy to accept, there's no way the masses will turn toward it. I'd often test myself by asking if that would interest Mom, who is quite representative of ordinary consumers. That's not what I post with respect to purpose though. It is often something just like this: Same goal as from the very beginning. Each automaker is expected to reach sustainable & profitable high-volume sales prior to tax-credit expiration. The approach Toyota took to deliver a robust battery-pack that's also low-cost makes their offering affordable even without subsidy money.
- 7-10-2018** **Waiting.** Every time there is something about Prius Prime published which points out a strength about the design, antagonists emerge. They started with the usual misrepresentations, move on to spreading lies, then turn to personal attacks. Their behavior is so predictable it would be agonizing... if it wasn't for the fact that their time is up. Expiration of tax-credits represents the end of this initial stage... early adoption. Without those subsidies, appealing to non-enthusiasts becomes far greater of a challenge. Toyota is positioned to deal with that loss. GM is not, the automaker many of the antagonists endorse. With Volt & Bolt squandering the last of those precious dollars, there is nothing to focus on. What comes next from GM? Not having a viable product for their own loyal customers yet, watching conquest sales use up what's remaining is more steps in the wrong directly... and they know it, all too well now. I have been one of the loud voices expressing concern about this very situation for years. Now, I only have to wait days. A few days after the initial post, I start filling the comment area with facts to dispute the wild claims. They have no idea how to deal with that, especially after their audience of enablers have moved on. The only readers at that point are typically those studying the market, people searching for constructive detail... which is what I try hard to supply.

- 7-11-2018** **Misrepresentation.** I don't want to include the provoke quote anymore, not at this stage. Spreading rhetoric is counter-productive. You want examples, there are lots in past blogs. Now, we shift attention entirely over to the response: Hoping that misrepresentation of what actually happened will be receptive to the new audience here? Prius PHV was rolled out 6 years ago, not 8, to only 15 states as a mid-cycle upgrade to gen-3 Prius. It was a test platform to measure the market prior to a large ramp-up & deploy. Toyota determined cost was too high to appeal to mainstream buyers, so they kept inventory limited... then later stopped production all together. Since Prime was already nearing final design, the approach made a lot of sense. Toyota could continue to collect valuable real-world data without influencing those untouched 35 states and the existing dealers could clear out existing inventory entirely. It would preserve the tax-credits for that next-generation Prius plug-in and allow every location to start fresh. The results clearly confirm that was a wise approach too. We see how well rollout sales have been and this video shows us how much Toyota learned from that low-volume beginning.
- 7-11-2018** **Rhetoric.** Here's more: Rhetoric related to the progress Toyota has made with plug-in support has been going on for years. They take a bottom-up approach, the complete opposite of GM, so misunderstanding is common from those unfamiliar with that business & economic perspective. In 2015, when Toyota ended production of Prius PHV, the antagonists immediately started to push a narrative of having given up. The spin was Toyota had called it quits and would focus exclusively on hydrogen fuel-cells. It was utter nonsense, proven blatant greenwash when the next-generation was revealed in 2016. It simply made no sense to proceed with gen-1 rollout knowing that gen-2 would deliver major improvements at a lower cost. Looking back, it is now easier to see the efforts to undermine. Design of this battery-pack makes it clear that Toyota placed pricing as a very high priority, doing everything they could to deliver robust operation without requiring heavy expense. Effective cooling without the need of a liquid is a complexity Toyota was able to avoid. Forced air is proving a good choice.

- 7-11-2018 Coolant Cost.** I made an interesting discovery today. It's an omission I should have picked up on years ago, especially since diesel supporters would do the same thing. They'd exclude routine maintenance mention. It's easy to do if that chore is something unique to the design. For diesel, it was the fluid used to cleanse emissions. A chemical called "*urea*" was required to be replenished on a regular basis. There was a tank in the trunk that would hold it. EPA regulations forced metering to ensure the system was not bypassed... which would save the owner money, but allow dirty emissions as a consequence. This complexity & expense is something supporters wanted to keep very quiet. The same thing is obviously true of my stumble across today. Turns out, that fluid used for cooling the battery-pack in Volt much routinely be replaced. 90,000 miles is the required regular interval; sooner is suggested for hot climates. It take 12 quarts of coolant. The price is roughly \$5 per quart. Then you must add labor and a disposal fee. I suspect there is a filter requiring replacement as well. This is a service you obviously can only have performed at a GM dealer, since it is totally unique to Volt... though, Bolt may employ a similar fluid & process too. The point is, owners never mention it. Think about where the drain-value and fill-port locations could be. I don't expect that to be easily accessible. In the post I made the discovery from, that person stated it is "*messy*" work. Knowing all that explains why we don't ever hear about it, even in posts stating total ownership costs. Omitting that information is an attempt to mislead... which needs to be called out.
- 7-12-2018 Path Forward.** Attacks continue. Ugh. Being so desperate, you'll say anything, is really sad. Yet, I'm still seeing it. But rather than go for that trolling bait, I keep on posting things to keep lurkers thinking. The stuff that keeps them silently following threads to learn more is a very effective means of supplying educational material. They simply desire to learn more... which I am grateful to provide: Once upon a time, some unknown person made some vague statement. Even if there was any substance to that in the past, how would it still be relevant? We clearly see the intent now for plug-in options across Toyota's fleet of hybrids. In fact, both Corolla and C-HR will make their debut with a plug next year. Following that is the expectation for RAV4. That makes thought about Camry joining later quite realistic. It's a path to electrification their customers (that means both consumers & dealers) can easily take. In other words, the twist of Prius not being important is in an odd way true if you look forward enough. We need to see the rest of the fleet join in. This is why GM has done such a horrible job with their supposed "*vastly superior*" technology. Two-Mode didn't diversify. Volt didn't diversify. Bolt is struggling. There is no path forward still, after all these years.
- 7-12-2018 Blind Hate.** As expected, the attacks continue. I don't give in. I push back: That narrative of loyalty doesn't work. I say positive things about Hyundai, BMW, Honda, Nissan and Tesla on a regular basis. All offer more range. Competition isn't other automakers anyway. The goal posted over and over and over again is to appeal to showroom shoppers, those loyal customers who couldn't care less what other automakers offer. They just want an affordable choice. This is why Corolla, C-HR, Camry, and RAV4 were all brought up in the discussion about Toyota. When there's a discussion about GM, the post mentions Trax, Equinox, Traverse, and the upcoming new Blazer. Each automaker must transition to something offering a plug. That means their entire fleet. Competition is from within the showroom floor.

- 7-12-2018** **2019 Thoughts.** The quiet provides reason to wonder... to speculate... to hope. I provided this to a chain of posts in that regard on the big Prius forum about Prime; It is reasonable to expect a mid-cycle update of some sort. Cost continues to be the primary influence. Toyota quite clearly stated delivering a robust, affordable pack was more important than the physical space it required for the first large-scale offering. We've seen Toyota working on a continuous-improvement approach. Upgrades will come when it makes sense. Keep in mind that Corolla PHV and C-HR EV are debuting next year. That rumored Prius CUV could make an appearance too. So, it's not like there's any rest for the engineers.
- 7-13-2018** **Understanding Rhetoric.** Dealing with the nonsense continued: Promises are interesting. They are usually vague and there's no accountability. Much is often implied, which in turn becomes promotion material from enthusiasts without anything to actually support the resulting beliefs. The *substance without action* problem is getting bigger too; an automaker will rollout a vehicle but not provide any plan for a next step. It really does come down to pricing. That's why there are some enthusiasts in a state of panic now. With tax-credit phaseout looming, sales that are currently challenging will become significantly more difficult. Achieving growth requires far more than just the low-hanging-fruit efforts we are seeing at the moment. Notice how those who claim "*winning*" go out of their way to call it the "*EV market*" rather than address the automotive market as a whole? That avoidance of mainstream consumers tells the real story.
- 7-13-2018** **Market Barrier.** The problem from the very beginning what GM set out to create a barrier and enthusiasts did everything in their power to reinforce it. Volt was flaunted as "*vastly superior*" with the absolute that nothing else would be acceptable. That fell apart on a regular basis, as other automakers matched or exceeded the criteria set forth. We see that happen in reaction to Ford, BMW, and Toyota. When Mitsubishi & Honda joined in, they simply accepted defeat rather than having to move the goal-posts yet again. After all, knowing Hyundai, VW, and Nissan were all on the same course, it made sense to abandon plug-in hybrid hope all together. That's how Bolt took precedence. Enthusiasts have all but given up at this point. It certainly wasn't that way in the past though. Everything was measured against Volt... which would have been just fine, if it was a viable product. Being only an expensive niche, it was doomed. Unfortunately, few cared. Mention of Volt would draw readers & comments. That's good business, even if the object of praise was a token effort funded by subsidies. Only those focused on economic well-being have interest in long-term outcome. It was a live-in-the-now problem. Thankfully, that is rapidly changing. Reality of tax-credit expiration is drawing a lot of attention to the uncompetitive MSRP. Fighting for sales from traditional vehicles takes far more than just empty congratulations.

7-14-2018 **Approach.** There is only one way to success as far as the antagonists are concerned. No other method of advancement will work. Progress must be obvious. Any type of unseen infrastructure or foundational improvement is pointless, viewed upon as waste. Ugh. Dealing with people who have no business background makes you wonder if it is worth it. Supposedly, there are lurkers who learn from quietly reading posts without ever participating. So, even just sharing wisdom with a few can be success. Progress isn't easy... as my continued efforts to deal with blatant trolling shows:

Toyota's approach is bottom-up, very effective for mainstream change. Not being top-down, equating to disappointment among enthusiasts, isn't a concern.

Toyota's advancement in that regard was to deliver the most efficient means of electrically heating the cabin available, a vapor-injected heat-pump. That means you don't consume as much electricity for keeping warm, allowing more for EV driving.

Toyota has also delivered a remarkably efficient EV drive rated at 25 kWh/100mi. That means not having to carry as much battery to travel the same distance as less efficient plug-in vehicles. That also means spending less time & money for recharging.

In this discussion topic, we learned how well thought out the battery-pack actually is. Arrangement of the stacks clearly delivers a robust approach with affordability in mind. Absence of the need for liquid cooling offers a clear weight, complexity, and maintenance advantage.

We all see how Toyota is preparing the hybrid fleet to receive those same upgrades. You obviously don't like that. And with the Volt blog now dead, we have to hear whining about it here. Do you really think this audience cares?

7-15-2018 **Obstruction.** There are some who never give up. Fortunately, they are few and far between. I've been attacked by countless many hoping engineering alone would be enough to overcome business challenges. Not understanding economics will give the impression that victory could happen. But in reality, that lack of balance makes it impossible. Only short-term gain can be achieved from delivering an incomplete solution. They never learn that lesson though. Belief that "worth" will overcome shortcomings is futile. That's why the obsession with range & power must come to an end... either by acknowledgement or by collapse. The effort to obstruct makes the latter more likely of an outcome. It never ceases to amaze me how much some people will fight to the bitter end, refusing to surrender. That sense of honor (selfish pride in this case) means I will need to back off. And I plan to, after confirmation on this new venue. Since Volt is just now one of many, instead of a spotlight vehicle, it may just fizzle on its own anyway. I jumped onto the GM website this morning... curious to find how Volt and Bolt were now being promoted. It was shocking to see how difficult it was to even find mention of them. Truck and SUV links are everywhere. The link to find an electric category wasn't obvious. There are subtle barriers everywhere, each adding to the obstruction effort. Remember ages ago when there were simple undermine posts? It's far more complex subterfuge now... with the goal of retaining the status quo. Ugh.

7-15-2018 **Desperate.** We are down to just the basic psychological defenses at this point. I just get replies of dismissal and reflection. It's quite remarkable to witness how clueless some people can be. He is basically just fighting himself now. I'm watching the spin, with each opportunity to respond a chance to provide more exposition. So, I do:

Spin of the "*too little, too slowly*" concern is an obvious attempt to prevent analysis of Toyota's timing to the tax-credit mistake GM made.

200,000 sales is the basis of measure for the first phase of rollout. Each automaker was given that limit for tax-credit availability. Upon reaching it, phaseout will be triggered. 1 quarter (3 months) of sales will continue at the 100% value. The following 2 quarters, it will be reduced to 50% but will not be restricted by a quantity limit. Following that, there will be 2 quarters also without limit but at 25%. Purpose of the tax-credit is to establish enough demand for the vehicle or technology to sustain high-volume profitable sales.

GM is expected to trigger phaseout at year-end. Demand is no where near the level it needs to be. Volt sales never drew GM customer interest; instead, they remained almost exclusively conquest purchases from elsewhere. Abrupt switch to Bolt didn't result in necessary demand either. That generous \$7,500 per vehicle would have ended up doing very little to actually change the status quo.

Toyota carefully observed the market and quickly recognized benefit of saving tax-credits later, when they had a strong base to build upon. This is why the RAV4 hybrid was rolled out in the meantime, which has become a top-seller in the US hybrid market. Camry hybrid was recently rolled out for that same reason. Both will be able to take advantage of the plug-in technology available in Prius Prime. Having both well established prior to triggering tax-credit phaseout positions Toyota well for taking advantage of that period which follows without limit.

In short, GM demonstrated how easily tax-credits could be wasted. They focused on enthusiasts praise, rather than being attentive to mainstream priorities. Upon phaseout, they still don't have a choice appealing to their own loyal showroom shoppers. Toyota won't be missing that opportunity.

7-15-2018 **True Competition.** Attempts to stir rhetoric elsewhere continue. Volt's struggle for survival is becoming obvious. That dependency on tax-credit money for the sake of maintaining poor sales is becoming overwhelmed by the need for growth. Knowing that all the subsidy did was keep it from vanishing entirely, the very idea of it somehow appealing to a wider audience with a high price-tag is laughable. Yet, that's the message being conveyed anyway. Hope comes from the belief that Prius Prime is the competition, not other GM vehicles. So, when the Toyota tax-credit also expires, it will struggle the same way. Problem is, that's not what the numbers show. Even with basically no inventory available in the Midwest still, sales for Prius Prime are better than Volt anyway. It's a distraction from dealing with the truth. I keep providing reminders of that: \$34,095 = MSRP base Volt. \$27,300 = MSRP base Prius Prime. It is very easy to see how the GM necessitates the \$7,500 to be feasible... and that's before pointing out the base Toyota comes with more safety features standard. But it doesn't matter. Those vehicles are not competing against each other anyway. Reality is, Volt must compete with other GM vehicles at the dealership. Traditional offerings are the problem, which is why the lower the MSRP the better. Toyota takes this situation seriously, striving to deliver a choice truly competitive with other vehicles sharing the same showroom floor.

7-16-2018 **Discovering Motive.** The ultimate goal of any seemingly pointless battle is to discover motive. You keep pushing. Eventually, something should shake out. Being attentive. That's what I did with this antagonist, to find out what truly was the source of his own push. Over the past few days, I wondered if anything other than some nice summaries would come about. Being forced to think through the immediate situation in context of the big picture is always useful... especially when the person stirring trouble is so vague. You get post after post with nothing but rhetoric. It's the same old nonsense too. He calls you on changing goals, but never actually states the before & after. That is intentional, to force incorrect assumptions. It's a common misconception tactic. You just confuse the audience by randomly stating things. No one bothers to verify dates or context. Online comments have become a haven for enabler support. They just go along with the narrative, never questioning. Anywho, I finally got what I was looking for. Way back, it was the simplicity of NPNS. That "No Plug, No Sale" mantra became quite popular, but was doomed to fail due to the lack of anything specific. What was having a plug supposed to achieve? No quantitative measure meant anything with a plug would be far superior to anything without. They learned that lesson the hard way... which got him to up the ante by focusing on range & power values. That failed too, when it became obvious that traits of Volt were being emulated by Prius Prime. Just copying them would have been acceptable. Delivering improvement was not... which got him to the problem I'm dealing with now... no engine. He's become an EV purist. That would be a problem if he was honest about it. The catch is, his history of being Anti-EV in favor of Volt is extensive. For years, EREV was far superior. Then abruptly, he took the hypocritical path and not only switched to EV... he also turned on GM itself. That loyalty shift is especially bitter... and he knows I could call him on that betrayal at any moment. Choosing to purchase a Tesla Model 3 rather than a GM Bolt isn't viewed favorably upon by his peers. Concealing that is his motive. Lashing out at Toyota is how he hopes to conceal what happened. I find that intriguing.

- 7-16-2018** **Why?** It's over... he knows it too. Even the attempts to derail discussion just plain don't work for him anymore: It's not random. You know precisely why. For years, I kept asking the same question over and over and over again: "*Who is the market for Volt?*" That reason is obvious now. GM neglected mainstream consumers, focusing exclusively on enthusiasts. Their goal was conquest sales... which the consequences of are quite obvious... no loyalty. Even the die-hard pushers have not only abandoned Volt, they have abandoned GM entirely. In fact, you did that too, choosing to purchase a Tesla Model 3 rather than Chevy Bolt EV. Toyota is working hard to appeal to their own customers, to retain loyalty established from their current owners. That's why those products never appealed to you and it never mattered. This is why I post over and over and over again: "*Know your audience.*"
- 7-17-2018** **Apologist.** Witnessing failure play out well beyond anything the best damage-control efforts can repair has been interesting. I get accused of being an apologist, supposedly a more insulting term than fanboy, but fails as the supply of constructive reply continues: There is no where near enough inventory to draw conclusions with yet. Within a 500-mile radius of Chicago, only 310 Prime are available. It is a global product with low priority in the Midwest of US. The entire first year of production was impaired by the new technology Toyota introduced with Prime. Carbon-Fiber for the hatch isn't what you'd expect from an affordable (\$27K base) vehicle. Yet, that's what got delivered. Toyota worked with BMW to get expertise on how to produce such a complicated piece of the vehicle with that strong, lightweight material... an obvious effort to improve efficiency. Dual-Wave glass is something you'll not find on any other high-volume intent vehicle. The distortion-free bend funnels air over the vehicle to improve aerodynamic drag. It's complex chemistry & manufacturing is more technology advancement... an obvious effort to improve efficiency.
- 7-18-2018** **Analogies.** They can be useful. In this case, it was a fresh attack on Lexus... since the attacks on Toyota haven't resulted in anything... and I was looking for a new way to present information: Don't any of you play poker? We know Toyota/Lexus is holding a good hand. Just because they don't have a "*plan*" doesn't mean they don't intend to play. Notice how others push, but it ends up just being a bluff? Look at the technology already deployed in Prius Prime. They have delivered an affordable system that returns incredible EV efficiency. Who cares if the range is currently short? Adding more cell-stacks is trivial compared to cost-reduction and operational improvements. High-Volt production of those components and refinement of related software & controllers is well underway. Have any of you actually looked at the hybrid system being delivered in the 2019 RAV4 hybrid? Think about the power potential with that configuration in something like a Prius CUV (the rumored replacement for the current Prius wagon). This group thrives on announcements from token & future efforts, yet they express deep disappointment & upset for industry advancements that aren't obvious. Shouldn't we expect more from those here? Why is there so much praise for range & speed at the expense of not giving substantive attention to design?

- 7-18-2018** **Pollution.** Every now and then, something other than EV purist perspective slips out of the group which has become disturbingly bias. In this case, it was a focus on actual impact to pollution, rather than the vague "*electricity is better under all circumstances*" rhetoric. I was happy to join in with: 2,300 miles from the most recent tank with my Prime. 85% of that was EV driving. Measure at the pump calculated to 250 MPG. It represents a remarkable reduction of air-pollution, despite having a gas engine. A key to this approach is the battery-pack is relatively small. That supports simplistic recharging, a huge benefit to those without high-amp connections to plug into. It also addresses current production constraints and lack of public chargers. Reaching large numbers of consumers as quickly as possible is very important, since vehicles will remain in service for a decade.
- 7-18-2018** **Audience.** Escaping from the mindless mantra of purity, I returned to the Prius forum for a bit and was happy to respond to: "*So enlighten me to see how I fit into this intended audience...what or to whom was the Prime made for?*" I really enjoy chatting with people who genuinely don't know and would sincerely like to find out. This is what I had to share about that: Simple, families grow up. Mom & Dad go from needing routine transport for children to using the back for occasional travel with adults. Having nicer seats with an armrest & cupholders makes far more sense than squeezing in a third person, for that new audience. You want a larger setting area, you buy a larger vehicle... hence all the other hybrids, some of which will offer a plug. Next year, it will be Corolla hybrid in some markets.
- 7-18-2018** **Babbling Idiot.** Watching one particular troublemaker completely lose it has been quite fascinating. I've witnessed others cornered after years of fighting, then abruptly finding themselves at a complete loss. But this particular one is on the edge of being delusional. He reminds me a lot of our president. He lies. He insults. He harms. With actions so blatantly uncaring, it will only be a matter of time before he finds himself quite alone. No one wants to associate with anyone so reckless. It's got to the point where he sounds like a babbling idiot. His entire reply to one post was just "*Bahahaha!*" The rest is nothing but cliché now. You wouldn't think a person would become so witless. But then again, maybe he always was. In the past, that would have been easier to conceal. There were plenty of distractions available. None remain. Hope has been crushed. Volt has died without passing the technology over to a viable high-volume vehicle. Years of promise without substance caught up to him, resulting in only one course of action... abandon ship. But rather than disappear like so many other troublemakers of the past, he became a hypocrite by supporting the very thing he had fought against for years. But rather than go from anti-EV to pro-EV but remain loyal to GM, they switched to Tesla. Endorsing the very thing they had mocked makes you really think about why they argued for all those years. What was the point? I thought I'd never find out, since they were silent afterward. Apparently, this one particular individual is going to proudly pretend none of that past ever happened and make an ass of himself in the process, going out of his way to draw attention. How bizarre. Of course, we do have a president doing the very same thing.

7-19-2018 **Spreading FUD, part 1.** How much time can pass before your information becomes FUD? There's a point to which repeated posts of the same thing will create conditions to stir Fear, Uncertainty, and Doubt. Even if the data was correct for that old market, there's no guarantee of relevance years later. I pointed that out after encountering this: "*the other 'myth' spread by FUD mongers*". It came from someone whom I respect, but most definitely don't agree with. He's been carrying a grudge for years about the topic of Lexus's stance toward EV support. Having that same issue posted as a concern after so much has changed deserves a reconsider. After those same circumstances still at play now? I asked that question this way: When do we draw the line and start calling the spread of outdated information FUD? Your grudge against Lexus is nearing that point. Remember how anti-EV the sentiment was from GM just a few years ago? A lot has changed since then. Don't become one of those sharing content out-of-context.

7-19-2018 **Spreading FUD, part 2.** He threw the topic of EV support from Lexus (and Toyota) right back at me with: "*I hate putting you in the odd position of having to defend them as they fall behind...*"

No defense necessary. We can all see that prices are still too high and production limits too real. That will change, but it is very much a primetime issue currently.

The problem is, you're falling for the rhetoric. Those hoping to undermine Toyota are doing everything they can to draw attention away from the component investment & refinement that's happening right now. Toyota is readying the fleet for plug augmentation, positioning everything they need prior to the onslaught of demand.

Haven't you noticed that the supposedly leader doesn't actually have a plan to electrification? We are witnessing GM flounder around aimlessly. Volt has been a disaster and Bolt is anything but the Tesla fighting it was promoted to be. GM customers don't want a compact hatchback or small wagon anyway. They want larger vehicles. Notice how Toyota is queuing them up? Camry, RAV4, Avalon, Highlander, C-HR, and that Prius CUV mule. Each of those hybrids could easily be Primed. For that matter, we will be watching that happen to Corolla hybrid next year.

I'm just doing what I can to refocus attention back on the need to adapt the either fleet... hence, primetime. Any automaker can rollout limited quantity.

7-20-2018 **Continued Attacks.** That daily blog for Volt has been mostly dead for over 6 months now. There are a few die-hards attempting to revive it... especially since trolling elsewhere hasn't been successful. There aren't enablers on other venues and the attacks on me don't work. I can't be provoked after so many years of dealing with the nonsense. Even on the diverse green website where commenters are clearly bias toward EV and look down upon efforts to reach mainstream consumers haven't shown any interest. GM blew it. Their tax-credits are about to trigger phaseout and the tech from Volt still hasn't been deployed to a vehicle GM shopper actually want. So, finding a receptive audience for more of the old spin, rhetoric, and belittling is proving futile. "*Here's hoping we get some new articles*" is the sentiment repeated over and over again on the blog, to no avail. After months of silence, I finally broke it with: What is there to publish about Volt on a regular basis now? The parent website has been a great resource for green articles. It simply makes no sense replicating that same content here.

7-20-2018 **EV Owner Rhetoric.** Some of them can be really bad, especially when it comes to EV purity. Arguments of range can get rather bad at times too. Worse is from certain Tesla owners, since some particular individuals add on an anti-legacy twist. That dislike for traditional dealers makes them underminers. They spread their own discontent to the rest of the market, setting a precedent of acceptable badmouthing, claiming an unwillingness to accept change. I'm unwilling to put up with that, as was the case today:

Sounds like someone is spreading FUD based on outdated rhetoric. It isn't as complex of a sales process as you portray.

Go to a Toyota dealer and watch the delivery bay. Notice how many RAV4 are hybrid models are driven out by new owners? Those frequent sales don't require anything special. The addition of a plug is a natural next step. Potential customers already instinctively understand the benefit of electricity from the wall. They already know it will green boost the driving experience. This is why Toyota emphasized hybrids not needing a plug in the past. They were setting the stage for this next step by making the difference stand out.

A simple test-drive is all it takes to sell that feature. You feel the electric power. They tell you recharging only takes a standard household outlet. You ask how much.

That claim of *"because they see them as difficult to explain and/or takes too long to explain"* doesn't even come into play.

7-21-2018 **New Photos.** There are so many I have yet to publish. The collection of unshared work continues to grow because I'm focusing on video & research instead. There's documenting of the changes taking place too. As the stage of early-adopter activity comes to a close, this very different new audience... mainstream consumers... has new questions. They are the market that really matters. They are the ones who will have more involved with learner & acceptance. So, I'm busy getting all that ready in the meantime. Eventually, photos will be made available. I'll have fun sorting through those memories. Some are trips from what is now awhile ago, back when Prius Prime was new to me.

7-21-2018 **Electric Draw.** The answer to that question of whether or not remote A/C will use the battery or the plug for power is not clear cut. People were hoping for an absolute, not a hybrid approach. I wanted to find out myself. It affects how recommendations of pre-conditioning are given. I gave it a try, watching activity on the graph of live data coming from my 240-volt charger. It showed 0.9 kWh of electricity taken directly from the wall when remote A/C began. Following that, the battery supplied power. Upon completion of the cooling cycle, power from the wall resumes. Another 0.25 kWh is drawn. Knowing the process started with the system already fully charged and knowing that the MAX setting will consume a lot of electricity, that seemed about right for consumption. The bulk came directly from the plug, but then a smaller part was from the battery. That's not as definitive as one would hope for knowledge of operation. Why does it do that? I wonder if there is secondary cooling of some sort, something related to the pack. Hmm? I guess more research is needed.

7-22-2018 **Critical Thinking.** It has been absent from much of the online posting. Most people comment about green vehicles without much thought. They focus on just the short-term or completely abandon logic by following emotion. That reality is beginning to emerge as an undeniable theme. In the past, it was easier to dismiss. Whomever made the observation would be labeled as a troublemaker, someone with an agenda counter to advancement of cleaner transport. The fact that a person could be providing constructive feedback was regarded as utter nonsense. Seeing the situation change is assuring. Unfortunately, there isn't much to take comfort in though. GM has fallout to address. Their enthusiasts & supporters have vanished. It's quite bizarre that Volt has pretty much become a footnote in history already, even before tax-credit phaseout is triggered. Bolt's struggle is the reason. Much needed high-volume sales were never achieved. Why bother with a high-cost risk when the vehicle type (wagon) is fundamentally unacceptable to their customers? GM shoppers want a SUV of some type... hence the wide variety of models being offered... none of which come with a battery-pack, unfortunately. That status of "*fallen leader*" is now forcing critical thinking. What went wrong? How could GM have missed such obvious opportunity? What should happen now? It's a mess other automakers must distance themselves from and supporters must somehow explain.

7-23-2018 **Beetle Hybrid.** People are singing praise for VW announcements. There's no substance yet. In fact, many of the upcoming new choices won't be rolled out until at least 2020. True, the announcements aren't quite as vague as what GM typically provided. They are mighty close though. You get nothing beyond basic information. Essential stuff, like an expectation for price or availability, is totally absent. Like the hybrid Jetta, it may not even get noticed as an offering. How much of a market is there for the Beetle now anyway? It's as if they learned nothing from GM. My guess is it's a move of desperation, more token efforts to repair reputation. Ugh. Why isn't there a mainstream vehicle being sighted for plug augmentation? Anyone else concerned that their aren't accountabilities for any of these news blurbs? Thankfully, we are getting some infrastructure updates as a direct consequence of the diesel deception. But what is there in terms of actually advancing the automaker itself forward?

7-24-2018 Hypocritical Posts. I found this amusing: "*We can learn from the past.*" It came from someone who lashed out at Toyota with assumptions, was proven that his rhetoric was indeed the spread of greenwash, then pretended none of it ever happened. Ugh. I responded to that with:

Who was among those that didn't believe the possibility of Toyota having ended early production of gen-1 Prius PHV because there was a much better gen-2 already being prepared for production? I remember certain Tesla owners backing the DOA claim based on rhetoric of Toyota abandoning the market. I also remember the reason why... low hanging fruit.

There is very real concern now growing about Tesla overcoming the critical transition from delivering a great vehicle to delivering a sustainable product that generates sufficient profit. It's a difficult challenge for a high-performance vehicle. They tend to stay in the niche category. Less exciting offerings are what business depends upon though.

The disaster playing out with GM right now overwhelmingly confirms that. Design focused on range & power. Favoring aspects of performance sacrificed balance, a critical requirement of mainstream sales. Those drawn the unique offering have already made their purchase. No one else is interested. Most everyone with a Volt were conquests, buyers from other automakers. Loyal GM customers were never drawn to it.

Toyota has carefully studied audience. They understand what their own shoppers will consider for purchase. Impressing the media, enthusiasts, or fanboys is of no concern. That rhetoric will persist regardless of what's delivered anyway. Think about what the other automakers will be up against... competition from every direction.

Watch what happens as the tax-credit phaseouts are triggered. What happened in the past won't matter. That new history in the making will shape the market. Designs with a production cost too high to compete with traditional vehicles directly will face serious decisions. No more will it even make sense to isolate the "*EV market*" from the rest of what we see on dealer lots.

It's about to get very real. Not every plug-in offering will survive. There will be some losses.

7-25-2018 **Trade War.** What a disaster... already! This is classic fallout from a "*gut reaction*" maneuver. It can't even be consider an "*unintended consequence*", since so many of us sounded off about the potential outcome long before any decision was actually made. The problem should have been obvious. Vehicles are global products. Their expense & complexity is why sighting them as a fundamental in economics is so effective. The wide variety of resources & expertise required to make them reliable & profitable is mind-boggling. You don't mess with such a fragile balance, especially when such monumental dependency for sustainability is in the balance. Yet, we now have this emerging: "*GM cuts 2018 outlook as Trump trade war drives up steel and aluminum costs...*" It was an inevitable outcome. Far too much of what we need comes from outside the United States. A policy of protectionism is doomed to fail. I can't imagine how costly such rash decisions will have. Seeing immediate fallout is very concerning. To make matters worse, there will be a short-term appearance of profitable gain in the meantime. Manufactures will hoard supply, placing orders for as much raw material as possible to bet the price hike coming from the tariffs. We are starting a trade war. No amount of relabeling can hide that situation. It is self-inflicted harm, despite how good the intentions are supposed to be.

7-25-2018 **Consequences.** They are difficult to see, especially when there is disagreement about goals... or none actually stated. The big picture can even be a problem to see as consequences play out. If you aren't paying close attention, how can you tell the difference between intended & unintended outcomes? Fortunately, some of that doesn't actually matter. Even if you aren't watching the market at all, you still must exist within it. Choices are limited to what is available. This is how I stated that reality today: It comes down to being able to stand the test of time. We are now witnessing some approaches that we not been able to... hence the low hanging fruit. Appealing to just a limited audience is a very real problem. Dependency on tax-credits made it even worse. Consequences of all that will be playing out soon. Watch what happens.

7-26-2018 **Feeding Hype.** Some people just plain do not get it: "*We are well on our way to introducing 20 new all-electric vehicle models globally by 2023.*" Those gullible Volt enthusiasts were the means of spreading greenwash for years. They would feed the hype by making assumptions and building excitement from announcements without any actual substance. It feels quite inappropriate to call some of them "*stupid*", but sometimes you have to say it like it is. Remember the "*basket of deplorables*" comment? As offensive as that may have been, it was accurate. Regret won't change that situation either. The lesson learned from such exchanges is to prevent future ones by taking a more concise stance sooner. Get in front of the issue by forcing a position of purpose. When you state goals, there's a clear effort to remove subjective factors. If you stick to criteria that can be measured, many problems can be avoided. What are you trying to accomplish? Asking things like that separate the emotion and contribution to constructive discussion. In this case, it's asking what "*model*" represents. We could see rebadging or repackaging, which would greatly reduce the diversity of what's actually delivered. Variety that's limited won't reach a wide audience. The quantity of what is produced is an even bigger deal. Problems from lack of inventory is an all too real barrier already. Only having a few available at each dealer doesn't change the status quo. Real change requires more than just token effort. I pushed back at post sighting the link with that quote by making my viewpoint clear: Typical GM announcement... so vague, there's nothing to be held accountable for. Notice the absence of detail? No commitment to volume or price is a red flag. This is how they fed hype in the past.

7-27-2018 **Voices of the Past.** I jumped on an effort to stir the pot. That old daily blog is dead. So, there's no surprise about boredom setting in. Those who fought want to fight again. Problem is, they lost before and have nothing new to fight with now. The attempt to move goal-posts back even further with hope of new conflict declare superiority about was nothing I would be willing to accept. That's worse than just giving up. It's intention rollback, pretending progress wasn't made. Having dealt with that type of deceit from Volt enthusiasts, it's the type of greenwash I have prepared well to prevent. So, I drew the line: Nothing about that is new. Remaining "*as it is*" was the position of concern. Finally offering the technology in a crossover 10 years after rollout is not what had been hoped for. Expectations were set for mainstream sales volume to have already been achieved by now, prior to tax-credit phaseout so the business could sustain a profitable level competing directly with traditional offerings. Notice the news for the Tahoe/Suburban/Yukon large SUVs? That statement of "*Hybrid variants of the vehicles are expected as early as 2022.*" is a rollback of expectations. 10 years ago, there was a Tahoe hybrid already on the road. It used GM's Two-Mode system, the predecessor to technology used in Volt. There was even a plug-in prototype being promoted back in 2009. Notice the reintroduction of Blazer? It fits nicely into the popular SUV line-up of Trax, Equinox, and Traverse... none of which offering any green option. All are still stuck using engines without battery-packs. In other words, the goal-posts have been moved back so successfully, people haven't noticed. All the hype turned out to be a bust. Those who were attacked for their critical thinking have been vindicated. Hopefully, this means constructive discussion going forward. Not taking into consideration the repetition of "*over promise, under deliver*" will invite it to happen yet again.

- 7-28-2018** **Making It Worse.** When a major oil-executive and refinery-owner speaks out with words against the current path being taken, the hope is enablers will finally notice the terrible course we are taking: *"They're doing whatever they can to close themselves off from the new, hold on to the past and prevent change."* Far too many not speaking is a major problem. It is that boil-a-frog problem. People just follow the rhetoric because it feels right. He went on to state: *"This is a natural tendency, but it's a destructive one because when people act in protectionist ways, they erect barriers, which makes everyone worse off."* In other words, they stay where it seems safe. It's self-destructive. You back yourself into a corner. Remember all the attacks I had to endure back when Volt sales first started to fall apart. It was like prey fighting for survival. They would lash out at anything I posted, knowing it was already too late. I had proven my point. They lost. We are at a point like that again, but with the approach as a whole for GM, not just the vehicle. The difference now is pressure from the oil industry. It is obvious "peak" has been reached. The indicator is the loss of stability. An unpredictable market makes risk significantly greater... hence the effort to prevent change. Even the poorly informed are starting to take notice of the barriers. They now need to speak out about them, rather than allowing them make things worse.
- 7-29-2018** **End of Life.** I asked the following: Range will reduce over time. But what about the next step in aging, when power also diminishes? It can be a sign of cells in the pack becoming imbalanced. The system will begin to rely heavily on the gas engine to compensate for the power loss. That brings about a major decision. GM designed their battery-pack for maximum longevity, adding cost & complexity for the purpose of never needing replacement. With the large T-shape and liquid-cooling, the process to swap in a new one will likely be quite expensive. Looking at the approach Toyota took, there's just a basic module in the hatch area. You disconnect wires and air-tube, then remove with an ordinary engine lift. That's a very simple process in comparison. This is where the audience question applies. Old Prius become great hand-me-down cars. A battery-pack replacement can bring about several more years of service. Keeping size small makes that a realistically affordable, a choice not shared by Volt. What do you do when the replacement point is reached? At some point, the vehicle will be traded in as a junker. With TCO (Total Cost of Ownership) quoted so often, how many miles should that actually include? In other words, what should be the expectation for end of life?
- 7-30-2018** **Design Assumptions.** It's quite a challenge to confront someone who obviously doesn't understand how Prime operates. They base assumptions entirely on observations of the past... without any clue that claims are way off, in some cases, quite wrong. Unfortunately, I encounter that a lot. Fortunately, Toyota is well aware of the situation. This is why rollout of Prime has been incremental. Each market segment reveals more about the consumer interest, which is especially important in this rapidly changing industry. You don't just dump something out there and hope for the best... which a certain automaker has done several times and failed several times as a result. Anywho, it starts with education. Find out what people know and don't know, then figure out a way to convey the missing & incorrect information. Sometimes, you need to be a little terse about it. I was rather annoyed by this individual who obviously didn't know what he was talking about: Clearly, you haven't actually driven a Prime. There's is very obvious difference for the electric power available compared to the regular Prius. The larger battery-pack combined with the one-way clutch provides a major performance advantage. You get the full EV driving experience.

- 7-31-2018** **Enthusiast Bewilderment.** Some genuinely cannot figure out what the problem is. Others simply don't want to acknowledge it. I tried to deal with the later with this: You know why. Just about everyone here does. No one wants to face that reality though. Production cost is far too expensive for plug-in offerings to compete directly with traditional vehicles still. Toyota is well aware of this problem and simply does not want to be part of the tax-credit dependency. Leadership is not about appealing to enthusiasts. It's the ability to change ordinary people. Delivering a product able to sway mainstream interest is very, very difficult... a topic rarely discussed on a venue like this. Next year, we'll see the debut of Corolla PHV and an EV model C-HR. That too is an effort to offer something mainstream, not really anything that may appeal to early-adopter shoppers. Toyota wants their entire fleet of vehicle to move forward with electrification, not to just deliver token vehicles. This is why the RAV4 hybrid will be included right from the start with the next-gen rollout. The endorsement of having a battery-pack is undeniable. That makes adding a plug a very easy next step.
- 7-31-2018** **Not Lagging.** Efforts to push the mindset of "*laggard*" aren't going away. They keep trying, despite the absence of substance. It's the new version of "*vastly superior*" rhetoric, that old chant which had the effectiveness of chest-pounding. It draws attention, but not much of anything becomes of it. That's basically just for show... which would explain why there were so many complaints about lack of advertisements. They truly believed a product would be better received if it was promoted more. The very idea of a better design winning favor wasn't important. So I pushed, especially due to the term "*Eco Warrior*" being used today in the original post: What is your criteria for Eco Warrior? 40 km (25 miles) capacity delivers amazing efficiency. So what if my last tank was only 85% EV driving. You are completely missing the point of a plug-in hybrid. If you want to avoid running the engine entirely. That delivered in an affordable manner is leadership, not lagging.
- 8-01-2018** **Dismissive.** I confronted an antagonist head-on today. The nonsense is going as fear of consequences from the upcoming tax-credit phaseout approach... or at least, I think that's what it is. Many of the antagonists are poorly informed, since they only read what they want to acknowledge. They have even stated that by recommending everyone to ignore & downvote. It is likely that same old blind hope of something magically changing. Perhaps not though. Toyota has been extra quiet this year, which adds to the wondering if a mid-cycle upgrade will be significant. Remember how quiet they were about the price of Prime? Despite it being so impressive upon reveal, we didn't hear squat prior to the official sharing. Oh well, that gives antagonists even more to try to deny. I simply pointed out the nature of the problem this time, since that's more effective than biting at their troll bait: Like the political scene... dismiss what doesn't fit the narrative. Too bad, it's time to face reality. You can only evade detail so long. With so many attacks on Nissan & Toyota claiming they are unworthy offerings, it's time to face the music. There are tradeoffs. We now have real-world data. You want discussion here. That means it must be constructive... not dismissive.

8-01-2018 **Failure.** It looks like the upset revolves around GM's failure, not what Toyota could potential deliver mid-cycle. That became easy to pick out from replies to my previous post. My effort to draw attention to audience appears to have been effective. I was always keeping focus on that "Who?" question. Never being able to overcome their own rhetoric is an ironic victory. Some many times, the Volt enthusiasts choose to repeat the greenwash of Prius being the most traded vehicle for Volt. It was true, at first, back when those killing lease deals were offered. Why not swap an old hybrid for a new plug-in without any long-term obligation and payments so low you are practically stealing it? The catch was, when those leases expired, most of the people abandoned GM. Many either took advantage of Ford's great deals or popped for the expensive choice of Tesla. And now that Tesla prices are becoming affordably competitive with GM, we see neither Volt nor Bolt stand a chance of conquest. The entire burden of sales depends upon loyal GM customers... who couldn't care less about the tiny plug-in vehicles GM offers. Here's my summary of that warned about sales disaster: GM's choice to deliver a "*superior*" product in the form of conquest sales failed miserably. Growth beyond enthusiasts was never achieved. Now, it faces the challenge of sales without tax-credit. So much opportunity wasted...

8-02-2018 **Without Context.** Spin emanating from selective perspective is a challenge to deal with. People with narrow view of the market draw incorrect conclusions. It makes sense that being unaware of other things taken place would send you down the path of assumption... unknowingly, which is why I try to correct oversights as directly as possible. In that regard, hopefully, this will be taken well: That view of Toyota is the impression you get by viewing the raw data without context. The real story is we are witnessing a market shift, combined with a styling disinterest. So, the status claim is not an accurate reflection of what's truly happening. Sales of the RAV4 hybrid remain very strong, despite the fact that the model has reached its life-cycle end. The next-gen will be rolled out for 2019, with the lead offering a hybrid model. Sales of Prime have been hampered by lack of inventory. You can't buy what isn't available. Distribution worldwide has created a supply shortage for central United States. Sales of Prius always lagged for this generation because the style was so polarizing. Either you liked it or you didn't. That extreme is why the mid-cycle refresh will change the look rather significantly.

8-02-2018 **Audience.** The denial is slowly turning into acceptance. None of the recent posts like this have been taken as a provoke. That's not how the information is perceived anymore. In other words, the enthusiasts have lost their audience of enablers. It's over for that greenwashing as a norm. What had been daily efforts to mislead is becoming a questionable portrayal of the past. After awhile, people won't believe what actually happened and will call it a false narrative. Problem is, I have proof to the contrary. These blogs document those experiences to an extreme level of detail. Now at that turning point, here's what I have to say: GM learned this lesson the hard way, delivering a compact hatchback to their customer base of SUV buyers. No surprise, those previous buyers of GM vehicle didn't care. They just plain were not interested. So, Volt was marketed to external shoppers instead. The result was a disastrous waste of tax-credits... since the outcome was not a change on their own showroom floor. Customers continued to shop for SUV offerings. Nissan may end up with the same struggle. This is why Toyota is setting the stage with RAV4 hybrid. Stepping it up to offer a plug won't take much when there is already a loyal base of hybrid owners. Same thing for Camry hybrid. This is also why we're hearing about the potential for bring the AWD model of Prius to the United States. To change the status quo, technologies must be adapted to what buyer preferences. Know your audience. This is why GM's failing to deliver a SUV using Volt technology after so many years is becoming such a big issue now. That loss of a \$7,500 subsidy makes the effort to finally do that even more difficult.

8-02-2018 **Oh Really?** How does one respond to such a statement: "*GM's resolve is suspect.*" That's such an absurd point. Suspect? Umm, isn't it obvious? GM just plain does not care. Neither Volt nor Bolt were targeted at GM's own customers. How is that not an issue of resolve? We still have no idea what purpose or intent GM really has. The fact that technology in Volt was never implemented in a SUV, despite the fact that its predecessor (Two-Mode) had already demonstrated plug-in hybrid ability, goes well beyond suspect. There is no doubt after almost 8 years since rollout. We saw how gen-2 of Volt never addressed the cramped seating in back or did enough to actually make it appealing without subsidy. Yet, they are the ones who belittle Toyota for delivering exactly that. There is now an affordable plug-in hybrid choice (Prius Prime) and larger hybrid platforms staged for the same (Camry & RAV4). We are expecting both Corolla & C-HR to get plugs next years, plans already in play. So, why is the "*laggard*" label supposedly appropriate for Toyota and GM gets off without any issue? This is the very reason I brought up the "*too little, too slowly*" concern all those years ago. I saw the hypocrisy and called it out. Getting attacked for presenting facts is not appropriate. Oh well. Now many others are expressing the same concern.

8-03-2018 **Non-Answer Replies.** Within minutes after my reply below, I got a response. It was 3 paragraphs of literally nothing. I guess some people feel if there are a lot of words, you don't need any actual substance. I tried. This is what started it: "*Being a loyal Toyota owner for years, I am disappointed that the Japanese are way behind in the PHEV and EV game, and I don't understand why.*" I had really hoped something constructive in return to this: Mainstream shoppers want affordability. Dealers don't want to carry inventory dependent upon tax-credits. Not recognizing that will prevent you from understanding why. Toyota's focus is low-cost, something dismissed as important when the measure of progress is only range & power. Their hybrid design supports a simple, yet very effective plug-in upgrade. Take a close look at the next-gen RAV4 hybrid rolling out for 2019, then tell us how "*behind*" could apply to that design.

8-03-2018 **Braindead Comparisons.** Every single time there's a plug-in hybrid review, some Volt antagonists stirs the pot. This time, it was an attack on Honda & Toyota with the same old brainless comparison. Each time, you get references to hydrogen as a distraction too. I ignore that bait as much as possible, choosing to address their trolling my way: As for being "*years behind GM in their engineering*", that's simply nonsense. Toyota has delivered a system that clearly more efficient and more affordable. There is no contest in terms of kWh/mile (electric) or MPG (gasoline) measure. There is no contest in terms of MSRP. There is no contest in terms of targeting audience. That criteria do you think puts GM further ahead?

8-04-2018 **Problem Comparisons.** My encounters with Volt enthusiasts provided lots of examples of arbitrary numbers. They'll argue something based on circumstances of a design, rather than taking the actual technology into consideration. It's a very common problem. Most people back off when confronted with real-world data to counter their stance. Those enthusiasts didn't, choosing instead to double-down. When that failed, they'd begin with dishonesty, then keep fighting until desperation grows enough to turn to personal attacks. It's an ugly cycle we witness far too often. Anywho, I tried to deal with a comment to that affect about Honda Clarity being vastly superior to the current Chevy Volt due to it offering a faster charging-rate:

Those numbers are off. That assumed time is inaccurate.

There is no possible way to walk from the car, get your item in the grocery store, wait at the register to pay, then walk back out to the car in just 3 minutes. A fast visit takes 10 minutes. More realistically, you'll have multiple items to get, which pushes it to 15-20 minutes.

I know this well, since I have been doing it for years. My fastest stop ever is just under 6 minutes, to get a coffee... no line and they already knew my order. Even that provides enough electricity to make it home from there using just the 3.3 kW rate. Typically, I get anywhere from 2.5 to 7 miles of charge from a quick stop at the grocery store.

Why should a vehicle with a much larger battery-pack get preference at a local charger? I could understand the situation being quite different along a highway corridor, but that isn't how you presented the supposed shortcoming of not being able to charge at the 6.6 kW rate.

Also, keep in mind that L2 is capable of delivering 19.2 kW from an 80-amp draw. So, that "BIG" difference sighted is actually quite arbitrary.

- 8-04-2018 Minnesota Assumptions.** This was interesting. Someone very new to the plug-in discussions made a comment about chargers not being available anywhere around Minnesota and surrounding states. I hoping this large provision of data will change his mind about that assumption: No charging in Minnesota? The 35 corridor from the Twin Cities to beyond Duluth already has basic infrastructure nailed. You'll find both L2 and SuperChargers. The stretch from Wisconsin to North Dakota along 94 is getting a more elaborate treatment now, using some of the VW settlement fund. There are random chargers throughout the state as well. Most are either ChargePoint network or non-commercial offerings. The first Blink chargers in the state were just installed at the Mall of America recently too. Up in the tourist location I frequent, the Brainerd area, there's a SuperCharger. Along highway 90 on the way to South Dakota, there are both available and proposed SuperChargers. Just yesterday, a new set of ChargePoint stations opened up in Lanesboro, a great location in the south for biking a beautiful trail along the Root River. So, long story short, you can charge in the wild in Minnesota. We are much more progressive here than it would seem. We also have a plug-in owners group with a strong & diverse presence.
- 8-04-2018 Rely.** This could become a problem: *"I do think public charging stations should be limited to BEVs who rely on charging stations being accessible and not blocked by an ICE or PHEV."* It's the attitude many of us have been trying to prevent from spreading. Sadly though, some choose to fight. At least the vague *"No Plug, No Sale"* was easy to understand. Unfortunately, it was very shortsighted. Not being able to see beyond the sale is as bad as not understanding how important of a role the dealer plays in the sale. In other words, you cannot cherry-pick. Endorsing a product means understanding & embracing all aspects of it. I fired back with: Sure glad that attitude is not what our plug-in owners group endorses. If someone has to *"rely"* upon a public charger, it means they purchased the wrong vehicle. That dependency is a sign of a problem. We make great efforts to ensure people are well informed prior to purchase. The purpose of public chargers in non-corridor locations (basically, not highways) is for convenience recharging. Being able to get home using electricity is a benefit to everyone, regardless of the tech employed.
- 8-04-2018 Turning a Blind Eye.** It's this kind of hate that become the real problem: *"give it a rest already"* We saw that quite a bit when Volt was first revealed. No one wanted to address GM problems of the past. They all dismissed Two-Mode as a mistake that couldn't possibly be repeated. When I pointed out that Volt was the successor to Two-Mode, retaining much of the original design in addition to much of the development engineers & management, they did everything possible to try to shut me up. I see hints of that emerging again, as the tax-credit phaseout approaches. My guess is news to confirm their error feels spiteful, so they turn a blind eye to the possibility of being constructive. They are tired of dealing with failure efforts and just plain don't want to accept overall defeat. I could imagine how difficult that is, but still see the purpose of not giving up on electrification. My response to that was: Pretending the problem doesn't exist is terrible advice. I refuse to become an enabler. What do you suggest the next step should be? Keep in mind the talks of tax-credit renewal. Not addressing how the first round was wasted isn't good for anyone. Remember how the point was to reach ordinary consumers... not just enthusiasts?

8-05-2018 **Already.** Unrealistic expectations is quite common. The response to that is often to sight an extreme: "*We all should've been driving fully electric vehicles already. Unhealthy, polluting, fossil burning vehicles should have become a thing of the past.*" That's a great example. Oversimplifying the problem is why progress is so difficult to recognize. People in general don't notice detail, the small influences that really make a big difference. Seeing that a better product exists doesn't mean adoption of it will come easy, even if you see that step as trivial. After all, that serves as proof of the technology being viable. Old habits are difficult to break though. The purchase of a vehicle is profoundly significant too. It's the most expensive decision you'll repeatedly make many, many times throughout your life. Annoyed by such complacency of the situation, I posted: Between all the anti-hybrid rhetoric of the past and the reality of battery-tech still being sub-par for mainstream acceptance (too expensive, not energy-dense enough), there's no need to mention infrastructure shortcomings (houses without sufficient capacity). We will get there, but it's not ready for primetime yet. Think about the challenge of selling a profitable \$35k vehicle without tax-credit. Thinking we should already be there is quite unrealistic... especially when it comes to competing with traditional vehicles priced in the 20's.

8-05-2018 **Dominant.** Understanding the technology is a fundamental mistake those nasty Volt enthusiasts never learned the importance of. It was always rhetoric like this that they were endorse & embrace: "*Linked here from a Forbes article and I think it's safe to say the days of the Prius being anything near dominant are definitely over.*" That's all that was provided, no detail explaining why. They just referred to the link with the hope of not being confronted on any detail. I always push for detail. They see that as refusal to acknowledge the conclusion someone else drew, something you are supposed to do without question. Asking why is how you learn. They know that, so calling what you do as "*spin*" makes responses appear to be denial. In reality, I see how they attempt to draw attention elsewhere. In this case, the word "*dominant*" is re-associated to Prius, rather than the hybrid system. They know HSD is used in quite a wide variety of other vehicles and Voltec is trapped in a car no one wants. GM exhausted the market, reaching out to all possible conquest interest... because their own customers had no desire for a compact hatchback. Toyota has strived to deliver a compelling SUV hybrid. GM never did. The hope of one with a plug is still years away, with nothing certain planned. That's why there is so much rhetoric still. I simply responded to this one with: The tech in Prius will remain profitable & sustainable for years to come. We will see many more hybrid & plug-in hybrid offerings taking advantage of advancing batteries, whether it gets attention or not. That's the nature of most automotive business, not just a single model holding a spotlight.

- 8-06-2018** **EPA.** We keep hearing about the upcoming rollback. The current administration is getting ready to announce the elimination of new efficiency restrictions introduced by the previous administration, freezing current levels for the sake of safety. They are using the same old misconception exploit that sacrificing safety is the only way to achieve efficiency improvements. Having been proven false is of no consequence. They simply pretend that never happened. They are telling people what they want to hear for the sake of being able to continue driving guzzlers. Do everything to retain the status quo. Sadly, that "safety" is only with regard to perceived benefit. It's really a loss though. Emissions from that extra fuel consumption are harming people slowly. Pollution is costly, whether you acknowledge it or not. They couldn't care less. We'll have a similar problem with coal later this year too, except that is expected to remove many barriers... allowing for much greater pollution than the current levels. That excuse is for job security. Supposedly, that will save employment, even though the act of extracting & processing coal is becoming more and more automated. It's really sad. Even with that terrible head of the EPA having been removed, some of the destructive behavior continues. Our environment's well being is being traded for profit.
- 8-07-2018** **Doomed.** The message of doom for Toyota is remarkable. People without business background are judging the based exclusively on what they see right now, in the moment. That's called using anecdotal evidence. They figure their engineering expertise or their desire to pursue green solutions is all it takes to understand the "Who?" question. It's quite obvious they lack economic, accounting, and marketing knowledge. That causes them to make incorrect assumptions and follow false leads. It also leaves them vulnerable to repeat problems of the past, those only recognized from a business perspective. It's very, very easy to overlook the signs when you are looking for them. It usually comes down to thinking a well-informed consumers is all it takes for the automotive industry to change. They don't see the market as a whole, everything it takes to appeal to those who make it possible for the consumer to even have that choice. Ugh. Oh well. I keep pushing to get that message across: Toyota's measure of leadership is being able to capture the hearts of their true customers... DEALERS. That's a fundamental mistake GM made they are trying to avoid. If their dealers have no interest in stocking inventory, ordinary consumers are doomed. This is why Toyota has been working so much to stave larger hybrids for a plug, like Camry and RAV4.

- 8-08-2018** **Going Private.** Hmm? The comment about Tesla considering the possibly to go private caused quite a stir today. You don't expect a random comment like that from a CEO. It's understandable. The stockmarket is influenced heavily by short-selling, rather than long-term investment. Tesla is very much in the position of focusing exclusively on long-term well being. Having to deal with minor shifts shouldn't be consuming time & resources. Not having a public offering prevents that; however, it also raises concern of intent. We see commentary on a regular basis of how luxury automakers should be taking Tesla more serious. Why? The target-market for Model 3 is mainstream consumers, not those in the luxury market. Remember? It's all about delivering an affordable offering with a price competitive with other high-volume vehicles. Luxury offerings are by no means high-volume. They are a well establish niche, which works just fine for that audience. You don't transform the world from gas to electricity with a narrow scope. That's why idea of going private raises alarm. What would that do to the mission statement? How would it change the business approach no longer being under public pressure? When would we get to hear about future plans? There are many questions.
- 8-09-2018** **Available Plug.** There's still this problem no one wants to address. Where will people plug their vehicle in to recharge? Taking it for granted that people will be able to front the setup money and understand all details of what that install entails rather naive. There's a lot of intimidation. There's also the reality of infrastructure shortcomings. I keep hearing there's a plug available to some percent of homeowners. None of those surveys actually sight any specifics though. In most cases, you'll be lucky to pull 8 amps, since it is an existing line that is already being used by some other device. That makes recharging a challenge for just one vehicle. For perspective, it takes 32 amps at 8 hours to recharge 200 miles of capacity. How many people are you aware of that have a 40-amp 240-volt line readily available to provide that? There's the logistics of simply how to park multiple vehicles for recharging overnight in the garage or driveway. We need to address these issues... so well, they become easy to respond to. Right now, I'm getting a lot of evade responses. That's not a good sign.
- 8-10-2018** **New Videos.** It was Summer break for me... time away from providing much Prius content online. My job actually changed, same location but in a significantly different role, that inevitable major shift you encounter at some point throughout the career. It's exciting, but lots of work. That made other changes, like work-time and parking-location, easier to embrace. So, I did. You get to see it in new videos. I filmed two yesterday. Unfortunately, the second (driving home) included a battery overheat issue with the 4K camera. Mounted in the windshield, it gets hot... blinks a warning... then shuts off. That's not good while you are filming. I managed to keep in cooler today. Between the drive being a little faster, the battery cool to start with, and leaving the camera cover open, I was able to capture the entire drive without issue. Phew! The other footage (driving to work) worked just fine first try. So, you get to see my full commute, the new ramp where I park & plug, along with the new route. More ideas to come. That at least rounds out the warm weather coverage.

8-11-2018 **Ramped Up Rhetoric.** Pressure from the upcoming phaseout trigger for GM tax-credits combined with the reality of poor sales has ramped up rhetoric. Anytime you bring up what's really important to mainstream consumers, there's a GM enthusiast there to evade the issue. They will typically either change the topic of Toyota's perceived lack of EV support or their interest in fuel-cell diversity. Both are obvious attempts to draw attention away, yet their actions aren't called out. We have large groups of enablers, no one will to speak up for what's really important. True, their silence is better than the meritless push for token rollouts of the past. Nonetheless, it's a clear barrier to progress. Efforts like that to impede advancement are undeniable after awhile. That's getting really easy to see at this point too... especially when "*laggard*" is brought up to describe work to advance the technology that aren't related directly to large battery offerings. I simply fired back to the post that set me off this way: Calling Toyota a laggard for delivering a more efficient and more affordable system is a disregard for what's truly important.

8-11-2018 **Priorities.** I climbed up on the soapbox today to address the rhetoric, with the intent to provoke new discussion by starting a new thread:

It's time to finally address them, moving beyond just the basic support for plugging in. We shouldn't allow EFFICIENCY and AFFORDABILITY to continue to get pushed aside, especially at the market becomes more of a challenge with the phaseout of tax-credits.

Plug-In vehicles can be guzzlers, wasting fuel just like the traditional vehicles they replaced. Needing more electricity to travel the same distance increases both vehicle & operational cost. We shouldn't turn a blind eye to that, or worse, feed rhetoric to draw attention away from the issue.

A simple example of EV efficiency is to look at the most common comparison, Volt verses Prime. 31 kWh / 100 miles is efficiency rating for Volt. 25 kWh / 100 miles is efficiency rating for Prime. That means it requires 6 additional kWh of electricity for Volt to travel that same distance in EV as Prime. (Put another way, Volt delivers only 80% the efficiency of Prime when consuming electricity for propulsion.) It also means more battery is required, as well as extra recharging time.

Even if electricity was provided entirely from renewable sources, would we really want to promote wasting it?

We are long overdue to finally start addressing issues like this. Seeing this group not take the responsibility route of encouraging the better technologies and pointing out those with shortcomings would be unfortunate.

In other words, don't allow enablers to distract from the importance of EFFICIENCY and AFFORDABILITY.

- 8-11-2018** **Measuring Efficiency.** It became obvious within just minutes of posting that message about priorities that some plug-in supporters have no idea what the heck I'm taking about. The discussion immediately took a turn in the direction of battery-pack size. In their mind, more equates to better efficiency. That's as absurd as the vehicle carrying a larger quantity of gas being more efficient. Ugh. I'll share a post shown the dashboard display with a miles/kWh readout. That alternate perspective of the same measure may help. It's not really any different from explaining how backward & misleading the MPG system here is. The rest of the world shows consumption in other terms for good reason... what we use is very misleading... as we see the same problem coming from capacity now. Ugh, again. I attempted to convey the message with this, but am sure more follow-up will be needed... which is good, since getting a discussion going was the point: You are comparing the size of the "*tank*" not the actual efficiency measure, think MPG but for a plug. kWh/mile is that measure for EV travel. For EPA rating, it is the number of kWh of electricity it takes to travel 100 miles.
- 8-11-2018** **Video: New Route, New Parking (to work).** The quest to provide as much detailed real-world data as possible continues. With this drive, I took a new route to work and parked in a new ramp. In this case, it was also quite a warm morning for here in Minnesota. So, there's nice variety to observe. Being warm already, I had the electric A/C running. That's a reducing factor in how far you can drive in EV mode. Another is the speed of travel. On this drive, there was about twice as much at 70 mph than with my old route. Upon conclusion of the 21-mile drive, there was a third of the usable battery-capacity remaining. That means I would have been able to travel roughly 30 miles total in EV, despite also using the A/C at the same time. It's a nice example of how under-rated the system in Prius Prime actually is... [Prius Prime - New Route, New Parking \(to work\)](#)
- 8-12-2018** **Setting Precedent.** I spoke out because no one else had. Drawing attention to the fact that no opposition or even acknowledgement makes you an enabler is important. That silence is setting precedent. Today, that silence was broken. An administrator reached out, saying the naming-calling (use of insulting & denigrating terms) is unacceptable by using my drawing attention of an automaker as an example. I pointed out that was just following what had been established, posting the same way others had been. He stepped up and deleted those previous posts, leaving mine to represent & document the change of policy. No more. Finally! It was the hypocritical stance of "*no plug, no sale*" that was getting to me. That supposed unity wasn't reality. An attitude of "*vastly superior*" had worked its way into the group. I was able to successfully get recognition of the problem that brought about. An administration reiterated goals. Phew! We're at a turning point. The stage of "*early adopter*" is coming to a close. That will bring about a new audience. This group isn't prepared yet to deal with it. Making sure we share goals is the start. There's an interest in equality, regardless of whether or not a vehicle guzzles electricity or is far too expensive for mainstream consumers. The goal is to push plug-in technology of all sorts. That's why the group embraced me years ago. Despite Prius PHV carrying such a small battery-pack, it was still an endorsement for lithium technology. Just imagine if those antagonists of the past had done the same thing. I wouldn't have learned so much from having to deal with their rhetoric... the precedent they set. As a result, I'm able to provide detailed education video & materials about plug-in vehicles.

- 8-12-2018** **Video: New Route, New Parking (to home).** This is the return trip home, a second half to complete the drive to work footage. Like that previous video, it is packed with detailed real-world data. With the new route and parking location, it adds to the collection of examples of what an owner may experience on their particular drive. There are so many factors of influence for efficiency, seeing lots of various sample videos if the only good way of building realistic expectations. Anywho, I enjoyed filming this particular commute. It was a nice summer day and just happened to end with a unique twist. That black car which cut in front of me near the end of the drive was a Tesla Model 3. Being able to follow that for a few blocks was a nice opportunity. As for the statistics, I enjoyed EV the entire 20.8 miles of travel, with an estimated 10 miles remaining. That's quite impressive for a vehicle rated for just 25 miles, especially when running the electric A/C at the same time. Notice that I just drove along with the flow of traffic, doing nothing special whatsoever to achieve those results... [Prius Prime - New Route, New Parking \(to home\)](#)
- 8-12-2018** **Attacks.** Watching Honda Clarity get attacked by Volt enthusiasts is interesting. I've been watching it take place on several venues. Some of the rhetoric is spreading to the EV purist too, those who are against anything with an engine, regardless of how it is used. I finally jumped into the wide-audience discussion: It comes from the basic misunderstanding of how they are designed and operate. It is easy to assume the system is just an enhancement to the hybrid, rather than being able to operate entirely without the engine. As with Prius Prime, everything is EV. There's a clutch to add in engine power, but that's unnecessary for ordinary drives, like the daily commutes. The larger hybrid systems, like that in RAV4 and Camry, can deliver more power too.
- 8-13-2018** **Opposition.** The rather terse debate carried on. I recognized many of the same problems that came from that daily blog for Volt. The old concern of "*too little, too slowly*" came about from the hope that more could be delivered sooner. It was the classic problem of trying to take on too much all at once. In other words, it was yet another form of "*over promise, under deliver*". They assumed delivering less more often would result in a diluted product that wouldn't stir much interest. To believe that, you have to choose an opposing position of progressive upgrades. That's a very expensive and very risky position to take... hence all my direct confrontations with Volt enthusiasts to stand their ground with actual fact. Much of what they presented was meritless, lacking any substance to actually support a position of successful paradigm-shift. In other words, what they proposed was too extreme... a heavy dependence on challenging cost & acceptance... no simple path forward. That's quite the opposite of Toyota... hence an oppositional stance. Anywho, I stated the situation this way: The supposed "*opposition*" comes from the unrealistic timing. It comes from not understanding audience. For example, the phaseout of tax-credit subsidies is about to reveal how the initial market didn't actually reach beyond just low-hanging fruit (early adopters). Appealing to ordinary shoppers (mainstream consumers) is a much greater challenge. PHEV offerings are strong in that regard, an easier step that will help stimulate infrastructure investment.

- 8-13-2018** **Fear.** If you push enough, listening carefully and being considerate of positions, you can sometimes squeeze out valuable information. True, you can do that with online combat too, but this is by far the preferred approach. In this case, the exchange today came down to: Being under the impression that PHEV doesn't endorse BEV works explain the reactions we've encountered. That's called a misconception. In reality, they help to support the future. Stepping up from hybrid to plug-in hybrid gets the upgrade process rolling, where you live and on the road. Both Mitsubishi & Toyota already offer CHAdeMO connections for their PHEV vehicles. Getting homeowners to setup 240-volt charger is an obvious bridge to BEV too. All you need is a 40-amp line to deliver 200 miles of range in 8 hours.
- 8-14-2018** **That Exchange.** It happened, the administrator came to terms with what I had been trying to draw attention to. Pointing out their is more than just innocent bias within your group needed to be done by someone. His decision was to shutdown the thread. After all, there were some obvious misconceptions at play feeding the problem. So, starting fresh later was an excellent choice. It was very clear the attack came from within. This person was a full EV family (two electric-only vehicles, no gas anything) who was clearly uninformed about what Toyota actually delivered. Like many, his assumption was that EV driving was just an enhancement to the hybrid system, not the fully capable design I enjoy everytime I get behind the wheel. The attack continued with an outright denial that we are witnessing the early-adopter phase come to a close. Phaseout of tax-credits is milestone ...he feels will have little impact. He also feels the "*laggard*" label is nothing but a identifier with no negative connotations and certainly in no way should be taken as offensive or insulting. A new thread emerged about the topic, specifically addressing responses to the other. Within an hour, there were over 80 replies. That discussion was about the very real "*shaming*" we, as PHEV owners, have to deal with from soon BEV owners. It was eye-opening. It also exposed a few misconceptions we were able to address, then debunk. I'm sure the administrator learned more about his group than he expected from that exchange.
- 8-15-2018** **Spreading Lies.** The death of that daily blog for Volt has left antagonists frustrated. Their venue for spreading lies is gone. Having an outlet for rhetoric is gave them purpose, since it was an common gathering location to build "*vastly superior*" propaganda. Being part of a team helping to spread the word about plug-in vehicle benefits is not what these particular individuals want. They are still very much holding onto the past of being the only choice available. That's not the world we are part of anymore, but they don't care. So, I'm seeing more meritless claims being posted: "*...cannot practically be driven with out the engine coming on to support the electric drive.*" and "*It's good to know that it's not truly a full-time EV.*" and "*Technically the Volt is way ahead in the PHEV game!*" are among what I stumbled across recently from those individuals in a forum thread attempting to mislead about the plug-in hybrid model of Honda Clarity. This is the very same nonsense they tried repeatedly with Prius. Over and over again, they'll post outright lies with the theme of Volt being more efficient overall. Evidence to that was always because it had a larger battery. That's why they are so aggressively dismissive about actual efficiency ratings. Try pointing out what happens if you don't drive far enough to use full capacity. They simply don't care about electricity consumption. They'll spread lies to conceal shortcomings. Ugh.

- 8-15-2018** **Ford Territory.** There's a booming market for SUVs. This is why Ford & GM all but entirely abandoned the car market. So, to no ones surprise, the first of the plug-in hybrid from Ford will be a SUV. Like with Toyota, they don't see benefit from messing with the delicate balance here. Work out the dealer's of customer preference, while also refining production & supply details, to address high-volume sales well. Next year, Toyota is doing that with an EV model of C-HR and a PHV model of Corolla. Seeing Ford do the same thing is a nice sign of accepting change. That effort to retain the status quo from GM is maddening. Antagonists get angry when I point of the lack of addressing their own customers. We have to wait several more years before anything for GM customers is rolled out. Heck, the latest promotion for Volt is \$500 of "*Conquest Cash*" at the time of purchase. That's a blatant sign of not targeting the right audience. Ugh. Details of this new Ford SUV, called "*Territory*", weren't provided. All we have been told is that it will be a plug-in hybrid. The 2 photos (1 interior, 1 exterior) released didn't give any sense of scale. But since intended use is for city driving, being small has obvious advantages.
- 8-16-2018** **Toyota's Future.** No matter how many times it is stated that their hybrids are vehicles to help transition to more electrification, all some people hear is the current advertising of "*no plug needed*". Regardless of the plans stated to offer more plug-in choices in the future, some absolutely insist that isn't what Toyota intends to produce & sell. It's maddening how they simply ignore some information. That cherry-picking is a dead giveaway you are dealing with someone who simply doesn't care. These are the same individuals who think nothing of spreading lies. I read an article this morning about the rollout of Corolla hybrid in Australia. They advertisements directly address the misconception of hybrids needing a plug. Antagonists are already spinning that to mean Toyota who ever be offering something with a plug, despite the press clearly including quotes from an executive (head of sales & marketing) there stating the contrary. Ugh. By the way, their expectation is for 20% of Corolla sales there to be the hybrid model. Premium for the hybrid model of each of the package grades available is \$1,500.

8-17-2018 **Suppliers.** Attention was focused on them today by Toyota, from statements about how production will be changing in the next decade as electrification takes hold. Rarely do enthusiasts take the role of suppliers into consideration. Most have engineering blinders on, resulting in a complete overlook of business impact from change. Those delivering high-volume production can't afford to be so blissfully unaware. That type of blatant disregard for the fragile system of production parts is financial suicide. The industry leaders cannot afford to make such impactful mistakes. This is why GM hasn't delivered much for either Volt or Bolt. They know change would be detrimental to profit. Keeping the status quo, but still appearing to be fully participating, is an unfortunate reality... one that early adopters fail to recognize. This is why "*leadership*" is so poorly misrepresented. They don't understand what it takes to actually change mainstream consumers. Looking at suppliers is a way of learning what's really involved. Unfortunately, telling that to enthusiasts is basically pointless. So, I kept my contribution to the discussion simple: Prime time will be the early 20's, a generation beyond the first profitable worldwide offering. That's exactly as anticipated. In fact, this quote confirms it: "*Toyota announced plans to add more than 10 all-battery models to its lineup starting in the early 2020s.*" In the meantime, we still have to deal with early-adopters not understanding how products are sold to mainstream consumers.

8-17-2018 **Market Disruption.** Quotes like this are reason to give pause: "*The real disruption from the EV adoption will be at the dealer level.*" You should ask yourself was what the intended message was from such a statement. Is that recognition of the true customer? If a dealer isn't interested in selling the EV, it doesn't do much good for the automaker to produce them. That reality is usually overlooked. The assumption is consumer education will solve the problem of limited inventory. That isn't how disruption works, though it is a contributing component. Demand can be driven by stirring interest. But when it comes to supply, the dealer must find a compelling reason to stock. If that resulting inventory is difficult to sell or results in a small profit margin, why bother? This is the issue GM has faced. Executives listened to enthusiasts, neglecting dealers in the process. That didn't result in real disruption. In fact, Volt was basically a failure... since sales never broken into the mainstream. There was always a dependency on tax-credits and GM's own loyal customers never showed interest. Selling in low-volume to only enthusiasts is a doomed path. That is not a sustainable business model, the process dealers must operate. So, we have a conflict of understanding... hence all the online conflict over the years. Today, it has pretty much come to down to just stating this: Dealers are the true customers of Toyota, hence... know your audience. Early Adopters have an extremely difficult time accepting that, consequently misunderstanding how mainstream acceptance actually takes place. That's why talk of supplier issues rarely gets addressed, yet is fundamentally important to profitable business.

- 8-18-2018** **Charger Issue.** That was screwy. We drove out to the lake to kayak, which is at a park with charging-stations. Problem was, I couldn't unlock the cord. The charger would begin the session, but hardware wouldn't release. I tried countless times, working that handle every way I could. Neither the wave of my card or my phone made any difference, on either side of the station. Both refused to let go, but started & ended sessions just fine. I finally gave up my efforts and called the toll-free help number. After a surprisingly quick welcome, I was already debugging the issue with support. His guess was something related to network communication was causing a problem. That didn't make sense. So, he tried sending a release signal. It worked. The cord was mine to use within seconds. Cool. Even better was seeing another Prime parked nearby after returning from our time on the lake.
- 8-19-2018** **Antagonist Attack.** My post from over a week ago was attacked. It came from an antagonist, one deadset on doing everything he could to belittle Prime in the past. Now, like the others, he's seeking out new venues to do the same... since that daily blog is now dead. This is what I woke up to today: "*A paltry charge, after ten to 15 or even 20 minute walk+task after plugging in my Gen I and Gen II Volts was enough to convince me that the slow trickle of juice was definitely not worth the frustration to myself or passengers to face the inconvenience.*" Seeing that was a true surprise. I didn't think anyone would be so desperate. It makes sense though. If Volt continues to suffer, why not take others with? That is obviously a terrible belief, but his beloved is struggling to retain attention and there is no successor. To make matters worse, that situation is what I predicted. The second-half of a second-generation is not where you want to be without any plan forward. Needless to say, I was happy to post this: Who are you trying to greenwash? Anyone who has even just a basic background in L2 recharging knows that a load of garbage. 7 min 56 sec delivered 0.389 kWh of electricity the other day when I stopped at the grocery store, paying close attention to the process... knowing any response to my previous post would be an obvious effort to undermine. That short, very convenient recharge resulted in 2.9 miles of estimated range... more than enough to get home from there entirely with EV drive. You flash your card or phone, then plug in. That's it. Spinning the process to be frustrating & inconvenient is big disservice to anyone who owns a plug-in vehicle.
- 8-19-2018** **Kayaking.** The racks for carrying stuff on the roof of the Prime work great. We carried 2 kayaks on top to enjoy Lake of the Isles in Minneapolis last week. Despite that massive added drag & weight along with having the A/C cranked, that 51.8 mile round-trip delivered 72.5 MPG overall. That's incredible performance for a Summer activity. Normally, I tell people not to even consider the efficiency impact of such an event... because they are too rare. How often do you actually get to experience recreation on that scale? My wife and I had a blast. It would have been totally worth it regardless of MPG results. The location is literally ideal, a treasure for paddling around. It's so incredibly scenic there. Right on the edge of the city, you wouldn't expect so much nature. We paddled through the maze of islands, along the waterways to both adjoining lakes, and just floated around for awhile. We got to watch a few kids jump off the bridge too. It was a good time made convenient & efficient with the Prime.

- 8-20-2018** **Rapid Dismissal.** You typically only have 10 seconds to captivate an audience. Within just 1 or 2 sentences, people listening would have already made up their mind. It's the nature of how we operate. Whether assumed or learned, the information people collect leads their daily activity. Wanting to find out more or question past experience generally doesn't happen. That's a rare event, not something you'd hope would occur routinely. That means you need to assess the audience quickly & correctly to make whatever you share really count. If it isn't compelling, they will just reply with a rapid dismissal. Losing attention is all too real of a problem. That's why knowing whether or not to convey "200 MPG" or "25 miles" or "2 hours" is vital. Those are all brief responses to encourage an ask of another question. Whatever the person did to stir the topic, usually a question, make sure your effort to promote provides something directly related. In the event of an emotional appeal instead, return whatever their observation was with a confirmation... otherwise, opportunity is missed. This is why I pushed so hard against enthusiast appeal. That provides nothing of interest to mainstream consumers, who just dismiss what you point out so rapidly, you lose them before even finishing the comment.
- 8-21-2018** **Efficiency.** Speaking of rapid dismissal, you'd be amazed how often I encounter it with respect to plugging in. The person will just make a comment about electricity source being dirty, then end the topic. It's a read-between-the-lines moment. You hear a dismissal of the plug. But what they actually just did was justify continued support for traditional vehicles. Had there been something mentioned with regard to non-plug hybrids instead, that would be different. That wasn't the situation though. Getting any type of endorsement moving forward is what you need to listen for. Absence of that is the real problem. Pick something green. They say no. It's what makes them feel better. After so many generations of hybrid being on the market, there is no excuse anymore for not looking forward. Just outright statements of being unacceptable for not being an ideal is no excuse. So what if the electric isn't from an environmentally pure source. That's no reason to refuse to acknowledge its use results in far less waste than traditional vehicles. Efficiency isn't an all-or-none choice.
- 8-22-2018** **Appearance.** We are witnessing the end of sedan appeal. Push of highly profitable SUV offerings has been so successful, people are losing perspective. Few question the move away from efficient choices in favor of a large vehicle. It's that simple... so much so, anything that doesn't share the bulky profile is labeled as ugly. Have you noticed that change? Hearing it only about Prius makes the subtle shift very easy to overlook. Go ahead. Ask someone which looks better, the new RAV4 or the new Camry. This is why the remaining cars are taking on such a "sport" type look. The image of a family vehicle has transformed to tall guzzlers. It's an unfortunate trend that had no other path. Human nature is to obsess for more. That's why we hear the "ugly" label getting used so often. People don't want to say what they really think. They want a SUV. That's why the original push was they were safer. It was obvious they were not, but people turned a blind eye to the appearance difference (pun intended) to justify their choice. This is why the more powerful system we see in the larger Toyota midsize hybrids offer so much potential. Think about how easy it would be for RAV4 to take on a larger battery-pack and plug. The only necessary alteration for propulsion is that one-way clutch the Prime model of Prius introduced.

8-23-2018 **Greenwash Articles.** Many have titles that present bait: for example: "*Would YOU Ever Sacrifice LOOKS For MPGs?*" When you read them, there's nothing to actually support what was claimed. Most articles will simply discuss something else instead. In some circumstance, you'll get something that does address topic. However, it will just gloss over it, for example: "*Without leveraging the battery of the Prius Prime, I chalked up 59 MPG on my way home from my Manhattan office. In addition, after spending quite a bit of time with the vehicle, I netted 55 mpg without even trying.*" The purpose of that was to lead you astray. That wasn't even an attempt to downplay. Benefit of plugging in was just outright dismissed. That was literally the only reference in the article about efficiency, despite the fact that MPG was mentioned in the title. Ironically, there was only one tiny photo and nothing at all mentioned about looks. That part of the greenwash was obvious. By omitting anything to actually look at, the hope is you'll make incorrect assumptions. How many people have actually seen a Prius Prime? Not realizing it doesn't look like the regular model is the mistake the writer hoped readers would make. It's sad to see automotive publications work so hard to mislead like that. But then again, leaving out vital detail is nothing new to hybrids.

8-24-2018 **Teaching Moments.** That plug-in owners group I am part of is missing some. Right now, they are part of the "*Eco Experience*" at our state fair. A person there are spoke with had fallen into the same trap I have seen countless others fall victim to. They become well-informed about current offerings without any real understanding of what's to come or what kind of impact that will have. It was basically a relay of information without any thought. It was throughout, but in no way forward-looking. It lacked substance about importance to how that will apply to ordinary people. You had to become a plug-in enthusiast to be part of what was being conveyed. That perspective is limited, a short-sighted portrayal of the future. Rather than teaching people about what's to come, it was really an effort to encourage change. Understand that fundamental difference? We want people to see the paradigm-shift as the next natural step forward. To do that, you must downplay. That's not exciting. That's just blah. But it's how business-sustaining profit is made. High-Volume sales absolutely require "*ordinary*" appeal. In general, people will do everything possible to avoid change. You must present change as an effortless gain. Some of the most successful changes have basically been invisible... to the point where some will argue that it was anything but inevitable. Stirring effective enthusiasm is difficult. Most people get excited about speed & power, but being willing to pay a premium for it is an entirely different matter. Think about the progress of computers. It wasn't overnight. It took countless years... actually several decades... of exposure to become thought of as common. Now, we carry them in our pocket with very frequent use. Teaching about technology acceptance is about seeking moments to do it... often & discretely.

8-25-2018 **Turning Point.** Our current administration here is a replica of what I dealt with in the past. They would just spin and spin and spin. Their goal was to simply keep conclusions from being drawn. Way back when, it started with the "*up to the chore*" discussion thread. No one ever imagined it dragging on for 1.5 years. That's because prior to it, no one expected outright lies and direct contractions easy to disprove. You figured when the person was caught intentionally being deception they would stop. We have since learned that doesn't happen. Volt enthusiasts would do everything possible to prevent any type of closure. Every technic imaginable was employed. Trouble is, that only gives the impression of victory. Reality is quite different. Consequences of pretending all is well resulted in progress not actually being made. In the case of our automotive business here (in the United States), cost of poor decisions or efforts to retain the status quo means being left behind by the rest of the industry. That's why the claim of "*falling behind*" and "*laggard*" name calling happens so often. It's a physiological effect known as "*projection*". We look upon that as an acknowledgement of the situation. GM supporters are keenly aware of "*falling behind*" and "*laggard*" due to it always being on their mind, but fail to recognize that is actually description of themselves. This incorporates blame shifting. They know there is trouble but don't understand the source, resulting in accusation of others for the situation they ended up in. Anywho, hope from those witnessing this self-destruction keep expecting a turning point. With the plug-in disaster, it can obviously be identified as those loss of subsidies. Will it? There's lots others to blame and excuses to be made... much like the administration. Notice how no particular event or revelation is ever significant enough to derail the destructive trajectory? Each seems to have the potential, but it never plays out that way... because the next distraction is introduced. Don't look everyone see what really going on. Misdirection is interpreted as being off course... with the hope no one will notice the course was never correct in the first place. Volt was flawed from the very beginning. Targeting a niche audience never made any sense; yet, there was an effort from the very beginning that Toyota's effort to appeal to mainstream consumers would never be good business. Much like bad politics, there are consequences for being wrong. That's what confirms we are truly at a turning point.

8-25-2018 **33 MPG.** As the years progress, it's becoming easier for GM enthusiasts to recognize the problem I've been pointing out for years. Their hate for Toyota clouded reason, preventing them from noticing the pattern: "*Chevrolet could work harder to close the cost gap if they wanted to, and upsell many/most Cruze buyers to the Volt.*" Sadly, that quote represents only a rudimentary understanding of the problem at hand. However, it is progress. At least they are now comparing GM vehicles to Volt, rather than thinking other plug-in vehicles are the competition. That's progress... despite being so painfully slow. Oh well. It's not like I didn't try to stir awareness sooner. This is what I had to say about that situation today: Volt hasn't ever been able to compete with Cruze, even with the \$7,500 tax-credit. Belittling CVT efficiency from a non-hybrid won't change that. It's a cold, hard reality for enthusiasts to accept. 53 miles of EV capacity makes it basically impossible to compete... which is why GM has focused on conquest sales instead. GM's own loyal customer simply are not interested. Toyota is well aware of how much of a challenge it is to appeal to mainstream consumers, which is why they would never succumb to the same "more" trap GM did. That's why Prime is priced \$6,000 less than Volt and comes better loaded as that base level. Competition with Corolla for their showroom shoppers is very difficult. Think about the Corolla plug-in hybrid Toyota will be introducing to shoppers in China next year. How will that be configured to compete directly with the CVT model? How should GM have configured Volt to better compete with Cruze? Trying to place blame or responsibility on those involved with sales to work harder to upsell reveals a grave misunderstanding of the market.

8-26-2018 **Old Posts.** Every now and then, someone will post a comment or question in a very old discussion thread. In the example today, it was on a video I shared for the Classic model Prius. That many generations ago doesn't stir much interest anymore; however, there are some intrigued about the differences. Finding out about how a technology evolved can be very informative. That type of well informed background is what gives you insight to make accurate predictions. Figuring out what is to come depends upon a strong understanding of technical limitations and consumer reaction. You must keep the discussion from getting too in depth though. It's a matter of drawing them into conversation by sharing something they may find of interest that they wouldn't have otherwise come across. This is the information I chose to share with respect to being asked why the engine ran so much more frequently than it does in the current generation of Prius: Stealth drive (as it was known back then, that's a maximum draw of 10 kW from the battery-pack for EV speeds up to 42 mph) didn't last long. So, you'd often see the engine running to recharge. Also, don't forget that engine-off isn't the most efficient use of the hybrid design. Blending is better overall when there isn't a plug.

- 8-27-2018** **Solution.** GM raised the price of Volt for next year by \$300. That opened up new discussion with a new audience. I dove into that head first with: Delivering an affordable choice for the masses has always been the intended outcome. Rollout would balance design cost to be directly competitive with traditional offerings. Automakers could set their own pace based on tax-credit sales count, followed by phaseout calendar. GM didn't care about that and instead flaunted enthusiast appeal. It's a real-world example of the tortoise and the hare. They now find that focus was not on what was important to appeal to ordinary consumers... in other words, actually winning the race rather than getting cheered on by spectators. \$34,395 base MSRP for a vehicle that is small, inefficient in both EV and HV modes, and doesn't include features shoppers now expect to be standard (like dynamic/adaptive cruise-control) makes it a very hard sell. What dealer would want to stock that inventory? What salesperson would want to take the time to show it? How many people have a 40-amp dedicated circuit at home to deliver 7.2 kW charging anyway? That begs the question: How is Volt a solution for mainstream buyers?
- 8-27-2018** **False News.** That's what the revelation of "*fake*" news has brought to light. It's what I have been dealing with for years that others never believed could have any meaningful influence. Memories of being laughed at from pointing out how seriously people took the greenwash are still quite vivid. They didn't believe me... until now. My pointing out of how influential the misleading blogs could be were just outright dismissed. I'd draw attention to how GM would release an ambiguous statement, knowing the Volt enthusiasts would spread meritless hope. The reality that claims being made had nothing of any substance to support them didn't matter. It's what emboldened them to interject outright lies. There was no consequence of intention misleading. They could undermine all they wanted and get others to pass along their false news. That went on for so long. Ugh. It's hard to imagine anyone being so gullible; yet, witnessing that became a daily routine. Some would go out of their way to make sure it was difficult to figure out what was true anymore. I sure am glad that terrible history was so meticulously documented. Learning from the past is how you prevent bad outcomes from repeating.
- 8-27-2018** **Unaware.** Not having full information is quite common. In fact, that's usually the situation. Most people aren't well informed; however, you'd expect the daily posters in big forums to be aware. Some are not though. I end up putting them on ignore after awhile, once they reveal no desire to learn. Sadly, some simply find the online experience entertainment rather than a source for sharing knowledge. Fortunately, not all posts from such a source are counter-productive. Sometimes, they do queue up an opportunity for you to provide exposition... or even outright education. Today, those provided such a predicament: "*And if Toyota ever adds higher charge capability to their Prime ... or if/when Toyota returns to building EV's ... this bad boy can deliver an incredible 22kW's !!*" I was happy to jump on that: Toyota already has delivered that. 80% recharge in 20 minutes. Remember, the CHAdeMO plug for Prime in Japan? 7 kWh in 20 minutes works out to 21 kWh for 60 minutes of charging... a rate of 21 kW. In other words, very close to incredible.

- 8-27-2018** **Predictions.** Today, it was: "...predicts that Electric Vehicles will account for over 50% of light duty personal transportation in as little as 20 years." I found that start of a new discussion thread worthy of jumping all in on. So, I did: 20 years from now is 3 full generations, starting with the successor to Prius Prime. Keep in mind that simply stocking inventory is far from the end game. To achieve 50% penetration, some major infrastructure updates will be required. Many will face the challenge of just getting a single high-speed charger setup at home. How many cars are in your garage? One 40-amp line will deliver 200 miles of range from 8 hours of charging. That's 32 amps sustained (20% safety buffer), which is a rate of 7.7 kW. Draw will slow as "full" capacity is reached. There are some charging losses from the AC to DC conversion too. Figure an efficiency of 4 miles/kWh for the anticipated EV travel. So, even if affordability is reached and there's a diverse choice of electric vehicles offered, the challenge of acceptance is far from over.
- 8-28-2018** **Setting Precedent.** With an entirely new venue for green discussions (new forum with new participants), I was intrigued what a topic about GM would stir. It was about the new Cruze offering a CVT model. That's the traditional equivalent to Volt, as was Corolla to Prius from the perspective of typical comparisons. Sure enough, Volt came up with a vastly superior claim. I jumped in with "*inefficient in both EV and HV modes*" which clearly wasn't liked. I was happy to provide a reminder that his own peers were the ones who pushed the basis of measure. So, I pushed back, but not as much as I could have. They love to refer to gen-1 specs. I could have easily done the same... by pointing out HV efficiency of the Classic model Prius was more efficient than what GM delivers now, all these years later. Instead, I stuck to the basics: EPA rating is a standard measure for non-bias comparison. Finding an example of results that are higher doesn't mean that's the norm for everyone. 31 kWh/100miles and 42 MPG is not efficient. Keep in mind it was Volt owners who set this precedent, forcing everyone to acknowledge the EPA rating as the only proper comparison measure.
- 8-29-2018** **Rhetoric Spin.** That saying of "*There's a sucker born every minute.*" is not well understood, despite the obvious recent example of the con we've witness in our own federal government. People follow a path without question, not realizing their actions would be different if they took the time to really think about what just happened. In this case, I witnessed the reset of ethanol arguments. The same old FUD was being spread by the same old online trolls. But with a new audience, it appears to be new debate. I recognize the pattern. It's the same old claims but with newer dates and slightly different numbers to make searches more difficult. This resulted in a turn on me: "*You are the one making the claim. Burden of proof is on you, kiddo.*" That's what happens when the original poster appears to have a credible statement and you question their claim. Just like our president, a wild claim is made to get in front of an obvious losing battle. Make it appear that you are the defense, rather than the opposition. They create FUD... Fear, Uncertainty, Doubt ...about a topic that had already been well established. It's like pressing the reset button. If no one notices what they just did, the resulting debate will preoccupy discussion. It's a surprisingly effective undermining technique. I wasn't going to put up with it, even if that "*sucker*" wouldn't ever figure out he was being used to enable an effort to mislead. I ended it with: That's how rhetoric works. They begin the FUD, then expect you to debunk their deception. They click "reset" afterward too, keeping it from ever ending by drawing in a new audience who never witnessed that past.

- 8-30-2018** **Debate Takeaways.** That encounter with a Volt enthusiast brought about an interesting new perspective. Debates often do, if you can stick with them and pay close attention. The key is to remain concise and to not take their bait. All most care about is winning, even if the declaration of victory has no merit. Having the appearance of being cornered is what they look for. I hunt for substance, like buried treasure, some little nugget of new information. In this case, it was a revisit of the Volt "*lite*" model. Remember those discussions? Few do. So, this was pretty much a new discussion without anything to start from. He just made the assumption "*lite*" meant a smaller battery-pack. That was it, nothing else. In the past, other aspects of design would be tapered back too. But those weren't ever really addressed, since the rhetoric impeded progress. That didn't happen this time. I was able to actually address design. It was rewarding to be able to sight such a simple and oversight on their part, something I'll be able to use later in other discussions to quickly bring debates to an end. That's the type of takeaway you always hope to gain. Here's is the one I got: Think about the unnecessary cost & complexity of the T-shaped battery back. None of that would have been needed with a smaller capacity.
- 8-31-2018** **Knock Knock.** One form of spin that is actually appropriate is to turn the spotlight back on the antagonist. After all, their effort is often a means of taking attention away from them. Putting it back on is constructive, especially if you can take advantage by using some of their own rhetoric against them. Today, this was the provoke: "*...but it shows that Toyota is still dragging its feet and would not be entering the EV market unless it had to.*" I was amused. That only works if you cherry-pick by refusing to address the next stage, as I asked: How is that any different from GM entering the market, but not doing anything with it? That passive-aggressive stance GM has taken is actually worse. They rollout token offerings, do nothing, then end up claiming there was no interest. Sound familiar? Rather than waiting to come out with a product that competitive with traditional vehicles, they rushed. When has not taking time to do it right been a bad choice? People are portraying Toyota's effort to make plugging in a sustainable business that doesn't have tax-credit dependency a mistake. That makes no sense whatsoever. Yet, we hear "*fallen behind*" all the time without any actual substance to support it. If GM were really far ahead, they would have sales to prove it; instead, we see Volt & Bolt having eaten all the low-hanging fruit... a market without any early-adopters remaining. In other words, no one is knocking on GM's door.

9-01-2018 Product Approach. A well known troll attempted to stir the pot by diverting attention to management, away from product... either that, or he's completely clueless. Whatever the case, someone who has been a very frequent poster for many, many years should know better. Of course, dealing with a person who thrives on debate, you should expect efforts to keep conclusions from being drawn, anything to continue discussion. A dead thread isn't of any value for online participation. I didn't take the bait. Instead, it was met with a detailed description to get back on track:

Toyota's approach from the beginning has been to deliver a product that's affordable for the masses right from the start. That's why component size, power, and capacity was always limited by production cost. It eliminates dependence on subsidy and provides a clear upgrade path. It also provides opportunity for quick adaptation. That significantly reduces financial & market risk.

This is why the approach with a plug-in Prius was always targeted by Volt enthusiasts, their source of unending torment. GM's decision to take the risk instead by betting the farm on something with a costly & inflexible design has proven a terrible choice. That gamble of rapid market acceptance and rapid battery advancement didn't pay off.

As Prius supporters, we had to endure an onslaught of ridicule & downplay about this approach difference... which is now becoming quite apparent. Toyota didn't rely on tax-credits. Toyota didn't succumb to niche appeal. Toyota stayed true to their mission of emissions & efficiency for mainstream consumers. The result is a product capable of competing directly with the true competition: traditional vehicles.

All along, it should have been a design from GM that would draw high-volume profitable sales. That's what bottom-up is all about. Toyota targeted ordinary consumers, delivering a well-balanced platform which could be easily diversified to a wide product-line. We see that with the Corolla, C-HR, Camry, and RAV4 hybrids... each capable of simple adaptation to provide a plug, as Prius has now proven. The "start from the top" approach with both Two-Mode and Volt resulted in nothing but sales struggle. Whatever you want to call that difference, it clearly didn't reach the masses.

9-02-2018 **Understanding Efficiency.** There was an article published 2 days ago pointing out the extreme inefficiency of an upcoming EV from a high-performance automaker. Of the 204 comments posted, only 1 understood what was being addressed. Everyone else had the same old rhetoric to spread about electricity being better, regardless of how it was used. Interestingly, they don't actually know. This quote from the article itself is what I found especially disturbing: *"We don't know why, exactly, efficiency is rated as kWh per 100 miles instead of the obviously-more-sensible miles per kWh, but that is what the government has proclaimed to be the proper metric, so pipe down."* That's not good for a website thought to be a green authority not understanding how efficiency is depicted. They are obviously expecting a unit in terms of the way MPG is represented. Not having any idea how flawed the MPG system is should raise concern. It's not used by most of the rest of the world because it is so misleading. Think about a small truck getting 30 MPG and a large car getting 35 MPG. The difference is 5 MPG, right? What does that really mean? People don't know. Traveling 100 miles, the 30 MPG vehicle will consume 3.33 gallons. The 35 MPG vehicle will consumed 2.86 gallons. That implies the 5 MPG difference equates to 0.47 gallons. It doesn't though. Traveling that same 100 miles with a 40 MPG vehicle will consume 2.5 gallons. The 5 MPG difference equates to 0.36, not 0.47 gallons. The next 5 MPG increment reveals a 0.30 difference. In other words, the measure is not linear. People assume it is. That's a very real problem. This is why the government is not using that measure for electricity. It would allow misrepresentation the same way. Too bad the publisher thinks the *"miles per"* representation is more sensible. You want to know exactly how much fuel is used, that's the *"gallons per"* measure... or in our case, *"kilowatts per"*. Note that the rest of the world uses a distance of 100 kilometers. Our government uses 100 miles. The point is, you want a lower value. The fewer the kilowatts (kWh) of electricity consumed, the better. That's the opposite of MPG, which a higher value is better. See why there's confusion? Take the time to really understand what it all means. Once you do, it opens up a world of comprehending even the supposed experts don't see.

9-03-2018 Understanding Change, part 1. Most people don't recognize what's happening. They simply don't pay close enough attention or have the background experience to see the pattern. Not knowing means they are less likely to understand where this change will take us. So, I must interject observations to help the process along:

Simple... our market here is in a state of chaos... which is why Toyota found worldwide rollout all at the same time a better approach.

A little over 51,000 were delivered in 2017. That's amazing for a first-year rollout. Think about how complex the production process is for the intricately shaped carbon-fiber hatch and that distortion-free dual-wave glass, both new tech introduced by Prius Prime. There is also the vapor-injected heat-pump. Getting enough of that spread to each market to begin the education process for business & consumer has been a major undertaking.

As for the chaos, much of that has to deal with the push of Tesla (a non-legacy automaker) combined with the fallout GM has been facing, each heavily dependency upon greatly reduced production-cost. Why get involved in that mess when neither is targeting mainstream consumers in the short-term anyway? Toyota is refining in the process, using early-adopters to provide real-world feedback in the meantime.

Consider the obsession with SUV offerings. It seemed absurd 2.5 years ago when Toyota revealed a change of focus for Prius. The Prime model was aimed at families who have now grown up, hence seating to become more a sport/luxury design. Since RAV4 now targets the "*family hauler*" buyer, why not? We see the entire industry shifting away from sedan market for that very reason. It now makes a lot of sense that Toyota embraced the shift; after all, it will be easier to adapt a SUV to carry a larger battery-pack than a sedan.

Watch what happens with the market as tax-credit phaseout is triggered. Also, keep in mind the potential mid-cycle upgrades Toyota has had to consider for Prius Prime, as well as Prius itself. Change is coming.

9-03-2018 **Understanding Change, part 2.** The inquiry which started this was more complicated than a single post could address. The second part has to deal with infrastructure... which is beyond a mess... as I attempted to explain:

Most people have little to no understanding of how recharging actually works. Sadly, that includes many enthusiasts. So when it comes to plug-in hybrid operation, there's a huge void filled with misconception, confusion, and discouragement. We have much to address still before the inhibition of dealers to stock inventory subsidies.

It starts with education of what is needed for recharging at home. Do you know? If you are lucky, there will be a standard household 120-volt outlet available in your garage for recharging. That works well for charges overnight for one vehicle, but what if you have two? Most people have no idea what it takes to run another line for more electricity. That unknown creates trepidation, enough to deter the pursuit of even just a first plug-in vehicle. Why bother with the extra expense?

Public recharging is in the earliest stages still. We see a lot of standard uncertainty combined with a user-base poorly informed about what kW and kWh represent. Not understanding efficiency measure values and charging speeds, as well as the related costs, make adoption a nightmare. How do you attract business & consumer interest when there is such a basic shortcoming of knowledge along with the lack of actual chargers to use? There's the unknown of charger-etiquette too.

9-04-2018 **Careful.** A few days ago when sales results were revealed, we got the typical "*vastly superior*" response from a Volt enthusiast. Ugh. It was that same old nonsense I had dealt with for years. My reaction to that was posting some advice: Careful with the LOL posting. GM was able to deliver at a loss with tax-credit dependency. Doing the same without subsidy help for a profit is far more difficult.

9-05-2018 **Mainstream.** Measure of progress shouldn't change. If it does, that's called "*moving the goal posts*". Targets (and milestones along the way) are set for very specific reasons. That's how you determine how well things are going. If there's a shift of some sort, it should relate to refinements of the product itself, not sales. You still must have purchases to have a viable product. Falling under a predetermined threshold means you'll lose money. Contracts with vendors and expectations from resellers is a delicate balance of supply & demand. This is why minimums are identified. Back when Prius was still new, that level was clear. All efforts to exceed that success equated to selling more than that minimum. It was that simple. To "*out Prius, Prius*", you must achieve more purchases. That doesn't mean delivering an excessive inventory, then having to slash prices to clear out what doesn't sell at a profitable level. It means true sustainable sales. I was annoyed by someone attempting to redefine "*mainsteam*" and rewrite history as a result: For the last 15 years, the term "*mainstream*" has represented a green vehicle available nationwide that was able to support itself financially. With respect to sales, that worked out to minimum annual sales of 60,000. This is why sales of Volt falling well short of 5,000 monthly was always a concern. Not achieving that prior to tax-credit phaseout meant business sustainability of the tech would be in jeopardy... which is exactly what we are witnessing now. In other words, dealers will have no desire to stock a low-profit vehicle.

- 9-06-2018** **Plug-In Basics.** I started writing up a new document to inform people of how a plug-in vehicle works. It covers the basics, providing an introduction. We have a new audience emerging. These are those who have nothing in common with early-adopters. These are the wondering minds who have heard about plugging in but really don't know where to start. I'm hoping to provide that type of guide with this. It's a high-level summary sharing concepts you need to know for understanding how to start your purchase research. Since the goal is simplicity, it will take quite a bit of effort to find the right content. There will be some photos & illustrations, but nothing complicated. Think of it as a summary for confirming interest. We need to show that there really isn't anything to be intimidated about. It really is next step many can take without concern. In reality, you're just plugging in your car just like you do with your phone. The power needs truly are simple to fulfill. You just have to understand the basics.
- 9-07-2018** **Prius Recall.** Looks like 192,000 Prius from 2016 to 2018 model-years in the United States will be recalled due to a potential wear issue with a wire-harness. Over time, there could be the possibility of that causing a short circuit resulting in a vehicle fire. Worldwide total is roughly one million hybrids. Either a protective sleeve or tape will be installed, depending upon the condition of the wire. This is a voluntary recall, the type that is looked upon as a proactive measure... but you know the potential it leaves for antagonists to spin it as a major problem. Ugh. Oh well, it's not like there won't be some other recall from some other automaker at some point. Remember, you reap what you sow.

9-08-2018 **The Last Word.** This came from the very last voice on the dead daily blog: "*At first blush, this seems like good news. After 3 days though, I wonder if it doesn't signal GM's abandonment of the Volt (EREV) paradigm. Gas for long range vs ultra-charging...*" He has been continually posting new messages hoping to stir discussion. It hasn't worked for weeks. No one cares anymore. I figured, why not indulge his one last time, giving him an opportunity for the last word based on his own quote:

Bolt is what raised the question of intent. It was an undeniable shift away from the "*range anxiety*" solution. Rather than evolve their plug-in hybrid system, the choice was made to endorse much larger battery-pack offerings instead... a blatant contradiction to GM's previous stance.

Gen-2 Volt made that shift obvious, confirming abandonment. Rather than focus on making their own heavily promoted "*40 mile*" range approach affordable for the masses, GM disregarded that goal, choosing to deliver a next-gen with increased range & power... traits neither of which ordinary consumers had been asking for improvement of.

Reduced cost, specifically a MSRP at the long-promised \$30,000 target, was supposed to be the highest priority. Gen-2 fell well short of that though, instead remaining heavily dependent upon tax-credits to subsidize purchases. Elimination of the complex T-shape for the battery and unnecessary liquid-cooling would have gone a long way toward achieving that pricing goal. Those were clear opportunities wasted.

Focus of GM is now on delivering "*ultra-fast charging system that could add 180 miles of driving range in just 10 minutes*" which is feature of no value to a system with small battery-pack capacity... another feature potential "*EREV*" consumers were never asking for.

Stepping back away from the technology itself, there's the reality that GM dealers and GM customers simply aren't interested in compact hatchback offerings. They want SUV and CUV choices. Not seeing anything with a plug, or even just a regular hybrid, in that type of vehicle makes you wonder how long it will take for something competitive with traditional choices will finally be offered.

9-08-2018 Purpose & Intent. I continued on that soapbox, providing a part-2 for optimum understanding... with special attention to timing:

Volt's antithesis has always been Prius. The reason why is simple. GM's focus was enthusiasts. Toyota's focus was mainstream consumers. That resulted in vehicles with profoundly different traits; yet, Volt was promoted as a competitor. That contrast never made any sense. Know your audience.

Leaving that all aside and focusing on the technology itself, there's a very real problem of timing. GM will trigger tax-credit phaseout within the next 6 months. That puts the 2019 model-year in a very difficult sales position... especially if Toyota really does rollout a mid-cycle upgrade along with their ramped up production & distribution. Would GM respond with commitment to applying the technology to a SUV or CUV platform?

Prius Prime has proven the Toyota hybrid system can easily support a plug. The existing design simply needs the addition of a one-way clutch. That's their answer to delivering an affordable solution. Both RAV4 and C-HR hybrids are strong candidates for the upgrade. We already know that Corolla will next year for the market in China.

GM announced intent to debut at least 20 new EV in the next 5 years, back in October 2017. Within the next 18 months (which would be March 2019) the expectation was set for 2 new all-electric offerings. That most likely means we will get reveals at key autoshow... especially with the inevitable tax-credit phaseout rapidly approaching. LA is a strong possibility, in late November. Detroit is another, in early January.

The past is loaded with examples of GM obscuring misfortune with reveals. Volt is the most blatant, an obvious attention diversion from the terribly disappointing rollout of Two-Mode.

Whether you like hearing those facts or not doesn't change them. Choose to embrace GM's advancement by endorsing their investment in high-speed charging. We ultimately need each automaker to choose some electrification path. So what if GM's is different from Toyota? The point is to focus on replacing traditional vehicles, not winning some silly "*vastly superior*" contest.

Remember who the customers are.

- 9-09-2018** **Understanding Design.** I like reading comments like this: "*I really don't understand Toyota's design.*" It was in a discussion thread that brought up the choice of making Prime a 4-seater. Some people have an extremely difficult time accepting change. They don't recognize how little value a tight middle seat actually delivers. They simply see it as a loss. Coming to accept the fact that want can be costly is quite a challenge in a society when most things are perceived as need. Nonetheless, a balance must be delivered for high-volume sales to be both profitable & sustainable. That means looking at the entire package, not focusing entirely on just a single attribute. Far too often, people obsess with a trait that doesn't deliver a large return. Volt is a great example, since the capacity of the battery-pack so clearly demonstrates the problem of diminishing returns. Cost of miles delivers less and less as more and more are added. Think about it. If you don't drive the distance of the entire capacity, that extra is excess. It's a waste to buy more than what will actually be used routinely. Of course, people don't see that. So, responses must start out simple, sticking to the basics... outward appearance. I pointed out: The market is changing. Toyota recognizes the shift away from "car" appeal. Anything that doesn't resemble a SUV or CUV must take on a more aggressive styling to survive. It's not rocket science. It's the business of high-volume sales.
- 9-10-2018** **Plug Where?** It's nice seeing this come up from time to time now: "*Most people have no place to plug-in an electric vehicle.*" That was an issue often brushed off, dismissed as an effort to undermine. Ugh. It's bad enough not even having a plug. But when you look at the power coming from each plug that is actually available, there are issues too. Most of the articles you read promote charge-rate maximum as something you'll just naturally get at home from an ordinary 240-volt connection. That's far from the reality for most. I didn't get into that detail though. I kept it basic: That is exactly why fuel-cell vehicles will co-exist with electric-only vehicles. Hydrogen is a means of storing renewable electricity. Whether or not that is the best carrier of energy doesn't matter... especially with the hypocritical stance some EV supporters have taken, choosing to turn a blind-eye toward guzzling electricity. When the sun is shining and the is wind blowing, we'll have banks of batteries and tanks of hydrogen holding the electricity with what would otherwise be missed opportunity. Our grid can only hold so much at a time. Also, production can be shifted to more practical locations. It's really unfortunate that so many early EV adopters don't think about those who won't have a plug readily available or where the electricity to recharge comes from.

- 9-10-2018** **Why?** I'm watching the rhetoric fade into background noise. There's no reason to ask "why?" anymore. People don't know. For that matter, asking the question of "why not?" is rather pointless too. Minds have already been made up, based on misconceptions & misinformation. Substance is not needed to make claims, nor does anyone bother to provide it. Disregard for the bigger picture has become the norm, because it is no longer recognized. This is why it serves no purpose to try explaining. For that matter, the complete lack of understanding is why the tax-credits should be allowed to expire. No one knows what they were for anyway. You'd be surprised by the variety of responses queries about goals will bring. It reveals a lack of information. Many have no clue how the technology works... or what the infrastructure needs... or the many costs involved. Even related facts are brushed aside as irrelevant. It's all a big mystery surrounded by unknowns people don't bother to research. Most aren't interested. When something is revealed, they quickly make assumptions to connect the dots. It has become a game seemingly without consequence. While all of this sounds like a "gloom & doom" status, it is actually encouraging. It marks a turning point when rhetoric no longer has much influence. To that, I say: *Phew!*
- 9-11-2018** **What About?** The end has come. Talk of mid-cycle updates for Prius has killed off all but the most ill-intent posts. How this happened is simple. The speculation overwhelms the antagonists. Those wanting to undermine simply don't have a voice anymore. A few are rather desperate though, hoping to derail the topic by causing a distraction. Catch is, they have run out of subject matter for that. All that's left is rhetoric related to hydrogen... and now one is biting their bait anymore. The subject simply doesn't stir emotion when its so easy to focus on the opportunities that await. So, I help to point some of them out to get back on topic. In this case, it was a discussion about 2019 model years of Prius and Prius Prime, the potential they bring: Using the "What About?" technique to attempt to divert attention is telling. China gets a Corolla PHV and an EV model of C-HR. For that matter, Australia gets the Corolla PHV too. These are clear attempts by Toyota to shift the paradigm, offering popular vehicles with a plug. That experience there will provide value information about how to shift the SUV obsessed market here... something even GM hasn't attempted yet. RAV4 hybrid with a plug.
- 9-11-2018** **Charger Installation.** It's nice to see questions about them come up on a regular basis now. Here's my latest contribution to those discussions: How many vehicles do you think will need recharging at the same time? Remember, your service-panel only has so much capacity. 8 hours from a 40-amp circuit will deliver 200 miles of range. Knowing that rule-of-thumb, we installed two 40-amp lines in our garage. Choosing to use 3/4" conduit meant higher gauge wire could be pulled later. For now, our JuiceBox Pros are set (via the software interface) to only allow the 80% draw (32 amps). That 7.7 kW max rate should be fine. After all, many public chargers top out at 6.6 kW. Odds are, a future vehicle wouldn't stop at the charger's max of 10 kW anyway, so having allowed for 40-amp draw (50-amp circuit) wouldn't be much of an improvement. The spec for that port's protocol can actually handle 19.2 kW. Delivering that requires a 100-amp line though, which would be very expensive and brings you back to overall capacity available. So, don't worry about the numbers or future proofing. 50-amp line could be nice. 40-amp is fine.

9-12-2018 **GM Recalls.** Well, this is interesting. Last week's Toyota recall has already been overtaken by one from GM. This one isn't as simple either. It's a power-assisted steering problem. The issue involves 1.2 million Pickups & SUVs. Unfortunately, it's an extension of the previous recall that included another 700,000 Pickups. The steering can briefly shut down, leaving wheel turning entirely under the driver's own control. Not being aware of the sudden need for muscle does pose a risk of accident. 30 reports of crashes are on record. Hopefully, that will be addressed quickly. But that doesn't sound like a fast or cheap fix. It's really unfortunate when stuff like this happens. It eats into profit-margins for the automaker, causes full schedules at dealers, and impact resell values for owners.

9-13-2018 **When?** Some people never learn. They keep getting pulled into the same discussion without recognizing the pattern. Remember back in 2009, when GM promised "*14 hybrids by 2012*" with a grand announcement everybody got so excited about? Most people don't. That's why the "*At least 20 new EVs by 2023*" has become such a source of excitement. A new audience is getting drawn into a new round of substantless hype. That's how the Volt enthusiasts came about. Anything that pointed out an absence of merit was attacked as an effort to undermine. They became a brainless group of propaganda spreaders. GM took advantage of that too, routinely feeding them with vague tidbits of info. When you'd request detail, pointing out the suspicious nature of what had been stated, they'd attack you. Since there was never any accountability, this terrible behavior went on for an entire decade... to the point where it became normalized. What a nightmare. Looking back at that in a discussion about GM's future, I provided this reminder:

Anyone who has closely watched GM over the years recognizes there's a lot of hype. Press releases are ambiguous to serve as a means of stirring interest & discussion. That has led their reputation of "*over promise, under deliver*" to transform to a concern of "*too little, too slowly*".

We have witnessed the rollouts of BAS and Two-Mode go nowhere, despite so many expectations having been set. The real-world results of the technology didn't meet the business return needed. That knowledge & experience was carried over to e-Assist and gen-1 Volt, which also fell well short of the hope outcome. Looking at Bolt and gen-2 Volt, we see nice technology struggling to compete with traditional vehicles, even with generous tax-credit help.

So, what's different from this latest round of announcements? There's no substance, just a looming phaseout of subsidies and a challenging market that's becoming increasingly difficult to address. There is no spotlight for GM to take advantage of anymore. There is no politic will to support green offerings. There is still little understanding of what electrification actually means.

Remember how GM said there would be 2 reveals within the next 18 months about 11 months ago? What should we expect at this point? When will something aimed at their own showroom customers shopping for a SUV have a choice with a plug?

- 9-13-2018** **Approach Choice.** Each automaker has their choice of how to use their tax-credits. It's a untimed limit of 200,000 vehicles, then switches to an unlimited quantity with a time limit of 1.5 years of phased reduction. One of the Volt enthusiasts who gave up on Volt and switched to Clarity made this comment: "*I find it an odd choice that Toyota chooses to use up all their tax-credits on the Prime.*" That was it. Nothing else, despite years of discussion on the topic. Why? My guess he still doesn't understand the business. Some people have it in their mind that only a single approach works, that no other choice is actually available. Seeing how close-minded our current president is, that is now a very easy perspective to accept. Some simply never learn. Ugh. To that, I kept my response brief: Having a vehicle profitable as it hits the phaseout stage is ideal, since there are no quantity limits at that point. Toyota is doing exactly what's needed to capitalize on the opportunity.
- 9-14-2018** **Motivation.** Sales of Tesla are often used as a basis of measure to gauge legacy automaker progress. That never made any sense. Such an expensive product that was supported in large part by investors seeking new opportunity is dramatically different from trying to change an extremely well established traditional production & distribution process. They have so little in common, it's futile to compare. Yet, we see those without a good understanding of business do it on a regular basis. They don't understand change. It's a problem GM has done a horribly bad job at addressing. One terrible choice after another... often repeating the same mistake. Ugh. With respect to the discussion at hand today on that, I jumped in with: Low-Hanging fruit isn't a motivator for legacy automakers. They depend upon high-volume profitable sales that have a strong outlook of being sustainable. Tesla hasn't proven that yet. Model 3 has great potential, but it could be a one-hit wonder. Looking across the legacy product-line, there's good reason for trepidation. The Osborne effect is a very real problem. For example, GM announcing a plug-in hybrid version of Trax or Equinox could cause their traditional sales of those vehicles to tank.
- 9-14-2018** **False Information.** Spread of it in the past was a very common problem to have to deal with. That was before "*fake news*" was identified as a legitimate threat. I so clearly remember comments just brushing off the source as having no power of influence. Such naive belief is how it got so out of hand. Fortunately, the truth has triumphed in most places. Not all circumstances getting the attention needed to squash the spread. Some comments slip through, like this one today: "*Take the gas engine out of the Prius no movement. Take the gas engine out of the Volt you get a total EV.*" You can guess how the text that followed was an endorsement for Volt. Anything that can be said to mislead about Prius has been tried. This one struck me as odd though, since it is so easy to recognize it as being false. Of course, it was in an article pointing out how much better Toyota sales have been compared to GM. So, attempts belittle were expected. The means to which it happened wasn't though. Deception source is difficult to pinpoint, quite unlike motivation. I punched back with: Poorly informed or intentional greenwash? That's the question to ask when reading a post which spreads such false information. The plug-in model of Prius is just like Volt, an EV with a gas-engine available for when the plug-supplied electricity is depleted. The notable differences are that Volt offers a larger capacity battery and more power motor while Prius delivers both more efficient EV & HV drives and more efficient electric-heating.

- 9-15-2018** **Death of Diesel.** We're seeing BMW & Cadillac announcements of diesel offerings being discontinued. EV fans are doing all they can to distract from plug-in hybrids, attempting to have focus be entirely on EV offerings. They don't want you to know other choices are available. They don't want to endorse small battery-pack capacities. It's quite a gamble targeting diesel enthusiasts who thrived on MPG numbers, especially when a plug-in hybrids can so dramatically exceed diesel. It was only a matter of time. Why some automakers even bothered to certify their new vehicles is a mystery. What a waste effort. Taking about short-term thinking. To think that I fought so many for all those years, warning them of ever-improving hybrid performance. They didn't care. In fact, they all turned a blind-eye to how diesel MPG numbers didn't add up. It never made any sense how the claimed improvements were achieved without emission sacrifices. They wanted you to believe it was some type of engineering miracle. They were wrong, very wrong. Our suspicions were correct.
- 9-16-2018** **Reverse FUD.** It has been interesting to witness the change of market. With the early-adopter phase coming to an end, there's a new audience to appeal to. That's putting the current "*not as good as Tesla*" mantra as a new challenge to face. Dealing with the "*vastly inferior*" posts is a pain, a twist on the old "*vastly superior*". We went through that with a certain plug-in hybrid and now see the same emerging with electric-only. Thank goodness the conflict of green is being brought to the attention of others through a variety of sources now. That's a big difference from the past. There is a day-of-reckoning on the way, when the tax-credit phaseouts are complete and choices must be made. Lack of a standardized new infrastructure and no common message of intent are obvious problems still not dealt with. Achieving growth without a clear direction and no more subsidies is something we should be far more concerned about; instead, there are arguments among the ranks. Not good. Some are spreading FUD with that message of it not being good enough. It's a problem that could get out of hand. This is how the quick-to-dismiss mindset takes hold. People see other offerings don't measure up, so they don't bother at all. It gives them an excuse to wait, just sticking with traditional vehicles for another generation instead of even taking what's available now into consideration. That's something to watch out for and fight against early on. Don't let someone else's lack of critical thinking make you miss out on opportunity.
- 9-17-2018** **Audi e-tron.** Countless announcements have been made recently, many with prototype reveals. Plug-In choices are coming. The catch is, many will be extremely expensive. The average price paid for a Tesla Model 3 is currently \$60,000. That long-awaited \$35,000 model is still not available. It will be... someday. In the meantime, there are other expensive choices coming. Today, it was a big event to declare Audi's commitment to change. At \$74,800 base for their upcoming EV called "*e-tron*" there isn't a large audience, but that's ok for the luxury market. Offerings are all over the place for those with money. For those looking to get something affordable... competitive with Corolla or Camry... the choices are very limited. This is why Toyota's choice to position Prius Prime in that market. It will be many, many years still before we see others able to offer something able to compete directly with other mainstream vehicles at the price people in the middle are willing to pay. That's too bad, since the electric-only driving experience from Prius Prime is a luxury trait. That smooth & silent drive is wonderful. Anywho, Audi does take it to the next level for the price they are asking. You get virtual side-mirrors, with screens nicely integrated into the interior. You also get a 100 kWh capacity battery, which translates to roughly 250 miles of range.

9-18-2018 **Not Yet.** Early adopters like to get way ahead of themselves. Seeing the technology up close and so frequently, it's easy to lose perspective. As a result, they need reminders... like today, with this: "*EV has gone mainstream.*" I wasn't sure what exactly was meant by that. It certainly wasn't with respect to cost or availability. It wasn't with regard to understanding or recognition either. We don't see charging-stations in great abundance... or even in scarcity. Sightings on the road are rare too. So, what was it? I jumped in to point out: Mainstream sales are not government subsidized. Until we see purchases without tax-credit dependency, we are still in the early-adopter phase. Patience, it will happen... but hasn't yet.

9-19-2018 **Ditching Diesel.** Talk of automakers abandoning the dirty & wasteful technology in favor of something with a battery is bringing out attempts to rewrite history: "*The Chevy Volt was from day one intended to be a limited production halo car...*" Spinning the intent GM had and the actions that followed is now surprise. Volt is among the industries largest blunders. Simply ask yourself what the point was and how much was spent to supposedly achieve that. It's a great example of what not to do. You don't design a vehicle for enthusiasts and promote it as a product for the masses. That's doomed to fail... and it did. Remember all the "*too little, too slowly*" posts? That was with regard to Volt's intent. It was supposedly the successor to all green technologies of the past... in other words, diesels and Prius. That obviously didn't work out. Sales never exceeded niche, even with tax-credit help. I corrected the attempt to mislead with: WHO IS THE MARKET FOR VOLT ?

That question was asked literally hundreds of times during the gen-1 offering of Volt. Each time GM did something that to give the impression of mainstream promotion, enthusiasts would defend Volt's position as a Prius fighter with the claim of mainstream sales coming for gen-2 Volt. The targeting intent was obvious.

Admitting Volt was really only a halo didn't come until near the end of gen-1 production. All the years prior to gen-1 rollout and while it struggled with sales the first few years of availability, we were very much under the illusion GM had high-volume plans.

There was no doubt that GM goals set the expectation of Volt becoming a profitable vehicle. In fact, that technology was part of the bankruptcy recovery strategy. Nothing became of it though. We have yet to see Voltec rolled out in a vehicle GM customers actually want... a SUV.

For that matter, quite the opposite happened. GM promoted traditional vehicles heavily, rolling out Cruze & Equinox diesel choices instead.

9-19-2018 **No Choices.** The discussion started to take an ugly turn. I hoped to prevent an emotional stir, especially with the hit of anger coming. Some simply stop listening when they hear something they don't like. There's a lot of defensiveness with regard to Volt still. The technology didn't result in any mainstream offering. Diversification never happened. All the claims of GM rolling out green choices so much better & faster than Toyota never happened. In fact, basically nothing beyond showcasing happened. GM proved they could deliver great things from their engineering, but didn't apply it to any of their own product-line. Quite unlike Toyota with all of its hybrid choices, there's virtually nothing from GM... hence all the rhetoric I have to routinely deal with. If you want to purchase a GM vehicle and you are wandering around on their dealers showroom floors, what is there to choose from just as the phaseout of GM tax-credits is about to be triggered? The goal of those subsidy dollars was to help establish green choices able to compete with other vehicles there at the dealer. That didn't happen. Meanwhile, we see Toyota scrambling to make their hybrid models available for each vehicle they offer, with the hope of plug-in models to follow. There is still plenty of tax-credits available before the Toyota phaseout getting triggered too. I responded to the GM nonsense this way: That line of reasoning falls apart when taking hybrids into account. Those sales are quite strong with respect to any "*halo*" offering. For example RAV4 hybrid, an offering clearly greener than traditional choices, saw 5,058 sales last month. There's the growing availability of plug-in hybrids too. How come those choices are conveniently overlooked, especially when GM doesn't even offer a "*halo*" of any sort for their own customers, who overwhelmingly prefer SUV choices.

9-19-2018 **VW 100 kWh.** It is difficult to take announcements like VW made today about the intent to deliver a vehicle using a 100 kWh capacity battery-pack seriously. Exactly when & where will that actually happen? How much will it be priced? How many will be produced? It's all so vague, what's the point? Toyota remains almost totally silent; we really don't ever hear much. Hype doesn't result in sales. In fact, hype often feeds enthusiasts... making the vehicle take on the image of a niche, rather than targeting mainstream consumers. In other words, putting a spotlight on it can have the opposite effect. Notice how many people there are that don't want a standout vehicle? That's why there are so many blah SUVs now, most sharing the same basic lines and in dull colors. It's strange how black, gray, and white have become the dominant choices now. But it is what the masses are currently drawn to. That's why questioning what the right capacity is for a high-volume seller can be such a critical thing to ask. We really don't have a good idea what priority people will place on range. After all, look at how poor sales of Volt were. Price & Size were far more important than Range & Power. We can clearly see that now. Early on though, I was a lonely voice pointing out what ordinary middle-market consumers would be drawn too. Anywho, there's something to look forward to from VW. The announcement today really didn't tell us much about it though. In fact, it barely told us anything.

- 9-20-2018** **Admit/Acknowledge.** It's bizarre to witness same brainless claims I experienced countless times online with plug-in battles while watching political interviews. The host will acknowledge something, the guest will claim that was just an admission. There's a profound difference between stating words of recognition and actually taking a stance. That refusal to see a world of compromise is how we became so polarized. It's all about absolutes. In fact, the word "*compromise*" is no longer thought of as seeking a balance. It's been given the stigma of losing, a sign of weakness. Basics of being polite are gone for some. They just plain don't want to listen. How did we lose a mindset of progressive updates? Seeing upgrades routinely in the past was a norm. You could expect each iteration to be better. That's how the spirit of competition thrived. Somehow, that got lost along the way. That often happens from attrition. As those with knowledge depart, the remaining support struggles with the difficult challenges. Instead of seeing them as opportunities, they incur "*technical debt*" as a matter of survival. That's the consequence of not continuing to invest. Just getting by is how I watched software developed at my employer become increasingly difficult for the customer to use. Upgrades to the newer software were met with only minimal coding updates. It was a recipe of falling quality. That's when the defense nature of ownership emerges. They come to realize sacrifices were being made... but don't want to acknowledge how. So, they get others to "*admit*" it was the fault of someone else. Ugh.
- 9-21-2018** **Identity Crisis.** Long ago, I said the lack of any clear message would have consequences. It was summed up with the most basic question of "*Who?*" That inability to identify audience meant everything related to promotion would be a challenge. All those claims of being "*vastly superior*" positioned Volt as direct competition with Prius; yet, none of the traits attributed with demand for Prius matched what Volt claimed as strengths. It never made any sense. Now, we see many of the former supporters looking at Volt's struggle for sales as confirmation of it really only having been a "*halo*" or a "*stopgap*" offering... which is a narrative that doesn't work in a market where the supposed successor is also struggling for sales. This is the inevitable disaster that was predicted back when it became obvious the tax-credits were being wasted on outside conquest, rather than actually helping contribute to customer change. Proof of the problem now has emerged with the 7.2 kW upgrade for Volt. That's double the current recharge speed. Why is that necessary if 53 miles was declared enough to cover all daily driving needs? Think about how often we hear from Volt owners who claim their engine hasn't started for weeks, or even months. Portraying that operation as common means there's nothing to gain faster charging. It's quite hypocritical. What is Volt for? The term "*plug-in hybrid*" upsets Volt owners. The term "*electric vehicle*" upsets EV promoters. The term "*EREV*" is an ambiguous identifier. None of it makes any difference in the end though. Volt is simply too expensive for the masses. Being a compact hatchback starting at \$33,520 and lacking some features available in much less expensive choices (like the base Prius Prime), it simply doesn't have any more than just a niche audience. It's really too bad GM never delivered the technology in a vehicle their own customers would actually want.

- 9-21-2018** **Mainstream Attention.** There isn't any. Enthusiasts don't watch the larger market. They don't care, as this quote stressed that point: "Yawn... Toyota... Yawn" That came from a plug-in enthusiast website... and was no surprise at all. It's no different than what we heard from enthusiast magazines for all those years. Neither has any interest in what happens for ordinary consumers. Their focus is niche... to the extreme where they aren't even aware they are seeing the world with blinders on. It's unfortunate how much of a voice they get anyway. Despite the obvious bias, people turn to them for advice on mainstream offerings. Why? Anywho, I replied to that with: Mainstream sales have always been a yawn. That's the basis of appealing to the masses. You see Camry & RAV4 all over the place, almost never noticing whether or not they are hybrid models. Corolla & C-HR are available as hybrids in other markets the same way. All can upgraded to offer a plug... without stirring any attention. Achieving profitable & sustainable high-volume sales is not exciting, yet that is what automakers require. Do you really want a standout vehicle that is nothing but an expensive halo sold to only enthusiasts?
- 9-22-2018** **4 Sightings.** That was sweet. I saw 4 today. With supply in this region nothing but special orders from extremely limited inventory, the chance of seeing another Prime simply isn't realistic. Doing a search for some for sale within a 500-mile radius only reveals 72 available. Within a 100-mile radius, there are only 2. So, this wait for the 2019 model-year with potential mid-cycle upgrades is agonizing... though, quite worth it. A refinement to the system followed by actually having some in stock at dealers would be wonderful. I understand the reason for holding back. There's no reason to rush. Do it right, not quickly. Know your audience. For the case of Toyota with Prime, it is very much a situation of appealing to showroom shoppers. Those wandering the floor their local dealer hoping for something to jump out at them will discover this new plug-in Prius. It's not easy drawing interest from those who owned cars all their lives by are now compelled to consider a SUV. With Prime, there's a chance. More sightings on a regular basis could be realistic next year. Until then, it's still rather lonely... on roadways packed with guzzlers.
- 9-23-2018** **No Loyalty.** Yet another former antagonist has said goodbye. Tomorrow, his Volt gets replaced by a Model 3. It's ironic how the "Who?" question has become so relevant. Even the supposed die-hard supporters are jumping ship. Those conquest sales didn't result in any long-term support, exactly what I expressed concerned about. They were just enthusiast taking advantage of cheap prices to entice early-adopters who would just chase the next low-hanging fruit later. Since those were the only people who purchased a Volt, it was a very real problem to come. No loyalty from them and no interest from ordinary GM customers. It was a recipe for disaster; yet, those antagonists simply didn't care. They would belittle & insult Toyota, then pretend none of it ever happened years later. They just vanish, exactly as I said would happen. Having witnessed that in the past, the pattern was easy to recognize again.

9-23-2018 **False Information.** I find it remarkable by the quantity of posts just like this I encounter on a regular basis: "*The volt does not have an engine. It has a small generator to charge batteries. Why so many uninformed people commenting?*" It comes from people reading supposedly credible sources spreading that false information. As with problems like that in the past, there's a very real possibility that it feeds what will eventually become history. Misconceptions unable to be verified as true or false do that. There isn't anyone to verify or contest at some point. It distorts expectations going forward if you don't have an accurate past. For that matter, you cannot even measure progress if there isn't a base to compare with. This is what undermining is all about. Antagonists will misrepresent things to their favor. Whether it be dishonest about their own preferred product or about the competition, the outcome is the same... a confusing mess... which is exactly what they hope for by spreading false information. As usual, I was annoyed and kept the reply brief: Because that claim is false. Volt's engine is the same size as some used in traditional compacts and it provides power directly to the wheels at times.

9-24-2018 **New Blazer.** Looks like GM completely abandoned the expectation they had set long ago for affordable green choices. Enthusiasts had set a great deal of hope on the MSRP of \$29,995 for Volt. That never happened. The system is simply too over-engineered to achieve that price and still be profitable, especially when that base lacks features Toyota offers standard. GM's own customers certainly haven't been interested, even with tax-credit knocking down the price to about \$27,000. The reason why is simple. Those GM shoppers want a SUV instead. That's how the new Blazer came about. It's yet another choice and it's at that magic \$29,995 price. GM strived to make it competitive too, giving it a 9-speed transmission with 2 engine-sizes available. It's quite obvious from the reveal articles published today that GM wanted to make this offering very appealing. It isn't green though. Not a peep was said about emissions or efficiency. There clearly won't be anything to that affect soon... despite the reality that Toyota is upgrading both RAV4 and Highlander to next-gen hybrid systems. This is why the "*too little, too slowly*" concern was conveyed so relentlessly. It should have been obvious Volt wasn't going anywhere. It's tech will take a painfully long time before it finally makes its way into a GM mainstream vehicle.

- 9-25-2018** **Just Plain Wrong.** I was somewhat blown away reading this today: "*If you live in the mountains, there's a special Mountain mode that prevents the car from juicing up to 100 percent -- that way, if the first part of the commute is entirely downhill, the car will use brake regeneration to add that last bit of charge, saving a few bucks' worth of electrons in the process.*" That was so wrong, even the Volt owners reading the article went out of their way to correct the author. How could such a mistake be allowed? It's one of those sources where you wonder if a test-drive was actually ever taken. The way that mode actually works is, when pressed, a means of forcing a recharge from the gas-engine. It only provides a small buffer though (20%) to serve as extra power for when driving in the mountains. That reserved electricity is supposedly for helping with steep climbs... which, ironically, Volt owners claim is never actually needed. But since GM was strongly opposed to providing a "*hold*" mode (since that would make it too much like Toyota) then gave in later, this served as an alternative back then. Of course, now Toyota offers Charge-Mode which much more aggressively replenishes the battery-pack and does it all the way to 80%. Any well informed writer would know that options like this exist. So, you'd think, they would research which the vehicle they are writing about delivers. Unfortunately, making up a story to explain what's offered is far too common of a problem. We saw that quite a bit with "*EV-Auto*" mode for Prime. The review would characterize behavior incorrect to what they assumed the system would do. Ugh.
- 9-26-2018** **VW Battery.** It was interesting to see conceptual drawings today of what VW is planning to deliver in a few years. They are basically just jumping on board like everyone else, saying they are investing in development with intent to produce too. VW is going with the "*battery under the floor*" type design. This allows for a simple cell layout, where stacks are neatly arranged without having to introduce much complexity. That's nice, but it becomes so integrated as part of the vehicle's platform that replacement becomes nearly impossible. That is a reasonable tradeoff, actually. To keep things affordable, you sometimes need to strike a balance like that. Ironically, the approach with Toyota to achieve affordability was just the opposite. Rather than integrating the battery, a drop-in pack was designed. It comes down to what you are building upon. VW has pretty much nothing to work with, due to their heavy investment in diesel... and subsequent scandal with severe penalties. Toyota has well established diversity among affordable hybrid choices to augment. Whatever the case, it is always welcome news to hear of any automaker investing. You wish them luck and give them continuous reminders of their promise.
- 9-27-2018** **Infrastructure Upgrades.** Reading about incentives like this is great: "*New York Offers \$4,000 Rebate To Install Charging Point*". That's to entice business owners to offer chargers for their customers. Whether you own a coffeeshop, restaurant, office, or apartment, you are the target of that money. The state recognizes the challenges that groups faces when trying to accommodate patrons & renters. Getting some money to help with the initial setup is great. That's just enough to provide some education & experience. Because once you have made an initial effort, anything you do following that is much easier. It makes for an excellent start. Good thing too. We have lots of other states who could benefit from similar incentive programs. Having New York become a success example to model from would be quick helpful.

9-28-2018 **2019 Volt.** It is interesting to read comments posted about a product without an audience. There simply isn't a mass-market for this small, expensive hatchback. True, it is what people had asked for, with respect to specifications. But that's the problem with commentary derived from autoshow. You don't get feedback about what people will actually purchase. Basically, all you hear about is what people desire. There's a huge difference. That fundamental disconnect is becoming apparent. You can see that based on replies from new articles, as was today about the newest model. I jumped in with: 10 years ago, a strong selling point about the revolution Volt was to bring was its target price of "*nicely under \$30,000*". GM set that expectation because it was vital to being able to achieve high-volume sales. Business requires that type of goal for profitability. In fact, the upcoming new Chevy Blazer will have a starting price (including destination charge) of \$29,995 for that same reason. Now, halfway through the second generation of Volt, we see a vehicle selling at niche levels even with the \$7,500 tax-credit. That's an undeniable sign of sales struggle for the compact hatchback; however, the technology itself could still be a source of business opportunity. Putting it into a body style GM customers prefer... a SUV model... like Blazer... would make sense. When will we see GM finally offer something to compete with its own product-line? We've been waiting 10 years for a vehicle able to take on GM's traditional offerings. It's not real change unless shoppers have a choice on the dealer's showroom floor that is actually competitive.

9-28-2018 **Beyond Confusing.** The labeling, which turned into propaganda for awhile, has devolved to a state of confusion: "*It's a very interesting compromise between PHEV and EREV.*" Who could read that and actually understand what it means? I certainly don't. People shopping for plug-in hybrids won't have any idea what those labels refer to. They shouldn't need to either. kW/mile and MPG are measures of performance, not some arbitrary label. Anywho, I took the offensive before anyone else could grab the ball:

Each design from each automaker is unique, which makes labels like that arbitrary. There's nothing consistent across the industry or even particular markets. It's basically just branding. The actual operation is meaningless. Ordinary consumers focus on the same priorities they have always considered important, like price, comfort, and convenience.

With respect to operation, Honda has a pedal feature, Toyota has a button, Chrysler doesn't offer driver control. Some have electric heaters of various types, others rely on the gas engine. Cold affects the battery-pack in each differently too. It's all just mix customers couldn't care less about... since the typical buyer doesn't cross shop brand anyway. They go to a dealer and choose among that selection there.

Of course, none of that matters. When a customer walks into the showroom at a dealer, all they will really see is:

PLUG
ENGINE
ENGINE + PLUG

Those categories are what people recognize. Detail of differences is pointless. We know this from decades of observing buyer behavior. This is why such passion has grown for large & expensive guzzlers to become the norm. This is why the tech from Volt must be put into a SUV for the shoppers at Chevy dealers to take notice. They couldn't care less how it is labeled.

9-29-2018 **Watching Change.** I liked this question: "*Is there anybody who frequents this site that actually learned anything from this article?*" It was posted as a comment to an article that was essentially an introduction to vehicles with battery-packs. That provided a great venue for reaching a new audience. People will stumble across articles just like this later on. Providing some context for this history, as it is playing out, can be quite informative. So, that's exactly what I did: 2,674 miles from my last tank. I refilled last night, since I'll be taking a long trip this weekend. It took just under 8 gallons. That's 11 weeks to use 70% of the gas capacity... which overwhelmingly demonstrates the 25-mile electric capacity from Prius Prime is quite capable of delivering impressive results. The devil is in the detail with plug-in hybrids. The electric-heater in Prime is more efficient than the electric-heater in Volt. So, the one uses less electricity than the other. But at least both are electric. With Ionic, the gas-engine must start for you to have cabin heat. Efficiency of the electric-motors for propulsion differ too. Just like with traditional vehicles, driving results will vary. In other words, simply putting the choices into categories or comparing capacities is not enough to make an informed purchase decision. Discussion of the seemingly basic article can reveal facts & experience frequent site participants may not have been aware of or overlooked the importance of.

9-29-2018 **Understanding Audience.** A conversation emerged from that introduction article: "*Such articles should be run on a regular basis to educate newcomers to the EV community. Every article need not be written for the existing community.*" It's nice to see most of the antagonists are gone now. So many of them stirred trouble just for the sake of keeping the spotlight on Volt. It was a seemingly endless effort to undermine. Their hope was a miracle would happen, that somehow battery cost would drop so much that larger pack in a plug-in hybrid would make it a compelling draw. That never made any sense. If cost were to plummet to that degree, why not just buy an EV with a ck large effort to negate any "*range anxiety*" concern? None of them wanted to admit there was a self-deprecating possibility. Now, they recognize the flaw in their logic... which is why they have abandoned Volt. That's the consequence of cherry-picking. They only saw & promoted what they wanted... which works fine for a niche, but fails miserably when attempting to appeal to the masses. I climbed up on the soapbox for this reply:

This audience will drop like flies when the tax-credits expire, those who are taking advantage of that pricing offset to help along progress of the technology. That's what early adopters do. We have already seen a large number who already moved on from Volt to Model 3. It's a natural next step for that group, because they are well informed about the hurdles of electric driving.

For those who are just ordinary mainstream consumers, what happens here during those initial years will never be known. They will be blissfully unaware of the challenges faced by technology requiring subsidies to assist with rollout to a new & uncertain market. They will never know... or care... about what it took to overcome issues will production & infrastructure. For that matter, they won't even understand what it took to convince dealers to carry plug-in choices as regular inventory.

Notice how simple things, like home & public chargers, are still far from standard? For that matter, even early adopters really don't know what kW charging rate makes sense as a recommendation for home & public locations... and they are the well informed about equipment cost & installation. Think about how much of a mystery that "kW" reference is to the typical showroom shopper.

We are only just now seeing what the market could be like as the early-adopter stage (clearly identified by when the tax-credits expire) comes to a nnd. The choices loyal buyers of traditional vehicles will likely be different from what those early adopters had envisioned. That's what happens as a technology evolves. Adaptation to appeal to a wider group means bringing up 101 education on a regular basis as a means of measuring the progress. Comments posted will reflect the change of audience.

9-29-2018 **4 Cars, 2 Spots.** The shift here is beginning. With so few public chargers available, it was only a matter of time. This morning at the grocery store, there were 4 plug-in vehicles all at the same time... Clarity, Cadillac ELR, Model 3, and the Prime. I parked across from the chargers, saying "*Hi*" to the Clarity owner as I passed. Got out, then I had to wait to cross as the Model 3 drove by. It was an unexpected, but welcome, experience... especially for a quick 10-minute coffee run. I took a photo and shared it online. That stirred quite a response. Lots of others were excited to see that too. In fact, some have experienced similar. It's a nice change from loneliness of the past.

9-30-2018 **Implied Audience.** It was interesting to read someone's assumption in the form of a reply that I implied something. That's quite different from when an antagonists intentionally twists your words, spinning them to mean something else. This was an example of a new participant simply not having enough information yet. That's exactly what we want on those topics aimed at new audiences. If you can get a person with a fresh perspective to join into the discussion, you have new opportunity. I took advantage of that:

15 years later, we have an entirely different audience. Those buyers may have shared similar traits, but in no way are they the same people. Just because someone may have been part of a prior group does not mean only those included in that can be part of the next. An early-adopter is anyone who jumps in to make a purchase when the mass-market has yet to be reached... or even targeted. Notice how the current plug-in offerings are being positioned for mainstream buyers, but are not actually offered to them yet?

Model-3 doesn't exist as a \$35k choice. It will. There's a great deal of obvious potential, but that affordable production hasn't started. Cost & Profit isn't at the necessary balance yet. Infrastructure is still being built up in the meantime too. Tesla is striving to make that all happen soon.

Volt suffered from cost & profit not being addressed. Dealers had to be enticed to carry inventory by GM providing lease prices at a loss. It was a way of stirring early-adopter participation, but meant a setback for reaching the mass-market. It was not a sustainable approach.

Prius Prime is addressing that same dealer (legacy sales) problem, but with a different approach. Toyota delivered a plug-in choice at a MSRP low-enough from the start to directly compete with traditional vehicles sharing the showroom floor. It meant waiting until mid-cycle to rollout beyond the initial regions, but that reduces dealer risk by confirming mainstream buyer appeal.

And let's not forget the role early-adopters play. They are the ones who provide education & promotion efforts... not dealers or automakers. Owner endorsements are far more effective than anything the business can do.

9-30-2018 **Making A Difference.** We are finally bringing the rhetoric to an end. Far more voices are asking why, confronting the antagonist, rather than having to put up with their rhetoric. Today, it was nice to see this: "*Why do people keep describing the Volt as a series hybrid?*" I like when it is presented as a question. The old days of having to directly confront the obvious efforts to undermine are over. Yeah! Now, it's responses like this that do the trick: It's a throwback to the "*EREV*" days, when enthusiasts tried to promote Volt as a successor to "*PHEV*". Problem was, their definition only applied to the concept model. The actual production model ended up the parallel type. To confuse matters even more, rollout of BMW's plug-in hybrid truly was the series type. Yet, they ignored that and persisted with the confusing term anyway. Realistically, it doesn't matter. Ordinary consumers won't care. Labels don't mean anything to them. It's the results. That's why kW/mile and MPG efficiency ratings are so important, as is price. That's what matters.

9-30-2018 **More Spin.** If you carefully re-read some posts, they make even less sense after the initial impression. For example, this snippet stuck out on that first pass: "...as the market for EVs has proven." Looking for detail about what it actually meant, I couldn't find anything. It was pointless. Antagonists often do that. It's the "what about" technique used in a subtle manner. They hope to draw attention away from the current topic, in this case, it was a discussion of audience... not going well for them, hence their quiet attack and my punch back to reveal their meaningless effort:

Again, know your audience.

I put up with the rhetoric here from enthusiasts for years, since I saw the bigger picture. My response over and over and over again was to ask: "Who is the market for Volt?" That's because I knew there wasn't one. The supposed die-hard supporters abandoned Volt as their leases expired and the EVs without "range anxiety" became available. They were early-adopters, which is why they moved on.

What they left behind was a disaster. All those years of pushing GM to create a niche that would be abandoned just as the tax-credits were nearing phaseout, leaving behind a vehicle mid-cycle with a MSRP so high it couldn't compete on the showroom floor and no one remaining to help promote it.

Why is faster recharging important to a vehicle that already delivers what has been claimed as enough for daily driving? It simply does not make any sense. What benefit is there from a battery-capacity that is said to be enough that only overnight recharging is needed? It's contradictory marketing.

In other words, what has actually been proven?

10-01-2018 **Renewed Attacks.** With third-quarter sales on the way, it's easy to see why recent posting activity has included renewed attacks. Those few troublemakers who feel a need to defend GM have emerged. Their daily posting nonsense is long gone, just a terrible memory. But when actual results are posted (on the quarter, monthly are only estimates), it's easy to understand their timing. This morning was an obvious effort to mislead about BMW i3 operation: "*Limping on the right lane at less than 50 MPH...*" Having already been through this with him, there's simply no excuse. Comments like that are intentional undermining. I turned it around using this: The gas-engine easily generates enough electricity. Cruising at highway speed takes very little kW draw. That's how Prime is able to deliver an EV speed of 84 mph. Not much electricity is actually needed. In fact, that is why even at 70 mph you still have some power available for passing.

10-01-2018 **Mistake Repeated.** It was inevitable: "*You spin those platitudes at odds with GM's HEV work, whereas I and the auto industry recognize GM's seminal HEV work as a well-done engineering achievement.*" The trophy-mentality is what fed the problem all those years ago. Seeing it return for the renewed attacks was inevitable... as well as reassuring. There's more data available now. I have a collection of 4K videos to refer to. So, that's what I do. I also suggested what the antagonists should do: Go ahead. Do it. Continue focusing solely on engineering achievement... just like countless many in the past did here too. It's quite remarkable to watch that same mistake repeated over and over again. That obsession with seeking praise is the downfall. You should move to helping promote what was delivered, rather than forcing the topic to first-year physics. Reality is, GM engineering achievement still has not been taken to the next step... actually implementing it in a vehicle GM's own customers would be interested in. Paying no attention whatsoever of that failure to advance the business is the mistake. There is nothing left to prove. Let it go. For example, I drove 2,674 miles using 7.896 gallons of gas over the past 11 weeks. That worked out to 338 MPG. What else do potential buyers need to know?

10-02-2018 **Move On.** I asked: "*What are you suggesting the "move on" to should be?*" Knowing the reply will be just like in the past, a vague reference to what I had posted followed by some lame excuse, there wasn't much to expect. Basically, I was just looking for closure and took advantage of the timing. Quarterly results, the very last just prior to phaseout, was the perfect opportunity. So, that's exactly what I got by posting:

That is a sincere question. After 10 years of the course change, what do you think should happen now?

Throughout the original development of Volt, it was promoted by enthusiasts as having an engine for backup purposes only. That gas-powered source of electricity would be sized for efficiency, to serve as supplier of energy for those rare occasions when you needed range extension. This is why a 3-cylinder engine was considered for gen-1, then delayed due to cost until later for gen-2. Neither got that; however, the BMW i3 did.

That "REx" system BMW delivered is exactly what had been the hope for Volt. The gas-engine is tiny, just enough to maintain a steady cruise while on the highway. Specifically, output is 25 kW.

The definition of Volt's system, given the "EREV" label, changed upon the discovery that gen-1 would indeed have a direct mechanical link to from engine to wheels. That was never supposed to be. It made the system a "*parallel*" type hybrid rather than the hope for "*series*" type. GM took it a step further for gen-2, making the feature enable over a larger span of power & speed demands for greater overall efficiency. That blending of engine & motor power made enthusiasts furious, since it made Volt more like a Prius and less like an i3... hence another definition change. Now, it means you get "*full*" power with both HV and EV modes.

That is, of course, rhetoric spin. No label can change how the system actually operates. Enthusiasts can push an automaker in a particular direction though. Proof of that is the innovator's dilemma they contributed to for gen-2 design. Enthusiasts pushed for more range & power. There's no reason they couldn't push for something different now.

Prius Prime has become the antithesis of Volt, due to its superior efficiency in both HV & EV modes and its much more affordable price. With temperatures in the low 40's and speeds varying between 60 and 70 MPH, my 175-mile trip up to Northern Minnesota last weekend delivered 61.5 MPG while leaving 90% of the battery for my travel later at the destination. Efficiency for the electric-only drive averaged 5 miles/kWh throughout the summer.

In other words, what direction do you wish the technology in Volt to take? Should it become more like i3 or more like Prime?

Think about how consumers view the EV driving experience now. Will they really be open to paying a premium to get a gas-engine tuned for power rather than efficiency at this point? With so many other green choices coming to market, you have to ask fundamental questions like that.

Then, think about how uninformed most consumers are about plugging in. We know that people have become mentally lazy. The lack of critical thinking is frightening. How much are they willing to pay to upgrade their garages when they have no clue what's involved or what doing that will actually deliver.

Put another way, how will you promote whatever it is that you choose to suggest?

10-02-2018 Well Deserved Rant. Sometimes, you just have to give a purist a dose of reality. It was well deserved too. Some of us are working hard to bridge the divide. Getting posts counter to that effort are frustrating to have to deal with. They forget the overall goal. I'm more than happy to give them a terse reminder in the form of a rant: 60 MPG from a low-emission hybrid system is considered a gasser? That's some serious cherry-picking. It's becoming easier to see the Reverse FUD problem. Try to open your mind. My last tank was 89% electric. Who cares if some gas was used. That's a remarkable step forward into the world of plugging in with such a supposedly small battery-pack. Put another way, GM has some serious marketing problems to address. We've seen countless former Volt owners turn on the very approach they praised for years once a selection of EV choices became available... especially since many didn't stay loyal by choosing Bolt. Think about how much switched over to Tesla. I know quite a few previously outspoken Volt enthusiasts who now own a Model 3. The goal at this stage is to replace traditional vehicles with those offering a plug. So what if it becomes a "gasser" on an occasional highway trip. Most of the time that vehicle is driven, it will be using electricity.

10-02-2018 Spewing Insults. There wasn't a pleasant mood on the blogging website for all plug-in vehicles. Insults from Volt enthusiasts started up. There's obvious anger without an outlet for expressing it anymore. That daily blog where they would attack outside opinion is gone. Now, they must remain civil. So, we get this: *"If it were the Clarity PHEV at #1 I could understand it, but the Prime is coasting entirely on name and is not as good of a product as the Volt or Clarity."* That resulted in a reply adding this: *"The Prime has more standard features (AEB and ACC) and optional features (sunroof and a HUD) than the Volt."* It set off an emotional outburst including *"distinctly inferior"* and *"underwhelming"*. Things feel apart from there. I ended up chiming in to that mess with: Who is that supposed to impress? Mainstream consumers couldn't care less about what enthusiasts have to say. What Toyota achieved with Prius Prime is what GM continues to struggle to deliver for Volt. It delivers efficient EV driving with efficient HV driving at an affordable price. As for what an enthusiast believes the competition to be, there's a rude awakening coming around the corner. That low-hanging fruit is almost all gone. Those purchases with government help don't in any way represent what the masses will face. Think about how many sales must be repeatedly achieved to really make a difference at reducing the number of traditional vehicles offered by dealers. Insults directed at Toyota are a waste. The real problem is what shares the showroom floor with Volt.

10-03-2018 **Know Your Audience.** I kept fighting back with that as my lead in. This followed: For many years that message of dealers being the true customers, not who ends up with the vehicle in their driveway, fell on deaf ears. Enthusiasts were so obsessed with the engineering, they fought tense online fights trying to convince others that's all it takes to achieve high-volume profitable sales. They believed a sustainable demand was driven from end-user influence only. The topic of carrying supply as ready-to-purchase inventory was attacked as an attempt to undermine. The importance of the business was brushed aside as unimportant. This is still way MSRP is such a touching subject. Enthusiasts don't want to face the reality of the sales so far really only being low-hanging fruit. Faced with the big picture of 60 million new vehicles being put on the planet every year, it's too large of a problem to not take seriously. Yet, the "*EV market*" blinders are still being used. That's all a bit of a downer. But until those here not addressing the affordable market and recognizing the role dealers play in that sales process, more opportunity will continue to be wasted. Think about how a middle-market consumer goes about making a purchase decision. It isn't anything like what those of us here do.

10-03-2018 **Narrative Pushing.** It looks just like this when slipped into an article about the evolved plug-in industry: "*You mean to tell me that Toyota has been dumping all of its EV budget into hydrogen cars for nearly two decades now? I find that hard to believe.*" Certain groups want you to believe Toyota is only in favor of fuel-cell technology, turning its back entirely on battery vehicles with the hope of a hydrogen-only future. It's a frustrating narrative to have to address, since people hear that and accept it as is. The lack of critical thinking on the part of listeners is sad. They have no idea they are being manipulated, nor do they care. It's a feel-good attitude they seek, rather than actually working to find a true solution. I punched back with: That's because it isn't true. Anyone with knowledge of EV design can easily see the investment Toyota has made in electrification. Look at Prius Prime... 25 kWh/100mi efficiency rating... vapor-injected heat-pump... carbon-fiber hatch... aero-glass window. How are those not serious investments in EV design? There's also the reality that all but the ECO model of Prius has been switched over to lithium batteries. This is a push into high-volume production, exactly what you need to achieve profitable sales that are sustainable. The hype involving hydrogen interest from Toyota also requires turning a blind eye to the reality that Honda, Hyundai, and GM are investing in development of the technology too.

10-03-2018 Too Complicated, part 1. This is what happens when you don't bother to consider the big picture: *"Honestly, I don't understand plug-in hybrids. They are too complicated. You already have a BEV but instead of adding to the size of the battery and be done with it, you add a whole ICE power train. It's like two cars, one on top of the other. You double the problems."* It is yet another example of *"not seeing the forest"* cliché. They just cannot figure out why that single tree is having issues. Ugh. All I can do is point out the perspective they are not seeing with the hope there will be a glimmer of recognition of the true problem. Today was yet another attempt: Spoken like countless others here... enthusiasts focused entirely on engineering and not considering what's involved on the business side. It's a fundamental mistake we have watched play out by GM twice with Volt, both generations falling well short of expectations. The problem was indeed not understanding plug-in hybrids. They are perceived as more complicated than traditional vehicles, despite the fact that their transmissions & operation can be elegantly simple. Neither dealer nor potential customer recognize this. That belief of *"too complicated"* makes traditional vehicles an easier sell. This is why the *"coasting entirely on name"* argument against Prius success is often used by antagonists to justify lower sales of their own preferred plug-in. Their hope is to conceal the reality that Toyota found a means of overcoming the *"too complicated"* concern. They simply proved the reliability by demonstrating it. The name became attributed to quality. So even though it wasn't actually more complicated than a traditional vehicle, there wasn't any reason to make that argument. People felt comfortable with the choice... which is why dealers stocked the hybrid models and consumers purchase so many.

10-03-2018 Too Complicated, part 2. I continued with a second post: There's a catch, of course. It must also be affordable. This is the primary reason Volt was doomed from the start. The approach taken was far too expensive. So, even though it worked fine from an engineering perspective, that high price-tag screamed *"too complicated"* to potential customers... scaring them away... which the dealer sees as a very real problem they don't want to have to deal with. So, many didn't bother, choosing to not carry Volt. You'd be amazed how much of an influence MSRP makes. Enthusiasts of Volt learned that the hard way, spending years arguing *"it is worth it"* to an audience just plain not interested in spending a premium for efficiency. Look at the simplicity of Prius Prime. From hybrid to plug-in hybrid is basically nothing but dropping a larger battery-pack into the hatch area. Shoppers naturally equate increased capacity to an increase in electric power. How it happens makes no difference to them. It just makes sense... simplicity at its finest. They consider the option based on price-tag, not engineering. Like it or not, legacy automakers are in the business of making profit. That means appealing to dealer & consumer, not enthusiasts.

- 10-03-2018** **Concern.** Thoughts about how to compose a final response took awhile. I simply didn't care what this particular antagonist had to say, but still wanted a wrap-up of some sort. The concern of *"too little, too late"* turned into the frequent asking of *"Who is the market for Volt?"* over the years. There was no progress and no audience. That meant nothing had been achieved. So much opportunity was wasted, not to mention tax-credits. It was a ironic twist of resting on laurels. They claimed GM would not do what Toyota would do. Turns out, what actually happened was the very opposite. No need to point out any of that detail though. I referred back to the beginning and summarized as follows: In those old times, there was a refusal to acknowledge the market for Volt was not GM's own loyal customers, those who shop the showroom floor looking for a new GM vehicle to replace their old GM vehicle. It was all about conquest sales then... which are not business sustaining. You should be concerned about that not having changed yet.
- 10-03-2018** **Back To Basics.** Within the crazy banter expected from disappointing sales results for others, we get some refreshing questions simply asking for more information about how Prime operates. This one stood out: *"Car is "heavy" and unlike other "pure EVs" doesn't have that quick off the line zip in pure EV mode."* Naturally, there is no direct question actually asked. It is usually just someone trying to understand more by sharing their observations with the hope of getting constructive feedback. My contribution to that was: Compared to most pure EV choices in this market, yes. Compared to the traffic you'll actually encounter routinely, no. Prime is quite a bit faster off the line in ordinary driving. The reason why is simple. You drop the pedal with a traditional vehicle, the engine roars and everything shakes... so you avoid ever doing that. But with electricity, it is always smooth & quiet. So, you quickly become accustomed to taking advantage of that.
- 10-04-2018** **BMW i3 REx.** It looks like the increase of battery-capacity for i3 to 153 miles will hit a threshold of EV enough to make the gas-engine generator of little interest to the market in Europe. So, BMW will be dropping the option there. Think about how different driving situations are from here. Carrying a backup power-source simply isn't worth the value we place on it in our circumstances. In other words, they don't drive as far. It may also become a reality that charging-stations will emerge as common enough to worry of getting stranded simply isn't what we have. I suspect the next upgrade will end that offering here too. After all, why is that much considered necessary anyway? The newest model of Leaf delivers a range rating of 151 miles. That's enough for many Nissan customers. Why not BMW too? It's a very good question to ask... and quite timely, as we see the phaseout trigger approach for GM without any clarity what future for Volt or Bolt will have to come. Will there be a more affordable version of Bolt be offered, using a smaller battery-pack to reduce the price currently unreachable for the masses? Volt isn't selling well, even with the \$7,500 tax-credit. What makes the complicated & expensive design it requires a good approach for ordinary GM consumers? Needless to say, we will see much close evaluation of value in the very near future.

- 10-05-2018** **Called Out, part 1.** I let things settle a bit, then fired by my assault: Dismiss what you don't like, then personally attack the messenger hoping important facts get forgotten along the way. That pattern of terrible behavior was same activity here for so many years, people who wanted to be true supporters stopped participating and left. I was curious how the remaining few voices would respond, hence a brief return from being gone to find out... and got a very clear answer. You were presented with solid facts, then repeated the same old nonsense. In this case, it was confirmation that the claim about driving at highway speeds would be under-powered was false. Detail of engine output was provided as proof. The small gas-powered backup delivers 25 kW, which is indeed enough power. To further validate that the effort here was to mislead, this is a quote from an owner who routinely has to deal with attempts to undermine the system from BMW: *"I've tested it myself, the i3 REX can cruise at 70-72 mph with A/C (Florida), 3 people, and all the stuff needed for a weekend trip with a toddler, and still maintain the charge."*
- 10-05-2018** **Called Out, part 2.** It wasn't over with a single post. I continued with: Data from my Prime also helps to show that claim is false. I have collected some data points using Charge-Mode. That's the ability to propel the car and recharge the battery-pack at the same time. During the summer while cruising at 65 mph with the electric A/C running, I witnessed a charge-rate of 6.5 kW. Two days ago, I charged from 45% to 75% in just 10 minutes. That's 1.58 kWh of electricity, which calculates to a rate of 9.5 kW. That short burst of power to the battery while on the highway is quite impressive. Yesterday with the temperature near freezing, I witnessed the charge-rate at 7.6 kW while driving at 45 mph and 8.1 kW while driving at 65 mph. It took 37.5 minutes to recharge the battery-pack from 0% to 80% while driving. Power was never an issue, at any time. It worked just fine... despite having an engine that Volt enthusiasts constantly claim is under-powered. Watching the same obvious attempts to mislead & undermine about BMW is unacceptable. You have been called out.

10-05-2018 **Surprise?** I found this comment within an article about September sales of interest: "*Not surprisingly, the Toyota Prius Prime lands in the four-spot for the month and the second-place position for the year as a whole, with sales on the rise from last month, at 2,213.*" So, I started a discussion branch in the comments to directly address it:

Actually, it should be at least somewhat surprising that was achieved despite large areas of the country not ever getting any real inventory. Rollout basically hasn't started in many regions yet. Here in Minnesota, some dealers only had a handful available for the entire year. Thoughts dwell on that holdout possibly being due to a mid-cycle upgrade on the way for 2019.

Toyota tends to quietly advance without much indication of when & how progress will take place. After all, the Prime/PHV design was a worldwide effort with lots of new tech and the opportunity to be used for other hybrids. In fact, we'll be seeing a plug-in hybrid of Corolla in China next year. There are also rumblings of CH-R hybrid getting the plug-in treatment, an easy step since it shares the same platform as Prius. We also see the great potential the next-gen RAV4 hybrid (just revealed in Paris a few days ago) has for support of a plug. Don't forget about the upcoming cross-license Subaru will have with Toyota for its AWD plug-in hybrid offering (2019 Crosstrek) either.

In other words, we see Toyota gearing up for a serious push to stir the status quo. So what if the battery-packs are small. That's still far more of a reach into the mainstream than any other legacy automaker is making to end the reign of traditional vehicles in the near future. Delivering profitable high-volume is quite a challenge. Having an entire product-line of hybrids easily adapted to offer a plug is a major step forward.

10-05-2018 **No Outlet Available.** How do you purchase a Tesla Model 3 without having a place to plug it in? The guy lives in a condo and apparently thought the process to get a charger connected would be simple. Ugh. A friend posted online with a request for help. I responded with the reach out suggesting: A key component to gaining access to electricity for charging at a public location is making it obvious to everyone that there is a transparent means of billing usage. If it is clear how that electricity is measured and who will be paying, then you get a blessing to proceed. The best way to do that is for the user to pay for an in-line meter to be installed. They start at \$39, so hardware cost isn't a big deal. With it, everyone can easily see how many kWh of electricity has been used by the charger. Having served on an association-board for several years, I know that you won't make any progress without a solid plan. You will need to show that you have considered every aspect already, including expected usage and anticipated monthly payments. btw, I only live a few miles from there if you need any help.

10-05-2018 **Not Easy!** I was quite amused to read the following... and not at all surprised: "*Thing is, offering a plug is *not* easy. Not only does it require a much larger battery - along with a place to fit it without compromising passenger/cargo space - but also a more powerful motor, and well adapted control software. The Prius Prime falls short on all of these measures...*" It was a reply to my post about sales. That provided a great opportunity to climb up on the soapbox, an unexpected teachable moment:

Like so many others, the assumption of how power is achieved is quite incorrect. In fact, that is so wrong, it's easy to understand why countless posts on this website don't recognize what has happened so far or what is to come.

Prius already has enough electric power. The traction-motor was always under-utilized due to lack of a large enough battery-pack. The draw simply wasn't available with less capacity. Combine that with a one-way clutch to add thrust from the generator-motor, you end up with a surprising increase for EV driving.

True, the stack packaging could be better, but that kind of improvement is what mid-cycle updates can deliver. We know for a fact the initial rollout of Prime focused on delivering a robust pack that offered much more punch for an affordable price... low enough to make it directly competitive with traditional vehicles. Size simply wasn't a priority for 2017.

As for well-adapted control software, there should be no dispute that was delivered already. The system is remarkably efficient, seamless, and adaptable. Don't overlook the fact that CHAdeMO charging is offered in Japan and speed of Charge-Mode is more than double the current L2 rate.

Lastly, don't forget that impressive larger hybrid system in the newest Camry and the upcoming next-gen RAV4.

In other words, it really is easy if you are aware of what it actually takes.

10-05-2018 **Incorrect.** The response to that was the same old spin: "*The Prime activates the combustion engine when more power is requested — so clearly the electric motor is *not* powerful enough on its own.*" And of course, that was followed by some hype for Volt. Ugh. I punched back with: Incorrect. That belief is the result of poorly informed writers rushing to deliver a review. Never trust at face value any article information coming from someone who sat behind the wheel for only a few hours. Most of what you get is anecdotal observations based on assumption. In this case, the review assumed "EV-AUTO" mode meant as much EV as possible. It doesn't. That actually means you are instructing the system to automatically start the gas-engine to maximize EV by saving it for the less demanding parts of driving. Owners... those who actually drive a Prime on a regular basis... will tell you not to use that mode if you want to keep the gas-engine from running. To get pedal-to-the-floor driving with just electricity, you must use "EV" mode.

10-06-2018 **Renewed Attacks.** That individual who created a new id just for the sake of attacking me had some sense pleasure returned from encounters of the past. The intent was blatant, quite obvious an effort to obscure & offend. I never cared. So now, all this time later, it's payback time. Each renewed attacked gets a return with research results. I now have the means of collecting real-world data... which is exactly what I do. Sharing that is my own sense of pleasure... vindication. In this case, I'm also helping deal with the obvious efforts to undermine BMW. It's so sad when a Volt enthusiast chooses to mislead rather than actually compete honestly. Oh well. I definitely have the upper-hand now. In this case, it was responding to this: *"Are you a BMW i3 expert? Are you a BMW engineer?? BMW does better than Toyota so your "experience" will never apply!"* That's what came after directly replying to his *"50 MPH"* claim. I was more than happy to continue contributing information: No data. No detail. No reason to listen. From me on the hand, I have lots to share. Today was another confirm of *"Limping in the right lane at less than 50 MPH"* claim having no substance. I set the cruise to 70 MPH, started up Charge-Mode, then watched detail on my aftermarket gauge. I witnessed a steady of power flow from the gas-engine at 23 kW while it delivered propulsion thrust to the wheels and 7.2 kW (at times higher) of electricity for charging the battery-pack. Just a little over 37 minutes later, the charging ended with the state-of-charge having reached 80% of the usable EV capacity from the 8.8 kWh pack (that's 5.07 kWh). What more proof do you need that a gas-engine with 25 kW output is capable of sustaining a cruise on the highway? My plug-in hybrid did it using just that rate of output while also replenishing the battery-pack at the same time.

10-07-2018 Leadership Shuffle. A stir within GM executive staff was inevitable. Remember what happened just prior to Volt rolling out? Everyone involved in the prior stage moved on. It seemed quite bizarre. When would any project advancing to the most vital phase... rollout... have those who know it best no longer be available. Reassigning them to other projects before work is complete made no sense. Of course, we later had our suspicions confirmed that such a shuffle eliminated accountability. Whatever goals had been stated no longer applied. Those now in charge were allowed to convey whatever narrative they wanted. They did too. It was an advanced move to deal with damage-control efforts. They knew Volt fell well short of expectations. Now all these years later, the struggle with Volt has grown worse. The ultimate goal of solving "*range anxiety*" issues ended up becoming Bolt, which has issues of its own. It's all quite a mess as the disastrous loss of tax-credits is about to make the situation an even greater challenge to overcome. No affordable solution for the masses is available yet. So, GM leadership is now changing. I chimed into that discussion with: Who is the market for Volt? That was the question asked hundreds of times with the hope of drawing attention to the reality that GM wasn't actually targeting its own loyal customers. Those shoppers walking around on the showroom floor hoping to replace their old GM vehicle with a new GM vehicle pretty much never encountered a Volt; instead, there was a line-up of SUV choices. Soon, GM will be adding another, the new Blazer. It is even has a base price of what Volt had as a goal, but never delivered. Conquest sales were all that Volt really ever achieved. GM attracted buyers from elsewhere, rather than actually stirring their own status quo. It happened with both generations, then carried over to Bolt. This all was made worse by the dependency of the tax-credits, which will soon begin phaseout. In other words, we need to see GM no longer afraid to address change to get their dealers interested. The problem is it will trigger the Osborne effect. A compelling plug-in choice for a SUV will sour the appeal of their guzzlers. There will be demand without supply. It's an ugly situation getting worse each year. So, the announcement of leadership shuffling is no surprise. That's long overdue.

10-08-2018 Renegade Plug-In Hybrid. We got this announcement today: "*The Renegade plug-in hybrid will be one of 30 different new models worldwide from Fiat Chrysler Automobiles to use electric, plug-in, or conventional hybrid drive systems.*" That couldn't be much more vague. There's no specifics... time, quantity, price? Nonetheless, it is still nice to see an expectation of change being set. Even if the efforts are only token at first, it does at least set the stage. Removing barriers is how it starts. None that diesel is finally gone, there's a "*What's next?*" type of mood. People expect change. That's why each generation of vehicle stirs new interest. The key is figuring out the right balance. Too much just scares away the masses. They simply don't see the worth when there's a lot of difference to accept. That's why enthusiasts have such difficulty trying to understand why niche vehicles don't appeal to mainstream shoppers. That audience isn't drawn the same way. This is the very reason why there was such a push a decade ago for hybrids to be offered as mainstream vehicles. So, it makes perfect sense that an ordinary choice like the Jeep Renegade would get targeted to become offered as a plug-in hybrid. Though, it does make you wonder why GM hasn't done that yet. My guess is concern about the Osborne effect. Fortunately, we don't see Fiat Chrysler in the same position.

10-09-2018 **Winter Travel.** A new Prime owner posted a question asking about how to prepare for a cross-country trip through northern states during the cold season. It seemed odd to ask. The advice given in reply was just plain bizarre though. Strange suggestions from those who obviously don't have experience in those conditions shouldn't reply. They do though. So, those of us who live in those regions try to deal with the confusion. This was my contribution: Here in Minnesota, Winter is simply called Tuesday. This coming cold season will be my 19th driving a Prius. It's no big deal. My suggestion is to make sure you have tire with good tread (all-seasons are fine) and don't drive like it is nice out. We take trips in Winter. The most demanding is during the holidays, from the east side of Minnesota through South Dakota to Wyoming. We encounter snow & ice on the highway. There's no drama. Just be alert. Slow down. Keep safe distances. That's all we do.

10-09-2018 **Lexus Approach.** The recent advertisement push from Lexus to electrify its product-line sure has some EV supporters spreading FUD concern. It's ironic how they perceive that effort to phaseout traditional vehicles as somehow being against a plug-in future. They don't recognize how short-term market change can have a profound influence on long-term support. I was intrigued why they felt it was an all-or-none situation. Turns out, some of that concern stems from not really knowing what Toyota actually offers. This is especially difficult to recognize from only looking at Lexus, which it turns out many have. I brought the discussion back to a little bit of a constructive nature by providing some obviously absent Toyota detail. Hopefully, this will dissipate some of their Fear, Uncertainty, and Doubt about Lexus intentions, as a reply to a post where there was an obvious lack of keeping up with upgrades: That misunderstanding of Toyota's hybrid system is quite common. Most of it comes from outdated information, a common problem after a technology has been around for over 20 years. Prius Prime introduced to-the-floor electric-only acceleration by adding a one-way clutch to the existing hybrid system. This allows the generator-motor to contribute propulsion power. Combined with the traction-motor and a larger battery-pack, you can acceleration & drive from 0 to 84 mph in EV mode. In the larger hybrids, like Camry & RAV4, it's easy to see the power potential Toyota's hybrid system has to offer with future plug-in models at little extra cost. Prius Prime also introduced charge-mode. This is a feature designed to recharge the battery-pack using the engine. It sounds counter-productive, since plugging in would clearly be more efficient overall than gas consumption. But surprisingly, it can still yield useful results. You can use the electricity later for local travel, a handy feature when on a long-distance trip without any outlet available. At 70 mph in Fall temperatures (low 40's for me last weekend), I was able to recharge the battery-pack from 0% to 80% EV capacity in a little over 37 minutes. That's 5 kWh of electricity generated while also delivering 40 MPG during that travel. In short, most people are not aware of what's possible after 20 years of refinement.

- 10-09-2018** **Lexus Potential.** My effort to educate continued: Clearly, you didn't see the recent Paris reveal of the next-gen RAV4 hybrid. 36,995 sales of the outgoing RAV4 so far this year in the US market have been hybrid. Think of the potential for both getting customers to abandon traditional engine-only models in favor of the hybrid and how much easier next time around it will be for them to purchase a plug-in model. In other words, Toyota (and Lexus) are setting the stage for when large capacity battery-pack offerings become realistic. Face it, they currently are not yet. Between the high-cost & production-limitations, it just plain is not viable for the masses yet. In a few years, it will be. Remember that luxury buyers tend to replace their vehicles sooner than those of us in the mainstream. So, the Lexus approach will naturally be different anyway. Again, think of the potential. How much would it really take to add a larger battery-pack and one-way clutch to that SUV platform to offer a plug-in hybrid model for both Lexus & Toyota shoppers? The raised platform makes a good means of introducing an EV model as well. So what if a few more years must be waited. We have had GM and VW (both legacy automakers) making "*in a few years*" announcements for quite awhile now. At least with Lexus, we see a clear effort already underway to phaseout traditional offerings.
- 10-10-2018** **Suggestion.** Hearing about a bill that was proposed to abruptly end tax-credits for plug-in vehicles has caused quite a stir. Those who proclaim "*laggard*" are celebrating. They see the 200,000 vehicle limit as a barrier to success. From their perspective, they see it as an unfair advantage... since they believe the competition is other plug-in vehicles. In reality, the competition has always been traditional vehicles. That subsidy money was to be used for helping the shift away from guzzlers. It was support for electrification, not to boost the reputation of those who rushed to market with a product unable to compete. Needless to say, there's an obvious panic building about GM support taking a plummet. We already see Tesla taking away attention from the bleeding-edge audience. The mainstream audience is far more fickle though. That's where the legacy automakers needed help. That's was the intended purpose of the tax-credits for them. Instead, GM squandered that money. Looking back, it's easy to see the wasted opportunity. So many chances to bring about change were neglected. I called them "*missed*" at the time. Now, it's easy to see those involved simply didn't care. The bet everything on hope of an abrupt shift, a very risky gamble with serious consequences. That mess must now be dealt with. I kept my reply to the situation very simple: Revise the bill to reward those building vehicles that actually target mainstream consumers.

10-11-2018 **What Will They Sell?** That suggestion of targeting mainstream consumers was not well received. There's a lot of hate still for having been wrong about the market... and me being correct. There's nothing to gain from saying "*I told you so.*" though. Instead, I push the look forward by asking an important question: Don't overlook the purpose of the tax-credits and why the phaseout stage switches to unlimited quantity. That subsidy was to assist each automaker with production & distribution, allowing them to get their product to a high-volume profitable sales level prior to hitting that 200,000 threshold. This would make it easy for dealers & salespeople to continue on with business-sustainable sales, despite the reduction of that boost from the government. GM didn't focus on their own showroom shoppers; instead, sales focus was on conquest. Rather than use those tax-credits to entice their own loyal customers to replace their aging GM vehicle with a new GM vehicle offering a plug, they focused on selling more traditional SUVs... hence the introduction of both Trax & Blazer, neither featuring a plug. Existing popular vehicles didn't get Voltec (the technology in Volt) either. The rollout stalled with a compact hatchback that wouldn't be competitive on the showroom floor without the tax-credit. In other words, consider the true competition problem. What will dealers prefer to sell?

10-11-2018 **What Happens Now?** I keep pushing for answers... or at least acknowledgement: GM squandered their tax-credits, using them for conquest sales rather than changing the status quo. This was the problem brought up as a concern way back in early 2007, when details of development indicated more of a trophy-mentality. Praise for performance became the draw. It should have been what it meant to actually be green. We saw the potential for an EV that guzzled electricity. But the bankruptcy recovery plan addressed that by raising the "*too little, too slowly*" concern. Volt could be rolled out any way that would stir market interest, then GM would move on to a more practical offering. Problem is, that never happened. Instead, Toyota & Hyundai stepped in with efforts to deliver EV offerings that used less electricity to travel the same distance. Sound familiar? Detroit obsessed with the wrong thing, yet again. History repeated. It's ugly now too, since so much time & opportunity was wasted. Look at the efforts delivered from Honda & Chrysler. Consider what BMW & VW are ramping up to deliver. The other big legacy automakers are taking the situation seriously... well, all but Ford. So, what happens now? What will GM reveal as that 18-month promise comes to pass, which just happens to be the same timing as the tax-credit phaseout transitions to the 50% level?

10-12-2018 **Compared To What?** All I can say is: Wow! This article title, from a supposed GM expert, caught my attention: "*With the 2019 Chevrolet Blazer, GM May Score Another Win Over Toyota*". Knowing the next-gen RAV4 coming in a few months will be rather impressive, I was quite intrigued to find out what the writer had to say. To my bewilderment, there was no mention of RAV4. Instead, the entire article compared the upcoming Blazer to Venza. That's right. The 2019 GM was compared to a 2009 Toyota. It made no sense whatsoever. The claim that Venza was the only proper comparison, since it was a CUV just like Blazer, was beyond absurd. It's the same old nonsense we dealt with for Ford. Remember when C-Max was compared to Prius v rather than the regular model Prius? The hope was no one would take the time to discover that was totally inappropriate, that those 2 vehicles of the time were very different sizes. Turns out, all the MPG claims Ford made were bogus too. Even though Prius v was larger, it did in fact deliver higher efficiency. It was a misleading effort that failed on multiple fronts. So, there's not much reason to be concerned with this either. Though, GM did briefly try to portray Bolt as a CUV. It is obviously a compact wagon. Blazer is obviously a SUV. It will be compared to RAV4... even if some fans attempt to spin it as something else.

10-13-2018 **Understanding Customer Priorities.** Now, all I can say is: OMG! The spin simply takes a different form. "*Let's Talk About Engine Stop-Start, Part 3: Stop-Start On The 2019 Chevrolet Blazer*" This was especially bizarre. It sighted the mixed feeling about the rapid fuel-saving strategy of halting the engine everytime you come to a stop works. Part 1 focused on the design and feature random customer comments. Part 2 mentioned how it could be disabled, using a system hack. Part 3 pointed out how the newest offerings provide a button. All of it left you wondering what the heck the point was. Why would you spend so much time & effort for a feature that customers could shut off? Remember how Prius was mocked years ago for behaving like a golf cart? It didn't actually. But since most people didn't understand how the hybrid system actually worked, they assumed incorrect. This feature from GM actually does work that way. What was GM hoping to accomplish? In other words, this is yet another example of the problems faced when not understanding customer priorities. This is why I so often end online posts with: Know your audience.

- 10-14-2018 Profitable.** Time for a reality check. I see a stir growing for GM's well being. That hope many had held onto with nothing to support such optimism is falling apart. For far too long... well over a decade... focus had been almost entirely on engineering. When you have an economy that's recovering and a generous tax-credit to help new endeavors along, it was a time for taking some risk. It's wasn't a time for catering to enthusiasts though. That bordered on stupidity even back then. Now, it's being looked upon as just plain foolish. What was GM thinking? How could a vehicle resembling a Honda Fit possibly compete directly against a sleek looking sedan? Bolt never made any sense at that price and we knew cost wouldn't drop prior to tax-credit phaseout to make it even remotely competitive. Who among GM customers would be interested? This is why further investment in Volt technology to implement it within a SUV would have been a far better choice; instead, the approach of further deploying that tech was abandoned entirely. I jumped into today's discussion with a dose of business reality, a bitter pill for many to swallow: GM's profit is mostly from large guzzlers. That's a formula for major financial challenges to come in world of high production-cost choices with a plug. Their opportunity to focus on affordability was, sadly, wasted on conquest. Attention should not have been on chasing Tesla customers. It should have been on their own demograph. Legacy customers will be very difficult to sell narrow-margin vehicles to.
- 10-15-2018 Value.** You'll find that enthusiasts have very different priorities than mainstream consumers. What they value is what they feel is most important. That's often a want, not a need. Mainstream consumers tend base more of their purchase criteria on necessity. This is why the shift to smaller SUV choices has seen some success. This is also why saying "*it is worth it*" does not influence such an audience. True, some of what enthusiasts focus on is beneficial. But selling the idea of paying extra for a premium feature is challenging, even if it is worth it. This is why the tax-credit only had an influence on early-adopter buyers. Know your audience. For GM, it was those willing to accept risk. For Toyota, it will be those wanting a vehicle already well proven. How to approach audiences with so little in common explains why we have rollouts so different. Unfortunately, many looking at the tax-credit are not as mindful. Short sightedness blinds them from recognizing this is not a one-size-fits all situation I try to provide that insight: Punishing automakers who carefully studied the market, rather than rush to it, doesn't make sense. They will provide that better value for the money. It's unfortunate opportunity was wasted, but that's no reason to pull the plug (pun intended) prior to others getting a chance... those who took the time to do it right. Keep in mind how few vehicles 200,000 actually is. Our market alone sells over 17 million new vehicles every year.

10-15-2018 **Video: Charge Mode (drive data).** Planning for this particular capture got quite involved. I needed to verify numbers, to make sure I wasn't choosing a circumstance that misrepresented what you'd encounter from ordinary travel. So, I tried it several times while on my recent trip to Northern Minnesota. That set some realistic expectations, as well as provide me with a few ideas about how to best film the drive itself. You'll see that in the new layout for the video. I needed a decent span of time to actually do the filming too. So, this was quite awhile in the making. It turned out well. Here's my comments with the publish: Charge-Mode is a feature Prius Prime offers where the gas-engine can be used to recharge the battery-pack. In most cases, this isn't as efficient of a charging option as just using the plug. But when you are on a road-trip and don't have an outlet available, being able to generate electricity while cruising on the highway can be helpful. That electricity can be used later when you are driving short distances at your destination. That avoidance of engine warm-up is overall beneficial, especially when taking advantage of steady-speed driving to charge. Watch data presented on that phone-app (vertical display on the right) connected to the car using an aftermarket OBD-II reader. It provides detail about power coming from the engine and how much of that is diverted to the generator while charging. Note overall results upon reaching completion. Also, notice the turn-around about halfway through the drive. This helped to take into account any influence of wind or hills. Watch it here... [Prius Prime - Charge Mode \(drive data\)](#)

10-16-2018 **Explain.** I was asked to provide some insight to what I was sharing in that video. Feedback like that is how you "*know your audience*". Understanding comes from exchanges just like this. With such diverse backgrounds from people participating in discussions online, that's a good way of moving forward. So, I tried my best to convey more information without being too overwhelming with detail. This will hopefully be effective: The aftermarket device with phone-app give an inside view of what's actually happening as you use the gas-engine to charge the battery-pack. It's especially important to understand, since misuse of the feature could have a negative impact on overall efficiency. Also, other plug-in hybrids may not operate in the same manner. What stands out for me is the bar in the upper-right corner. That shows how much electricity is getting sent to the battery-pack from the generator. Notice how that value is often in the low 7's for kW rate? It's proof that Prius Prime can already accept a faster recharge... another Toyota design feature that's under-utilized initially. That's a common practice for their tech rollout.

- 10-17-2018 Zero-Emissions Vehicle Division.** Investors of Toyota understand long-term plans and clearly see beyond current early-adopter hype. Prius Prime demonstrates a profitable path to affordable plug-in hybrids. Enthusiasts don't see that. So, response this announcement of a new division being created being negative online is no surprise. Other automakers are doing the same thing, but they don't get the spotlight. Green has been measured against Toyota for the past 20 years. So when you hear similar from VW, it's definitely not the same. They have to diesel disaster to overcome, being forced to help with our country's electrification effort as a result of the pollution added by their emissions cheating. GM isn't the same either. They put tell a story of electrification, but there's little actual substance behind it. Their offerings aren't selling well and there's no investment toward infrastructure. That's why so many turn to Toyota with the hope of rapid advancement, not understanding the work it takes behind the vehicle itself... hence today's press release. It comes down to raising awareness. It couldn't have been done any sooner either. This early-adopter phase we are only now starting to see beyond is how a receptive audience of mainstream buyers is beginning to emerge. Until tax-credits expire, not much with respect to acceptance by the masses will matter. Ordinary consumers just plain don't care. In other words, the difference between short-term and long-term strategy should be easier to understand now that the short is coming to an end.
- 10-18-2018 Watching It Fall Apart.** We seem to be rapidly drawing near to an end of GM's current existence. The reality of what I had been saying for years is becoming so difficult to deny, there's no strategy to repel it. All of the excuses have been exhausted. All of the distracts have becoming uninteresting. All of the hope had faded away. They have nothing left. Heck, even personal attacks fall apart. I wondered how it would all come to an end. I always knew what the timing would be though. Such heavy dependence on tax-credits made it obvious. Sales of GM plug-in offerings were a major struggle even with that \$7,500 subsidy and basically no outside competition. But with Tesla, Nissan, Honda, and Toyota all making their mark, you don't even need to consider the new pressure Hyundai, BMW, and VW will add. It's a mess that will grow worse very fast. I jumped into the floundering defense of GM with: It has been interesting to read opinions here from those who endorse niche approaches with hope of mainstream acceptance. Their opinion makes sense from an engineering perspective, since design is usually well thought out. But from the business perspective, their stance is disastrous. Betting the farm on a plug-in choice that will mostly likely never be competitive with that own automaker's traditional choices is like watching the Titanic sink. What's the point of pushing a product that dealers won't accept? This dislike for Toyota's recognition of need is bewildering from a group claiming to want the masses to embrace plug-in technology. So what if the specs aren't pushing the envelope? That isn't how business is sustained. Niche offerings are impressive, but it the so-called "*boring*" vehicles that bring in the dependable profit. It's ironic how much Prius gets mocked for being plain, ordinary, unexciting; yet, millions have sold. That's the very point of mainstream acceptance. Being ubiquitous means not standing out. Oh well. Some people won't ever figure it out. That's their loss, not Toyota's.

- 10-19-2018** **Guzzling Electricity.** There are a number of EV offerings now available that guzzle electricity. Unlike Toyota, some automakers simply haven't bothered optimizing operation. They just figured out how to make a vehicle go with battery & motor. The effort to refine their propulsion system isn't as much of a priority as simply having a presence in the emerging plug-in market. That's overwhelmingly obvious with the reveal of I-Pace today. That will be Jaguar's first offering. Focus was clearly on speed & power, not efficiency. Rating numbers make that obvious. *80 MPGe City. 72 MPGe Highway. 76 MPGe Combined.* With values that low, it's compete with Prime's 133 MPGe rating. But then again, it was never intended too. Nonetheless, you don't want to just waste a fuel... even if it is greener than gas. Of course, generating electricity isn't as clean as it could be yet. Sadly, we still get electricity from coal in many states here still. For perspective, remember that Volt was rated at 106 MPGe... in a market where efficiency gets far more attention. But then again, compared to Model 3's best rating of 130 MPGe, that value of 76 is pretty bad no matter how you look at it. Luxury or not, guzzling on that level isn't sending a good statement for EV adoption. Think about how much more battery is needed to deliver competitive range. That makes the vehicle very, very expensive.
- 10-20-2018** **Charge-Mode Warming.** It's getting cold here (Minnesota) now. That brought about an idea. A new use for Charge-Mode came to mind: electricity for warming the cabin. If you have the engine running in an efficient manner before parking anyway and you'll be coming out to a cold car later, why not? That new video shows it would only take a few minutes to generate enough electricity for that. The point of Prius is to significantly reduce emissions & consumption, not to eliminate them entirely. That's use of electricity is clearly an improvement over what traditional vehicles do... just run the engine while the vehicle is idle. It's another way of squeezing out efficiency, while at the same time improving the driving experience. Think about how the smooth & quiet of Stealth-Mode evolved into EV. We get preconditioning from the plug to warm the cabin anyway. If that occasionally comes from the gas engine, it's a little bit of an offset. There's tradeoffs with technology. Having a flexible system can allow you to optimize. So, give it a try.

10-21-2018 **Gone.** The biggest of all the antagonists, that one who would always try to get the last word in, is finally gone. He used every trick in the book to try to get me to stop posting about how GM was missing opportunity. So much time was wasted on conquest. Not targeting mainstream consumers made it a futile endeavor. How could a legacy automaker thrive when none of its traditional offerings had the choice of a plug? Status quo not changing is a recipe for failure. None of their vehicles even became greener. Popular choices, like Equinox & Cruze, instead added a diesel option. No plug. Not even a hybrid. It was a disaster in the making... with the tax-credit phaseout as the undisputable end. Unless GM would be able to achieve profitable high-volume sales with the potential to be sustainable prior to hitting that point, it would all be over. Now, we see that is exactly what's happening. Those 200,000 credits weren't used to actually bring about change on the dealer's showroom floor. Their loyal customers never showed any interest. All those years of expressing the "too little, too slowly" concern have been validated. In fact, it will be precisely 1 decade when the final moment is reached. That will be the end of March 2019... exactly when the phaseout changes the credit is cut to 50%... and exactly when GM's 18-month pre-announcement wait limit will be reached. The assumption is Detroit's auto show in January will bring about that long-overdue change announcement. The antagonist abandoned ship already though. His die-hard effort to protect the reputation of GM ended with the purchase of a Tesla Model 3. Knowing the absence of tax-credit help would basically kill Volt & Bolt, he gave up. There's simply no way such small vehicles with such large prices could appeal to GM customers. We've been watching the GM stockholders get nervous as share prices remain flat and even more dependency on high-profit large vehicles continues to grow. There's no path forward. It's not like Toyota, where the entire product-line at dealers will be offered with a hybrid option. He's gone now. He doesn't have to listen to my sensible analysis of business choice. GM chose poorly.

10-21-2018 Cannibalize ICE Sales. The topic of ICE (Internal Combustion Engine, better known as "*traditional*" vehicles) replacement is finally getting some proper attention. Most of the plug-in enthusiasts simply didn't care when the tax-credit was available. But now that it is about to trigger phaseout for GM, there's a state of panic growing. Taking about vindication for my "*too little, too slowly*" concern over the years. I predicted this very dilemma ages ago. But instead of getting constructive feedback, I got attacked... over and over and over again. Thankfully, my thousands of blog entries serve as proof of the level of resistance people have to change. So many techniques & excuses for not dealing with problems and taking responsibility... Ugh. Anywho, today's discussion topic really hit that mark. It focused specifically on GM. I jumped in with one of the first comments posting:

It's as simple as asking how our children will look back at this. You had the technology; yet, you chose to not make an effort to actually use it to change the status quo.

That has been GM's problem even before the plug. They had Two-Mode, then abandoned it. They had Volt, but roll out the tech to any of their ordinary offerings. Loyal GM customers looking to replace their old GM vehicle with a new GM vehicle simply had no choice. After all those years of supposedly being market leader, you still cannot purchase a green model of a traditional vehicle from GM. Their SUVs should have taken on the plug-in Two-Mode design a whole decade ago. Remember the prototype plug-in Saturn Vue?

Seeing GM move on to Bolt is a head-scratcher. Are they going to abandon plug-in hybrids entirely, completely contradicting their own "*range anxiety*" approach they pushed for all those years? If so, when can we expect a competitively affordable version of one of GM's traditional vehicles as a EV model?

Toyota is often claimed to be an industry laggard, but their path to electrification is clear. Prius already offers a plug. Corolla hybrid will next year as a plug-in hybrid. A model of CH-R hybrid as an EV is expected to follow. There are new generations RAV4 and Highlander hybrids on the way. Camry & Avalon hybrids are now available and competitive with their traditional counterpart. There is even a rumor of a new CUV hybrid on the way. All that is most definitely an effort to change the status quo.

Legacy automakers have the enormous problem of getting their dealers to embrace change. If they aren't interested in stocking green inventory, there's no way for shoppers to actually make a purchase. Cannibalizing ICE sales is much easier taking a smaller step to the plug by offering something compelling with a battery-pack first.

Watch what happens with GM over the next few months. Their tax-credit opportunity wasn't used to change behavior of their own dealers & customers. It's going to be a painful transition as a result.

10-21-2018 Osborne Effect. It was interesting to read a detailed post about GM's predicament, explaining how they were now facing innovator's dilemma. Anyone unfamiliar with the what that means would have easily accepted what had been attempted to be explained. I knew that was quite wrong. To be that situation, it would be a struggle of how to improve Volt to attract a wide audience. GM had listened to enthusiasts, resulting in even more of a niche. So, that does sound right. But GM has pretty much abandoned Volt entirely. There is no effort to delivering something with those characteristics for mainstream buyers; instead, GM must basically start over. See the problem? They have the tech already. So, that isn't the challenge being faced. It's the impact the next offering will have on GM's own current market. It could be profoundly negative... since the choice itself would likely be very positive. This is called the Osborne effect. Look it up. The name came from a real-world "oops!" in the business world that had disastrous results. Knowing that, I replied: No, that isn't the case. It was with Volt though, but that is the past. The situation now is different. The moment GM announces a plug-in hybrid SUV, sales of the traditional model will stall. It's known as the "*Osborne Effect*".

10-21-2018 Serious Discussion. Today's topic about the problems GM is about to face sure is stirring the pot. I jumped back in almost immediately, responding to a post starting with: "*As soon as one of the Legacies gets serious about US EVs, the whole house of cards will come down...*" It was followed by a vague statement that didn't actually say anything. There was no next-step suggestion provided. You know, I won't settle for that:

What does "*serious*" actually mean? Think about the situation from a mass-market perspective. How do mainstream consumers shop?

From a dealer perspective, that means the vehicles with a plug must be cost-competitive to the traditional offering. GM's approach with both Volt and Bolt have been disastrous in that regard. Neither supports a profitable approach and neither even resembles anything in their current product-line. What loyal GM customer would be interested? Seeing such strong demand for the highly profitable SUVs that GM dealers carry, it's easy to recognize the lack of interest.

Salespeople face an even greater challenge. Should the dealer decide to push plug-in choices, what incentive is there for a change sales approach? A fast & large commission from a traditional SUV is far more appealing than making an effort to educate a consumer about how to upgrade their garage for plugging in. That's a major challenge to address without even talking about the vehicle itself.

Think about how much easier the transition could be getting customers who already own a plug-in hybrid charged with an ordinary 120-volt outlet to consider the upgrade to an EV with a 240-volt charger. In other words, expecting a jump directly to EV for masses is not a "*serious*" approach... especially when you consider cost & production restraints. 17 million new vehicles in the United States alone are purchased every year.

- 10-21-2018** **Rhetoric Spin.** It has actually been awhile since someone tried to stir the pot: "*Toyota has dragged it's feet all along the way.*" That was to be expected though, on a discussion thread about the challenges GM is about to face. I don't let that opportunity for me to point out observations of my own on the topic. So, I did: That's just rhetoric spin. Anyone taking the time to actually look at the technology Toyota has delivered, they would see a remarkably efficient & affordable design. Their approach of rolling out first to hybrids is a very effective means of establishing high-volume production to take advantage of economy-of-scale benefit... which is absolutely vital for a successful paradigm shift. The upcoming next-gen RAV4 hybrid is another big step forward. Like with Camry hybrid, we are witnessing great potential for vehicles larger and more powerful than Prius to capture sales from a very large audience. So what if a model without a plug isn't available yet? Motor & Inverter production is well underway. Real-World rollout of their heat-pump and carbon-fiber tech is taking place too. Let's not forget the lithium battery-cells being used either. In other words, the claim of "*dragging*" actually reveals Toyota's electrification effort to reach mainstream buyers without tax-credit help is well underway.
- 10-22-2018** **Frustrated GM Investors.** There's a lot of attention growing for GM. The reason is simple. A comprehensive third-quarter financial report is about to be released and the prospect doesn't look good. It's much like the lead up to bankruptcy a decade ago. Profit depended heavily upon large Pickups & SUVs. Investors want sedans to be phased out entirely to help keep that revenue stream flowing. This time, there aren't serious retirement losses at stake though. Instead, it is the reality that neither Volt nor Bolt captured customer's interest. Both were major resource drains that didn't result in new revenue. Not deploying the technology into a mainstream vehicle shoppers would be drawn to was a colossal mistake. The stock value for shares here and for the division in China, which had been flat, are now both down. There is the uncertainty of GM in Korea as well. Authorities are questioning whether or not GM's 10-year commitment as part of that division's bailout early this year will hold. Needless to say, pressure is building for the CEO to be replaced. It seems like a narrative, something I would make up... especially since the timing of the tax-credit phaseout is drawing so near. But anyone who has been watching closely for the past few years would recognize my push for GM to take a next step forward. Volt's gen-2 upgrade was a step in the wrong direction, delivering more for enthusiasts and even less for GM's own shoppers. Bolt has just been a confusing mess; it changed the message for "*range anxiety*" and was supposedly designed to compete directly against Tesla's Model 3. Needless to say, sales of both are well under expectation. Sound familiar? Remember the timing & circumstances of Two-Mode's death? There was a genuine concern about "*too little, too slowly*". The situation now confirms there was valid reason for it. To all those who attacked me for pushing for an actual change to the status quo, rather than appealing to early-adopters, you now have frustrated investors to deal with.

- 10-23-2018** **Looking Ahead.** I shared some wisdom: Knowing there will be a mid-cycle refresh of the regular Prius and that tax-credit phaseouts will shake up the market, it is reasonable to wonder if something could change for the 2019 Prime. Late November is the LA auto show. That is likely when we'll either find out or get a teaser. My guess it will be the latter with a full reveal in Early January for the Detroit auto show. Think about the positioning of GM with respect to plug-in hybrid choices. The expected 50% drop for their tax-credits in April and how much of a struggle sales have been anyway, it makes sense that Toyota has simply been laying in wait. After all, we saw them do the very same thing already. We witnessed the quiet of gen-1 plug-in Prius, with lots of spin during that supply halt that was just plain wrong. Why compete when it will only serve to confuse potential customers, especially when you can focus on refining (production, design, cost, etc.) in the meantime?
- 10-24-2018** **Spreading Narratives.** It was called hype, seemingly so far back, you could say "*once upon a time*". That was obvious. You hope for a miracle. It turned into "*fake news*", where there was on-going effort to deceive using enough apparent material to form a believable story. When confronted, the story simply changed to something else. Each time built on assumptions and the knowledge that most people don't apply critical thinking. Just accepting what you are told at face value, without ever bothering to research, is key. That eventually fell apart, since you can only change the story so often before people get confused. Now things are settling back into an approach of spreading narratives, where you just keep telling the same tale repeatedly. You don't even bother to provide any substance. For example: "*The hybrid is going to be phased out, and it's sad that Toyota is going to be dragged kicking and screaming into the future.*" Sadly, I run into claims like that often. There's nothing at all provided to so support it. There's just a mantra repeated over and over. I keep my reply simple with: Toyota already produces electric-motors, controllers & chargers, battery-packs, and a rather impressive heat-pump. They are setting the stage for large-scale customer acceptance of plug-in vehicles, as well as refining their production & software along the way.
- 10-24-2018** **Facing Reality.** This quote speaks for itself: "*So what does GM do now? They've used up their 200,000 tax-credits that were supposed to help them transition to non-subsidized plug-in cars, but I don't see any future product plans. The Bolt and Volt are not compelling products without the tax credit, so unless they can cut prices on them and be profitable (doubtful) where are they?*" Seeing such a sentiment pop up from time to time now in discussion threads is encouraging. Rather than an army of enthusiasts doing everything possible to provide excuses, there's a message coming through expressing concern. I endlessly posted my own concerns about GM moving so slow, this day would come. Sadly, it seems as though the momentum forward has actually stopped. That's what is drawing attention now. Bolt clearly wasn't competition with Model 3. So, what is it? That was supposed to be GM's premiere plug-in product, an offering so impressive it was the "*range anxiety*" solution Volt failed to be. However, that perceived progress didn't result in strong sales. In fact, it's rather obvious the loss of that \$7,500 incentive will bring an end to the effort as we know it. I suspect early next year will bring about a reset of sorts... a reality enthusiasts really don't want to face. The claimed leadership position will be lost. Starting over is all but inevitable though. That's why milestones to consider lessons learned are vital. Skipping them, as enthusiasts did, makes the penalty for trying something different much later a much larger loss to deal with.

- 10-25-2018 EPA Dismissals.** We just learned that EPA has dismissed 2 advisory panels of outside scientists. They provided information about smog & repository concerns. That fear we had about properly addressing pollution related issues is proving to be a very real problem. There are clearly efforts underway to undermine. It's really sad when such blatant favoritism for business is put over the well-being of people & planet. This reminds me of what the administration 18 years ago did. They just ended a well established green program abruptly under the guise of starting a comprehensive study. Remember the PNGV program? They tried to pretend the existing effort had failed and this was a bold new initiative to stimulate progress. We all knew it was a reset. We also knew it would be half-hearted. The vague nature of what is being established as a replacement is a dead giveaway. We see people taking power who favor business over environment, people who will sacrifice a great deal to protect old-school industry. It's an effort to hold back progress. Think about the intentional damage relaxed regulation will cause. We know how to prevent, but choose not to. Imagine how future generations will look upon this time.
- 10-26-2018 Closed Minds.** There are a few on the big Prius forum who focus entirely on the short-term. They just plain don't care what's coming. That means any effort that's long-term is simply ignored. Closing your mind to anything except the immediate is a terrible waste, since it makes progress a challenge. People don't want to invest in the future. That's why the tax-cuts were received with such high praises. Barriers that move to live in the now created weren't taken into consideration. It's a selfish move. You intentionally sacrifice the future. Yet, there are many in our society who do that. This is how great powers fall. We have many examples throughout history. There is a cost to pay. Sadly, some contribute to the mess. You have to turn on former allies as a result. It's the figurative slap-in-the face, with a hope of waking them up to their complacency. Maybe it will work. Maybe it won't. The point is, I tried: You are feeding a greenwash narrative by cherry-picking like that. Prime was clearly designed for profitability. Compliance vehicles don't bother. Toyota's effort to deliver affordability is overwhelming evident that it is targeting mainstream sales. Choosing to only acknowledge the short-term perspective is intentionally misleading.

10-27-2018 **What A Mess.** There's an obvious effort beginning for GM's defense of their end as supposed leader. Proposing a new mandate was today's desperate move. It's obvious because it was so vague and set the bar so far back. Bold initiatives of the past are all but forgotten. It is that reset we've been expecting. I took the stage for this one. No soapbox this time. It's an all out battle declaration:

This is the same old rhetoric repeating, apologists cry FUD when actual change to the status quo is brought up. Inevitably, that is following by "*laggard*" claims as distraction. It all comes down to GM not having targeted their own customers with Volt or Bolt. Who shops the showroom floor of a GM dealer looking for a compact car to purchase? GM's audience is primarily SUV buyers; yet, all their SUVs offered are traditional still.

GM's plug-in hybrid tech should have been rolled out to a small SUV years ago; instead, there was an effort focusing on diesel. Both Cruze & Equinox diesels were offered post-dieselgate. Why? Now we see Trax & Blazer completing a full passenger SUV product-line, none of which offer a plug still. Why?

GM offered Two-Mode an entire decade ago. It was even followed by a plug-in prototype SUV. Yet, all these years later, there is not a single green SUV offering... nothing with a plug or even just a hybrid option... despite so much praise for supposedly being the leader of legacy automakers.

Now, we see an effort to downplay. Rather than make an effort to actually electrify their product-line, it's just more token gestures. Actually trying to change the status quo still isn't happening. Their dealer's showroom floors still look basically unchanged.

Toyota gets slammed all the time for their effort to change. Camry, Corolla, RAV4, CH-R, Highlander, Avalon... are all available as hybrids in different markets. That's an undeniable investment into electrification with an easy & profitable path to offering a plug. We also see Prime demonstrating potential for EV choices, by establishing production and promoting refinement of related EV components.

Remember all the hype about a "*Volt lite*" years ago, when enthusiasts tried to push GM to offer a more affordable plug-in choice? They knew the disaster of tax-credit phaseout would arrive someday, when GM would get stuck with plug-in vehicles totally unappealing to dealers. Why even try to sell an expensive choice that will deliver such little profit? Even if that inventory was stock, what salesperson would even bother trying to persuade a shopper for so little commission?

This has been a problem in the making since sales struggle of gen-1 Volt resulted in a dramatic price down... which didn't result in an overall sales increase. All these years later, we still see sales on the bottom of GM's list. That's a blatant sign the technology should either be diversified or abandoned. Seeing no progress in that regard to Volt and the rollout of Bolt as their solution to "*range anxiety*" instead, there's good reason to question motive of the recent proposal.

Notice the lack of detail and how low the bar is set for time & quantity? Rather than "*just do it*" to force the other legacy automakers to follow suit, there's a negotiation with

the our government taking place. Why? Talk is cheap. We're seeing pushes in Europe & China regardless of whether or not the United States joins in. The world will suffer from oil-dependency & climate-change regardless of whatever official mandate gets passed.

In other words, how long must we wait for an affordable Chevy Trax plug-in hybrid to finally be offered... or Equinox... or Traverse... or Blazer?

10-27-2018 *Getting Messier.* I got called a "*shill*" many times in the past for my critical thinking. They'd claim that under the pretense that it was really just a defense of Toyota. Seeing the reality that it was actually just good business sense for any of the automakers we too much to accept... because one can never agree with a competitor. Never wanting to accept the fact that traditional vehicles are the competition has been the problem. That means you much acknowledge a problem from within, rather than just blaming someone else for your own struggle. Oddly, they keep trying. This time though, it was so desperate, I was left beside myself. The claim now is that autonomous driving is an essential part of EV delivery. I fought back that nonsense with: Autonomy. Huh? The article topic didn't make any mention of it. That certainly hasn't ever been anything I've been interested in or even commented about. It's totally unrelated to any type of EV mandate. Why was it brought up? Let's try a different perspective... Profitability. That's how you know an automaker is attempting to deliver a product targeted at mainstream consumers. If the vehicle was designed to sustain high-volume sales, that's all the more confirmation you need. What does a mandate achieve? We've seen both Volt & Bolt rolled out as niche offerings, since they rely heavily upon tax-credits and haven't demonstrated appeal to GM's own loyal customers. If there was mandate already in place, it would be easy to label them a compliance rollouts. Remember, the goal is to replace traditional vehicles. That's means what is found on dealer's lots must change. Waiting many years for a few token offerings is not enough. The entire product-line must have some type of path to electrification. Without that, dealers simply won't bother, which means potential customers won't have anything with a battery-pack to purchase.

10-27-2018 *Phew!* It's nice to enjoy a pause from the fight. This was just an ordinary response to an ordinary discussion, a very nice change from the growing mess: The genius of Toyota's approach has been flexibility. "*Just drive it*" provides results well above that of traditional vehicles, regardless of your driving circumstances. The addition of a plug builds upon that. When you recharge from an outlet, results are amazing no matter what you do with that electricity. Having the option to recharge using the gas-engine is a bonus. If you want to exploit the design to squeeze out even higher efficiency, you have that ability. It is by no means necessary or required. Some owners will never take advantage of having it. Others will exploit the opportunity. The point is, you are given that choice. So, we make an effort to explain how it works. Keep in mind that you also have the choice of recharging speed. For 120-volt connections, you have 8 & 12 amp options. For 240-volt connections, it is currently limited to 3.6 kW. As demonstrated by this video, you can see that 7.2 kW may be offered in the future. It's a flexible design. Toyota carefully studies how it is used & responds and tweaks choices accordingly. Give it a try.

- 10-27-2018** **Whoa!** I just had a parking lot encounter at lunch today. It was with my 2003. I was able to confirm up close that it was indeed my old Prius from 15 years ago. The package was a rare choice, quite distinct in appearance, and I put a very unique dent in it. That was strange seeing it after having upgraded 3 times since the trade. There were a few new dents and one of the headlight fogged. But otherwise, it looked fine and was obviously still in use. Too by I wasn't able to chat with the current owner. I had been looking for years, hoping the purchase was local. I did see it roughly a month after having upgraded, but not since. Doubt about ever seeing it again is realistic; though, today was a heck of a surprise. At least I know it survived beyond the duration anyone expected it to. That's a great endorsement for Toyota's forethought. They really designed a system to last... something quite realistic for ending the reign of dirty guzzlers.
- 10-28-2018** **Behind.** It has been interesting watched firsthand: *"The fact that you continue to stick up for Toyota says it all. Had they continued to push forward to EV they would be light years ahead. They have buried their collective heads in the sand. When they come out with an EV they will also be years behind vs. the years ahead they should be."* That story is told over and over again... but without substance. There isn't ever any detail provided to support the claim. They just get angry and declare *"behind"* without follow up. Having studied business so extensively in college (it was my minor) and worked in retail for that many years, then followed the automotive industry closely for the past 2 full decades, I know what I'm talking about. You don't study so much for so long without recognizing success patterns. There's also my passion for computers which dates all the way back to the 70's. Watching that industry evolve was quite exciting. Anywho, I get tired of those who don't bother to do their homework. Making empty claims is unacceptable. If you have good reasoning, share it! Don't just start a quarrel without any intent to back it. Geez! Oh well. That's what I have to deal with. In this case, I responded with: Behind what? The market hasn't even emerged out of the early-adopter stage. Whether or not you accept the fact that Toyota is working to refine their already available EV drive, plus related components & software, is not their problem. They are busy setting the stage for dealer & salesperson, as well as building a process for traditional vehicle phaseout. It never ceases to amaze me how some feel *"ahead"* should be quantified based on short-term measure, even though production cost is still out of reach and energy-density still isn't quite there yet. As for where they should be, where exactly is that? There's no basis for a mass acceptance of plug-in vehicles yet. High-Volume sales without subsidy haven't even been attempted yet. Reliance on tax-credits is a problem Tesla is scrambling to avoid though, but it is not a legacy automaker. GM is and will inevitably pay the price from not having a competitive product prior to triggering phaseout. Toyota still has time and will smoothly pass by from having taken the slower path to adapt a system capable of sustainable profits with a clear path to a wide variety of plug offerings. They carefully studied the market, rather than rushing to it. It's like watching the Tortoise & Hare story playout right before our eyes...

10-29-2018 **Possibly Failing.** You can feel the pressure growing. With Tesla speeding ahead, the decisions for legacy automakers is finally getting some necessary attention. That's long overdue. Direct comparisons to a well-funded investor-supported startup is a terrible measure progress forward for the market as a whole. Many early-adopters are only now coming to realize that. Too bad they didn't listen to that message over a decade ago. Ugh. Oh well, they have no choice but to listen to it now... especially when attempting to belittle Toyota:

That claim about Toyota possibly failing is a narrative you should be smart enough to see beyond. You know Toyota is waiting for the cost tipping-point to be reached before deploying to the masses. It makes no sense doing that prior to the profitability stage being reached. That's why rollout is being held to limited markets. The tech is being refined in the meantime.

No legacy automaker can go all out with high-volume deploys yet. Batteries are still too expensive and density too low for that profitable level to be reached. It will happen, perhaps very soon. But until we see sales growth without tax-credits contributing to that, we haven't left the early-adopter stage.

Consider audience. Buyers of plug-in vehicles now are pretty much exclusively enthusiasts. Reaching mainstream consumers... those who basically just go to their favorite dealer and trade-up for the latest model of something there... will be extraordinarily difficult to appeal to. Current plug-in offers have too high of a price-tag still, even with the tax-credit, to be a realistic competitor yet.

In other words, look at the preparation is each automaker is making to address their own particular customers. What must they do to achieve & sustain profitable sales of plug-in vehicles? With that, you can see Toyota is well under way. Having a wide selection of hybrids in place makes taking the next 2 steps much easier for all involved... dropping traditional vehicles and rolling out plug-in choices.

What legacy automaker do you think is better positioned? It certainly isn't GM with their stubborn reluctance to spread plug-in tech to one of their mainstream vehicles.

10-30-2018 **No Longer Quiet.** The quiet of GM has changed to sending mixed messages. That sounds familiar. We are back to the uncertainty stage, yet again. It makes sense, knowing the timing of the tax-credit phaseout and how poorly plug-in sales have been. The downturn of the stockprice and market pressure from the new tariffs having a negative effect is really making a mess of things. What should investors expect? For that matter, what should customers expect? Both of those questions raises uncertainty for dealers. What will they sell? I took offense for today's play, grabbing the ball and running like hell with it. I don't think the antagonists saw this coming: GM did not target its own consumers; instead, they offered vehicles appealing to enthusiasts. That is the very definition of niche. Mainstream buyers should have been targeted. They were not. Technology developed for the purpose of widespread deployment was never widespread deployed. The origin of Volt was the Two-Mode hybrid, which we saw a prototype of with a plug way back in 2009. Yet, all these years later, there is still no SUV with a plug available from GM. Attempts to change the topic or make up info about the messenger won't change any of that.

10-30-2018 **Turning Point.** The antagonists didn't see it coming. I took them by complete surprise. This (along with an attempt to personally slander, of course) was all they could stir up: *"At least GM is taking a stance."* I found that particularly informative. But even better was what followed, a link to a video stating the predicament GM is now in. I took advantage of that for my secondary reply:

Listen to that video? The summary reveals the true story: *"In other words, a ZEV mandate would benefit a company if they already have the technology ready to go."*

Toyota does. They have already been producing motors & controllers that are affordably competitive with their own traditional offerings. That's because they invested heavily into driving costs down and efficiency up through their hybrid sales, which brings up the second point: *"If GM is going all in with electric in the future and already has vehicles in the pipeline, a zero-emission mandate could help fund development of those models as well as secure sales."*

It's GM being subtle about asking for more government assistance. That makes sense too, since also investing in improvements to traditional vehicles to meet the current MPG mandate would be very expensive... a problem Toyota does not have... since Camry hybrid already delivers 52 MPG and the upcoming next-gen RAV4 hybrid is expected to deliver similar efficiency.

That *"too little, too slowly"* concern has been validated. GM didn't use their tax-credits wisely. Their *"stance"* is really a request for help. And don't you dare attempt to spin this about me, because I'll just point out how many who use to frequently post here have traded in their Volt for a Model 3.

Like it or not, a turning point has been reached. It's time to move beyond niche offerings. The fleet itself must finally be addressed. GM must provide something for GM customers.

10-30-2018 **L, LE, and XLE.** Most of the time, what Toyota does goes unnoticed. Why should it anyway? Toyota focuses on its own customers. When something about them is brought up in automotive discussions, it is almost entirely negative. That's because enthusiasts just plain don't care about mainstream offerings, but find Toyota an excellent *"What about?"* to distract from their own problems. In this case though, even this slipped by quietly. That's probably because nothing good could come from pointing out that Prius is very much a mainstream offering now. Being available in the United States since for over 18 years now and being available in a wide variety of models, as well as having diversified the technology as rollouts in other popular vehicles, there's a solid history of not being a niche. After millions of sales, it is the new normal... especially as we approach the final year of the second decade of the 21st Century. Guzzlers just plain don't make any sense anymore. That's why the announcement last week of Prius package naming is such a fundamental move. Rather than the numbers, Prius now gets identifiers instead... just like the other Toyota vehicles. In this case, it is L, LE, and XLE for the 2019 model year.

10-30-2018 **Fallout.** I really hadn't expected such a negative turn for GM. I figured their would be the usual denial & defense, but the tone has become that of fallout rather than an attitude of resistance. The problem of delivering a product that focused on want rather than need has consequences. Like that analogy I used long ago, the homework GM turned in wasn't what the teacher assigned. So, regardless of how good the effort was, it completely missed the point. It's like buying magic beans. Ugh. Anywho, there are plenty of discussion threads popping up all over to focus on the disaster taking place. It's like the death of diesel. A realization of what just happened takes a bit to absurd. You need to accept the fact that there was a complacency so extreme, priorities were neglected on a scale so large there's no way to recover other than just starting over. That means, watch for announcements with an entirely new approach. The current efforts clearly failed. In the meantime, consider what I posted: GM will struggle with the Osborne effect because they have nothing to bridge the gap. That extreme product-line difference could have avoided by rolling out a modest version of Voltec long ago, back when enthusiasts were begging for a next step to be taken. Instead, we have watched innovator's dilemma ploy with Volt, leading to an abrupt approach change leading to Bolt. Just imagine if an affordable model of Volt or an Equinox with that technology had been rolled out years ago. So what if the range would have been less? That would have attracted new interest and explored new possibilities for electrifying the fleet without requiring a massive step all at once. GM brought this struggle on themselves. The reluctance to do anything to make a mainstream offering from the effort with Volt is a clear drop of the ball. GM knew when tax-credit phaseout would be triggered. GM knew the timing of Tesla's push for Model 3. GM knew legacy automakers would be also pursuing plug offerings. They will indeed end up undermining their own ICE sales. We all saw it coming.

10-31-2018 **Sales Expectations.** It's rather odd that so late in Volt sales (midcycle of second generation) to hear people focusing on conquest sales. How does taking away sales from other automakers actually help change the wants of GM customers? It's a blatant distraction that should have been addressed long ago. 8 years after rollout began is far too late. The expectation of status quo shakeup should be of great importance; instead, it's a landscape of complacency. There's nothing on the outlook for mainstream penetration. There's no push anymore. For that matter, there are almost no enthusiasts anymore either. It's just a blah crawl of uncertainty. If anyone ever doubted the concern of *"too little, too slowly"* as not being genuine and not having very real consequences, all they have to do is study what happened with Volt. The hype of a decade ago fizzled to a movement that lost its way... or as I put it, never had an audience. It's sad that they chose to hope for the best, rather than make a serious effort to understand change. They still don't get it either. I continue to provide reminders: Why would any legacy automaker focus on conquest sales? That certainly didn't work for GM. Their own customers haven't been interested in a compact hatchback. Toyota on the other hand, is targeting Prius owners and Toyota showroom shoppers, with Prime. The upcoming Corolla PHEV will obviously target Corolla shoppers. We could easily see the RAV4 hybrid offering a plug later too, targeting RAV4 shoppers.

11-01-2018 **Monthly Sales.** The complacency with regard to monthly sales is getting really bad. Tesla reports them on a quarterly basis. The hope was to get the industry to not obsess with minor fluctuations, to focus on the bigger picture instead. It didn't work. People found a means of getting monthly statistics to share anyway. GM is dealing with same problem. Enthusiasts live in the now and most don't show any interest the larger market. They only see the niche. So, my reminders about this current sales surge not necessarily being representative of what mainstream acceptance may be is falling on deaf ears. They don't care how much of an influence that \$7,500 is making. They don't care that these current buyers tend to have a large amount of disposal income available. They don't care about the potential for market saturation either. It's very much a hopeful bliss... with signs of reason to be concerned emerging. We've seen this before. Remember the fallout from Volt after the first few years? With a very hard push from Tesla to achieve an affordable offering, some of that could be avoided. But from a legacy automaker, like GM, what is the next step to prevent a big sales loss? Enthusiasts claiming leadership don't understand the consequences of slipping. Toyota is choosing the slower route with a tiered approach. VW is planning to go all out, but not until it is cost-effective. With the others, who knows? BMW and Hyundai aren't really growing much. Honda is a bit of a mystery. Ford is just gone. I'm obviously hoping for a midcycle bump. In the meantime, there's a looming phaseout that will likely contribute to monthly drops.

11-02-2018 **Sales Growth.** There's a new form of "*vastly superior*" emerging. Resentment from EV owners about having to share news about sales with PHEV offerings is becoming far too frequent... to the point of sending an unwelcome message. The moderators have not stepped in yet either. Recognize the pattern? Hopefully it doesn't get too bad. We'll see. That attitude of unwelcome is far from new. Only thing is, the shoe is on the other foot now. I'm enjoying the irony. For now, my response will be somewhat general: Isn't the point to get as many as possible to plug in? Focusing only on BEVs would be counter-productive. I traveled 2,674 miles with my last tank of gas. It took less than 8 gallons to refill because 89% of those miles were electric. That's a dramatic reduction of gas use from a small battery-pack in an affordable vehicle. Don't you want PHEVs to help contribute to the growth of charging infrastructure?

11-02-2018 Starting Threads. I don't actually do it often anymore. My role had become answer provider. But as Prime rollout progresses, there's reason to take a proactive stance. So, I am by starting a thread with this title: "*Electric Heating (winter driving with Prius Prime)*" It contained some basic info, along with some relevant videos from my collection, to stir discussion: I was fortunate enough to have my Prime prior to winter last year, so I was able to capture a few drives as the temperature dropped to share with those curious this year. The electric heating in Prime is provided by a vapor-injected heat-pump. That's the most efficient means of cabin warming currently available for electric-only driving. It operates in temperatures down to 14°F. In conditions colder, the engine joins in to help provide warmth. So, for most of the winter even here in Minnesota, I get to enjoy EV mode. Of course, when the engine does start, it eventually shuts back off to circulate hot coolant as you drive with only electricity. (Watch that data shown in the second and third videos, indicated by the 2 aftermarket gauges displayed on the right.) Here's a video of that electric-only operation at 16°F: [Ordinary Winter Commute](#). This is that same drive at a lower temperature, down to 7°F: [Heat-Pump with Engine](#). And here's one that even here in Minnesota, we fortunately don't have to deal with often: [One-Degree with Drive-Thru](#).

11-02-2018 Who Sells Prime. That was the title of a thread started today to stir discussion about distribution throughout the United States. Certain regions only got a teeny, tiny allocation... literally, just a few. Basically, they were only special orders. There was certainly no sense of inventory anywhere around here. My searches within 500 miles only reveal a few and that's all the more I have ever seen. That's why I'm thinking Toyota has plans to step up their offering... soon'ish. I put it this way: My hope is there's a midcycle update for Prime to coincide with the one for Prius... which I believe will be revealed at the LA show late this month. Then again, we may need to wait until early January at the Detroit show. Not stocking dealers with old inventory is both a wise financial/relationship move as well as good for understanding the tech itself. We have all had to deal with people referring to outdated specs & reviews. There's no need to make that situation worse when you know there's an update on the way. Remember those issues related to the previous upgrade? Speaking of upgrades, how many of you remember the "*generation*" Prius that came before the first that was rolled out here? What we got was actually a midcycle update. Toyota upgraded the battery-pack, switching from D-cell packaging to prismatic. For that matter, Prime itself was a midcycle update too. Knowing all that history and seeing the inventory situation now, it is quite reasonable to expect something like a change to Prime's battery packaging at some point in the near future.

- 11-02-2018** **Intentional Misleading.** Ford is up to their advertising tricks again. This time, it was Fusion being compared to Camry. What got me worked up was the reference to auto start/stop. For the "*not available*" to be believable, you have to ignore the hybrid offerings... from both automakers! It was bizarre to have no mention whatsoever about them, especially with direct reference to fuel economy. The other emphasis was on the self-park feature, the same thing I have in my Prime is what Ford also offers. The catch was, it was portrayed as a feature of great importance. In other words, that was a rather blatant effort to divert attention from Toyota's standard safety sense package. Those features are priceless for manual parking, what you are far more likely to do than with the automatic option only available for perpendicular & parallel parking. For example, when I pull into or back out of an ordinary angled parking spot, those sensors are priceless and have nothing to do with hands free driving. Needless to say, it was a great example of cherry-picking, where only select information was shared to create a false narrative... what we used to term as intentional misleading.
- 11-02-2018** **Desperation.** You know a tipping point has been reached when the excuses wildly fluctuate. The sign to watch for is when there is no longer a consistent message. Watch for something to come up out of nowhere. For example: "*Prius+Prime sales fell year-on-year again in the USA in October 2018. 5,773 down from 6,158 a year ago.*" No one has been using that metric to measure progress, because the message was never that of going groom hybrid to plug-in hybrid. Think about who would even consider that. It certainly wasn't GM enthusiasts, since GM basically skipped hybrids entirely. From EV supporters, we have seen only EV penetration in contrast to mainstream sales. This is mostly due to the fact that none of the automakers other than Toyota had an established hybrid customer base. And of course, we have a major non-legacy automaker (Tesla) serving as a source for confusion. Needless to say, I punched back at that desperate effort to greenwash: That year-on-year difference is only 1.7% (385 units), which is very much within the flat realm. As for 24 consecutive months, that's quite a stretch. Most deliveries for even the earliest orders didn't begin until 20 months ago... which meant unsold deliveries for immediate purchase took an additional 6 months beyond that. That perspective also requires putting on the blinders to ignore the rest of the worldwide rollout. Toyota rolled out to a wide variety of markets all at once, a move most automakers avoid... especially with new tech. Despite that, they were also to produce & sell over 51,000 the first year. Manufacturing that dual-wave glass and the carbon-fiber hatch isn't exactly a well established process yet. Lastly, I took the time to check the math and your numbers are very misleading. (Prime: Nov 17 to Oct 18 = 26,778) (Prime: Nov 16 to Oct 17 = 19,483) That's a significant growth rate, so significant you don't even have to use a calculator. That "*fell*" claim has been revealed as greenwash if you choose to cherry-pick a specific mix of plug & no-plug. RAV4 hybrid sales represent a growing market too, especially with the next-gen rollout happening in a few months.

11-02-2018 **Fight What?** That narrative of change only coming in the form of a full endorsement of a long-range EV continues to be a problem. This stems from GM's desperation to remain relevant. Both generations of Volt failed to draw mainstream sales. Heck, even growth with the generous tax-credit never happened. Nothing GM did resulted in a draw of attention from non-enthusiasts. Ordinary consumers just plain were not interested. That's why Prius was always flagged as the ultimate competitor. That idea was finally abandoned and focus shifted to Tesla instead. That audience cheering for GM saw that as a more realistic challenge than taking on a very successful legacy automaker. It is how Bolt came about. That failed too. So, attention is shifting back to Toyota again: *"...but Toyota continues to fight the transition to EV's with everything they got, too bad."* That message of resistance will likely backfire... since Toyota works hard to de-emphasize their technology advancements. They want their choices to seem as mainstream as possible. That's why the Camry & RAV4 hybrids basically go unnoticed. Making it seem as though you are taking a smaller step (think *"less risk"*) with a plug-in hybrid is exactly what is wanted. A perspective of *"no fear"* is great for sales. The key is making that choice affordable. (Discovering the remarkable efficiency and amazingly smooth & quiet drive experience can come later.) I responded to that nonsense effort to spread a misleading message: Toyota's emphasis on AFFORDABILITY doesn't count as a fight? Base MSRP for the 2018 model was \$27,100. They have no dependency on tax-credit help and it is technology easily adaptable for other hybrids. Think about how easily a RAV4 hybrid could be upgraded to include a plug. Toyota's effort to reach mainstream consumers shouldn't be dismissed solely on the supposed small size of the battery, especially with so many owners going months between fill ups.

11-03-2018

Spreading Fear. That has been a common technic used by politicians for as long as governments and ruling parties have been around. In the automotive industry, you'll often see "*FUD*" as the term to identify that activity. It is short for "F"ear "U"ncertainty and "D"oubt. I remember that from way back in the early 80's, when the primary way achieve improved efficiency was to reduce the weight of the vehicle... which meant making it smaller... which equated to a sacrifice of safety... back then. That was proven not to be the case, by a substantial margin, 20 years later when we found out SUVs were quite a bit more dangerous than an everyday sedan. In other words, fear helped to sell vehicles. People respond to instinct rather than actually researching. That's why safety ratings are still referred to "*crash tests*" without any mention of "*accident avoidance*". It's a sad reality. Worse though is they are now attempting the same with efficiency standards, but the government is now promoting fear rather than the automakers. The proposed SAFE program "*Safer Affordable Fuel Efficient*" vehicles rule for 2021-2026 cars & trucks. This is what was stated in the official overview released for it: "*The proposed SAFE Vehicles Rule seeks to ensure that government action on these standards is appropriate, reasonable, consistent with law, consistent with current and foreseeable future economic realities, and supported by a transparent assessment of current facts and data.*" Notice the insertion of fear? That not-so-subtle title says it all. If you take the time to actually read some of the information, it's a clear effort to stir uncertainty & doubt. Heck, just the "*appropriate*" and "*reasonable*" mentions provide an indication of intent. This is just like the FREEDOM program years ago. The government halts an existing effort to reassess worth. That worked too. They abruptly dropped PNGV funding with that excuse... and those of us supporting it had little power to do anything to intervene. It just died. This is no different. Who even remembers what the detail was for the 2025 mandate? Of course, this is where the uncertainty aspect comes into play. The administration released numbers that don't actually make sense. There's a bunch of number spin, where the outcome is totally misrepresented of the facts presented. Sadly, that's easy to do. Making it even more confusing is just a matter of adding some unsubstantiated assumptions and some vague estimates. That makes you doubt information shared in the past. It all comes down to finding an excuse to continue to sell guzzlers. In this case, the effort is to allow "*overcompliance*" credits. It's when an automaker pushes fleet emissions, focusing on improvement of only certain vehicles rather than actually trying to address the status quo. In short, this is a fight to resist change. We usually call this moving the goal-posts. By questioning, freezing, or rolling back standards, you effectively undermine progress... preventing a cleaner environment without dependency on non-renewable fuels. Ugh.

11-03-2018 **Holding a Grudge.** It has been interesting to read posts from a gen-1 Prius PHV owner who was upset about the battery-pack fit. For the past 2 years, he has done nothing but complain. The short-sightedness of his actions and absolute refusal to look at the big picture has been very annoying to quite a number of people. Lately, that has changed. Now, he seems angry about everything. There's no pleasing him on any topic. It has been an transformation I didn't expect. The resentment spans all topics now. This was the most surprising: *"our son is looking at an equinox (iirc) with diesel and start/stop tech, nearly doubles the mpg over gas"* Many of his posts are so vague, it's not even worth replying anymore. In fact, he has switched to replies without quotes, just a post in the thread with an implied target. That avoidance of detail is a dead giveaway of petulance. I wasn't going to let that go. So, I hit back with: Double of 28 MPG (combined for 2018 Chevrolet Equinox FWD 1.5 L, 4 cyl, Automatic 6-spd, Turbo, Regular Gasoline) is not the 32 MPG (2018 Chevrolet Equinox FWD 1.6 L, 4 cyl, Automatic 6-spd, Turbo, Diesel) rating no matter how you consider it, nor are the city or highway ratings. The outgoing RAV4 hybrids (to be replaced with a next-gen upgrade in a few months) delivers a 32 MPG rating and it is AWD. There's an expectation for it to get a significant efficiency bump, much like what we just witnessed for Camry hybrid. So, it makes no sense whatsoever to consider diesel (which is a more expensive fuel) as an efficiency choice. We know that turbulence in the oil market is about to get worse, causing gas prices to drop. That positions Toyota well to phaseout their top model of RAV4 as a traditional guzzler, replacing their high-end offering as a hybrid only. It's an important step forward that should not be overlooked... though, it will be. Toyota tends to make significant moves as subtle as possible. Think about how effectively that sets the stage for a plug-in hybrid model of RAV4.

11-03-2018 **Getting Caught.** A really, really well known antagonist who fought on GM's behalf for years only to abandon them entirely for Tesla, spoke out today. I was intrigued. What could he post that wasn't hypocritical? After an entire decade of praising GM for the Volt's solution to *"range anxiety"* then abruptly switching to a Model 3, my interest was peaked. That change from plug-in hybrid to EV and at the same time leaving behind a legacy automaker for a well investor-funded startup is something he himself would have attacked. But then again, he was known to lie. Being blatantly dishonest is what captured my attention. What kind of a person simply says whatever makes them feel better. Oh wait... you know. Anywho, he said this: *"I'd like to see this vehicle in the US, w/some cleaner styling, longer range, and 75kW DCFC."* It was about the upcoming plug-in hybrid GM is planning to rollout to the market in China. It is a size-category one model larger than Volt. So, we know it will require more electric power simply to maintain the same level of performance he sung praise for over the years and used to insult Prius with. I especially remember how arrogant he was about Prime. The obsession with power was overwhelming. So, this quote from the article he commented about had me quite intrigued: *"According to several Chinese news agencies, the maximum output of the motor is 85 kW."* That is only 114 horsepower, well under the 149 horsepower Volt delivers. That would put it roughly in the same power-category as Prime. I had caught him being hypocritical. How would he respond? Turns out, he pretended his focus was entirely on charging speed. Everyone reading that post can see otherwise. Figuring that would be the outcome, my comment was as follows: Here? In the land of vehicles where higher horsepower was claimed to be essential? Remember all those arguments? 85 kW from a vehicle larger & heavier than the 68 kW from Prime puts many in a contradictory position.

11-04-2018 Speculation. I took advantage of that sales discussion, after having stirred this reply: "*I would hope your speculation will come true. I think Prime is under appreciated car in public just as Prius Plug-in was.*" It's the story I have been waiting an entire decade to share, knowing GM would screw up the opportunity. How did I know? Simple, they were repeating the very same mistakes that had been made with Two-Mode. I recognized the pattern... and got attacked by enthusiasts whenever I pointed out the familiar course GM was taking. Ugh. Oh well, it's finally about to come to an end:

It is more like observation, rather than speculation. We witnessed a very similar inventory approach back with the Classic model. Toyota doesn't play their hand until the time is right. They wait for the market and study in limited areas in the meantime... even when it makes some supporters crazy with bewilderment.

In this case, it is to avoid the GM disaster. Getting caught up in their fallout wake would be bad for everyone. GM squandered tax-credits by obsessing with conquest sales. Focus on speed & power blinded them from the importance of actually bringing about change for their own customers. When things got so bad for GM with their "*range anxiety*" solution, they ended up making an abrupt strategy change. They abandoned Volt to create & promote Bolt.

Now as April 2019 approaches, that \$7,500 federal assistance they have depended upon heavily, will then drop to \$3,750 for the following 6 months. Following that, it will drop to \$1,875 for 6 months, then phaseout will be complete. That's really bad news for an automaker struggling just to retain attention. Sales have been far below expectations. The purpose of those tax-credits was to establish a high-volume profitable vehicle *PRIOR* to triggering the phaseout stage.

Remember, phaseout begins when an automaker exceeds 200,000 sales. At that point, there is no quantity limit. The automaker can exploit the opportunity by producing as many vehicles as possible... exactly what we are witnessing right this very moment with Tesla. It's an opportunity GM will miss, despite knowing years ahead of time that this very situation would happen.

Toyota will be ramping up as GM struggles to remain relevant, not having to deal with confusing comparisons to Volt from having waited. It simply didn't make any sense to make a major move any sooner, especially with the success of Tesla doing such a remarkable job of promoting plug-in vehicles. In the meantime, Toyota continued to refine their design to make it cost-competitive with traditional vehicles.

- 11-04-2018 Contining Attacks.** Just like with the other stages of fallout, there are a few who lash out with final words before fading away into defeat. Today, that came from a well known Toyota antagonist. I was assumed by his short-sightedness and feel quite vindicated for not having been pulled into such self-deprecating behavior: GM exploited tax-credits for conquest sales. They didn't focus on delivering something for their own customers. Like you, they focused entirely on "*out there now*" and didn't consider the consequences of not focusing on profitable high-volume sales instead. Quite the opposite of that is Toyota, who has focused intensely on designing a system to appeal to their own shoppers on their own showroom floors. Someone with an interest in Prius will be drawn to Prime. It's an affordable solution, without dependency on tax-credits. This is why the next-gen RAV4 hybrid is so important. It's path to a plug is a simple one, something those with interest in RAV4 will take into serious consideration. This is the same reason why Toyota is rolling out a plug-in model of Corolla hybrid in other markets next year. You aren't a Toyota shopper. So, what you think doesn't matter anyway. Know your audience.
- 11-04-2018 Fallout, narrative.** Things are picking up. Obvious pressure is growing. That means the narrative being pushed is no surprise. There is fallout from GM, what we have long waited for... so others can finally fill the void promised to be addressed by Volt but never happened. It was a monumental barrier that couldn't be overcome. How do you fight an idea? Delivery of promises fell apart. GM came up short of the price-point targeted all those years ago. Too expensive meant little to no interest from mainstream consumers. And sure enough, sales reflected that. Even with the generous \$7,500 tax-credit, there simply wasn't a market for a vehicle with such high cost. The choice to emphasize power & range was too much of an affordability sacrifice... and now we have overwhelming proof. Their nightmare has become a reality. Enthusiasts (the few who still remain) have fallout to deal with now, hence the spinning of stories now. The thread on that old daily blog struggling for an audience remains the home for them. So, I joined into the so-called discussion there with: That's a narrative being spread to avoid facing the reality of EVs not being cost-effective enough to compete directly with traditional vehicles. Turning a blind-eye to the mainstream market is why what you think doesn't matter. As for most everyone else here, they are early-adopters. Know your audience. Toyota is striving to deliver affordable choices that will actually be embraced by their dealers to stock & sell. How effective has that been for the other legacy automakers?

11-04-2018 **Fallout, treatment.** I could get a sense of unease immediately. The harsh treatment I routinely got in the past was about to return. So, I pre-emptively made the initiative. Why not? After all, nothing they tried in the past (and they would quite thorough) actually worked. It was attack after attack with every excuse imaginable attempted. They had nothing to lose back then. Right away, there were problems with Volt. In fact, that very first month the most prominent of supporters abruptly went quiet. Rollout revealed issues. The idea of promoting turned into damage-control almost immediately. A few things I had warned about had already been confirmed. They were not happy. Shooting the messenger was one of the few things that brought joy. I never let up though. It was always a matter of waiting until tax-credits expired. That artificial layer of protection was false hope... and now they know it. So, my hope now is to... ironically... provide damage-control. It's the very guidance they resented back then too, just sharing of important market information. Too stubborn to listen 8 years ago means a bitter pill to swallow at this point. Fortunately, it isn't too late. It's just a matter of not letting pride get in the way. Enthusiasts used their talent to create a very appealing niche. Oops! That's exactly what you don't want when the goal is to appeal to the masses. Oh well. Lesson learned, which I pointed out in this manner: GM's treatment of Volt says it all. Rather than forming it into a product their own customers would be drawn to, it was a game of conquest. The tax-credits were exploited to please enthusiasts. Now as the tax-credit phaseout rapidly approaches, GM has nothing appealing or cost-effective to sell. You know GM showroom shoppers. They are looking for SUV choices. That's why GM added Trax and Blazer to the product-line. But neither of which offers a plug or even just a hybrid model. They are all still guzzlers, despite having used almost 200,000 tax-credits to change that.

11-04-2018 **Fallout, status.** When you bring up GM fallout, there will naturally be a status for Toyota posted. No matter how hard you work to keep on topic, they always revert to basic diversion. A blog devoted to Volt naturally means you discuss everything except matters of GM. Ugh. It's so desperate of an effort to keep change from finally happening. Why do they fight the inevitable so much? It's just a stage, not an end. So what? Volt failed. It's not like another plug-in hybrid can't be offered. But to make themselves feel better, they have to insult & belittle others. The very idea of joining the team as an equal player is still shunned. That "*vastly superior*" attitude had stirred so much false hope, that's no surprise. Oh well, it's their loss not to be part of what happens next. It's not like they weren't informed about how to address change: As for that claim of missing the boat, there's no substance to such a statement. We are still very much in the early-adopter stage, which is clearly defined as the time when sales are not directly subsidized. Mainstream sales don't include tax-credits. They are just ordinary transactions from dealer to vehicle owner, purchased at a nearby location without any government incentive. None of the EV sales here have been in that manner yet. So, there's no merit to "*ahead*" or "*behind*" assessments of status. That stage... which represents actual change to the status quo... has not begun.

11-04-2018 **Fallout, shopper.** That didn't go over well. Effort to actually discuss GM on a website dedicated to GM is going to far, asking too much, expecting a miracle. Ugh. It's all about forcing a narrative about Toyota being so far behind, they'll never survive. That gives the impression GM isn't in trouble, that the end of tax-credits doesn't mean dramatic change. Oh well. The clock cannot be stopped. It will happen. We know when. Of course, knowing if enthusiasts will ever considering become supporters is an entirely different matter. No one has any idea what the response will be to this stage coming to a very predictable end. It's an odd situation, which should be this way. Purpose was obvious. Acceptance was far from inevitable though. Virtually all enthusiasts fade away prior to such conclusion. The void left behind is quite interesting as a result. In this case, I'm especially intrigued. Many of the original antagonist issues simply won't emerge with an entirely new audience. Much of the technology has changed since then. I summed up my long-term observations by pointing out the shopper's perspective: See where this is going? That "*GM must provide something for GM customers*" means people shopping at GM dealers are hoping to find something available that finally uses technology from Volt but doesn't require having to purchase a compact hatchback. They are loyal GM customers looking for a GM vehicle. When should we expect a plug-in hybrid Chevy Trax? You know a GM shopper will ask that question.

11-05-2018 **Fallout, replacement.** It continued... Buick Velite 6 will very likely become the Volt replacement, GM's move to finally take a first step toward actual change to the status quo. It will be configured the way many enthusiasts feared... a larger vehicle with a system that offers less power and less range. Heck, even the name itself suggests that "V"olt and "e"Assist and "lite" is a successor of GM's previous technology... which includes analogous naming. GM offering a vehicle for their own customers is long overdue. Tax-Credits were squandered for the sake of automaker conquest rather than GM addressing its product-line. Having that money to stir interest would have been quite helpful; instead, this new plug-in hybrid offering will have to compete based upon MSRP value. So much opportunity was missed, but at least GM is finally taking a step in the right direction. Their choice of the past to listen to enthusiasts here, who clearly led them astray, equated to a terrible amount of time wasted. Oh well. The experience gained from now rolling out in China first will help guide a sensible decision in the United States.

- 11-05-2018** **Fallout, apologists.** There's a defend-at-all-cost mentality to that happens prior to coming to the realization of being corner. It hasn't sunk in yet. The nature & magnitude of change to come is difficult for some to see. They get so hung up with their perspective, the impact to others is totally unknown. Something doesn't go right, they respond in a manner that everyone else sees as apologetic. Excuses seem realistic to the enthusiast, since they don't see the pattern. That's what happens when you only consider a narrow scope of time & audience. Looking at the bigger picture simply never happens. That's why much of what's posted really doesn't matter to them. They never see what really took place. Oh well. Hopefully, the lurkers do: GM must provide something for GM customers, who couldn't care less about rhetoric online. Those customers just want to purchase a passenger vehicle from GM that's cleaner and more efficient... Malibu, Trax, Cruze, Equinox, Impala, Blazer, Traverse, Tahoe... yet there aren't any. 2 plug-in vehicles that are small & expensive and won't be profitable until 2021 should be reason for serious concern. GM wasted tax-credit opportunity. Calling others who did not laggards (especially when they already offer a wide variety of impressive hybrids) is what an apologist would do.
- 11-06-2018** **Fallout, perspective.** That understanding of what went wrong can be so obvious years later, looking back. But when in the middle of it, perspective is often totally unknown. Responses are to the here & now, not to what overall goals are and why certain decisions are actually made. That's the reason market reaction is usually misunderstood. You have to know what to look for in the first place. This is why I stress purpose so routinely. What are they trying to accomplish. This is how races are lost. That story of "*Tortoise and the Hare*" provides a great analogy. Yet, even when pointing out the behavior pattern, it is still denied & dismissed. Like I keep saying, oh well. They'll eventually figure out the mistakes being made. It will be too late, but at least it's an end to the crazy competition we have been in. I keep trying to point out the situation though, prior to it drawing to what is now being an inevitable defeat: That would be a more accurate description of the situation playing out now. Being "*ahead*" at the moment is by no means a guarantee an automaker will win the race. This is where the often overlooked or dismissed detail of design cost & efficiency will really make a difference.
- 11-07-2018** **Fallout, redefine.** The world of the enthusiast is about to change. They won't provide the redefine as in the past... when things went wrong. Being able to just move the goal-posts only works for so long. You eventually back yourself into a corner. That time is near. They've exhausted absolutely every excuse for lack of progress. Not understand goals or even who is involved is why. It's basic avoidance. It will fail at some point; then, you're stuck having to deal with fallout. Soon. It will happen. In the meantime, words of warning: On a GM blog doing everything possible to avoid discussion about GM... Enjoy that while you can. Triggering tax-credit phaseout will bring about an abrupt end to the early-adopter bliss far too many enthusiasts didn't take seriously. Buick Velite 6 will very likely become the Volt replacement. Like it or not, that will redefine the "*range anxiety*" approach for GM.

- 11-07-2018** **Fallout, next.** It's pretty bad when you have to spell out the situation. After so many years of evade & deny, a few hope someone is willing to support the possibility of a miracle. That's why vague becomes so common. Detail isn't optimistic. It points out the cold, hard reality of having to accept defeat and move on. I'm happy to provide some: 196,986 sales so far. Time to take the situation seriously. 3,014 before year-end will happen. The point is to find out what comes next, from both GM itself and what's left of the enthusiasts. New vehicle. New approach. New audience.
- 11-08-2018** **Fallout, failure.** The end of tax-credits for GM clearly identifies a deadline having been reached. That expectation of high-volume profitable sales was not achieved. Volt failed to fulfill the goal of sustainability prior to phaseout being triggered. It's good reason for enthusiast disenchantment, which explains the irrational attempts to seek blame and divert attention elsewhere. The time to recognize market need over want is long overdue. GM's choice to sacrifice cost in favor of range & power was a tradeoff that did not work. Mainstream shoppers were not interested. GM will now focus efforts toward seeking a balance, reducing range & power goals for the sake of delivering a more affordable choice. We see in China there will be a plug-in hybrid offered by GM using a larger platform, providing a more comfortable interior to improve upon design shortcomings of Volt. We have confirmation that the power output will be much lower than Volt despite the heavier weight, delivering 85 kW (114 horsepower) rather than the 111 kW (149 horsepower). No mention of potential range has been disclosed, but priority for a larger space inside and a lower cost implies it will be less than Volt. In other words, this is the vehicle many had hoped GM would deliver years ago, but a group of enthusiasts fought fiercely against based on irrational fear that a "*diluted*" design would result in weaker demand. Since the stronger design failed to achieve needed sales, this is the next logical step. Put another way: Get over it.
- 11-08-2018** **AWD Teaser.** The timing is remarkable. Right as we are witnessing these final moments of fallout, the stir of hope has already begun. Toyota released a teaser photo today, complete with a rhyme to get people thinking: "*Fall is here, winter's near, but the 2019 Prius performs on roads whether snowy or clear.*" In that image, we can only see a little bit of the car itself. Most is obscured by a cloud of snow. So, there's no possible way to even get a hint of what the new tail-lights look like for the mid-cycle update. All we get the impression of is that AWD (All-Wheel-Drive) model of Prius that has only been available in the domestic market will soon be available elsewhere. That supports the rumor I had heard... and it makes sense, knowing Subaru is about to employ some of that tech from Toyota anyway. It's the next logical step to take for market acceptance... and great timing to do it. Within the next 2 weeks, we'll hear more about the new RAV4 hybrid. The week following that, new Prius stuff. Sweet!

- 11-08-2018** **New Audiences.** Ending of the early-adopter stage will bring about newbies, those who have no clue what happened in the past. You have to take the time to explain market operation & perception; otherwise, assumptions get out of hand. That's how mistakes are repeated. Learning about history is vital. Be a source willing to share your experience & observations. I do all the time, as I did today: MAINSTREAM has been defined for the past 15 years here as any vehicle selling at a minimum rate of 5,000 per month (average 60,000 annual) without outside assistance. The reasoning was simple, that level of sustainable sales was a benchmark for profitability. This rate from the automaker was necessary for suppliers & dealers to guarantee the on-going business without losses. The fact that EV and PHEV sales still have that tax-credit assistance for sales disqualifies them from the measure of mainstream. That's not a bad thing either. We are still in the early-adopter stage. It doesn't make sense to rush drawing any conclusions yet. Think about how different ordinary showroom shoppers are then our group here, which is very well informed and willing to spend extra for the sake of helping along the electrification effort. Wait to see what happens when the extra \$7,500 is no longer available. Put another way, the current sales are low hanging fruit. Attracting interest will be much more of a challenge when appealing to the wider audience, that group who is just looking to replace their old vehicle.
- 11-09-2018** **False Narrative.** The "fallout" thread ran its course. Time to bring it to a close: Why would a person on a GM venue continue to bring up Toyota over and over again, accusing someone else of doing that, despite obvious evidence to the contrary? It's really an effort to solidify a false narrative. By pushing the belief that Toyota is scrambling to catch up, it gives the impression that all is fine with GM. In reality, this is a means of undermining GM's position by preventing discussion of it. Notice how any attempt to share detail about GM design is obscured by a certain Tesla Model 3 owner trying to divert focus to Toyota? This particular thread has served well to reveal that pattern. Detail about GM to help provide a look forward to a realistic next step is followed Toyota rhetoric, just empty spin to confuse & mislead. That is clear confirmation of big change to come from GM. This end of tax-credits will force the status quo to finally break. Certain people have a very difficult time accepting that... especially when it will lead to a paradigm-shift with respect to how plug-in hybrids are accepted.
- 11-10-2018** **Change Is Coming.** I kept at it, pushing that message of change and drawing attention to the effort to prevent it: Use every technique available to avoid discussion about the topic at hand. Scream "*Troll*" and "*Toyota*" to dismiss any opportunity to be constructive. Our president couldn't have done any better. Major change is coming for GM. The failure of Volt to achieve high-volume profitable sales is not just an issue of oil-dependency and emission-reduction. It's having to answer to stockholders. GM is a business. The expectation is for technology investments to deliver a substantial return. GM should have diversified Voltec a very long time ago. A compact hatchback is a terrible platform for GM customers. That technology should have been deployed to a small SUV, like Trax, years ago. So much opportunity was missed. Both time & tax-credits were wasted. Now, we see the other automakers approaching with their more affordable and more efficient designs. They still have ample tax-credits available to, able to use them for the intended purpose of mainstream penetration. Evade the inevitable as long as you can. That behavior is obvious & pointless though. Major change is coming.

11-10-2018 Recognizing Efficiency. Phew! There are constructive discussion threads elsewhere. Today, it was a boost to the hope of raising awareness about electricity waste. To think that I was fighting that 8 years ago, raising concern about Volt owners dismissing electricity consumption as important. That terrible propaganda of "*saving gas*" was all they cared about. I'm sure glad that attitude is getting recognized as inappropriate, and gladly contribute to the effort to draw attention to waste:

This discussion topic is loooooong overdue for plug-in vehicles. Real-World efficiency verses estimated values have been a major problem for hybrids over the past 2 decades, but few seemed to recognize that same impact would affect users of plug-supplied electricity too.

Slower driving and the need for cabin heat during the winter, combined with the usual losses related to cold batteries should have been an influence often mentioned. Instead, there has been barely a whisper, despite being such a major factor to consider when comparing various designs.

When it comes to speed & power, I've been laughed at for pointing out "*electricity guzzling*" as a concern. Only now some are starting to recognize the problem that creates when waiting for your pack to recharge. You need to do that more often and it takes longer when the system is less efficient.

Simply adding more capacity brings about problems. Look at how expensive that made Volt. Giving it enough to deliver that "*40 mile, all condition*" range goal made it unable to compete directly with traditional vehicles... rendering it a niche, rather than being the next logical step in electrification. That's why the other automakers are trying to squeeze out greater efficiency, as we've seen from efforts by Hyundai & Toyota. Note their kW/100mi ratings verses other automakers.

Kudos to those helping to spread the knowledge needed for a better understanding of how electricity is consumed by plug-in vehicles.

11-11-2018 Attitude Adjustment. Sometimes you need to remind early-adopters that they are really just enthusiasts, not by any means representative of ordinary consumers. They forget. They lose touch. They can't see that perspective anymore. It's like trying to remember what the world was like before the internet. That connectivity becomes so second-nature, you don't recognize what life was like without. That leads to complacency, like this: "*Meh. 25 miles of range is truly uninspiring.*" Naturally, I was annoyed... but jumped on the opportunity to reply: Spoken like a true enthusiast. Know your audience. Mainstream consumers have different priorities. They quite pleased with the mix of EV and 200 MPG averages. Don't forget the success of Toyota hybrids in the past: Prius, Camry, RAV4. Were any of them given "*inspired*" reviews? No. They were just solid contenders in their market segment, paving a clear path to greater electrification efforts... which builds up a strong purchasing base for next-gen offerings. The goal of a legacy automaker is not to please niche consumers. Their bread-and-butter sales come from "*ordinary*" vehicles sold in very high volume with very little effort.

11-11-2018 **Calling Out Lies.** Our society isn't good at that. We are taught to avoid confrontation. In fact, this is how the problem with enablers came about. Not taking a stand to calling out issues, like blatant dishonesty... to the point of outright lies, isn't something we do but should. Timid moderators make it especially difficult online. That's starting to change. Some of it comes from the encouragement stemming from the political arena, where news teams weren't willing to directly confront. I welcome the attitude shift. More playing offenses is in order. This morning, I punched back to a personal attack. After a fluffy of meritless rhetoric, I had it. That technique of flooding a thread with distraction shouldn't be allowed to continue, especially when its such an obvious effort to greenwash & undermine: *"A compact hatchback is a terrible platform" says the guy promoting a 4 seat compact hatchback.* That crossed the line, since it left out of the rest of the sentence to change meaning. I left everyone know it too: Quoting out of context is an act of deception, intentional spin to mislead. That omission of *"for GM customers"* was an obvious effort to greenwash... which becomes especially apparent with what followed. I have been promoting SUV rollout for plug-in hybrids... TRAX, EQUINOX, BLAZER ...those are all familiar model suggestions for GM as a next step to take.

11-11-2018 **Cross-Forum Attacks.** Angered by their own failure, some enthusiasts will follow you from forum to forum looking for an excuse to make themselves feel better. That's what this post was all about. I'm drawing attention to his actions without direct reply, providing as much exposition as possible to catch up this audience to happenings elsewhere. Not sure how effective it is, but the practice of summarizing is always helpful: Toyota's goal is affordability. GM failed to deliver on their own *"nicely under \$30,000"* target and certain enthusiasts now hold a grudge, feeling the need to lash out at other legacy automakers for having got burned. So, don't listen to the disenchanted. \$27,300 MSRP for the base Prius Prime is an amazing achievement. That 25-mile electric-only range delivers impressive results for those not ready to spend a premium to get an EV. We're still in the early-adopter stage. So, drawing conclusions is far too premature. Ordinary consumers (those shopping the dealer's showroom floor) have yet to even consider the purchase of a plug-in vehicle yet. It's just a *"someday"* idea still. Sticking to a capacity that can be served by nothing but a standard 120-volt outlet overnight allows the opportunity to reach a very wide audience right away... which is ideal for legacy automakers hoping to quickly reach a large number of customers. Whether you accept that approach or choose to listen to the disenchanted makes no difference. That is their intent, like it or not.

11-11-2018 **Performance.** I was pleased to encounter this: "*EV owners have been making the wrong argument this entire time.*" That's very much a "*know your audience*" situation. We hear from early-adopters with authority, claiming to be a voice of the people. In reality, they're just enthusiasts. You can't take someone seriously who took advantage of a \$7,500 tax-credit claiming it won't be necessary to make the same purchase decision. Yet, they imply that it doesn't matter all the time. The biggest greenwash though is that the automaker will suddenly drop price \$7,500 to make up the difference. How does that work on vehicles targeted to make profit 3 years from now. We certainly won't be seeing Volt as a high-volume offering from GM with such a large automaker subsidy. Even if they did use profit from Pickups and large SUVs to provide that, what difference would it make? Sales are low already. Where the \$7,500 comes from won't matter... unless it is a direct markdown. But then again, what incentive would there be for a dealer to carry them? In other words, there is so much a play with cost, the topic of performance doesn't draw more sales. We've seen that approach fail miserably with Volt. GM delivered performance. Their own dealers & loyal customers weren't interested. Mainstream shoppers were not impressed. How many times can you point out the same issue? I did, one more time: "*Fun to Drive*" is a very difficult sell for mainstream consumers, especially if there's a premium involved. They have different priorities, like size & horsepower, as opposed to impressive handling. It's a diminishing return problem anyway. The suspension & body-stiffness upgrades to Prius, combined with the added torque from the larger battery, make Prime more compelling. But how much would even more actually draw if the audience is primarily SUV shoppers? Think about who you are trying to convince. Ordinary consumers... like my mother... couldn't care less.

11-12-2018 **No Pickup Plug.** An executive from GM made a statement today that shook the online community: "*The core business is going to be the core business for a couple of decades to come. There will not be any AV/EV pickups.*" Hope had been that there were finally be some type of EV (Electric Vehicle) or AV (Autonomous Vehicle) announcement related to pickups. Instead, we got nothing. There won't be a plug-in hybrid or even an ordinary hybrid. Either choice is long overdue. Remember Two-Mode? That long-forgotten technology for GM's fleet of SUVs was a complete disaster. It was expensive and didn't deliver much improvement. Pretending it never existed is what enthusiasts and even supporters choose to do. Having already tried is knowledge to suppress. Any technology to improve emissions & efficiency is unacceptable... since that supposed means compromise. The stiff competition for high-profit pickup sales is something they don't want to mess with. So, they will pretend it isn't important. Ugh.

- 11-13-2018 China Mandate.** I don't recall detail from the article. My main takeaway was simply that a mandate of 10% will begin next year in China. That means an equivalent of sales from each automaker is required. It's not a one-for-one situation. Different levels of electrification will earn different point values. Adding up those credits is how they will all meet compliance requirements. This is where the expectation of Corolla PHEV will play a large roll into Toyota's contribution. The rumor of C-HR as an EV makes sense for this too. A full electric-only offering would earn more points than a plug-in hybrid. Imagine if we had something like that here? California has a less significant mandate, but once upon a time, there was a CARB mandate that strict. Much as changed since then. That's really unfortunate... but explains why I have been so persistent over the years. Changing the masses is very difficult, but the impact is far more significant than token gestures... even though the latter makes a bigger impression. Actual change to the status quo isn't exciting. That's why mandates come about. Sometimes, you need to push. Seeing a lot of show with very little impact isn't acceptable to the environment. Our air requires more than just trophies. It is a relief to see China taking the situation seriously. When will that actually happen here?
- 11-14-2018 Cadillac CT6 Plug-In.** The second venture by GM into a plug-in luxury offering has failed. Just like ELR, price was far too high to be any type of realistic choice. How does something that expensive compete? Turns out, it cannot. Go figure. This is one of those very controversial aspects of intent. Why would GM rollout something doomed from the start? They don't get grief from it either. People praise GM for the effort... even though it is obviously not a serious effort. Who did they expect to purchase one? To see how much ridicule Toyota gets is quite hypocritical when you consider how much they strive to make their choices affordably competitive. It's a serious problem when people don't bother to actually study the market. They just cherry-pick and make anecdotal observations. That disconnect with true business issues being addressed is disturbing. But then again, arguing with people online is at best a hollow victory anyway. What really makes a difference is sales, not comment debates.
- 11-14-2018 Subaru Crosstrek PHEV.** We are starting to get speculation. The stir came from a document file by CARB. It was the measure of pack performance for this upcoming new plug-in hybrid. Knowing its origin is from Toyota based upon Prius Prime, there's strong interest. Interpreting results is a bit of a challenge though. We really don't know what some of those raw numbers represent in terms of what consumers will be informed of. They are just measurement numbers from standardized tests. Nonetheless, that's something to discuss while waiting for announcements to come soon. The belief is battery-pack capacity will be the same, but that vehicle less efficient due to the added bulk. We'll find out soon. Supposedly, this offering from Subaru will be available before the end of this year.

11-15-2018 Triple Sighting. That was quite a surprise. I had my first triple sighting today. It was a Prime sandwich, side-by-side... Blue, Red, Blue. I wasn't expecting to encounter 2 other owners randomly on the road like that, here in a region where there have only been a handful offered at random dealers still. Production & Supply will pick up, especially if there are mid-cycle updates on the way (as the inventory and timing with the regular Prius updates strongly suggests). There was the obvious wait for tax-credit fallout too. It has been pretty lonely otherwise. We're still on the early side of history. It's like the Classic model all over again.

11-15-2018 Great Product. I have been watching the desperate efforts of an enthusiast performing damage-control for several weeks now. This is what all that came to: "*Make a great product and people will buy it.*" That's when you truly have nothing. It's so vague, it could mean anything. But since sales never took off, despite having tried hard for 8 years, the time to draw conclusions is upon us. I summarized, then did exactly that:

Volt was supposed to "*leapfrog*" Prius. That meant become a sales leader in the green movement. It never happened though. The status quo at GM is stronger than ever. 3 MILLION sales in the United States each year with less than 1% being Volt, despite 8 years, 2 generations, and a generous \$7,500 tax-credit. People did not buy it.

The automaker you constantly mock has been striving to change their status quo, offering hybrids for each of their traditional passenger vehicles. Their newest Camry hybrid is amazing. We'll be getting a next-gen RAV4 hybrid in a few months. The upcoming Corolla hybrid will be revealed in 2 weeks. There's an Avalon hybrid available too. A new Highlander hybrid is on the way as well, to be built in Texas. C-HR is already a hybrid in other markets; rumor is it will be the first EV offering.

Prius Prime was their first hybrid to offer a plug. With just a simple modification to the existing hybrid system (adding a one-way clutch), it was upgraded to a more powerful EV drive. Corolla hybrid will be getting that same upgrade next year. Crosstrek will be getting it this year, along with electric AWD.

That's how the market evolves. Sales from within must embrace those new offerings, so the traditional choices can be phased out. It means no dependency on tax-credits and a primary focus of getting loyal customers to stay with the same automaker. True leadership is getting ordinary consumers to change, not appealing to just early adopters.

We still await GM to actually deliver an upgrade for their own product-line, offering something... anything... green. Where's that long-awaited SUV with a plug?

11-16-2018 **Initial Thoughts.** The upcoming next-gen Corolla was revealed last night. Sometime this spring, it will be rolled out. In a separate, small announcement, there was a note about a hybrid model on the way. That's what really stood out. The lengthy detail about the vehicle itself didn't matter... since all of that will still apply anyway. It's the addition of a battery-pack that matters. The move forward with electrification is vital. Corolla has always been key. That's the turning point. If you can reach that particular audience, there's a wave of buyers that will help bring about the end of traditional vehicles. Cost is a major challenge. To reach these consumers, there cannot be a noticeable premium. The option needs to be minimal, like that of a package upgrade. More would make it unreachable. But no need to mention any of that with an initial thought. Here's what I posted: We already knew it was coming. The plan for years from Toyota has been to offer their entire passenger vehicle line with a hybrid option. The Corolla hybrid is already available in some other market and next year it will be offered as a PHEV model in China. The next-gen Camry hybrid is amazing and we can see the same thing on the way for the next-gen RAV4 hybrid. Of course, there's Prius Prime too. We've come to expect Toyota to be comprehensive, affordable, and reliable with its tech.

11-16-2018 **Emotional Stir.** The statement which followed was annoying to me: *"This is really annoying... how Toyota keeps making the phev's exclusive for China... if Toyota don't start selling them worldwide they will start having problems with sales. Their hybrid system is amazing, but they are falling behind in every other market except the Chinese one."* How does the word "keep" apply? There is nothing exclusive yet. And how does "falling behind" apply? Who is making further progress with mainstream penetration? It's greenwash spin coming from the uninformed. Much of that comes from the short-minded, those who limit the scope of what they measure. That's not how a giant worldwide automaker works. I do appreciate how multiple markets are now being taken into consideration, but timing and the product itself cannot be disregarded. This was my response: Don't believe the "falling behind" rhetoric. Having a market now that's heavily subsidized and poorly informed should be major clues that something doesn't add up. Reaching ordinary consumers... which Corolla shoppers represent well... is extremely difficult. They want a basic sedan. No compromising that a hatchback requires is acceptable. They are a very different audience. As for China getting the PHEV model first, that's our politics combined with Detroit fallout. Remember, we still don't have detail on what a mid-cycle update for Prime may bring.

11-16-2018 **Random Attack.** Whenever you see a post count of just one, be suspicious. I noticed the tags right away. Most newbies don't have a clue how to use them. Seeing so many and for several to contain key words to stir fear, this appeared very likely to be an attack: *"safety issue! my rear window defrosters don't melt snow, and in snow, window is completely covered the entire road trip and very dangerous."* It's always possible that we were dealing with a case of basic stupidity. It's easy enough to imagine someone not even bothering to actually wipe off snow from their window before driving. Sadly, I see that on a regular basis. But being so early in the season and having no idea where this supposed new owner is from, benefit of doubt is not appropriate. The message was clearly posted to invoke fear. That likely equates to an attack. Nonetheless, I didn't fight back. Instead, I chose my words carefully: The very first post from a new member exclaiming a message of danger is a big red flag. It fits the pattern of a troll, so understand why it is getting called out. As for the message itself, what is the basis of such a claim? Those of us who experienced winter last year (like my wife and I, each in our own Prime in Minnesota) didn't have any trouble. Accumulating snow melted just fine. Completely covered is a rather odd statement too. At a minimum, the humps in the glass will clear themselves off from air push. Where do you live? Not having a brush available will catch some in more mild states off guard.

11-16-2018 **More Attacks.** These didn't come from newbies; instead, they were formulated responses from the disenchanted. Every forum has some enthusiasts who had set unrealistic expectations, been let down as a result, then held a grudge for years. You usually end up putting them on ignore. All that negativity and refusal to consider a different perspective is quite a turn off. This time, it came about from them having the expectation of Toyota progressing faster. They actually want a token of leadership to flaunt, rather than the slow & steady advantage of the masses. It's the trophy-mentality coming from a different audience. They focus on a dislike and dismiss everything else. That too is annoying. I responded to both with any direct quote, just providing some information on that new thread about the upcoming next-gen Corolla: Claims of focus solely on CARB and FCEV is just short-mindedness. We've seen a lot of that lately coming from those in a state of panic about tax-credit phaseout. Focus on early-adopter sales blinded them from issues related to mass appeal. Drawing sales from mainstream shoppers is far more difficult than the low-hanging fruit celebrations happening up to this point. Look at the disaster from GM called Volt. It exploited tax-credits to stir a green reputation, but didn't actually change the status quo. GM didn't get their own customers to switch to a plug. They just kept buying SUVs and the variety of SUV choices were increased. The compact hatchback stayed a niche throughout the entire duration of government incentive. Think about annual sales. GM sells 3 MILLION each year in the United States. Toyota sells about 2.4 MILLION here. That puts the 200,000 tax-credit into perspective. You don't squander them by offering a niche vehicle sold as a token of change. You want to stir actual change. Appealing to early-adopters is much, much easier than getting a showroom shopper to take the purchase into serious consideration. That's where Toyota's approach comes in. When they introduce Corolla Hybrid & PHEV here, they want high-volume right from the start. It means working out kinks in the meantime. That's what the limited market rollouts are all about. Take advantage of CARB and China for the sake of refining the product & production. It's a sensible move... even if it irritates the short-minded.

11-16-2018 **More Spin.** I did actually find this of interest: "*As to the other part, yes, of course toyota is late to the plug-in party. They should have a dedicated phev out by now.*" It was from an antagonist, the sort of person who may actually provide some useful information... if you have the patience. I do, though there is reason to doubt anything constructive will result. I tried anyway: Late to a party for early-adopters? That's completely meaningless, having no impact in any manner for ordinary consumers. As for "*dedicated*", are you really that blind? Prius hatchback from designed from day 1 to deliver EV drive. Remember way back in 2003, when we closely examined what had been delivered? That ability to travel at 100 km/h (62.1 mph) isn't a coincidence. That was quite intentional... should a battery-tech ever become available later to exploit it. That never happened, since battery-density remained far too low and battery-cost far too high. In fact, that's why the next-gen rollout was so limited, due to those same battery constraints. Prime was the first model of Prius actually able to capitalize on that design. So what if a non-plug model filled in sales while we waited? Prius has no traditional counterpart anyway. In the meantime, we got the one-way clutch enhancement. That's a nice affordable upgrade opportunity Toyota was able to take advantage of. Spin of somehow Toyota missing the boat requires quite a bit of turning a blind-eye about mainstream market acceptance. That's what Corolla PHEV will be all about. Delivering technology in the most subdued way to draw interest from ordinary consumers.

11-16-2018 **Sedans.** This is becoming quite obvious: "*People are moving away from sedans.*" On the roads, it is undeniable. At dealers, the trend is noticeable. Coming from automakers, there's a ramping down of production taking place. That's the case for Camry by Toyota. We've known the RAV4 possessed strong potential to overtake. We've seen C-HR reach out into that territory. We've witnessed the larger & smaller models of Prius loss popularity. Change is happening. I added comments to the mix: A few key sedans will survive the test of time. Corolla is the world's most popular car ever. It seems reasonable that affordably priced with the battery-pack concealed entirely under the rear seat, it will continue to persist... allowing Toyota to phase out the traditional model and other sedans. Keep in mind how tiny the SUV choices are becoming. I parked next to a Mazda CX-3 the other day. It was shocking to see how similar in size it was to Prime. It had more headroom, but Prime had a longer storage area. The point is change isn't abrupt and it favors practical. We're seeing the mighty SUV shrink to more efficiency sizes. Plug-In choices won't be for everyone. In fact, we could be seeing an ethanol-based based hybrid someday.

- 11-17-2018 Mid-Cycle Updates.** Ford Fusion Energi will be getting one. It's battery-pack will be increased in capacity from 7.6 to 9.0 kWh. That equates to an estimated 5-mile range addition, bringing the overall now to 26 miles. It's exactly the type of incremental improvement supporters have come to expect. Though with Prius Prime already at the desired target for this stage in EV market penetration, I suspect Toyota will put more focus on packaging. Being able to squeeze the 8.8 kWh capacity better into the space available without trading off the robust cooling & warming design would stimulate new interest. Stuff like that is how you reach out to a wider audience, rather than just bumping up an existing spec. We all see how poorly that did for GM with gen-2 Volt. More range didn't result in more sales. In fact, sales went from flat to fall. Seeing a few inches more of vertical space in the cargo area would be an obvious plus for Prius Prime. Think about how little trunk space Fusion Energi has to offer. That's a rather tight area to squeeze so much battery into. But that's the choice Ford made. We'll see if it makes much, if any, difference for sales.
- 11-18-2018 Understanding Basics.** Offering a nice balance doesn't make sense to most enthusiasts. In fact, their selective perspective is why they aren't recognized as supporters. The product must be well-rounded to appeal to a wide audience. This is what I get in response to such observations: "*You are all over the map.*" Seeing the bigger picture confuses them with so many influencing factors. It's their shortcoming. They don't understand the basics necessary for high-volume sales. I put it this way today: That's called good business. You cannot just focus on a single discipline. All must be addressed for the product to be a success. Accounting & Marketing are just as important as Engineering. Without, the effort is doomed to fail. That's why audience is brought up on a regular basis. Not understanding balance is the mistake GM made, as did the enthusiasts. This is the reason Volt struggled to achieve sales growth. Areas of importance were neglected, which is why expanding beyond just a niche was never achieved. Studying economics as a whole, you'll recognize the value of that balance. This is something Toyota does exceptionally well.

11-18-2018 **Focus.** The obsession with spinning "*too little, too slowly*" concern for GM into a "*too little, too late*" assessment for Toyota is becoming absurd. It's denial on such an extreme level, it's difficult to recognize the lines of reality. Certain enthusiasts turned antagonists are pushing their own distorted narrative so hard, they have lost touch. Stuff like this keeps coming: "*Again, focus your energy on TLTL Toyota.*" It boggles my mind how dismissive of evidence a person can become. They just ignore what they don't like. All you can do is continue to provide information, so those reading the insanity taking place within that discussion can see what's truly happening. For example:

I except your invitation. And since you obsess with timing, that is what I will address.

The claim of "*too little, too late*" is spin on the "*too little, too slowly*" concern which came about from GM's bankruptcy recovery plan. That task-force assigned to oversee that financial obligation wanted to ensure the Volt program would actually deliver some type of economic benefit for the automaker. That very specifically meant delivering a product that was profitable & sustainable. In other words, high-volume sales must be achieved. It never happened though; consequently, greenwashing emerged to undermine that concern.

GM pushed ahead with their plans, using up tax-credits by attracting customers from other automakers. Those purchases are known as "*conquest*" sales. They can be very effective for stirring interest, but financial success requires those initial purchases to draw interest from loyal customers. That outcome never materialized. GM owners didn't replace their vehicles with gen-1 Volt. So, to appeal to the wider audience, GM developed and rolled out gen-2 Volt. Sales growth was still not achieved. 8 years and a bulk of the tax-credits available had been wasted.

Toyota was carefully studying GM's struggle to reach ordinary consumers. Appealing to a niche was clearly a failed effort. The mid-cycle upgrade to gen-3 Prius adding a plug was limited to only 15 states, then rollout was halted entirely. Toyota used that isolated market to collect real-world data for their first mass-market offering. 1.5 years after the halt, that rollout in the form of a new Prius which included next-gen upgrades was the first choice for mainstream shoppers. This was an excellent means of avoiding Innovator's Dilemma, a common problem among emerging technologies

Toyota did not rollout that first dedicated plug-in Prius to all markets though. There was worldwide distribution, they introduce the product to a wide variety of audience, but availability was limited. In the United States, the rollout was limited to the coasts. Inventory in the Midwest and SouthEast only got very small deliveries, just enough for each region be introduced to the technology. It was an effective means of gauging interest while at the same time refining production of the technologies introduced, specifically the dual-wave glass, the carbon-fiber hatch, and the large battery-pack.

2 years into that, the limited rollout remains. It ensured tax-credits were not wasted and set the stage for a mid-cycle upgrade. It also ensured dealers would not get stuck with old inventory, to avoid the Osborne Effect, which could equate to large financial losses or even an end to sales opportunity. Most importantly though, it prevented confusion for shoppers. With limited or no supply in most markets, whatever happens in year-3 can be

considered a fresh start. Education of salesperson & consumer will not have to contend with outdated information.

As of 17 days ago, Toyota still had 109,301 tax-credits available before triggering phaseout. When that happens, an additional quarter (3 months) of unlimited quantity sales can take place before the 50% reduction of tax-credit value. GM will trigger phaseout in just 43 days. Their entire allotment of 200,000 will be used up. Labeling Toyota's position as "*too late*" is an act of pure denial. They have much opportunity available still.

With respect to "*too little*", that's a reference to audience. GM never found a way of appealing Volt or its technology to anyone but early-adopters. Toyota is striving to draw interest from their wide variety of car shoppers. Prius Prime is the first offering to do that. By year-end, that technology will be rolled out as a Subaru vehicle with AWD. In the first half of 2019, that technology will also be rolled out as a plug-in model of Corolla hybrid. Nothing about any of that supports a claim of being behind or struggling to catch up.

Toyota learned from GM's mistakes. It was a real-world depiction of the "*Tortoise and the Hare*" story. GM ran ahead without considering the entire race, celebrating along the way without any certainty of actually finishing the race. Toyota took the time to pace itself and not waste effort on things that may divert it from that finish line... tax-credit phaseout.

In short, the claim of "*too little, too late*" is just rhetoric to distract from what is really taking place.

11-19-2018 **Stupidity?** That question is worthwhile to ask, especially when getting this: "*Your last straw to grab at is tax-credits. How sad. This is just another example of how far behind Toyota is.*" I've been pointing out GM's dependency on tax-credits for years. He just chose to ignore that until now. His act of dismissal doesn't change my position. GM squandered those subsidy opportunities. Rather than use that money to change their own status-quo, it was just a trophy grab. Ugh. Oh well. The enthusiasts will learn the hard way. Something drastic will happen soon. They can't be so stupid they don't see it coming... or are they? Again, ugh. I wonder when we'll find out... before or after phaseout is triggered... hmm? These are the observations I posted about that: My final post on this thread will be to reiterate how often you reflect. That is GM, not Toyota. The purpose of the tax-credits was to establish sustainable sales. Each automaker would use their initial 200,000 to get dealers & salespeople working well with customers to set the stage for the UNLIMITED quantity aspect of phaseout. That is exactly what Tesla did. Notice how there was a massive ramp-up of Model 3 production just as the 200,000 limit was about to be reached? GM should have been positioning to do the very same thing, so Volt could see major surge of sales during the phaseout. Instead, basically nothing is going to happen during that upcoming unlimited period. Toyota, on the other hand, is doing exactly that. By pushing RAV4 hybrid and Corolla hybrid into the mainstream, they are showing a clear path to electrification. It's very easy for business & consumer to recognize & accept the addition of a plug, just like Toyota did for Prius. People understand the technology and cost involved. Seeing that there is also a tax-credit available is a well-timed bonus. Your deep hatred for Toyota and using me as a scapegoat won't change any of that. As for your feelings about GM, the disappointment is obvious. They squandered tax-credits on conquest sales. That's why they are lobbying for more now, to finally target their own loyal customers. TLTL reflection.

11-20-2018 RAV4 Hybrid. We are watching the problems of Detroit unfold again. Only this time, it is worse. They are depending heavily on profit from guzzling Pickups & SUVs again for survival. It's to an extreme now, where everything else is being phased out. That isn't working though. We are seeing buyout offers. A large number is required too. If that doesn't happen, the result will be layoffs. Financial trouble is looming. Making the situation even more of a challenge is the competition. When you do an exception job of knowing your audience, growth can come from gaining market share. This is quite different from conquest, since it very directly addressed loyal customers. In this very real situation, it is Toyota's rollout of the next-gen RAV4 hybrid. An expectation of up to 25% sales being hybrid has been set. How is easy to see. The 219 horsepower system will deliver 39 MPG combined for a starting price of just \$27,700. That news today shook the industry. Rather than making RAV4 hybrid favor efficiency, like Prius, it took on power attributes even more so that Camry hybrid. That makes it an industry-top for efficiency, but without compromise. In fact, that highest performance package is actually a hybrid. That will attract cross-shoppers... which is really bad if you are an automaker who has become very reliant on SUV sales and has nothing comparable. For GM, they don't have anything even remotely close. For that same price, you get 26 MPG. That's such a drastic difference, it's a game changer. Adding to this upcoming disaster is the reality that Toyota's hybrid system provides a very easy means of adding a plug. Put totally another way, Volt is dead. Competing against Prius never made any sense and now there is literally nothing the enthusiasts can say anymore. All those times I pushed for a SUV offering the technology in Volt, they were smug. Now, they are in trouble... too little, too slowly. This new hybrid will become a key contributor to change.

11-21-2018 Change. After so many years of having to put up with rhetoric, it's over. I'm on the offensive now. My effort to deal with "*fake news*" long before the term was coined... or even recognized as a problem... was challenging without real-world data. But that's not the case anymore. So, no need to put up with it anymore. After all, they allowed the tax-credits to be wasted. So much opportunity missed... Much of it came from enthusiast's blind hope. Sadly, some of that continues substance: "*I'm hoping GM surprises everyone with Voltec powered SUV.*" That isn't even a claim without substance. It is literally just a wish. I can turn-around the "*behind*" by pointing out how it is really a matter of being ahead: Not much of a surprise, since we've been waiting for years. Toyota is catching up too, by setting their stage with RAV4 hybrid. 39 MPG combined from a 219 HP system starting at \$27,700 is a nice base to provide a plug option.

- 11-22-2018** **Thanksgiving.** This was interesting to read: "*GM has decided to take a backseat in this fight. It's a shame they have gone from leading to also rans, great job.*" Coming from an enthusiast, it makes you wonder how much of my observations are now being taken seriously. I see supporters sharing similar sentiment, but not those who antagonize routinely. Their frustration was vented by using me as a scapegoat. Turning attention to GM instead is a switch. My guess is the reality of GM failing to exploit the tax-credit phaseout opportunity, quite the opposite of what Tesla is doing, has become a painful recognition of the situation at hand. Volt is in serious trouble. It doesn't matter whether or not Toyota puts on the pressure. We can see it building from other sources... like Honda and Hyundai/Kia. Eventually, VW will get into the game too. There's just nothing from GM anymore. The legacy that thrived on ambiguous press releases, and the stirring of hype which resulted, has become silent. The lesson learned from "*over promise, under deliver*" appears to have felt in a painful way. My guess is stockholders. Though, there is the difficult to deny shift from sedan to SUV that's making plug-in car sales more of a challenge. Who knows. Today, I'll simply be thankful for the recognition of that monumental problem GM got itself into.
- 11-23-2018** **Nissan Surprise.** Looks like the plan for the next-gen Leaf is now in disarray. Nissan's CEO has been arrested for financial crimes. That at a minimum will delay release of anything new. No one really knows what to expect. The surprise news has been quite a shock to the industry. There's a partnership with Renault that's left hanging as well. What does it mean for an automaker already dealing with complex challenges to suddenly and quite unexpectedly lose their leader? Did anyone else share the knowledge, experience, and foresight to take over? This is kind of like the situation for Tesla. Having a single-point-of-dependency can be a significant risk. Just look at the mess resulting from GM with their lost leader in the effort to deliver Volt. When he left, so did everyone else. Some of that was likely preventative moves to circumvent damage-control efforts before they are needed. Already being on a course to problems is nothing new. For Leaf, it was not having any active cooling of any sort. Neither air nor liquid for keeping the battery-pack from getting too hot never made sense. Yet, that was what Nissan delivered. This newest offering was supposed to change that, by introducing a liquid-cooled system. That isn't going to happen on the timeline anticipated now. Will it later? Who knows?

- 11-24-2018 Shame.** When antagonists turn to emotion appeal, you know they're in trouble. Struggling to deal with numbers is what causes that. They see shortcomings when constructive measure is used. That's why there is always such a push to dismiss counts. Being held accountable for specific milestones being achieved would reveal failure potential. It's especially bad when they try to turn that to a one-sided debate. Long story short, Volt is in serious trouble. Low sales even with a \$7,500 subsidy and years of visibility spell doom. How could it achieve necessary sales growth with such a high MSRP and the loss of tax-credit help? Compact hatchbacks are a difficult sell even with great performance. Who wants that when there's a growing EV market appealing directly to early-adopters? All those who wanted plug-hybrid choices as technology leadership have moved on. They couldn't care less about ordinary consumers. Ubiquitous equates to boring as far as they are concerned. If it doesn't stand out, what's the point? Their perspective meant problems from the start. It's that trophy-mentality issue... hence now the turn to shaming. Ugh. I kept my acknowledgement of their emotional appeal short: That's a double-standard, expecting "*significant sales numbers*" from Toyota to the point of SHAME but no mention of GM. Why not? Both Volt & Bolt are stuck as niche offerings, with no potential for high-volume due to such a high price. Notice how much Toyota strived to make Prime affordable? Notice the same for RAV4 hybrid and its potential to offer a plug?
- 11-25-2018 Golf Cart.** It is interesting when you encounter a comment from someone with so little background they post something like: "*I have seen this mentioned a few times now on different medias, referring to "Golf Cart". However, I can't seem to get any grasp on what this word relates to. What is the meaning of a "golf-cart" and why do the reviewers keep using it?*" Not having any frame-of-reference makes you wonder if what you post will be misinterpreted. I gave it a try though: "*Golf Cart*" has been the term used by reviewers for nearly 20 years. Specifically, it is a reference to the on/off nature of golf-cart operation. It's what they observe while driving on HV mode. To us, it means the reviewer is at a loss, without anything useful to contribute... a dead giveaway they are not a good resource for the required knowledge to actually to the review. Sadly, it also reveals the uninformed nature of the audience here. Not having knowledge of the past indicates they stand a chance of pulling the same greenwash nonsense again. Reviewers will continue to write based on anecdotal observations, rather than doing actual research. Post comments on those reviews. Don't allow them to pass off that dribble as journalism.

11-25-2018 **Build Up.** Can you feel it? I think others sense that the announcements Toyota is planning to make in 3 days will be rather significant. We know there's a refresh of the look coming as part of a mid-cycle update. What else would be enough to cause so much worry? Will the loss of tax-credits contribute to growth in demand for Prius? It's a screwy market right now with the price of gas so low. But with so much blame of sales slipping put on the visual appeal of Prius, this upcoming change eliminates all former claims. Antagonists will have to start over. That's really difficult, especially when sentiment like this is now circulating: *"I too am amazed by Voltec and amazed GM have failed to capitalize on it's greatness vs the competition."* Supporters abandoned GM due to that lack of progress. They expected the technology to be spread years ago. In fact, enthusiasts hyped how much faster that would happen compared to what Toyota did with their hybrid technology. That failed to happen though. GM dropped the ball. All that leadership bragging didn't result in substance to support expectations. Nothing else was rolled out to compliment or succeed Volt. No progress forward is a very real problem that no amount of spin can overcome, forgive, or excuse. There's a building up of something. Year-End will bring about a lot of tax-credit negativity reports. The articles will likely not be kind, especially with the Detroit autoshow so close at that point. My guess is we'll find out fairly soon, perhaps right before month-end sales are posted. Since GM doesn't share them anymore, the estimated values will include lots of commentary & speculation of what could come.

11-25-2018 **Holiday Road Trip.** \$2.29 today for me, on the way back from Wyoming. We celebrated the Thanksgiving Holiday with out-of-state family. Our drove back through the Black Hills of South Dakota over the weekend during a snow advisory. It was difficult to see lanes at times, but road handling was just fine. Overall efficiency, despite the 80 mph travel and no opportunity to plug in, was 45.2 MPG.

That 1,532-mile trip to coal country for the holiday really got me thinking about this upcoming oil crisis. We are about to see the bottom drop without any easy path to recovery.

We hit peak back in 2010, clearly marked by the loss of supply stability. That original measurement of oil quantity available in the ground still was proven worthless the moment investor activity started to become unpredictable. Seeing how much of a push coal has become in opposition to both natural-gas and renewables is what really made the problem obvious. The oil industry was already fighting among itself. That meant the entire energy market would end up getting turned upside-down.

Listening to the supposed "*experts*" related to plug-in vehicle support, any solution is problematic. Most have no idea what happened in the past. They don't bother to study hybrid history. Repeating the same mistakes will happen as a result. It's like reading reviews from over 15 years ago. There is no understanding of the market or what motivates mainstream consumers.

Our biggest problem in that regardless appears to be perspective. People here look at China as pusher of mandates and never bother to look beyond the government influence. If they did, it would become apparent that the culture there is more accepting of change. Our attitude here is if the vehicle isn't absolutely perfect, it will fail. We obsess so much with fine detail of reviews, we completely miss the point of the technology. That's really sad.

This plummet of gas prices will bring that point home in a painful way.

Watch what unfolds in the next few months.

11-26-2018 **Closure, Introduction.** Surprise! Things sure took an interesting turn. Exactly one month ago, the final attack took place and dragged on for weeks. It was the end of Volt was drawing near. Such an expensive offering unable to grow sales beyond a niche was doomed with the loss of \$7,500 subsidies helping it barely sustain. Today, a post declaring an end to production, complete with the March 2019 date specified, meant everyone still a hopeless enthusiasts would show up on that discussion thread to provide damage control. Keep in mind how much pride fundamentally influences their actions. Being misleading & dishonest had become routine for them. I could witness all kinds of emotionally driven responses. Objectivity never really existed. They selectively supplied information to create a narrative. That's why they were called "*enthusiasts*" rather than being seen as supporters. You can't just ignore what you don't like. In their case, it was business goals. They were compelled to focus solely on engineering achievement. That made them blind to profit & growth. Tradeoffs for the sake of delivering a balanced product was unacceptable. Their desire was a standout vehicle, not for something to become ubiquitous. That meant those enthusiasts would be at odds with supporters. It was the fighting that would emerge as a result which I concentrated my efforts on. What would they say & do to undermine themselves. It was a conflict of purpose. You can't have both. Either the technology would be for the masses or it would remain specialty. Those concepts are mutually exclusive. They didn't understand that. IT would spell their doom... and that's exactly what this topic was about. I suspect my blog entries for the next week or two to document that downfall, addressing the mistakes they made and the effort to conceal & deflect.

11-26-2018 **Closure, What A Mess.** Objectivity became a lost cause almost immediately: "*Where do you get that we've reached peak oil?*" When you are dealing with people who are supporting a narrative, it's easy for them to forget about their own blinders. They fail to see the bigger picture. This was a great example of that. I responded with an explanation: Instability of the market supply caused investor activity to become unpredictable. That marked "*peak*" oil. That combined with sedan marketshare has falling from 50% in 2012 to 31% now. Chevy Cruze sales have plummeted. The Lordstown assembly plant will be closed, as a result. That's where Volt was built. This is the "*too little, too slowly*" outcome those here shrugged off as a concern... the missed opportunity so often brought up as a problem not to be taken lightly. Volt is now dead without a successor established yet. That model of Trax or Equinox using Voltec should have been made available years ago. GM fell into the innovator's dilemma trap. That lead they had was lost. Meanwhile, we see EV rollout challenges that have not been properly addressed. What will happen with Bolt now? Will GM promote plug-in hybrids at the same time, despite the mixed "*range anxiety*" message? That abrupt change of approach going from Volt to Bolt is very confusing for potential customers.

11-26-2018 **Closure, Begged.** They claim to have had a consideration of the bigger picture. Evidence to the contrary is abundant. Whenever I brought up Camry hybrid, they would freak out and scramble to change the topic. That's why RAV4 has been even more of a scare to them. GM abandoned the idea of plug-in hybrids as a solution. We had confirmation (ambiguous in GM's usual approach) of that over a year ago. They announced 20 new "*all electric*" offerings to come. It was a vague reinforcement of the effort with Bolt... which makes sense, because GM makes terrible hybrids. They are expensive and are not efficient. It came down to this: "*The Volt was front and center when GM begged for their Bailout 10 years ago.*" No surprise that topic was stirred to look at the beginning, rather than focus on the end at hand. Look backward, not forward. Ugh. I punched back with: "*Too Little, Too Slowly*" was the concern raised by the bankruptcy recovery task-force in response to that. They had good reason to question how Volt would become a profitable contributor to GM's well-being in those next few years. Our government lost money in the end, selling their bailout shares of GM stock at a loss. Volt struggled with sales despite the \$7,500 tax-credit, never achieving growth to a sustainable level and far too expensive to be competitive. It has been a slow-motion disaster, as we watched GM fail to adapt to change. They have no clear path to electrification still, after all this time. There is no hybrid system in place to usher in plug options for any of their larger vehicles. Equinox should have been taken on the role of Volt successor long ago. There isn't even a hybrid option available yet. How is a 26 MPG rated vehicle going to be profitable when the competition is about to rollout an equivalent size & style offering with a 39 MPG rating? How will something with a plug addressed with such a disadvantageous stage now set? To all of you who were hostile to those words of warning, what do you suggest should happen as a next step?

11-27-2018 **5 Days Ago.** It was a loooong Monday at work. I wasn't able to sleep well as a result. So, I jumped online and stumbled across this reply to an old post: "*You hang out here too so you can bash the Volt just like you do at [the daily blog for Volt]? Geez. Not wasting my time with you here just like I don't waste my time with you there... Buh bye...*" In that post from 5 days ago, he could see the build up to the fallout about to come... a didn't like it. There are many who don't want to face reality. Consequences of the poor choices they endorsed were starting to emerge without any means of denial available. All the excuses have been exhausted. Pretty much anything you say at this point has become hypocritical. I was delighted to point out the situation too: Pushing GM to finally diversify by offering Volt technology in a vehicle like Equinox is bashing? You've got really messed up priorities if you think that. Of course, just 5 days later, I've been vindicated. The reason for my "*too little, too slowly*" concern was about Volt's financial viability. If GM didn't find a way to increase sales volume, it would be discontinued. That's basic economics. If the product doesn't grow, it will fail. Turns out, that is exactly what happened. Rather than the plant producing volume ramping down Cruze as it needed to build more Volt, the entire operation collapsed. The transition to an electrified offering failed. You wasted your time by not listening. My concern originated from the bankruptcy task-force, those put in charge of making sure GM had a solid plan to get back to good financial health. Volt was claimed to be part of that effort. Calling my contribution to get GM to diversify bashing is just plain wrong.

- 11-27-2018 Closure, Wild Ride.** That's how I describe today. Fallout from yesterday's announcement has been all over the place. One enthusiast came up with spin to label the 14,000 employee's GM is planning to layoff and the 5 production plants they will close as a move to electrification. Several stated this was the plan anyway, to abruptly stop production mid-cycle without any type of replacement already in place. Ugh. Our president got angry and threatened GM will some bizarre statement about taking away subsidies. What subsidies? The tax-credits will trigger phaseout next month regardless. One publication took substituted "Cruze" for "Volt", then went on and on about expectations not having been met. Of course, none of it matters. Production of both will end anyway. Impala will be discontinued as well. It's a nightmare for anyone who ever attacked me claiming the "*too little, too slowly*" concern was actually an effort to undermine Volt. That has been proven untrue to such an extreme, there's no recourse. They are simply screwed no matter what they say. As a result, it has been remarkably quiet on that front. I have been watching their wild ride. Uncertainty about what happens next is growing. The belief is GM will make an announcement in the next few months about an upcoming successor to Volt. It will undoubtedly be a scaled down version of the system adapted for a SUV... something long, long overdue.
- 11-28-2018 Closure, Downplay.** It's common to address defeat by downplaying the outcome. That's an expected response, as they put it: "*Much hand-wringing about nothing. We always knew that Volt was a gateway drug. This move by GM was expected. Continuing to produce models that are in a declining sales spiral would be worse.*" I was amused to read that, knowing there's never any substance to claims. That absolute of avoiding detail at all cost is their mantra. Next thing you know, they'll spin the plant shutdowns as preparation for a new electrification program. Trouble is, that couldn't be any more vague. What is GM attempting to achieve? Preventing job loss isn't getting addressed. It's that continued blindness of business. Keeping focus only on engineering efforts to advance technology can (and this case did) result in consequences of negligence. What the heck are dealers supposed to supply in sell if there is nothing to transition to? A diesel model of Equinox was such a wasted of resources. Yet, that's why GM delivered instead of something electrified. I posted this in return: That is a direct contradiction to what scores of enthusiasts have been saying ever since the topic of tax-credit phaseout was brought up years ago. Rather than abruptly stop production mid-cycle, GM's supposed plan was to drop MSRP to match the subsidy reduction. There is no expectation from GM. Using up limited tax-credits without establishing a successor in the process is a reckless business approach. What were they risking the PLUG-IN HYBRID approach for, to establish EV sales? That makes no sense. Even the narrative of succession is baffling. GM wants to produce Pickup & SUV only. Investing in a compact hatchback and a compact wagon is counter-productive... especially knowing that GM had already demonstration a plug-in SUV a entire decade ago, intended for rollout in 2009. Your attempt at damage-control is a load of rubbish. It's easy to prove too. Being an expectation would mean a plan has already been conveyed. What is the plan? What does GM intend? Tell us about the next move.

11-28-2018 Closure, Questions. The situation for GM has been revealed to be an economic disaster. The enthusiasts are quite angry by this outcome... what's remaining of them, anyway. So many became disenchanted, they are nothing but bad memories now. To think of how many of them moved on to other early-adopter conquests... That's why they hate me so much. To find out I was correct, that my concern for business well-being was indeed sincere, is too much to accept. What do you do at that point? I warned them about missing so much opportunity. Rather than persuade GM to take a better course, they obediently followed without question. It was a terrible choice. Fighting me made it worse. They have no doubt anymore that the outcome I warned about was a genuine concern... because that's what happened. Sadly, I was right. There was a hope someone in management would wake up. But with so many executives stepping down every time there was a problem, there wasn't ever a clear message of intent. What were they trying to accomplish with Volt? At each stage, the goals listed changed... and not for the better. Ugh. I ask questions for good reason. Here's are the most common:

Who is the market for Volt ?

The years of trying to evade that question and doing everything possible to avoid detail with regard to GM's intent are over. Volt failed without any successor established. Now, enthusiasts refuse to address the future. There's only vague mention of something coming... to the extreme of not even making claims of being "*vastly superior*" or "*10 years ahead*" anymore. This is disenchantment to an extreme.

Too Little, Too Slowly ?

That was the concern. It always comes down to the reality of economics. GM took a terrible approach with a half-hearted effort that did not result in the widespread acceptance required for a new technology to become a viable replacement for the old. No amount of spin can conceal that either. We all see that sales were a struggle, even with the \$7,500 tax-credit. Phaseout of that subsidy is rapidly approaching to. So, it makes no sense building a money-loser anymore... which brings up a new question:

Will there be a plug-in hybrid ?

GM's message of Volt being the solution to "*range anxiety*" was abruptly changed when Bolt was revealed. That EV offering was to become the new solution, since it offered 4.5 times the battery capacity, extending range without ever having to use a gas engine. Unfortunately, sales of Bolt did not achieve the significant growth that was required.

Where does that leave GM now ?

Hope to portray an image of industry leadership has been lost. GM has slipped into the bucket of automotive choices, no longer a choice that stands out. In fact, we see several other automakers all striving to deliver what Volt failed to achieve... being an affordable offering sold to mainstream consumers. It makes you wonder if GM leadership is willing to accept the idea of cooperation, becoming an industry player instead of being an example of what not to do.

What do you suggest GM should do ?

- 11-28-2018** **Closure, Get Over It.** Their denial is overwhelming. It really is over. Volt failed. Moving on after such a loss is difficult though, especially when they resist acknowledgement. Oh well. I'll keep reminding them of how they got themselves into such a mess and suggest ways of getting over it: My concern for GM not carrying forward the technology in Volt to something GM customers (those who are looking to replace their older GM vehicle with a new one) will actually purchase has been overwhelmingly confirmed as valid. Why would I go anywhere when the effort to get proper attention about the lack of advancement is finally taking place? I couldn't care less about hurting the pride of some enthusiasts not interested in supporting something for ordinary consumers. They'll just need to face the reality that range & power did not actually equate to a "*vastly superior*" vehicle. Volt was unsuccessful. Who cares. Try again. The goal all along has been to get each automaker to deliver something that would be able to replace their own traditional offerings. GM still hasn't attempted that yet. Rather than build an Equinox or Trax using Volt technology, but with a more affordably sized motor & battery configuration, GM wasted time & credits on conquest. That "*more is better*" approach Volt took failed. Neglecting mainstream priorities was a terrible decision. So what if I was the one who pointed that out years ago and kept reminding everyone that the imbalance was too much of a sacrifice? Get over it by focusing on what much be done next, rather than shooting the messenger. Continuing to evade the issue will not fix it.
- 11-29-2018** **Closure, Repeating History.** It's getting messy. They are stirring rhetoric any way they can to control the situation. It's hopeless, of course. But that's what happens when they come to realize the fight is over. The lost... which is why attempts to rewrite history are their focus at the moment. They want to prevent onlookers from noticing the pattern. I'm not going to allow that, especially after the hell they put me through: It was about preventing mistakes from being repeated. When pointing out lessons learned from Two-Mode and the recognition of following that same pattern again, the messenger was attacked and the message obscured. Enthusiasts didn't care. They kept up at attitude of hope without any substance to actually support such a stance. Volt was vastly superior, period. We all watched that fall apart with gen-1. GM focused on size & power for Volt just like they did for Two-Mode. But this time, the "size" was range instead of vehicle bulk. That imbalance was a costly mistake for Two-Mode and quickly become a mistake repeated for Volt confirmed by soft sales. The resulting price was too high. The rollout of gen-2 for Volt didn't address the problem. Rather than strive for a better balance to draw in more customers, that potential was wasted by increasing the range and increasing the power. That turned out to be a colossal blunder too. Sales never improved. That was a terrible sign, knowing that even with the \$7,500 tax-credit, reaching a sustainable level to remain an everyday offering would not be possible. That is why Volt was cancelled mid-cycle. Waiting for the normal product-cycle to conclude would be far too costly. So now, the technology is left without a successor established. GM will basically need to start over... which is now why the enthusiasts are so angry. Their arguments claiming other automakers are years behind have completely fallen apart. There will be a few who dispute this history. They'll remain in denial. It doesn't matter, since they are not the intended reader anyway. Know your audience.

11-29-2018 **Closure, Fail.** Do everything possible to keep focus exclusively on engineering. Never let anyone draw attention to business. Ugh. It's been that way for 10 years: *"Volt was and is a fantastic car with the best US plug-in sales for any model. To this day. I don't call that a fail."* Ironically, I get attacked all the time with the reasoning that no individual can draw a conclusion, since whatever goals they identify are their own. It's that spin they do day in, day out. Don't ever let someone outside your group of enablers to sight anything related to progress. Again, ugh. I knew the end of production for Volt would turn into a fight. That's what happens when an enthusiast gets cornered. They don't surrender or admit defeat. They defend their position to the bitter end. That's how pride works. Go down with honor. What a waste. Oh well. This is when it happens. Right now. It's official. So, I humor them with bittersweet facts: Better than any model is a relative measure, not what's necessary for sustainable business. The goal was to achieve mainstream sales. That specifically is a minimum of 60,000 annual without tax-credit dependency. Setting a target like that is how profit is achieved. Your opinion is that of an early-adopter taking advantage of a \$7,500 tax-credit... not GM... not stockholders... not EPA... not CARB... and certainly not ordinary GM customers. So, it doesn't matter. Know your audience.

11-30-2018 **Closure, Real.** Their reality is crashing down. Mine is simply the stage call closure. I get this: *"Let's be real."* They get this: GM wasn't able to face the true competition... traditional vehicles ...so you want to spin a narrative that Toyota won't be able to either. Who are you trying to convince? Know your audience. In this case here in the United States, a majority of the country has absolutely no idea what Prime is. That's because Toyota waited. As of the first of this month, they still had 109,301 tax-credits left. Allowing GM to use up the few they have left, while in the meantime reinforcing their commitment to traditional vehicle replacement, totally makes sense. The next-gen RAV4 hybrid and introduction of Corolla hybrid are undeniable moves toward electrification. Even the most uninformed consumer will recognize Toyota's commitment to using batteries more. The addition of AWD to Prius is a new draw too, as are the mid-cycle appearance changes. The advancement forward is quite clear, even without Prime. The fact that Toyota has been burning down Prime inventory and hasn't said anything whatsoever about the 2019 model-year makes us wonder if the Detroit auto-show will bring about some mid-cycle updates... perfectly timed to take advantage of the changing market situation. That lack of advertising will finally change. Toyota will have an affordable, extremely efficient, plug-in hybrid available... that they worked out all the details of high-volume production for already. In other words, your attempt to portray Toyota's silence as a lack of interest is really the calm before the storm. They have been preparing for wide-spread acceptance. That's why distribution has been spread so thin. Toyota was observing each market to come up with the best plan for mainstream penetration. This isn't rocket-science. It's simply studying consumer behavior. GM didn't do that with Volt. Rather than trying to attract ordinary consumers, they appealed to enthusiasts... giving that group of early-adopters exactly what they wanted. It's a business mistake known as *"innovator's dilemma"*. GM built a vehicle for a limited audience. Oops! It's their loss, not Toyota's. We see that Corolla hybrid is already planned to get a PHEV upgrade. The process is simple & affordable, as clearly demonstrated by the Prime update to Prius. Camry, C-HR, Avalon, and RAV4 hybrids can all be upgraded that way too. Facing the true competition is quite real.

- 11-30-2018** **Closure, Spin.** It is getting so bad, you can see why so many were so easily manipulated during the election. There's simply no critical thinking from some people. They just brainlessly repost what they believe, rather than actually give some thought to what is actually being conveyed. They have no idea. The words don't have any substance. It's all primal instinct at some point, just lashing out with whatever they have available rather than considering all factors. Oh well. That is their loss, not mine: What I see is that you are so vague, you aren't actually saying anything. It's the usual rhetoric, repeated over and over to avoid addressing issues. The absence of detail is a dead giveaway. No substance.. As for projection, to what? All automakers are held to the same standard market criteria. Without the necessary quantity, price, and efficiency, the necessary profit will not be achieved. That's how a business functions. GM failed to achieve that. So, they are moving on because they have run out of time (tax-credit phaseout triggered). As each of the other automakers reach the same point, they will be faced with a decision as well.
- 12-01-2018** **Closure, Attacks.** Once they've run out of things to retaliate with, you get attacked personally. The enthusiast transforms to an enraged antagonist. Lack of substance to their claims and evidence being presented as proof of their oversight makes that course of action quite predictable. I've seen the behavior routinely. At some point, they just give up and laugh. Sometimes it becomes so cynical laugh, the word smug is too kind. It borders on evil. That's quite bizarre to see in writing. This is how it starts: *"I see john is still spewing his filth... Some things never change. Happy I was able to add the 10th neg vote to several of his posts. LOL."* Disbelief is always my reaction to that. How bizarre to be so clueless: That stick-your-head-in-the-sand response to posts is what keeps me coming back. Hiding what you don't want to see isn't constructive. And in this case, it has been destructive. Volt gen-1 failed to address purchase priorities of mainstream consumers. It had a number of shortcomings the group of enthusiasts here worked hard to assure everyone the needs of the changing market would be met by the next-generation offering. Volt gen-2 failed too, by not even addressing the issues resulting in sales struggle. Rather than GM striving to meet its own pricing target and making the interior larger, the design was enhanced to further appeal to enthusiasts. That didn't work though. Sales remained flat. The significant growth required to persist beyond the expiration of tax-credits was not achieved. The fact that you use *"filth"* to describe essential business is the type of closure needed here to declare Volt dead. The *"too little, too slowly"* concern was quite correct. GM didn't spread the technology in time. Accounting is something enthusiasts always despise. I saw the trophy-mentality problem emerge on this blogging site right from the very beginning, over 11 years ago. Recognition of mistakes being made were dismissed and the messenger attacked by some, but most just left from disenchantment. Look at how many abandoned Volt and the growing resentment for GM being so slow to take a next step with plug-in hybrids... to the point where some wonder if GM will just give up and only offer EV choices. It's a disastrous outcome you contributed to, not me. I certainly wasn't any part of the enabling that took place to encourage GM to continue down a path that would not led to acceptance by ordinary consumers. No label or negative voting will change that.

12-01-2018 Closure, Know Your Audience. They don't... still... after all this time:

I repeat that mantra on a very regular basis. It has taken place for the "*Who is the for Volt?*" question I asked relentlessly in the past. Enthusiasts simply didn't care about the wants & needs of mainstream consumers. They had convinced themselves that Volt has "*vastly superior*" attributes ordinary showroom shoppers would be willing to pay a premium for. Even with the \$7,500 tax-credit, that approach failed to stir interest.

All these years later, the heavily promoted "*EREV*" campaign only served to confuse & deter. GM didn't understand. Enthusiasts didn't understand. It was only Prius owners who did. They understood. They knew their audience... which is why so much resentment has come about. Prius owners recognized how to reach out and capture the hearts of random consumers.

Potential buyers are customers wandering the showroom floor. They are looking for a vehicle with set attributes at a good price. This is where plug-in hybrids show great opportunity. Hybrids have become so well established, most all of the misconceptions are just a faint memory now. In fact, there is an expectation of the technology having improved over the years. That's why the addition of a plug is looked upon as a natural next step.

It would be incredible for every car to already have access to overnight 240-volt charging. Unfortunately, many consumers face the challenge & expense of just that for one of their vehicles in the household. Access to public rapid chargers (level-3) are pretty much non-existent still. Only a small number of initial locations have been built and connection-type is not standard yet. Sadly, most people don't even know what most of that means.

We know it signifies is overnight having to charge with a 120-volt connection, some with just an 8-amp rate. That very much limits battery-capacity; however, it does offer a very smooth and intimidating approach to mainstream acceptance. It simplifies the transition away from traditional vehicles. During ownership, many owners will likely consider a 240-volt upgrade for their overnight charging.

This information is what enthusiasts have refused to accept... hence the negative votes. They don't want to face the reality of change. It is monumentally complex and pushback intense.

12-01-2018 Closure, Stupid Decisions. The mess coming to light is an outcome far worse than they ever imagined. Their own "*behind*" claims are being revealed as reflection. Focusing on the wrong thing for too long has dire consequences. I certainly tried to get them to pay attention to what was important. They didn't care, until now. Of course, it's only denial at this point. But change has to start somewhere. Seeing the mistake is progress, though it could take a very long time before the next step is taken. I keep pointing out facts until then: Resentment for Toyota is understandable. The upcoming next-gen RAV4 hybrid (available in March) will deliver a combined city/highway rating of 39 MPG starting at \$28,745. With 118 horsepower output from the electric motors (AWD system), the combined output with the engine comes to 219 horsepower. That totally outclasses GM where it hurts the most, their premiere SUV. Why GM never bothered to put Volt technology in Equinox remains a mystery. Most likely, it came down to cost. There simply was no way to offer such a configuration affordability. Trax is a new, smaller SUV offered by GM. That could be a nice candidate as a plug-in hybrid choice. But that could seriously impact sales of Equinox. Whatever the case, this is GM's own doing. They focused on offering an expensive Cadillac plug-in hybrid and a Malibu hybrid instead. Both are sedans, a market GM clearly has little interest in. To make matters worse, GM just rolled out diesel models of both Cruze & Equinox. What in the world were they thinking? Stupid decisions like that is why GM is falling behind. It is why I get personally attacked, since there is simply no way to deliver such bad news without sounding bias. Those are the facts though... like them or not.

12-01-2018 Closure, Fake News. It's nice to finally have a term to identify the behavior. Naturally, it will be misused. We see that often the "*troll*" label, but the point of drawing attention still takes place. So, it's ok. Going unnoticed is the problem, which I continue having to deal with: That is a common "*fake news*" technique. They state a position, but provide supporting evidence for something else. Both make sense. They aren't actually associated though. The hope is people aren't paying close enough attention to notice. That's the case here. It's easy to prove too. Since the description doesn't contain any detail, there's no association to anything at all. That's the nonsense our president pulls. Vague is a dead giveaway of rhetoric. The nonsense about Toyota being behind is rather ironic. Because when you point out facts, GM is the one coming up short. With respect to electrification, we see Toyota offering a hybrid model for each of their popular passenger vehicles in various markets... Camry, Corolla, Avalon, C-HR, Highlander, RAV4. All are plug-ready. Increase battery-pack capacity, then add a one-way clutch. That's it. The approach sets a clear path forward with very little resistance, due to the approach being so inexpensive. In fact, the upgrade to hybrid for RAV4 provides such a significant MPG improvement, the price difference is trivial. And with such a strong reliability reputation already established, there is a strong possibility of drawing interest on the showroom floor. That sets the stage for easy plug offerings with the next round of upgrades. There's no rationale for the "*innovator dilemma*" claim. It's a clear path forward, advancement with significant return. Toyota will be able to discontinue production of traditional models at some point. Their plan is well underway already. GM literally has nothing yet for product-line advancement. It's all a big mystery, leaving both dealer & customer with no green choice available... which is the "*stuck*" situation described by innovator's dilemma. Notice how the definition focuses on sales & profit as the measure of success, not perceived superiority?

12-02-2018 Closure, Mistake. I'm hearing more and more comments like this, finally: "*GM's big mistake was not getting Voltec into a larger car, SUV, and truck.*" Imagined if they would have just listened in the first place. Sharing of experience was intended to help; instead, they felt their pride was in jeopardy. What a waste. Oh well. I share the observations regardless of how they will be received:

Do a search for Equinox & Two-Mode on this site. You'll find countless posts over the years of me saying exactly that... hence the "*too little, too slowly*" mantra. I kept pushing for diversification; the enthusiasts here kept pushing back.

For a Toyota owner to endorse GM's technology, sounding off favor for spreading it to vehicles across the fleet was too much. They absolutely refused even just the spirit of cooperation. Someone with over a decade of prior experience in the market couldn't possibly understand mainstream consumer better than a bunch of unrealistically optimistic early-adopters. Ugh.

Of course, they understood that the transfer of the same battery-capacity to a much less aerodynamic vehicle that weighed significantly more would compromise their principles. The result would be a lowering of range & power, making far too similar to the supposed competition... which exposed their underlying problem.

The enthusiasts didn't want to recognize the market as a whole, to acknowledge GM's own product-line. They forced a scope of "*plug-in owners*" instead. That was incredibly foolish, focusing on those who supported electrification anyway. It was only low-hanging fruit getting any attention. That far more difficult objection of appealing to SUV buyers was being neglected.

Now, we see the price of their choice to disregard homework the teacher assigned. Rather than turning in what was required, they put emphasis on other deliverables... many of which didn't contribute to the necessity of ending traditional vehicle production. They gambled that "*it's worth it*" promotion would result in high-volume profitable sales.

That effort failed miserably, hence attacking the very person would was heavily pushing the course that should have been taken years ago. They screwed up. They didn't listen to the voice of experience. They are coming trying to come to grips with how much opportunity had been missed.

Ironically, the claim of desperation to catch up are now true for GM. The tables have turned. Honda rolled out Clarity. Chrysler rolled out Pacifica. Mitsubishi rolled out Outlander. Subaru is about to roll out Crosstrek. Ford is working on an Escape. All are larger plug-in vehicles that are not Toyota. The enthusiast obsession was wrong, very wrong. Each automaker is working hard to appeal to their own customers. GM's focus on conquest instead was a terrible mistake.

That brings us to the catch-up effort. Will an Equinox or Trax with Voltec actually be endorsed by this group of enthusiasts? To do that, they will be falling back on their own words. It's an admission of error, a rather hypocritical one at that too. Swallowing pride to overcome such a mistake shows strength though... and will be welcomed. GM joining

the team to help quickly deliver affordable plug-in offers requires compromise, so that will definitely be useful.

I'm quite curious how such a big mistake will finally be reconciled.

12-02-2018 **Closure, Vision.** This quote from an article published today sums up the situation well: *"While it's not too late for GM to change course, companies are so often obsessed with short-term profit that they usually find it nearly impossible to sustain long-term vision."* I posted that, followed by: Your own assessment of the situation just now reflects that too. Rather than acknowledge what has happened over the years and how much resistance there has been to change, you took a snapshot of the situation at the moment. Of course the enthusiasts have been asking for GM to expand, but that's only as of setting gen-2 fail to grow sales and every single one of them has evaded the provision of any detail. Notice how they fight back when you mention price or range? They like the idea as a concept, but absolutely refuse to actually take a stance. That lack of commitment to a clear purpose, target, or goal tells the real story. As for you stating the situation as *"your magical 5,000/month"*, it shows a denial of business objective. Automakers have a purpose of making sustainable profit. They set production quantity levels to achieve a return. Falling short means losing money. Third-Party suppliers have contracts that must be paid in full, whether or not the vehicle is sold at full price or not. As for Prime itself, that 5,000/month (60,000 annual) level should be met. That should be close to what Toyota produced & sold worldwide in 2018, which would result in the return they had anticipated. Of course, it doesn't yet anyway. Each automaker's target for mainstream sales is for just prior to triggering tax-credit phaseout. For GM, that is this month. For Toyota, it will be sometime in 2020. In other words, I'm calling out your lack of long-term vision. Toyota is setting the stage for widescale plug-in hybrid rollout, offering Prius Prime initially, then adding Corolla PHEV. Following that could be any of the other hybrids, most likely either C-HR or RAV4. That transition from guzzler to plug-in for the entire fleet has a smooth & clear path being set, without disruption to dealer, consumer, or employee. What is GM's vision?

- 12-02-2018** **Closure, Ready.** The banter continued: Battery cost & density simply were not realistic until very recently. Infrastructure still requires a painful wait, for both commercial & home setup. Production capacity is obviously a major issue currently too. We're getting there though. Plug-In Hybrids help to bring that about somewhat faster. Buying one right away doesn't require upgrades at home or even much of a behavior change. You just plug in at night. Even with just a 110-volt connection, it works fine. Of course, there's the complexity of needing to charge multiple cars in the same household. Those plug-in hybrids at home will help encourage people to explore the EV charging & driving experience. Remember, most people will resist change by simply dismissing the new tech as "*not ready yet*". There's little to do in response to that when they just plain are not interested. Fortunately, the step from traditional guzzler to plug-in hybrid isn't intimidating and doesn't require much of any education for either customer or salesperson. The hope from automakers is it will become a no-brainer decision for everyone, including dealers stocking inventory. Put it this way. Ordinary consumers will see the tech as "*ready*" when they notice old plug-in vehicle still on the road, confirming they work just fine despite years of service. That is at minimum a decade from now. Do your part as an early-adopter by purchasing any type of vehicle with a plug, then making sure friends, family, and coworkers see you using it routinely.
- 12-03-2018** **Closure, Smug.** Loss of type of reason is a sign of an end approaching. This was the epitome of that: "*Hahaha!*" How does one respond to what is essentially a caricature of an evil villain laughing at your efforts? Did he know how stupid that appeared? It's somewhat bizarre to encounter something so extreme. I was rather taken aback. So, it was just a simple reply in return: What a great way to sum up a thread about what should have been done to prevent the losses of so many jobs... pretend its all a joke and do nothing whatsoever to address the next step.
- 12-04-2018** **Closure, The Point.** Some people never get it. They won't acknowledge what you are trying to convey, regardless of how obvious it may be to others. There's always a twist to get you to humor there obsession. "*What size is their biggest battery pack? How much torque is their biggest production electric motor?*" That seems reasonable, until you notice the pattern. I did, but responded anyway: I'll bite your trolling bait, a rather blatant diversion from the topic of GM... Battery-Packs are just stacks of cells. Increasing either increases capacity, as well as resulting power. With respect to electric-motors, Toyota's fuel-cell buses are rather substantial. But if you want personal, rather than commercial, look up Highlander hybrid (next-gen will be built in Texas, btw). GM produced Two-Mode for years. Heck, they even showed off a prototype plug-in model prior to Volt rollout. What became of those electric motors... you know, used in Tahoe... a large SUV. See the point?

- 12-04-2018** **Closure, Platform.** I deal with the engineer-focused routinely. They are the ones so blinded by the hope of technological solutions, they dismiss the realities of business. There's another type of antagonist I also must deal with. They are the one that are either clueless or careless. How do you interpret this: "*Why do you insist that the decades-old Prius platform is current technology?*" It's difficult to recognize the perspective. My guess is they have no idea how Prius actually works or how any of the upgrades have been implemented. Never having a good grasp of the technology would explain a lot of their behavior. It's hard to know for sure. Today, I responded with: Electric vehicles have been around for over a century. That's an old platform. Attempting to convince people upgrades are impossible is greenwash. I drive to work every day in my Prime using only electricity. All those EV miles from an affordable platform... It's what GM has yet to deliver. Volt had a terrible dependency on the \$7,500 tax-credit that GM didn't consider a priority to overcome. It's an example of what's possible for GM. Take what they learned from Volt, removing the enthusiast overkill to make a product for their own ordinary showroom shoppers. The system does not need to be that robust or that large. Sacrifices for power & range were too much. It traded efficiency & cost for early-adopter appeal. That lack of balance doesn't work for mainstream consumers.
- 12-05-2018** **Closure, Fake News.** Sometimes, they simply don't care: For years, GM would provide ambiguous press-releases and this site would spin them into blind hope. There wasn't substance to support what enthusiasts took away from them. Merit was lacking, but they didn't care. It built up excitement. Anyone who brought up a concern about lack of detail would get the "*troll*" label and their credibility attacked. There wasn't a term like "*fake news*" back then, nor was there an understanding of how influential the loss of objectivity could be. Critical thinking was lost. Rhetoric became the norm. Fallout was inevitable at some point. We have arrived at that time of reckoning. Volt will be discontinued without a successor established. There isn't even certainty about what direction GM will be taking for a next step. That concern in the past has been validated. Whether or not lessons were learned from the mistakes made are uncertain though. Most here are pushing back, unwilling to acknowledge what happened.
- 12-06-2018** **Closure, So What?** Good thing the end of this chapter is near: I never imagined all those years ago, collecting information to document events as they happened, that I would become the Jon Stewart of this news category. Of course, no one imagined the fall of Volt to be so "*vastly superior*" either. Here we are though. There's spin, denial, and outright lies all attempting to distort & mislead about really happened. The history is well documented. Two-Mode, Volt-1, and Volt-2 all failed to achieve sales growth needed to remain a viable product. That approach didn't work. So what? GM will just try something else instead. True, there's disenchantment to deal with and a history of false starts, but we are only now about to progress beyond the early-adopter stage. Lighten up and enjoy the market emerging for plug-in vehicles. GM can still be a player among the wide variety of choices that will be offered. No more claims of vastly superior though. Enthusiasts will have to play friendly with the rest of the team now.

12-06-2018 Closure, Hatred. Like I said, this is finally wrapping up: *"While Prime wins for the year, it has been declining as overall sales increase, indicating that Toyota enthusiast purchases have come a lot closer to being satisfied; and that the overall virtues of the superior Volt remained a major factor in Plug-In sales."* That's called not really understanding what has taken place and recognizing what will next: Speaking of hatred, there's no excuse for such misrepresentation of supply. Prime has never been offered in a large portion of the United States. Rollout has been limited to CARB states and special-order for a small number of dealers. That means there's no possible way to measure demand yet, especially since we have observed inventory burndown this year... which is usually indicative of change coming. As for the superiority claim, those "virtues" are very much that of early-adopters, who in no way are representative of mainstream consumers. That's a real-world example of innovator's dilemma playing out. GM focused on feedback from enthusiasts, making that fundamental mistake of not delivering something with the "virtues" of ordinary shoppers... the very thing Toyota has strived to avoid with Prime. To sight a specific, consider MSRP. Toyota delivered on GM's own target of *"nicely under \$30,000"*. GM did not, hence the vaporware assessment. That affordable choice was never delivered, which was an essential component of Volt being able to meet business sales & profit without dependency on tax-credits.

12-06-2018 Closure, Mainstream. Refusing to acknowledge the basics of business: *"So you made up a number that is close to doable for Prius Prime worldwide for this year - good to know."* Ugh. How else do you respond to such close-minded individuals. I keep trying: Posting that indicates you aren't familiar with this site. Each month I would post numbers with respect to GM's own fleet. Toyota never came into play. The enablers here were the ones to do that, as an obvious effort to distract from GM's own internal problem. 234,379 = Equinox. 109,662 = Cruze. 107,458 = Malibu. 13,243 = Volt. It was that reality (numbers above are from 2018 thru Q3) which made enthusiasts absolutely crazy. They knew Volt's true competition was traditional vehicles, not other plug-in choices from other automakers. Yet, they kept posting their own perspective, downvoting facts as a head-in-sand tactic to ensure their own narrative would persist. Reading through those old posts, you'll notice the rise of Equinox. That SUV became the sales leader. It became Volt's ultimate foe. Popularity grew so much, even the well-being of Cruze came into jeopardy. Trax coming into the picture spelled the end of Volt though. At 67,538 thru Q3, the writing was on the wall for Volt. Even with the \$7,500 assistance, sales couldn't even remotely compete. In short, say whatever you about *"mainstream"* measure. GM's own choices on GM's own showroom floors tell the story about profit for the non-giant (large SUV & Pickup) offerings. This is why the shuttering of plants for the smaller cars is taking place for GM. No amount of rhetoric can hide that.

- 12-06-2018 Closure, Saying Nothing.** The worst of the antagonists don't. It becomes meaningless gibberish. There's no substance. How is nothing of any type of measure is helpful? They somehow convince themselves that despite not having any evidence, nothing more than "*facts*" based on hearsay, that they are absolutely correct. It's so strange to see someone so dead set on a stance which there is no support for. All you can do is point out their fallacy: That literally says nothing... an excellent example of rhetoric. Setting an expectation without any detail is an attempt to feed hype. We all know words like "*leapfrog*" and "*forward*" are meaningless. Vague is a dead giveaway of greenwash. You're doing everything possible to avoid accountability... again. GM must achieve high-volume profitable sales, period. That means something matching sales of their profitable vehicles, which is where the 60,000 minimum counts into play... specific detail. Add to that a timeline, like 2 years from rollout, there's accountability.
- 12-07-2018 Closure, Selective Omission.** I especially liked reading a post that intentionally tried to divert focus and went out of the way to exclude the vital bit of information I was trying to emphasize: "*the non-giant (large SUV & Pickup) offerings*". So, I posted it again by quoting myself, then adding: You went out of your way to disregard that part of my information. Those offerings have never been part of the discussion. It simply makes no sense to compare Volt to a Silverado or Traverse. No one takes such extreme vehicle type & size differences as a consideration to a compact hatchback seriously. Your choice to include them is obvious greenwash. As for RAV4, haven't you been paying attention? 219 horsepower from a vehicle delivering a combined city/highway rating of 39 MPG is the new focus. As the market shifts to SUV choices as the norm, that is naturally what efficiency offerings should target. Its hybrid platform is an excellent next step for a plug upgrade. Keep doing whatever you need to for the sake of drawing attention away from Equinox inefficiency. The lack of any type of electrification is quite a GM shortcoming, undeniable evidence of how far behind they are. Remember Two-Mode? Unwillingness to address that confirms you are painfully aware of the problem. This is the history that repeats. I saw that pattern in the past and knew it would be followed again. And, it was.
- 12-07-2018 Closure, Repeating.** This was interesting: "*History is repeating itself.*" It came from a troublemaker who really didn't have any idea what had happened in the past. His naive nature made him gullible to hype... which I witnessed firsthand. It transformed him into a true believer of the propaganda being pushed. It's when rhetoric gets so out of hand, the person has no idea they have been misled. In this case, it was a matter of thinking he knew all the relevant information. Missing key points will cause you to draw incorrect conclusions... which is exactly what he did. Being poorly informed is one thing. He chose to dismiss the warnings and pretend the detail offered about omitted facts never happened. Choosing to remain poorly informed is just plain stupid. But when you see an end coming to what you had fought & lost so much for, convincing yourself it was a good cause is a typical outcome. I get my closure from seeing him get his. It's a strange situation. I provided this: Are you aware of Toyota's history, how much of a different path to success they took? Many here don't, hence the never-ending conflicts. Know your audience. Forcing a paradigm of GM to fit into the same approach makes no sense, hence the objectivity about engineering being lost. Understanding that fundamental difference is vital.

12-08-2018 **Closure, Confirm.** Repeating the same old false information based on misleading facts is how I confirm you are worried. Adding to that is the continued effort to send a message of no progress. That could be recognition of the fundamental mistake you made about mainstream buyers. Toyota has been painfully quiet about their plug-in and isolated rollout. Last time they did that, it was because they had an upgrade on the way. Evading that topic, as well as the EV drive, the newly introduced AWD-e, and the upcoming RAV4 offering tells an interesting story of understanding their customers. GM's failure to set a path for electrification of their product-line should have you worried. Their dealers keep on selling the same old guzzlers without any expectation for improvement. Ignoring the all-electric drive experience you now get from Prius, while at the same time turning a blind-eye to the lack of anything beyond a discontinued plug-in hybrid and a tax-credit dependent electric-only vehicle, is all I really need for that confirm. The rest was a bonus.

12-08-2018 **Closure, Change.** It's happening. We are witnessing another chapter in history coming to a close. I'm enjoying the opportunity now to remind people of what took place and how important this moment in time truly is: With Volt disappearing from the media and Tesla consuming what's left of low-hanging fruit (final full tax-credit purchases from those with high disposable-income), we can see change coming. The most obvious sign is witnessing outright lies being posted without challenge. The other is red-herring being followed on a regular basis. Since none of that audience represented mainstream consumers, the problem should be obvious. To them though, it is not. That's how misconceptions and narratives take hold. The industry has seen this before. It's the stage when leaders lose their lead. In other words, the moment when the tortoise passed the hare. This is very familiar. It reminds me a lot about the death of Two-Mode. The supposed advantage GM had completely fell apart when the early-adopter pool of buyers had become entirely saturated. They had no one else to sell those monster SUVs to. GM failed to address the needs of ordinary people, those who could not justify a high sticker-price regardless of how the vehicle performed. It all comes down to reaching buyers on the showroom floor. They couldn't care less about efficiency. That's a bonus if the vehicle is already affordably price, not by any means a priority. Gas is only \$2.29 per gallon here. The obsession with large vehicles has become such a norm now, it is an expectation. Cars are now lumped into the categories of "*economy*" and "*sport*". That's why Prius Prime dropped the middle seat and took on an aggressive look. It was the economic recovery of GM that made me realize years ago that they would fall into the same profit trap. Rather than actually invest in Volt to spread the technology, it would become a trophy and the pursuit of money from guzzlers would resume. That temptation to follow the money, rather than invest in the future is very difficult to resist. Change can be painful. I suspect more and more rhetoric to stir as the reality of the situation becomes apparent. Toyota didn't focus on short-term gain. Toyota followed their own approach to success again. Study that history. You'll recognize the pattern.

12-09-2018 Closure, Reality. That painfully long, drawn out online battle is coming to an end. Antagonist posts have become nothing but mindless rhetoric: "...because you make no attempts to educate yourself about reality." Seeing that with literally nothing in reference was the closure I was looking for. Post after post from me with detail showing the research I did to educate was outright dismissed by an act of looking away. He chose to ignore those posts. That's bizarre. Everyone can see what I shared. How could he expect anyone to pretend that never happened? It's in plain sight for all to read, right there in the discussion thread. Ugh. Oh well, that's his choice. Mine was to post this: That's how you are going for closure, claiming I'm the one that's uninformed? Well, here's a dose of reality you're especially not going to like then. It's from Autoweek's article titled "*What killed the Chevrolet Volt?*" The statement in their final point says it best: "*Finally, we can cite the demise of sedans as a popular segment during the Volt's two generations, especially the second one, and the concurrent and rapid growth in the popularity of crossovers and SUVs of all sizes. Simply put, the Volt was not a crossover, but it should have been.*" That fact is how my question of "*Who is the market for Volt?*" came about, long before any of the enthusiasts here changed their tune and endorsed some points I had been saying. They read the writing in the wall, coming to understand why dealers were so resistant to selling Volt. You foolishly focused only on the engineering aspect of the vehicle, choosing to dismiss the obvious trend away from small car offerings. That's why you get so angry with me now about RAV4 hybrid and do everything possible to belittle & discredit Toyota for recognizing that trend and responding accordingly. GM failed to. There should have been an Equinox with Voltec years ago. In fact, that's what gen-2 Volt (which we all know is actually gen-3 Two-Mode) should have been rolled out as. The answer to the "*Who?*" question was clearly not GM's own customers... who undeniably prefer SUV choices. Now, GM is scrambling to make up for missed opportunity and complaining about the tax-credits they squandered on conquest. That's reality.

12-09-2018 Closure, Economics. The nature of that previous post seems to have stirred things in a poignant manner. That was the hope. For someone to have so passionately fought for EREV, then to have abruptly abandoned ship in favor of EV, there's a reasonable aspect of regret to watch out for. This is where I come in as a scapegoat. The enthusiast who lost everything will seek out a source to blame, rather than accept the outcome he created for himself. In this case, it came across as: "*Same old broken record from...*" I was in turn delighted to response with yet another reminder of priorities: Economics is your enemy, not me. Refusing to accept the reality, that GM is a for-profit business which will be compelled to follow money rather than technology, is your problem. I'm simply just a reminder of it. RAV4 hybrid happens to be an excellent example of that reality. It is projected to be 20 to 25% of sales (which is extra impressive when there's an expectation for it to be a top-seller for the brand), due to its low premium for a high return. So what if it doesn't offer a plug yet. The next version likely will and it will be affordable by reusing the same platform. The design inherently already supports the upgrade. Swapping in a 12 kWh pack and adding one-way clutch is all it takes. That EV drive is what scares the heck out of you, as the childish name-calling clearly shows. You know it puts GM in a difficult position. While Toyota is building reputation and a customer base to offer plug-in upgrades to, GM is stuck selling SUVs that don't even get 30 MPG. Too bad if you hate getting the reminders of business reality.

12-09-2018 **Closure, Foolish.** It has been attack after attack. The writing on the tombstone has made a few so irrational, they'll say anything: "...because you make no attempts to educate yourself about reality." That particular quote stood out. I provided a lengthy analysis packed with detail. He attempted to dismiss it with a vague reply. My nightmare of dealing with illogical banter coming to an end means a start of accepting failure for them. I get my closure by pointing out the foolish choices: That's how you are going for closure, claiming I'm the one that's uninformed? Well, here's a dose of reality you're especially not going to like then. It's from Autoweek's article titled: "*What killed the Chevrolet Volt?*" The statement in their final point says it best: "*Finally, we can cite the demise of sedans as a popular segment during the Volt's two generations, especially the second one, and the concurrent and rapid growth in the popularity of crossovers and SUVs of all sizes. Simply put, the Volt was not a crossover, but it should have been.*" That fact is how my question of "*Who is the market for Volt?*" came about, long before any of the enthusiasts here changed their tune and endorsed some points I had been saying. They read the writing in the wall, coming to understand why dealers were so resistant to selling Volt. You foolishly focused only on the engineering aspect of the vehicle, choosing to dismiss the obvious trend away from small car offerings. That's why you get so angry with me now about RAV4 hybrid and do everything possible to belittle & discredit Toyota for recognizing that trend and responding accordingly. GM failed to. There should have been an Equinox with Voltec years ago. In fact, that's what gen-2 Volt (which we all know is actually gen-3 Two-Mode) should have been rolled out as. The answer to the "*Who?*" question was clearly not GM's own customers... who undeniably prefer SUV choices. Now, GM is scrambling to make up for missed opportunity and complaining about the tax-credits they squandered on conquest. That's reality.

12-10-2018 **Closure, Long Overdue.** I knew all along the attitude of those enthusiasts would bring about their own doom. With my BS degree having a minor in business, I was well aware of the common mistake people make when judging the market... because I made them too, taught to see beyond assumption by professors. Some of those exercises were really fun too, especially the team projects lasting several weeks. One in particular was fascinating. We had to compete against several other teams, making decisions about how much to spend on a variety of resources... the same type of decisions executives routinely have to make. You choose budgets for research, production, marketing, distribution, support, investment, etc. Then the professor would run software to collect & impact each team based on economic decisions he sets for that cycle. It was an intense game of analysis & prediction. You had to really be observant to strike the right balance. Anywho, stuff like that in college taught me what to look for. 20 years of closely watching the automotive market gave me the experience to properly understand how this outcome with Volt would come about. I share much of that though. I try to avoid self-promoting. I do though point out the mistakes of others with candor: Conquest sales are only good if it grows market, adding to sales from loyal customers. GM did not achieve that; instead, it was a flurry of pricing bargains combined with tax-credits. That's an unsustainable approach. High-Volume profitable sales are required to compete with the true competition, other vehicles sharing the showroom floor. The next step of integrating Volt's tech into something like an Equinox is long overdue.

12-10-2018 Closure, Ouch. It burns and they it especially stings that I'm the one deliver that news of failure. It didn't have to be that way. The outcome could have been a series of adjustments instead, course corrections to target properly. Pride got in the way though. It prevented them from being open-minded. They chose to hold true to their original goals, even though they were growing less and less viable. The outcome of high-volume profitable sales from Volt were futile. It was too expensive and did not appeal to a wide audience. It was a niche with a major subsidy about to expire. That inevitable doom was reason to attack me personally, as a scapegoat to help relieve the pain. All I can do is respond with a reflective "ouch". So, that's exactly what I'm doing:

Toyota is rolling out a plug-ready platform that directly targets the changing market. That's the affordable, high-volume approach GM should have also taken. Instead, all GM customers have to choose from is a diesel model of Equinox, nothing green in the SUV category. Heck, the smaller Trax doesn't even deliver 30 MPG.

Being profitable is a something this group of enthusiasts clearly does not understand. Fortunately, MotorTrend gets it:

"Toyota's new hybrid SUV is powered by a 2.5-liter four-cylinder unit producing 176 hp and 163 lb-ft of torque. That engine is mated to an electric motor sending 118 hp and 149 lb-ft of torque to the front wheels and 54 hp and 89 lb-ft to the rear wheels for a combined system output of 219 hp, more than the last-gen hybrid's 194 hp and the 2019 non-hybrid's 203 hp."

"Although the new RAV4 Hybrid makes more power, it also saves more gas. Toyota estimates the 2019 model will deliver 41/37 mpg in city/highway; that's much better than the 2018 model, which got 34/30."

That's an amazing platform to build upon for a plug offering later. Just like the upgrade from Prius to Prius Prime, it's just a simple process. Swapping in a larger battery-pack and adding a one-way clutch is all it takes.

So what if it isn't a full EV for awhile still? The market clearly isn't ready for that anyway. Even with the generous tax-credits, demand simply isn't there yet. It will be. But by then, Toyota will have a large base of plug-in hybrid owners looking to go full EV. Delivering a large vehicle with power that customers want, but without a huge price. That's key, a lesson GM still hasn't learned... despite finding that out firsthand with Two-Mode all those years ago.

12-10-2018 **Closure, Prime.** The spin to make downplay of Toyota's correct assessment of the market is ramping up. Having taken a stance on the expectation of rapid price drops, to the level of battery being directly competitive with gasoline, was absurd. How could the technology advance so quickly that the market itself would be able to embrace change on that scale? Anyone studying consumer & retailer behavior knows that's unrealistic. Rapid adoption simply never made sense in this place of cheap gas and little environmental concern. That's what Toyota's references try to draw attention to. There are many aspects to a technology being competitive. I stated the situation this way, this time: You must first learn what "*prime*" refers to, as the mentions above help to point out. BEV most definitely is not ready for competing directly with traditional vehicles. Disregarding all the technological hurdles related to misconceptions and lack of enough real-world data yet, there's the reality of cost. Even with the \$7,500 discount, pricing is far too high. Why would anyone consider a compact hatchback with a cramped rear and a MSRP starting at \$33,520 when you can get a larger interior compact SUV with a MSRP starting at \$21,300? That's the pricing difference between Volt and Trax, both Chevy vehicles. Trying to convince anyone that paying the extra \$12,000 is worth it would be a fool's errand. There is obviously a great deal of potential, following a few more battery generations. But that is not the situation yet. They are not ready. VW's assertion of their upcoming gas-engine being their last makes sense, validating exactly what Toyota has been saying for quite awhile now. Too bad if you don't like the reality of automotive business, that profit is a stronger motivator than helping make the world a better place. That's the reality we must find a way to deal with... like trying to get electrified vehicles into the mainstream as quickly as possible. Having a small battery-pack now is far better than waiting for "*someday*" to finally arrive.

12-11-2018 **Closure, Forward Thinking.** The irony with some of the enthusiast dealing is intriguing: "*Forward-thinking companies are willing to plant a seed which will grow into profit in future years.*" They sometimes convey the very message you have been spreading without recognizing it applies to them. That was the very thing I was telling them about Volt for years. GM seeded, then didn't do anything. They rested on their laurels, exactly what they claimed Toyota had done. Progress with Toyota never ceased. Camry hybrid was an amazing advancement with the hybrid system and soon RAV4 will take it even further. The larger vehicles offering more power while still delivering a significant efficiency gain is progress. When you have need to use a gas-engine, it should use as little fuel as possible and be as clean as possible. How is that not forward thinking? Profit will grow later when that established platform is taken advantage of by increasing battery-capacity and adding a plug. That's exactly what Toyota is doing by electrifying the fleet with a variety of hybrids. Their production & sales of vehicles utilizing those motors & controllers is what they will build upon... growth from the seeds being planted now.

12-11-2018 Closure, Online Discovery. The online fighting with enthusiasts turned antagonist took an interesting twist today. My research revealed a key detail everyone else has simply just glossed over. That's quite common. Rhetoric is usually so vague, there's nothing of any substance to actually consider. That's how the loss of critical thinking became such a problem. If there's nothing to discuss in the first place, you don't stand any chance of constructive posts to follow. It all falls apart when enablers simply congratulate attackers on their clever spin. I notice the pattern after awhile though, which makes seeing beyond hype & greenwash easier. You look for subtle clues. Lack of any interest in detail made be curious what there could be to avoid. Sure enough, when I started to dig, I actually found something. In this case, it was the on-going effort to discredit Toyota by claiming they were wasting effort on fuel-cell vehicles. That's easy to see as untrue when you recognize market diversity... location and commercial use are significant differences where hydrogen could be practical, especially when you consider an automaker branching out beyond just selling vehicles. There's a massive potential business for stand-alone power, you know... generators. Anywho, on vehicles themselves there's diversification opportunity too. In this case, reuse of the propulsion source. I put it this way: You're forgetting the full electric drive already used for Mirai. That synchronous AC motor delivers 152 horsepower and 247 lb-ft of torque.

12-11-2018 Closure, Vague. Seeing desperation is perplexity. What do you do at that point? When the person is no longer making any rational points, when all they are doing is spewing rhetoric, how should your response be formulated? I chose to draw attention to their absence of substance. Merit is earned by presenting data for readers to draw their own conclusions with. They can see you are making an attempt to avoid a narrative by providing detail for analysis. Simply claiming Toyota is "*behind*" but not explaining why is an act of the desperate. They hope others will take the statement at face value... because they have nothing to actually argue with. Vague is their tool. It happens again and again and again. I recognize the pattern all too well. In this case those, I welcome it. Confirmation of the exchanges now being regarded as closure is great. Volt's demise was foreseen. GM clearly didn't want to do anything with the technology. What a waste. Oh well. It's not like the warning signs were hidden. Ugh. Here's my continued shoveling of soil on the coffin: Again with the vague, a blatant attempt to mislead by excluding detail. Looking at that actual detail, none of the legacy automakers are producing anything more than token quantities. They face the same issue, cost. Profit is not realistic when competing against traditional vehicles yet... hence GM whining about having squandered their tax-credits and now needing more. 60,000 annual (mainstream minimum you will never here the end of) is specified for that very reason. It's a line in the sand indicating roughly what automakers target for supplier contracts and the setting of dealer supply expectations. You can't make sustainable profit selling on niche counts.

12-12-2018 **Closure, Group Think.** One of the most common problems online is that of venue... hence the "*know your audience*" advice. Are you on a website that is open to diverse participation or one which caters to specific opinion? That daily blog most definitely was the latter. It attracted enthusiasts and drove away those who didn't agree. From within, most members don't see that. If you watch other websites, you'll discover they typically don't participate anyway else. The issue that comes about from that limited scope is often referred to as "*group think*". Everywhere there tends to agree with everyone else. They make anyone who stirs a difference unwelcome. For example: "*That number has been brought up countless times BY YOU. No one else...*" That response about the mainstream minimum I have been pointing out about the realities of business get labeled as my own opinion, even though I just pointing them out. That count was most definitely not of my origin. I'm simply the messenger passing along that information. But since no one there ever encounters that detail from any source other than me, they draw that incorrect conclusion. I kept my reply to that brief: Through the lens of just this blog, that impression of only me is valid. Elsewhere on other green sites, the view & expectation of sales is quite different. Know your audience.

12-12-2018 Closure, Failure. This is what I plan to be my final post on that nasty daily blog, in response to: *"Sales in the USA are what we in the USA care about. Prime has been out long enough for it to have had a nationwide rollout. Your refusal to admit it is a design failure obviously is not shared by the dealerships around the country and by Toyota itself."* That venue served as a valuable resource in the past, providing ample opportunity to learn about denial and the efforts to impede. Their claim of green was shrouding with problems. I pushed and pushed and pushed to make them understand, while at the same time figuring out why they didn't over the course of an entire decade:

WHO IS THE MARKET FOR VOLT ?

That question was asked over and over again as sales of gen-1 Volt became a struggle. It was obvious GM had focused on appealing to a niche and the impression was they'd repeat that with gen-2. It was also obvious that those posting here couldn't care less about the global market. That meant they would force that perspective on others, even though it only applied to GM.

Toyota's focus has always been on the global market, targeting ordinary consumers, and not having a financial time-constraint like GM. So, waiting until year-3 of Prime for rollout to the rest of the United States and not really advertising until then was perfectly fine... no loss, especially with the state of the EV market and the timing opportunity for mid-cycle updates.

As for the impression of *"unbridled hatred"* being portrayed, that should be obvious. I was correct about GM doing too little, too slowly with Volt. Certain individuals will always resent the fact that I called out concern, seeing the financial risk growing as sales continued to struggle. GM didn't diversify in time. Volt died as a result.

There's extra resentment due to the fact that Toyota did diversify. From Prius came several other hybrids in several markets. Now from Prime, we see the same potential. And I most definitely do not *"lambaste GM"* for not having electrified everything yet. I get on them about not having set any clear expectation. There's nothing still. Their own loyal customers have no idea what step GM will take next. It's that uncertainty that makes investors and dealers uncomfortable. Know your audience.

12-13-2018 **Closure, Bad Business.** Outside of that terrible daily blog, there are some efforts to discredit Toyota. They aren't as blind or desperate though. Somewhat objective discussion does take place. Sadly, most posts are just abandoned without any follow up. I suspect this will be one of them: *"What I would say is, this effort by Toyota will probably deserve an entire chapter in: The Book of Bad Business Decisions."* It originated from an attack against hydrogen. Unfortunately, there are quite a few EV supporters who don't like fuel-cell use in any form. They think it is a waste in every regard. The thought that it serves as a means of storage for electricity when large banks of batteries are not practical doesn't ever get addressed. Think of some commercial applications. That absolute doesn't make sense. We need capture as much energy as possible. So what if that isn't the most efficient means? Our goal is to be carbon-neutral. Don't forget purpose. It's far too easy to fall into that trap. Many do. Again, we don't want to add carbon to the air. If conversion from hydrogen to electricity isn't the best use of energy, but it doesn't result in any type of pollution, why is it still considered bad? Think about that for the big picture and end goal. In the meantime, consider what is good & bad business, as I did: 152 horsepower, 247 lb-ft torque from the AC traction motor used in Mirai. That's a component essential for a future EV that is already in real-world use. Imagine that transferred over to a Corolla with a plug. Toyota is clearly planning ahead for widespread reuse of their developing technology. Nothing bad about that.

12-13-2018 Closure, Rushing. The entire development-cycle of Volt was rushed. GM had fallen far behind and was struggling to recover from that, as well as bankruptcy. You could see the temptation to take shortcuts was overwhelming. Rather than study their own customer priorities to draw appeal from them, they would pursue sales any way they could. 200,000 tax-credits seemed like a massive quantity, especially when no other automaker was offering a plug-in hybrid yet. It was only a matter of stirring interest from early-adopters, getting sales from that low-hanging fruit. Turns out, there weren't that many actually interested. Price cuts and incredible lease deals were required to keep demand alive. Supply was piling up. GM rushed a product to market that didn't appeal to anyone beyond those just looking for the best opportunity at the moment. Nothing related to loyal was done to retain those buyers. When leases expired or the next best deal came along, they abandoned GM. The story repeats relentlessly throughout recent years in these blogs. Those enthusiasts didn't care. They just moved along. So much wasted opportunity... I always stated the situation of rushing as not bothering to make the choice affordable. GM hoped for a miracle that would drop battery-cost so low, it would make Volt an obvious choice. I wonder for who. If batteries became cheap, why not just purchase an EV instead? A large-capacity pack would be the better choice if the point was to avoid using the gas-engine as much as possible. Notice how many Volt owners took great pride in going extremely long durations without refilling the tank? With charger availability increasing, the EREV concept made less and less sense. They became their own worst enemy. That's what happens when you rush. Enthusiasts didn't think things through and their own push on GM for their beliefs ended up contributing heavily to Volt's demise. This is why I kept repeating the message of purpose. I could see their obsession was preventing the recognition of priorities, as I again repeated today: Why don't you consider the priority of being affordable for the masses serious? Sacrificing price for the sake of more range & power was a gamble which clearly didn't pay off for GM. Keep in mind that a fuel-cell vehicle is an EV with a small battery-pack to supplement the stack. All the necessary components are used for electric-only propulsion. So, the technical expertise & experience provides a dual benefit. Heck, even the platform itself can be shared as Honda has demonstrated with Clarity. Toyota is refining design while waiting for the uncertainty from Tesla and the mess with GM to settle down. There is simply no reason to rush to a market still in the early-adopter stage.

12-14-2018 Closure, Looking Back. It has been a wild ride over the past 3 weeks. The worst of those antagonists attacked relentlessly. He feared the day would come when Volt would die and I'd be there to deliver the eulogy. Pointing out that engineering was a victim of imbalance, where neglect of business need was the problem, made it too much to accept. I'm not supposed to say anything good about the technology. I was spun as an enemy to defeat, a competitor seen as squashed by an ironic twist of fate. "*Know your audience*" held true though. It became overwhelmingly obvious the real competitor was indeed traditional vehicles, that I was correct from day 1... well over a decade ago, back when Volt was first revealed. That left him cornered. He literally had nothing else to try. All the tactics & excuses had been exhausted. It was just like when Two-Mode died. I still remember that well. The analogy then was the antagonists were trapped in a corner, like prey about to be killed. In a surprising ironic twist, his very last post to me even sounded like that. It was: "*Hisssssss...*" He was attempting to call me out by identifying me a snake; you know, I was supposedly trying to sell snake oil. That fact that he was actually reflecting and made such a specific sound was truly remarkable. It was him, not me. Snakes are indeed predators. So, he thought he was safe, despite being in a corner. He didn't realize snakes can also be prey. I have proven to be an eagle (note always seeing the bigger picture). Oops! He went silent. Thank goodness that's over now. It wasn't a waste of time either. I had always wondered if that was the best use of resources. Turns out, much was learned from the experience of attempting to have constructive discussions with those who do not want to. Rather than a friendly venue, I chose foe. The fights there revealed much about what must be done to appeal to ordinary people. Those mainstream consumers couldn't care less about the opinion of enthusiasts; however, they do want to know which offerings have a reach beyond just being a niche. My effort was to research & confirm. The technology in Prius is a clear winner for the middle-market. That's the target, not early-adopters. In that regard, Toyota's effort is paying off. They worked hard to strike a balance. The needs of business were not neglected in favor of trophies. They know their audience.

12-15-2018 **Closure, Promises.** The biggest problem I had with Volt was it came from GM, who had a very well established position of *"over promise, under deliver"*. Most people don't remember any of the *"stop gap"* campaign from GM. It was a smear effort when Prius was first rolled out from GM. The greenwashing message conveyed was that hybrids were a waste of resources, since fuel-cell technology was the future. That's what GM was to deliver by 2010. We all know how well that turned out. GM embraced hybrids, delivering Two-Mode and BAS... neither of which worked well. In fact, they were failures almost immediately. Price was high and efficiency gain low. Both were discounted, rolling out next-gen offering with new names to disguise the previous attempts. Volt gen-1 and eAssist, both of which found struggle right away. Volt was especially bad. It had so many shortcomings, enthusiasts diverted attention to gen-2 early on. The rhetoric got nasty. Lies about the plug-in Prius were rampant... hence the problem. Volt got in the way. Promises of *"leapfrog Prius"* were broken. The sales never materialized, despite heavy discounting and irresistible lease offers. Conquest obscured actual progress. That created a barrier for Prius. The effort to advance forward on the affordable front stalled. Volt was in the way. With its abrupt death though and Toyota well thought out timing, we are suddenly seeing a surge of Prius interest. The move to deliver a more aesthetics more appealing to a wide audience and offering AWD seems to be a winner already, even before rollout. 50 MPG from a better looking, more capable Prius with a highly competitive price is a winning formula. It's a nice complementary offering at the side of RAV4 hybrid too. Meanwhile, GM has nothing... but is no longer blocking with an empty promise. I was so tired of always hearing about Volt whenever Prius was mentioned without any substance to actually support the comment.

12-16-2018 **Closure, Dead.** A blogging topic was posted yesterday on the big EV website. It was about GM having hit the tax-credit limit and how difficult it will soon be for GM to compete. Naturally, the distortion element of "EV market" was what it had been based upon. Rather than actually addressing the reality of Volt & Bolt having to face traditional vehicle competition, we got the usual slant of other automakers. Fortunately, the tone of that was lighter than in the past. GM's failure to capitalize on the timing opportunity for getting Volt technology spread to other offerings long before this is finally getting attention. It's still not much of a priority though. Most people are just writing off GM entirely, giving up on their hope about the legacy giant. This is precisely what the *"too little, too slowly"* concern was all about. It came about from the automotive task-force assigned to help GM with bankruptcy recovery. That's a scope far bigger than Volt, something the enthusiasts absolutely refused to accept. Now, they are dealing with a dead Volt. Few care anymore, as the lack of response to my post on that topic confirmed: *"GM's choice to concentrate on conquest sales, rather than focus on their own loyal customers, will be confirmed as a terrible decision for tax-credit use. What suggestion is best for their next step, knowing that generous subsidy won't be available?"* No one had anything to contribute. That's because there is nothing whatsoever coming from GM. The silence is deafening. Not a peep, from an automaker who usually brags about industry leadership, it a sure sign of it being over. This race was lost. The hare failed to beat the tortoise.

12-16-2018 Closure, S-Curve. I'm really surprised to see the market-spin taking on such a deceptive approach. More and more articles are being published about the boom of EV sales. True, we are seeing a genuinely impressive ramp-up of Tesla production... which is why so many have given up on GM, especially since their own ramp-up had been promised. But vital information about tax-credit phaseout isn't included. That intentional omission is very, very misleading. There's a huge interest in Model 3 purchases right now simply due to the fact that tax-credit phaseout has already been triggered. In just 15 days, that \$7,500 subsidy will be cut to \$3,750 and you won't be able to collect it for an entire year. That's a potent reason to rush purchases. A reasonable expectation is that demand will drop noticeably next month as a result. That isn't mentioned though, nor is all the promoting of fossil-fuel sources by the current administration. It's a greenwash effort from an unexpected source. They are feeding a narrative that will ultimately present barriers, very much like Volt did. Good intentions created a problem extremely difficult to overcome. That's bad enough when there aren't many challenges to deal with anyway. This is denial on a dangerous scale, since it promotes an effort to ignore signs of trouble. It's really unfortunate people don't use critical thinking anymore. Rhetoric has far more of a hold on attention than what we were taught to do. The brainless terms, like "*big oil*" and "*global warming*", are trouble. Call out for detail. Push those refusing to provide it to step aside. You're in for disappointment otherwise. We must set realistic expectations. Tesla Model 3 sales will drop soon. That's ok. It's part of the normalization process, if you plan accordingly. If not, expect damage-control to get out of hand... just like we saw with Two-Mode, Volt-1, and Volt-2.

12-17-2018 Closure, Plans? It was like dealing with a black-hole. You know at some point there will be a collapse and everything near will get sucked in. That's been the situation with GM. You knew they'd screw up and harm efforts the industry have been striving for. It became obvious early on. Volt was losing money. Enthusiasts would lie about that, claiming the design was profitable despite an overwhelming amount of proof to the contrary. The recent layoff announcements provided confirmation. All doubt has been removed. Of course, there shouldn't been any in the first place. Seeing how hard Toyota struggled to squeeze out razor-thin profit from Prius is all it took to understand the difficult challenge of making money from new technology. Anywho, that brings us to the collapse. If we are about to witness GM placing all its bets on Bolt instead, abandoning EREV in favor of EV only, how will that profit be made? Hyundai is about to rollout their own EV, one that very much takes on Bolt directly. Their plans to penetrate deep into this emerging market include taking advantage of tax-credits GM no longer has. How exactly will GM compete with that, especially knowing Hyundai's offering will be a SUV rather than a wagon? This is why I kept redirecting discussion back to GM's plans. It made no difference whatsoever how Toyota approached the market. That was clearly just a red-herring. Toyota is focusing on their own customers anyway, not making a conquest play like Hyundai. Think about the differences between the well-established Japanese automaker and the up-and-coming Korean automaker. Hyundai seeks growth. Toyota retains loyalty. That leaves GM without much hope... hence the collapse. What will an automaker dependent upon large guzzlers do without any type of affordable green technology?

12-18-2018 Closure, Mixed Messages. The fundamental problem which hampered progress of Volt was never really knowing what it was for. This reaches beyond even the "*Who?*" question. What was GM attempting to accomplish with the technology? No one ever really knew. It wasn't like with Toyota. Their hybrid technology had a blatantly obvious purpose... to reduce emissions & consumption. With the technology from GM, answers differed depending upon who you asked... hence all the reminders of audience. Enthusiasts pushed the angle of all-electric driving. That primarily came about as a differentiating factor from Prius PHV. They wanted the goal of Volt to not have those same blending operations known. They did everything in their power to suppress mention of it at every stage, especially when GM tried to promote it more as a gen-2 refinement. That message of purity ended up drawing the most attention, drowning out mentions from GM, like the "*1,000 miles or more per tank*" advertising. Never using the gas-engine was a direct contradiction to the purpose of Volt. It repurposed the device, portraying it as nothing but an emergency backup... a very, very expensive rarely ever used backup. Why bother with such an expensive & complexity when increasing battery-capacity would serve the same purpose so much better? That's how Bolt came about. Enthusiasts claim that was the plan all along. Abruptly shuttering the factory where Volt was built and laying off those employees proves otherwise. That most definitely wasn't what GM intended. Of course, no one knows what GM intends now. The outcome is already disastrous. Could GM make it any worse?

12-18-2018 Closure, Support. Those mixed messages certainly have confused our clueless president. He took the "*all-electric*" reference to mean exactly that... all GM vehicles being totally electric. Ugh. This is what happens when you send out press-release material that's ambiguous to feed hype with. Enthusiasts were always delighted to spin the message to whatever suited them best for Volt promotion. I'd call them out on it. They'd attack the messenger. That lack of substance set a precedent of claims not requiring merit. They didn't need to be supported by facts. All that was needed was a sense of hope. Ugh. That's how we got into this mess now... the one that makes it very easy to see why Toyota kept its distance. Why would you want to be associated in any way (pulled into the black-hole) with GM's efforts? Prius would always be recognized as different for good reason. Ironically, the increase in battery-capacity from the next-gen upgrade brought about more power, giving Prius Prime electric-only traits similar to Volt. But at that point, enthusiasts were sending a new message of purpose for Volt... which brings us to support. Who will be providing it now? Enthusiasts are gone. GM seems to have abandoned the "*EREV*" approach. And the president is angry toward any type of electrification, choosing to support the coal industry instead. That's good reason for the automakers with interest for plug-in hybrids to stay quiet while refining their offerings. I'm expecting some from Toyota at the Detroit autoshow. That venue and the timing seem ideal for taking the next step toward mainstream appeal. New packaging for the battery-pack to make it fit better is a nature choice. Increasing charge-rate from the plug would too. It's little refinements like that which make mid-cycle updates a big deal. You don't need fundamental changes along the way to demonstrate continued investment. You do need to do that with next-gen upgrades though. Big things are expected then. Volt-2 didn't deliver. There was no other vehicle here rolled out using Volt technology either. Where's the support?

12-18-2018 Demand Spin. Much of the ado about the "closure" related to Volt (yes, an intentional dual-meaning play on words) went from dealing with GM's failure to actually do anything with the technology to bring it mainstream to spinning the situation as preparatory actions to introduce full-electric choices instead. We know that isn't the case. People don't abruptly lose jobs in the normal steps of technology progress. Vehicles established as having high-volume intent are not halted during the effort to increase sales. Tax-Credits do end predictably though. Other automakers continue with their plans as well. Demand for green choices will not cease; however, reading the spin makes you wonder. The latest attempt to mislead and provide damage-control is claiming: "*While many Volt owners got fairly disrupted at Volt production finalizing, what this really means is that the OEM's know that people are holding off for affordable EV's.*" There's simply no evidence to support that; however, there is an enormous amount of material facts proving people are holding off for affordable plug-in choices. Notice the spin? Since GM failed to make Volt affordable, enthusiasts will protect reputation by implying the plan all along was to deliver EV choices. The history of all that "*range-anxiety*" campaigning is just a misunderstanding of intent, not seeing the big picture. That's a load of garbage. People would jump on plug-in hybrid choices if they were both affordable and readily available... a condition which Toyota is strongly positioning them business to deliver, to take advantage of demand when the time comes as we see with the hybrid progress. Apparently, GM will be doing the same with EV choices, but there is nothing to actually support the hype.

12-18-2018 Hybrid Progress. Speaking of that topic, it sure is getting attention today. I see several new articles about the AWD Prius coming next month. My favorite quote is: "*If Toyota is great at engineering, it's a long-distance military sniper when it comes to targeting a feature's cost-benefit sweet spot.*" Like I said, that magic affordability target is how demand will grow. People will see the AWD design delivering 50 MPG for additional cost of \$1,400 and want to know more. That's a compelling draw. No parasitic drag by using an induction motor rather than a permanent-magnet type makes the approach quite sensible. It's just like any other package decision. You want the AWD feature? It's like asking if you want the upgrade that includes dynamic-cruise control... of was in the past, now that it too has become standard. Perhaps AWD will someday too. For now, Toyota is in the introductory stage. We always said such a minimum approach could deliver a huge return. 7.1 horsepower and 40.6 lb-ft torque doesn't sound like a lot. But with so little tradeoff, you get a second set of wheels providing additional traction. That's exactly what compelled many to choose Crossover offerings. They wanted improved control in snowy conditions... which is precisely what this new features delivers. That's progress. Ironically, it should see an immediate draw too. Normally, rolling out a new vehicle in the dead of winter is a terrible idea. But with the AWD being the central focus of the mid-cycle update, it's the ideal timing. That's genius.

- 12-18-2018 Sales Struggle.** Looking at the bigger picture, this comment in an editorial summed it up well: *"The truth is that Japanese auto makers can sell sedans at a profit, and GM can't. And GM is struggling to compete on its home turf in SUVs too."* Quite a bit of attention is now focused on Toyota's amazing improvement they'll be delivering for RAV4 hybrid. For such a large & powerful vehicle, that's an impressive hybrid system. It's an especially painful blow to consumers who may be interested in Equinox... which looks like a terrible guzzler in comparison. So with respect to market retention, GM is in a world of hurt. Simply shifting to more SUV production won't actually solve their financial issues. Making matters worse is the overlooked efforts of the other automakers to deliver plug-in hybrid SUV choices. Even shorter range offerings, like Mitsubishi & Subaru, provide reason for GM worry. There's a very real threat of customer loss to Hyundai/Kia, in regard to both plug-in hybrid and full-electric. All that adds up to the concern about *"too little, too slowly"* becoming a death notice. What comes next after closing 5 assembly plants and laying off 15,000 workers? This is why I pushed. Others chose not to acknowledge what I was witnessing.
- 12-19-2018 The Real Story.** How many years did it take for someone to finally just post this: *"You mean dealers are not ready to kill their cash cow."* The proper response to that, of course, is the face-palm emoji. Ugh. To think that the most basic of economic principles in the automotive market could be dismissed as important for so long blows the mind. If the reseller isn't interested in selling the producers product there will be a much more difficult path to success. Knowing how challenging profit has been, that point of easy revenue should have been obvious. Duh! That brings, yet again, back to the *"Who?"* question. Why would a dealer stock a vehicle their own showroom shoppers wouldn't be interested in, especially if the return for the sales effort is marginal at best. Selling a large guzzler is quick & easy and there's a substantial payback for both the dealership owner as well as the salesperson. That's the real story. This is why Volt was doomed to fail. Cards were stacked against it from the very beginning. Enthusiasts refused to acknowledge that reality though. It took worker layoffs and shuttering plants for that message to finally be accepted. That's really unfortunate. So much time & opportunity was wasted.
- 12-19-2018 True Customers.** It is interesting to witness the turn. GM's announcement has really stirred the early-adopter discussions. This is making my experience & observations something to really leverage now. Patience, tolerance, and documenting really pay off. It will be interesting to see where the posts take us. This is my contribution at the moment: Toyota studied the mainstream market carefully, rather than listening to enthusiasts. They know that the bottom-line is a challenge anyway. Dealers taking on inventory that requires extra effort to sell and provides only a razor-thin profit in return wouldn't be appealing. Volt enthusiasts hated me for pointing out that dealers were the true customers, not those who end up owning the vehicle after purchase. It's a cold, hard reality GM learned the difficult way. We see how that worked out. Know your audience.

12-19-2018 GM's Collapse. In the past, it was quiet abandonment. Disenchanted enthusiasts would simply disappear. So many of those who had turned antagonist and attacked me relentlessly have faded away into the past. I look back at those discussion threads from years ago and see many names who have vanished without a trace. And since countless of those individuals were anonymous, hiding behind a made up login name, there is basically no record of who they ever were. They were cowards from the start, unwilling to share even the most basic aspect of their identity. That's why blogs of the past thrived. There was never any accountability. This is why the reputable services forced traceable accounts. You had to yourself, not hide behind an avatar. In fact, this is the very reason the last of the troublemakers fought so hard to make me feel unwelcome. He was protecting one of the last venues of that old era to survive. It was that daily blog for Volt... which is no more. Suddenly, I'm no longer alone. Scores of former GM supporters, enthusiasts, and even some antagonists have turned... angry about having been let down. GM squandered its lead, wasting opportunity exactly as I had expressed concerned about over the years. That warning of "*too little, too slowly*" has been so overwhelmingly confirmed as a genuine problem, there's nothing else to say... except, goodbye. They have turned on GM, voicing disappointment. It's even worse than the abrupt fall of diesel. This is a failure where the potential for success was enormous. In just a few months, I went from having to deal with "*behind*" claims to watching those same people post about GM having lost its way. The reality of the situation was that GM never had proper aim. The direction they were headed was always a dead-end. Remember those observations of turning in work that wasn't assigned? They thought the teacher would be impressed by going above & beyond, even though it had little to do with the expectation of what was to be delivered. It's all about that want verses need problem. GM never learned that lesson Two-Mode taught. GM continued to repeat the same mistake over and over again. Volt-1 was a disaster. Volt-2 was so bad, many don't even want to talk about it anymore. Sales never grew. Volt remained an expensive niche. What a waste.

12-20-2018 **Worth It.** There is much to be learned on the EV blog. Many have no sense of history. Their naive nature of never having been part of the automotive market prior to an interest in plug-in vehicles makes for a troublesome crowd. They are doomed to repeat mistakes if they are unaware of how they played out in the past. I'm seeing quite a bit of that recently. The collapse of GM in this market has pushed Volt into the "*don't talk about*" category now with an expectation of the same soon for Bolt. Remember how so much hope had been placed on GM's plan to increase Bolt production this Fall? They milked that anticipation for an entire year. Hype never emerged though. Tesla's obvious success combined with growing expectations from Nissan overshadowed all that. GM press-release narratives fell apart. No one cares anymore. VW learned well about how to manipulate with announcements. They are building a future with no accountability... something Toyota strives to avoid. Not saying much of anything and simply just quietly deliver is Toyota's approach, one I really appreciate, as I state on a regular basis. They understand their customers: Know your audience. We witnessed the "*it's worth it*" argument fail for 8 years with Volt. That premium justification was never enough to draw mainstream buyer interest, who have very different priorities than enthusiasts. That's why there are different categories of vehicles. It's something early-adopters either don't recognize or don't want to. Try selling the acceleration benefit to my mom. That's a futile endeavor. She's happy to purchase a new vehicle, but going fast simply isn't of any interest. A good balance for a good price is the goal. A common affordable choice is fine. This is why a \$28,000 RAV4 hybrid delivering 39 MPG will be a popular choice. We'd all really want to see the plug option added soon, but that just isn't on the profit-for-dealer radar yet. So, don't expect it to be something ordinary shoppers will be drawn to in the near future.

12-21-2018 **Purpose?** Doomed to repeat the same mistakes again? It's hard to tell. I'm certainly seeing signs of that emerge already. I'll be keeping a close eye on the apparent trend, as I pointed out today: Over the past few weeks, I have witnessed a pattern emerging... a familiar one. It is a focus on concept, rather than addressing the actual business at the moment. Volt ended up in an identity crisis as a result of this, twice. Mixed messages made it very difficult to sell. What was Volt's purpose? Some believed it was designed to seamlessly transition to the gas-engine, delivering outstanding overall MPG. Others believed the goal was to drive EV almost exclusively, only having a gas-engine as a backup for "*range anxiety*" just in case. Why not just make battery-capacity just a little larger and not bother with a gas-engine at all? This is how Bolt came about. In fact, many enthusiasts claim that was the plan all along, that the EREV concept has served its purpose and GM simply plans to let Volt fade into history. In other words, if GM was to deliver a Voltec based vehicle, what specifically would it be? How many kWh capacity? How much HP output? How large should it be? How should it be priced? With so many unanswered questions of purpose, it is no surprise GM is waiting for the dust to settle before hitting the reset button.

12-21-2018 Leadership. The potential discussion fell apart almost immediately. Many online posters don't pay attention to the messages other share. That makes dealing with their lack of history awareness even more difficult. In this case, the following that I posted was just outright dismissed. He clearly didn't comprehend the difference, which was intentionally subtle. GM didn't want people to notice. All that 40-mile promoting feel apart as soon as the first Winter arrived. What I had been saying about heater power-consumption finally got some attention... not proper attention... but at least acknowledgement. GM recognized the lack of understanding about how plug-in vehicles utilize electricity. People expect "40" to actually mean "40". The lessons learned by the hybrid market were dismissed as relevant by their plug-in effort. That was a terrible mistake. People don't read the fine print. People don't understand engineering. People don't have the background. Know your audience! Needless to say, GM bumped battery-capacity for the next-gen rollout. Had they stuck to the 40-mile delivery expectation, that would have worked fine. Taking heater use into account would have been really smart; instead, they hyped increased range. Ugh. All that work to stress the importance of "40" was wasted by the obsession for more. GM is its own worst enemy. True, we can say that of other automakers... including Toyota in some regards... but that's more in a general sense. The very specific trait of delivering 40 miles was changed without explanation. Prompting awareness of heater consumption and how GM dealt with it would have been an entirely different matter. But GM chose not to. It was an executive choice which confused potential customers. Leadership didn't lead. Rather than stating clear purpose and sticking to it, there continues to be an ever-changing story. Remember way back when Two-Mode was being developed? Same problem! They don't learn from prior mistakes. Since I'm just repeating myself at this point and there's little hope of change, I kept the response today short: GM leadership changed their message, from "*40 miles all electric*" to 53 miles AER. That in itself derailed the understanding of purpose. They made it worse by not keeping it clear what Volt was competing against.
